MPC8260 UPM Timing Diagram

The three user-programmable machine (UPMs) of the MPC8260 PowerQUICCTM II integrated communications processor are flexible interfaces that connect to a wide range of memory devices. At the heart of each UPM is an internal-memory RAM array that specifies the logical value driven on the external memory controller pins for a given clock cycle.

This application note presents a series of timing diagrams for several UPM usage scenarios. All the timing diagrams are based on simulations and are for the 60x bus. Timing for the local bus is basically the same as for the 60x bus, except that there are no PSDVAL and TA signals to indicate the termination of the memory cycle. Also, the local bus has its own signals:

- Local address bus
- Local data bus
- LBS
- LGPLx

Local address pins are multiplexed with PCI signals. To select the local bus function of these pins, configure the HRCW[L2CPC] bits to 00 during configuration or program them to 00 after configuration. Because of the similarity of the timing for the 60x and local buses, refer to the 60x bus timing diagrams for local bus timings.

UPM Programming

1 **UPM Programming**

The basic steps to program the UPMs are as follows:

- 1. Set up BRx and ORx.
- 2. Configure MxMR[OP] = 01 for writing to a RAM array.
- 3. Write patterns to the RAM array by accessing the UPM with a single-byte transaction.
- 4. Program MPTPR and L/PSRT if refresh is required.
- 5. Configure MxMR[OP] = 00 for normal operation.

Example 1 shows the detailed assembly code for completing these general steps.

Example 1. Assembly Language

MPC8260 UPM Timing Diagram, Rev. 2

UPM Timings

2 **UPM Timings**

Figure 1 shows a 32-bit single beat read/write on a 32-bit port.

Notes:

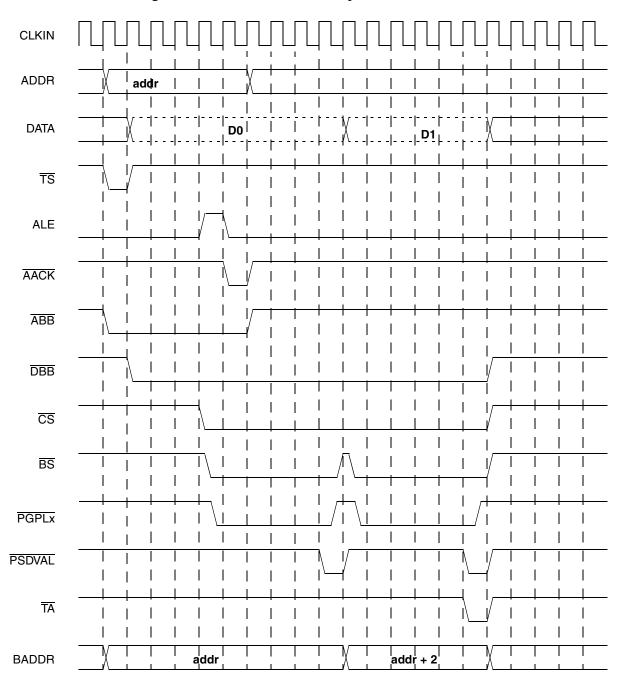

¹ RAM word for a single-beat read (a single-beat write starts at RAM address 0x18)

Figure 1. 32-Bit Single Beat Read/Write on 32-Bit Port

² Data bus end at PSDVAL for both a single-beat read and write. For a write, the data bus starts when DBB is asserted. For a read, the starting-point depends on the RAM pattern and the memory UPM controls.

Figure 2 shows a 32-bit single beat read/write on a 16-bit port.

Notes:

