This TPU Programming Note is intended to provide simple C interface routines to the pulse width modulation TPU function (PWM). The routines are targeted for the MPC500 family of devices, but they should be easy to use with any device that has a TPU.

1 Functional Overview

This output function generates a pulse-width-modulated waveform in which the period and/or the high time can be changed at any time by the CPU. PWM uses two modes of operation: level and normal. In level mode, a 0% or a 100% duty-cycle waveform can be generated. In normal mode, waveforms with duty-cycles between 0% and 100% can be generated.

In general, any changed period or high time is used in subsequent waveform synthesis, after a low-to-high transition. An immediate update is possible in either mode. After an immediate update, the new period and/or high time is reflected in the output waveform during the immediate host-service state, instead of waiting for a subsequent low-to-high transition.

2 Description

To start a PWM waveform, the CPU configures or updates parameters PWMPER (period desired) and PWMHI (high time desired), then issues an HSR 0b10 for initialization. After CPU initialization (refer to Figure 1), the TPU generates a low-to-high transition and calculates the pulse timing (next fall time, next rise time). The time of the most recent rising edge is moved from parameter PWMRIS to parameter OLDRIS, where it can be read at any time by the CPU. Calculation of the fall time is made by adding OLDRIS to PWMHI. The next rise time is calculated by adding the period desired from PWMPER to the rise time, now in OLDRIS, and then placing the projected new rise time into PWMRIS.

1 The information in this Programming Note is based on TPUPN17. It is intended to compliment the information found in that Programming Note.
In level mode, where the high time in PWMHI is zero (indicating 0% duty cycle) or is equal to or greater than the period (indicating 100% duty cycle), a match without a pin transition is set up for the time (OLDRIS + PWMPER). In normal mode, a match and fall time is set up for the time (OLDRIS + PWMHI), and an interrupt request signal is asserted on each match event if the interrupt enable bit is set. To change the PWM parameters, the CPU coherently writes new 16-bit values to either PWMPER or PWMH. If both PWMPER and PWMH are to be changed, a coherent 32-bit write is required.

In both normal and level modes the new parameters are referenced to the next low-to-high transition. An immediate update of either or both parameters may be selected by the CPU by issuing an HSR 0b01. The immediate result to the waveform depends upon the point at which the immediate update is taken. For further information, see Section 10, “Performance and Use of the PWM Function.”

An optional CPU interrupt request can be made at the beginning of each pulse in any mode or after an immediate update. This allows the CPU to schedule parameter changes in relationship to a known point in the waveform.

3 FQM C Level API

- Initialization Function:
  
  void tpu_pwm_init(struct TPU3_tag *tpu, UINT8 channel, UINT8 priority, UINT16 period,
  UINT16 hightime, UINT8 timer)

- Change Operation Functions:
  
  void tpu_pwm_update(struct TPU3_tag *tpu, UINT8 channel, UINT16 period, UINT16
  hightime, UINT8 immediate)

  void tpu_pwm_force(struct TPU3_tag *tpu, UINT8 channel, UINT8 state)

- Value Return Functions:
  
  UINT16 tpu_get_pwm_period(struct TPU3_tag *tpu, UINT8 channel)

  UINT16 tpu_get_pwm_hightime(struct TPU3_tag *tpu, UINT8 channel)
Using the Pulse Width Modulation TPU Function (PWM)

3.1 Initialization Function (tpu_pwm_init)

**void tpu_pwm_init**

This function initializes the PWM function and sets the initial period and duty. To change the operating mode, this function can be called again. This function has the following parameters:

- **tpu** (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- **channel** (UINT8) - This is the channel number that has the FQM function assigned to it.
- **priority** (UINT8) - This is the priority to assign to the FQM function. The TPU priority definitions are defined in mpc500_utils.h. See Table 1 for values that are defined for the channel priority.
- **period** (UINT16) - This parameter sets the period of the PWM waveform.
- **hightime** (UINT16) - This parameter sets high time of the PWM waveform.
- **timer** (UINT8) - This parameter sets whether the TPU3 TCR1 or TCR2 clock should be used for measuring the incoming frequency.

</tr>
<tr>
<td>TPU_PRIORITY_HIGH</td>
<td>0b11</td>
</tr>
</tbody>
</table>

3.2 Change Operation Function (tpu_pwm_update, tpu_pwm_force)

**void tpu_pwm_update**

This function allows the PWM parameters to be updated. The parameters are changed on the next rising edge of the PWM, unless the immediate parameter is set. **void tpu_pwm_update(struct TPU3_tag *tpu, UINT8 channel, UINT16 period, UINT16 hightime, UINT8 immediate)**

- **tpu** (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- **channel** (UINT8) - This is the channel number that has the FQM function assigned to it.
- **period** (UINT16) - This parameter sets the period of the PWM waveform.
4 Using the Pulse Width Modulation TPU Function (PWM)

- hightime (UINT16) - This parameter sets high time of the PWM waveform.
- immediate (UINT8) - This parameter determines whether the updated parameters are effective immediately or at the beginning of the next PWM cycle.

**Table 2. TPU PWM Update Immediate Definitions**

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>TPU_PWM_NORMAL</td>
<td>0x0</td>
</tr>
<tr>
<td>TPU_PWM_IMMED</td>
<td>0x1</td>
</tr>
</tbody>
</table>

**void tpu_pwm_force**

This function forces the state of the PWM channel to 0% (always low) and 100% (always high).

- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.
- state (UINT16) - This parameter sets the period of the PWM waveform.

3.3 Value Return Value Functions (tpu_pwm_get_period, tpu_pwm_get_hightime)

**UINT16 tpu_pwm_get_period**

This function returns the current period of the PWM waveform.

- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.

**UINT16 tpu_pwm_get_hightime**

This function returns the current hightime of the PWM waveform.

- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.

3.4 General TPU Functions

The following routines are generic and are useful for all TPU functions.
void tpu_enable
This function enables the TPU channel and can be used to change the channel priority.
- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.
- priority (UINT8) - This is the new channel priority.

void tpu_disable
This function disables the TPU channel. It sets the priority to 0 to disable the channel.
- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.
- priority (UINT8) - This is the new channel priority.

void tpu_interrupt_enable
This function enables the interrupt bit for the specified channel.
- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel - This is the channel number that has the FQM function assigned to it.

void tpu_interrupt_disable
This function disables the interrupt bit for the specified channel.
- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.

void tpu_clear_interrupt
This function clears the interrupt bit for the specified channel.
- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.

UINT8 tpu_check_interrupt
This function checks the interrupt bit for the specified channel to see if it is set. This function returns TRUE if this channel caused the interrupt, FALSE otherwise.
- *tpu (struct TPU3_tag) - This is a pointer to the TPU3 module to use. It is of type TPU3_tag which is defined in m_tpu3.h.
- channel (UINT8) - This is the channel number that has the FQM function assigned to it.

4 Configuration of PWM Function
The CPU configures the PWM function as follows:
1. The appropriate channel priority bits are cleared, disabling the channel.
2. The PWM function number is written to the channel function select bits.
Using the Pulse Width Modulation TPU Function (PWM)

3. CHANNEL_CONTROL, HIGHTIME and PERIOD are written to channel parameter RAM.
4. The host sequence bits are written, selecting the desired action edge and mode of operation.
5. An HSR is issued to initialize the function.
6. The channel priority bits are written to enable the function and assign channel priority.
7. The TPU executes the initialization state.

All of these steps are included in the C level tpu_pwm_init() function. See Section 3.1, “Initialization Function (tpu_pwm_init).”

5   Example Code

The following code shows an example program that initializes the TPU PWM ROM function using the C level API (see Section 5.1, “Code Listing”). This example initializes the PWM function on channel 0 and channel 1. A PIT interrupt is initialized to update the high time every 1 second. The first channel is updated normally (at the end of the current PWM cycle) and the second channel updates the hightime immediately. The period of the PWM is approximately 1.220 KHz with the MPC555 system clock running at 40 MHz.