Figure 2. 32-Bit Single Beat Read/Write on 16-Bit Port

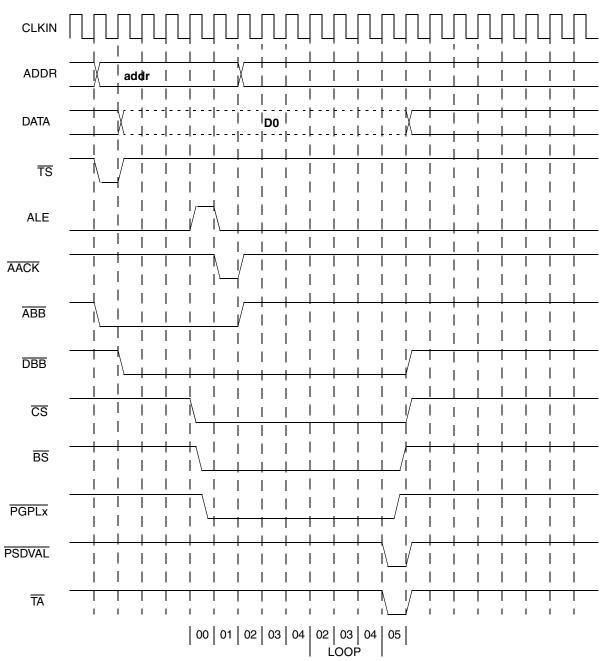

¹ RAM code is the same as for Figure 1.

 $^{^{2}\,}$ The single-beat 32-bit access is split to two 16-bit back-to-back accesses due to port size limitations.

UPM Timings

Figure 3 shows a 32-bit single-beat read/write on a 32-bit port.

Note:

00: 08ea a800 03: 00a0 0000

02: 00a0 0080 //LOOP=1 05: 01b5 5405

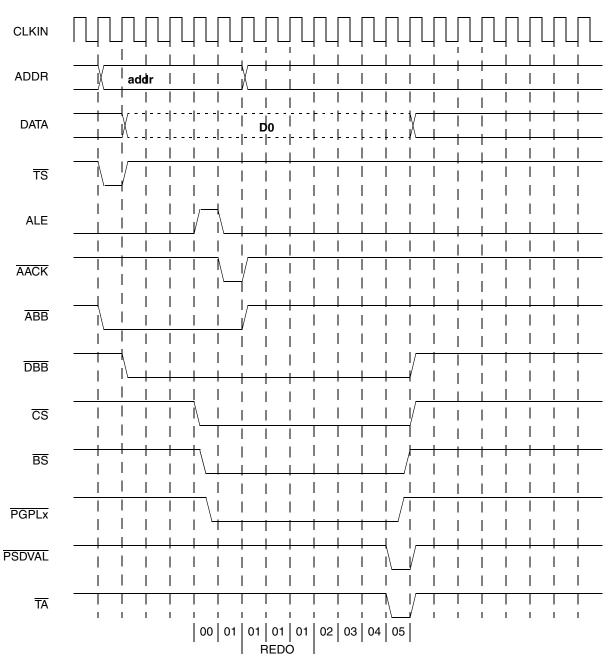

Figure 3. UPM with LOOP, 32-Bit Single Beat Read/Write on 32-Bit Port

¹ RAM word for single beat read with LOOP:

² Loop number is set at MxMR. RLFx for read, WLFx for write. Loop number is one for the above figure.

Figure 4 shows the UPM with REDO.

Note:

 00: 08ea a800
 03: 00a0 0000

 01: 00a0 0300 // REDO=3
 04: 00a0 0000

 02: 00a0 0000
 05: 01b5 5405

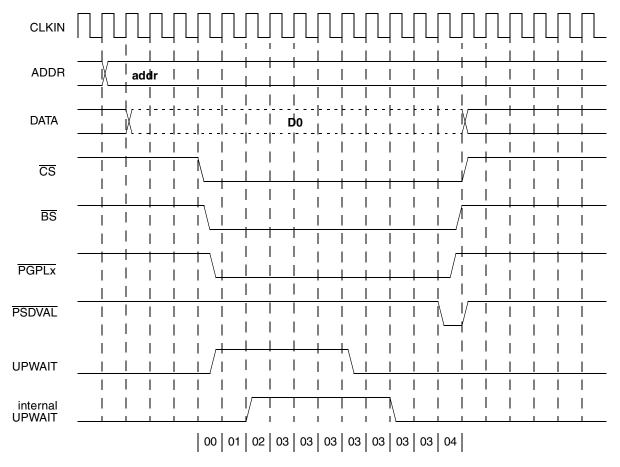

Figure 4. UPM with REDO

¹ The RAM word for a single-beat read with REDO:

UPM Timings

Figure 5 shows the UPM with two consecutive WAEN.