5.1 Code Listing

```c
#include "mpc555.h"
#include "tpu_pwm.h"
#include "mpc500_util.h"

/* Initialization parameters */
UINT32 loopctr = 0; // Loop counter for main loop
UINT32 pitctr = 0; // Counter for number of PIT timeouts
struct TPU3_tag *tpua = &TPU_A; /* pointer for TPU routines */

/* Example specific values */
UINT8 chan_a = 0;
UINT8 chan_b = 1;
UINT16 init_period = 0x2000; /* This generates a 1.2 KHz square wave initially. */
UINT16 init_hightime = 0x1000;
UINT16 step_size = 0x100;

void init555(int freq)
{
    USIU.SYPCR.R = 0xffffff03; /* Disable watchdog timer. */
    * WARNING: this is a WRITE ONLY register. */
    USIU.PLPRCRK.R = 0x55ccaa33; /*Unlock PLPRC with special key */
    if (freq == 56)
    {
        USIU.PLPRCRK.R = 0x00d3d000; /* 14x PLL operation on normal power mode */
    }else
```

/************** TPU Set up **************/
/* Set up the TPU */
void setup_tpu(struct TPU3_tag *tpu) {
    tpu->TPUMCR.R = 0x2020; /* TCR1 prescaler divide by 2, supervisor and user access. */
    tpu->TPUMCR3.R = 0x0040; /* enable enhanced prescaler - divide by 2 */
    tpu->TICR.B.CIRL = 5; /* set interrupt level to 5.... */
    tpu->TICR.B.ILBS = 0; /* (but this example will not use TPU Interrupt) */
}
void main()
{
    init555(40); /* Perform a simple 555 initialization */
    Init_MIOS_PIO();
    initPIT(); /* Init PIT to generate interrupts */
    setup_tpu(tpua); /* Do general TPU set up. */
    tpu_pwm_init(tpua, chan_a, TPU_PRIORITY_HIGH, init_period, init_hightime, TPU_PWM_TCR1);
    tpu_pwm_init(tpua, chan_b, TPU_PRIORITY_HIGH, init_period, init_hightime, TPU_PWM_TCR1);

#ifdef __MWERKS__
    asm(" mtspr EIE, r3"); /* FINAL STEP: SET MSR[EE], MSR[RI] BITS */
#endif

while(1)
{
    loopctr++; // Increment loopctr for something to do
}

5.2 Example Description

This example sets the Enhanced prescaler to divide by 2 and it sets the TCR1 prescaler to 2. This gives a TCR1 clock frequency of 10 MHz (divide by 4 of the 40 MHz system clock). This yields a resolution of 100 ns. This example sets the period to 0x2000 (8192) TCR1 clock periods which equals 819 microseconds or 1220 Hertz. The high pulse width starts at 409.6 microseconds and is incremented by 25.6 microseconds until it reaches 640 microseconds at which time it is reset to 25.6 microseconds.

\[
\text{PWMFrequency} = \frac{1}{\text{TCR1 period} \times \text{PERIOD}}
\]

\[
\text{PWMFrequency} = \frac{1}{100\text{ns} \times 32768}
\]

\[
\text{PWMFrequency} = \frac{1}{819.2\text{microS}}
\]

\[
\text{PWMFrequency} = 1220.7\text{Hz}
\]

6 FQM C Level API Code

6.1 PWM Initialization Function

The `tpu_pwm_init` initialization routine initializes the channel to run the PWM function.

```c
void tpu_pwm_init(struct TPU3_tag *tpu, UINT8 channel,  
                   UINT8 priority, UINT16 period, UINT16 hightime, UINT8 timer)
{
  UINT16 channel_control;
  UINT16 tbs;
  UINT8 hsq;

  /* disable channels so they can be configured safely */
  tpu_disable( tpu, channel);

  /* PWM is function 0x3                  */
  tpu_func( tpu, channel, TPU_FUNCTION_PWM);

  /* disable interrupts on channels so they can be configured safely */
  tpu_interrupt_disable( tpu, channel);

  /* mask off illegal values */

  tbs = ( timer & TPU_PWM_TBS_MASK ) << 5;

  /* Initialize Parameter RAM */
  channel_control = ( tbs | TPU_PWM_PAC | TPU_PWM_PSC );

  tpu->PARM.R[channel][TPU_PWM_CHANNEL_CONTROL] = channel_control;
  tpu->PARM.R[channel][TPU_PWM_PWMPHI] = hightime;
  tpu->PARM.R[channel][TPU_PWM_PWMPER] = period;

  /**********************************************************
  /*    Configure the Channels.                     */
  /**********************************************************/
  tpu_hsr(tpu, channel, TPU_PWM_INIT);

  /* Enable channel by assigning a priority to them. */
```
6.2 **PWM Update Function**

The `tpu_pwm_update` routine should be called to change either the high time and the period of the sample window.

```c
void tpu_pwm_update(struct TPU3_tag *tpu, UINT8 channel, 
                     UINT16 period, UINT16 hightime, UINT8 immediate) {
    UINT32 update_val32;
    update_val32 = ((hightime << 16) | (period));
    tpu->PARM.L[channel][TPU_PWM_HIPER32] = update_val32;
    if (immediate) {
        tpu_hsr(tpu, channel, TPU_PWM_IMMED_UPDATE);
    }
}  /* End tpu_pwm_update */
```

6.3 **PWM Get Value Return Functions**

The function `tpu_pwm_get_hightime` returns the number of TCR clocks of the current high time of the PWM channel.

```c
UINT16 tpu_pwm_get_hightime(struct TPU3_tag *tpu, UINT8 channel) {
    UINT16 hightime;
    hightime = tpu->PARM.R[channel][TPU_PWM_PWMHI];
    return (hightime);
}  /* End tpu_pwm_get_hightime */
```

6.4 **PWM Get Value Return Functions**

The function `tpu_pwm_get_period` returns the number of TCR clocks of the current period of the PWM channel.

```c
UINT16 tpu_pwm_get_period(struct TPU3_tag *tpu, UINT8 channel) { /* End tpu_pwm_get_period */
```
Channel Control

```c

void tpu_pwm_get_hightime(uint16_t *period)
{
    UINT16 period;

    period = tpu->PARM.R[channel][TPU_PWM_PWMPER];
    return (period);
} /* End tpu_pwm_get_hightime */

7 PWM Function Parameters

This section provides detailed descriptions of PWM function parameters stored in channel parameter RAM. Figure 2 shows the parameter RAM assignment used by the PWM function.

7.1 Channel Control

CHANNEL_CONTROL contains the channel latch controls and configures the PSC, PAC, and TBS fields. The PSC field forces the output level of the pin directly without affecting the PAC latches, or forces the output level to the state specified by the PAC latches. The PAC field specifies the pin logic response as either a timer channel input or output. The TBS field configures a channel pin as input or output and configures the time base for output match/input capture events.

This parameter is used by the function to initialize the channel. It must be written by the CPU prior to issuing a host service request and assigning priority to the channel. The only legal values for this parameter are shown in Figure 2. Any other values cause indeterminate operation. Bits 9–15 are not used and are ignored.

### 7.1.1 PSC

The PSC field determines the setting of the pin after initialization. In normal mode, PSC is set to force the pin high. In level mode, where a 0% duty cycle is desired, PSC should be set to force the pin low at initialization. The PAC field specifies the pin logic response as a timer channel output; however, the PWM function does not use the PAC field, but uses direct control by the microcode. CHANNEL_CONTROL must be written by the CPU before initialization.

### 7.1.2 PAC

Since the PWM function is an output function, the PAC bits are not used and are therefore set to the value of 0x4.

### 7.1.3 TBS

These bits are used during initialization to select the timebase for the function. Either TCR1 or TCR2 can be selected.

### 7.1.4 OLDRIS

OLDRIS is the time of the previous low-to-high transition. The PWM microcode uses this value when calculating the next rise time. The TPU updates this parameter and should not be changed by the user.
7.1.5 PWMRIS

PWMRIS is the current calculated rise time calculated at the beginning of the pulse (on the low-to-high transition) by adding OLDRIS to PWMPER. The TPU updates this parameter.

7.1.6 PWMHI

PWMHI, which is updated by the CPU, is the current pulse high time that may be updated at any time. Estimate for best-case minimum value for PWMHI is greater than 32 system clocks, assuming a single channel operating. When more than one channel is operating, the minimum value for PWMHI depends on TPU configuration (the variables are described in Section 10, “Performance and Use of the PWM Function”). The maximum value is 0x8000. The user should calculate case timing to ensure proper execution of this function.

7.1.7 PWMPER

PWMPER, which is updated by the CPU, is the current PWM period and is used by the TPU to calculate the next low-to-high transition time. Estimate for best-case minimum value for PWMPER is greater than 32 system clocks, assuming that a single channel is operating. When more than one channel is operating, the minimum value for PWMPER depends on TPU configuration (the variables are described in Section 10, “Performance and Use of the PWM Function”). The maximum usable value is that which satisfies the condition: (PWMPER – PWMHI) is less than or equal to 0x8000. PWMHI and PWMPER must be accessed coherently. The user should calculate the case timing to ensure proper execution of this function. Normal, 100%, and 0% duty cycles are defined as follows.

\[
0\% \rightarrow \text{PWMHI} = 0 \\
100\% \rightarrow \text{PWMPER} \leq \text{PWMHI}, \text{AND PWMHI} \neq 0 \\
\text{Else normal} \rightarrow \text{PWMPER} > \text{PWMHI}, \text{AND PWMHI} \neq 0
\]

8 PWM Header File

The following header file listing provides common definitions for the PWM functions.