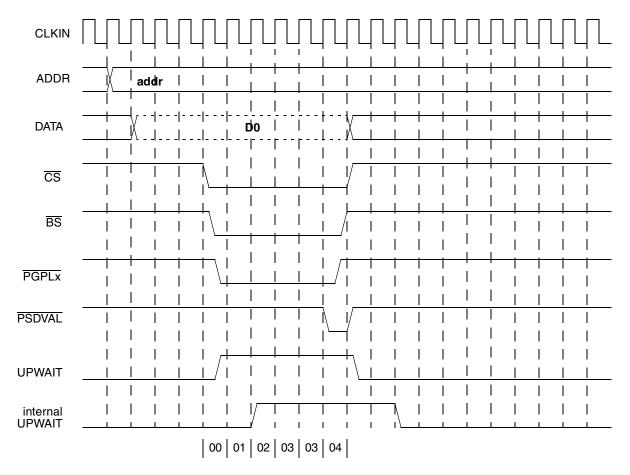

Note:

- Minimum RAM words for UPWAIT to take effect:
 - 00: 08ea a800
 - 01: 00a0 0000
 - 02: 00a0 1000 // WAEN=1
 - 03: 00a0 1000 // WAEN=1
 - 04: 01b5 4405
- WAEN needs to be set in two consecutive RAM words. The UPM waits at the second RAM word. Figure 6 shows what happens if only one WAEN is set.
- Due to synchronization of UPWAIT, the internal UPWAIT is two cycles later than external UPWAIT. If the external UPWAIT goes active half a cycle after $\overline{\text{CS}}$ is active, the first WAEN that has an effect is at RAM address 02 for a read. Even if WAEN values of 00 and 01 are configured, the UPM does not wait because UPWAIT has not arrived yet due to delay.

Figure 5. UPM with Two Consecutive WAEN

Figure 6 shows the UPM with UPWAIT and one WAEN.

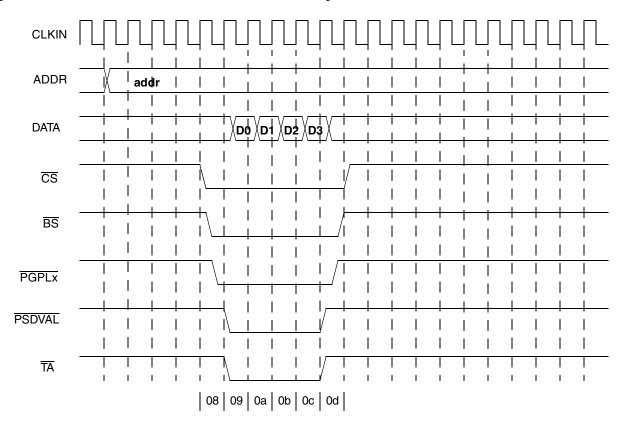

Note:

- 1 RAM words with one WAEN
 - 00: 08ea a800
 - 01: 00a0 0000
 - 02: 00a0 1000 //WAEN=1
 - 03: 00a0 0000
 - 04: 01b5 4405
- Setting WAEN at RAM address 02 causes a single-cycle wait at pattern 03.
 If UPAWIT is negated, of course the UPM does not wait. However, even if UPWAIT is asserted, a single WAEN causes a wait of only one cycle for next the RAM pattern. Then it proceeds while ignoring the UPWAIT. That is why two consecutive WAENs are needed for a continuous UPWAIT.

Figure 6. UPM with UPWAIT, One WAEN

UPM ARTRY Cycle

Figure 7 shows the UPM burst read/write on a 64-bit port.

Note:

- Example RAM words for burst read:
 - 08: 08ea a800
 - 09: 00a0 0004 // UTA=1
 - 0a: 00a0 0004 // UTA=1
 - 0b: 00a0 0004 // UTA=1
 - 0c: 00a0 0004 // UTA=1
 - 0d: 01b5 5401
- ² A burst write starts at RAM address 0x20
- ³ Care should be taken to program the correct number of UTAs in the burst code so that the UPM generates the required number of PSDAL signals for a burst.

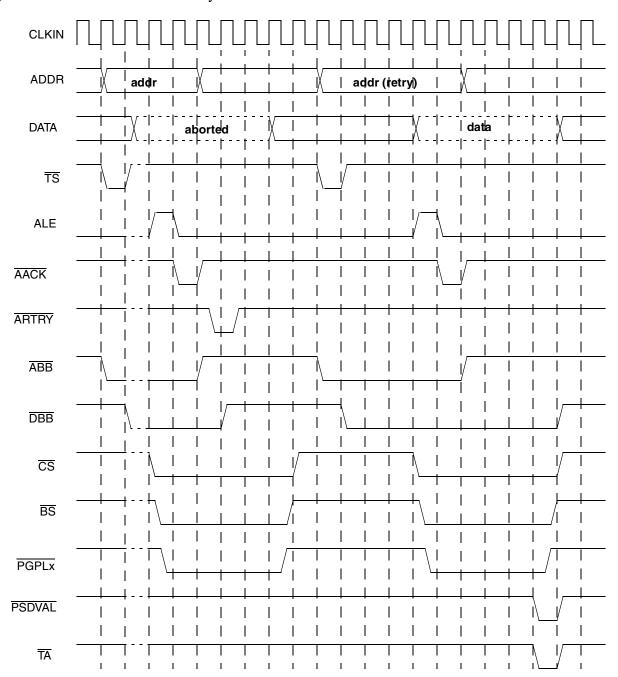

Figure 7. UPM Burst Read/Write on 64-Bit Port

3 UPM ARTRY Cycle

In 60x-compatible mode, the address transfer can be terminated with the requirement to retry if \overline{ARTRY} is asserted during the address tenure and through the cycle following \overline{AACK} . The assertion causes the entire transaction (address and data tenure) to be rerun.

Figure 8 shows the UPM ARTRY cycle.

Note:

¹ RAM word for ARTRY cycle:

 00: 08ea a800
 03: 00a0 0000

 01: 00a0 0000
 04: 00a0 0000

 02: 00a0 0000
 05: 01b5 5405

Figure 8. UPM ARTRY Cycle

MPC8260 UPM Timing Diagram, Rev. 2

When a valid ARTRY is recognized, the UPM finishes running the current RAM pattern without asserting PSDVAL and TA. After that, a retry phase starts.

UPM Read-Modify-Write Cycle

4 UPM Read-Modify-Write Cycle

If the UPM is programmed for read-modify-write parity checking or ECC correction and checking, every write access to memory that is less than the port size automatically causes a read-modify-write cycle.

The following is an example of RAM code:

Read Pattern:				
00:	08ea	a800		
01:	00a0	0000		
02:	00a0	0000		
03:	00a0	0000		
04:	00a0	0000		
05:	01b5	5405		
Writ	e Pat	tern:		
18:	0800	0000		
19:	0000	0005		

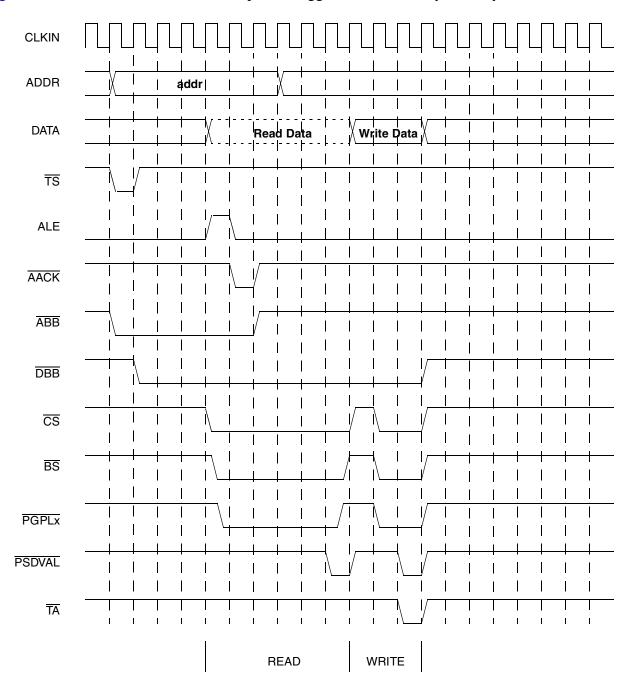

Figure 9. UPM with Read-Modify-Write Cycle