```c
#include "m_tpu3.h"

#ifdef __cplusplus
extern "C" {
#endif

/*****************************/
/*            Definition of terms and initial settings       */
/*****************************/

/* Define HSQ values (mode) */
/* HSQ values are not used by the PWM function. */

/* Define the Immediate values */
```

9 Host Interface to PWM Function

This section provides information concerning the TPU host interface to the PWM function.

9.1 Channel Function Select Registers

Encoded 4-bit fields within the channel function select registers specify one of 16 time functions to be
executed on the corresponding channel. The channel function bits should be set to 0x3 to select the PWM
ROM function.

9.2 Host Sequence Registers

The host sequence register is not used by the PWM function.
9.3 Host Service Request Registers

The host service request field selects the type of host service request for the time function selected on a given channel. The meaning of the host service request bits is determined by time function microcode. See Table 6 for the Host Service routines defined for the PWM function.

<tr>
<td>0b11</td>
<td>Not Used</td>
</tr>
</tbody>
</table>

9.4 Channel Priority Registers

The channel priority registers (CPR1, CPR2) assign one of three priority levels to a channel or disable the channel.

10 Performance and Use of the PWM Function

10.1 Performance

Like all TPU functions, the PWM function performance in an application is to some extent dependent upon the service time (latency) of other active TPU channels. This is due to the operational nature of the scheduler. When a single PWM channel is in use and no other TPU channels are active, the minimum time between any two pulse edges is greater than 32 CPU clocks. When more TPU channels are active, performance decreases. However, worst-case latency in any TPU application can be closely estimated. To analyze the performance of an application that appears to approach the limits of the TPU, use the guidelines given in the TPU reference manual and the information in the PWM state timing table below.

10.2 Changing Duty Cycle

The CPU can change the duty cycle at any time once the TPU has completed the initialization state (indicated by HSR 0b00 or a CPU interrupt request). Changes are made by writing a new high time value to PWMHI in the channel's parameter RAM.

The minimum duty cycle (and the maximum non-100% duty cycle) is dependent on the number of active TPU channels and the maximum channel latency as discussed above. A 0% duty cycle is generated by setting PWMHI = 0. A 100% duty cycle is scheduled by setting PWMPER less than or equal to PWMHI when PWMHI is not equal to zero.

Duty cycle changes take effect at the completion of the current period unless an immediate update (HSR 0b01) is also requested. Immediate updates may be requested for any duty cycle including 0% and 100%. A new PWMHI value with an immediate update HSR causes the TPU to change the currently scheduled high-to-low time. This can cause the undesired side effect of an improper duty cycle for one period.
10.3 Changing Period

Once the TPU has completed the initialization state the CPU may at any time specify a new period by writing to the PWMPER parameter. Unless the CPU also generates an immediate update service request the new period takes effect at the beginning of the next period, as shown in Figure 1. That is, a new rise time is calculated at the next low-to-high transition. Thus, the current period is allowed to complete before the new one begins.

10.4 Counting Periods

The TPU generates a CPU interrupt service request during the channel service at the beginning of each period. The CPU can respond to these requests to keep track of how many periods have elapsed. In this way, new pulse widths can be scheduled at a known position in time.

10.5 Stopping the Function

Once PWM operation is initialized on a channel, it runs without CPU intervention until a reset occurs. If it is necessary to turn off a PWM channel, the CPU can write zeros to the channel function select bits in registers CFSR[0:3]. This disables the function on the channel. Another way to disable output is to select 0% or 100% duty cycle in the channel parameter RAM. In this case the PWM continues to run and receive channel service but no transitions are seen on the pin.
