Introduction

This document shows how to generate clock signals for each the following HC908 Motorola 8-bit MCU Families:

- HC908JK/JL
- HC908AB/AS/AZ/MR
- HC908KL
- HC908GZ
- HC908JB
- HC908GP/GR
- HC908BD
- HC908LJ
- HC908GT
- HC908LD
- HC908KX
- HC908SR
- HC908EY
- HC908QT/QY
- HC908RF/RK

The figures in the first section are illustrations of clock distribution for each group of MCUs. They depict main sections of the MCU, clock generation, and distribution blocks and define the main clocks' limits, their respective control bits, and values. In the final sections are descriptions of methods of programming the phase-locked loop (PLL) modules, with several example values.

**NOTE:** With the exception of mask set errata documents, if any other Motorola document contains information that conflicts with the information in the device data sheet, the data sheet should be considered to have the most current and correct data.

© Freescale Semiconductor, Inc., 2004. All rights reserved.
The frequency of a crystal element is determined by the following equation:

\[ f_{BUSCLK} = \frac{f_{CGMXCLK}}{4} \]

Maximum bus frequency for 3-V operation is 4 MHz; for 5-V operation, it is 8 MHz. Either the external crystal or the external clock source frequency can be used as the clock source.

**NOTE:** The analog-to-digital converter (ADC) clock should be set to approximately 1 MHz as recommended in the data sheet.

For example, for an 8-MHz bus clock, the ADICLK register should be set to $60; for a 4-MHz bus clock, it should be set to $40.
The frequency of a crystal element is determined by the following equation:

\[ f_{BUSCLK} = \frac{f_{CGMXCLK}}{4} \]

The low-speed USB data rate is nominally 1.5 Mbps. The CGMXCLK signal driven by the oscillator circuit is the clock source for the USB module. It requires a 6-MHz oscillator circuit connected to the OSC1 and OSC2 pins.
The frequency of a crystal element is determined by the following equation:

\[ \frac{f_{BUSCLK}}{4} = f_{OSCXCLK} \]

The low-speed USB data rate is nominally 1.5 Mbps. The signal driven by the oscillator circuit is the clock source for the USB module. It requires a 6-MHz crystal element connected to the OSC1 and OSC2 pins.

There are two identical PLL frequency generator modules, which are designed as two independent, fully programmable clock generators, intended for 27-MHz RF applications. Each module contains all the function blocks for the PLL internal voltage controlled oscillator (VCO) control and are designed to be used with a crystal reference.
The low-speed USB data rate is nominally 1.5 Mbps. The clock source for the USB module is the bus clock. It requires a 24-MHz crystal element connected to the OSC1 and OSC2 pins.

The ADC clock should be set to approximately 1 MHz as recommended in the data sheet.

If the crystal frequency is equal to 24 MHz, the ADICLK register should be set to $60. In this case, the ADC clock is equal to 0.75 MHz.

The recommended working bus clock frequency of the sync processor is 6 MHz. This module is designed to detect and process sync signals from separated Hsync and Vsync inputs, or from a composite sync input signal inside a digital monitor system.
Figure 5. Distribution Clock Signals in the GT Family

The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the bus clock can be used as the clock source for the ADC.

If an 8-MHz bus clock provides the clock source for the ADC module, the ADICLK register should be set to $60. If the bus clock is equal to 4 MHz, the ADICLK register should be set to $40.

The internal oscillator is free-running at a standard frequency of 307.2 kHz ±25% and can be trimmed to max ±5% by setting the value of the TRIM register.

The internal clock generator (ICG) provides the internal clock source (ICLK), which is an integer multiple N of the internal oscillator frequency.

**Programming the Internal Clock Generator (ICG)** shows detailed information on programming the PLL and gives several examples.
The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the bus clock can be used as the ADC clock source.

The baud rate for the SCI is determined by this formula:

\[
\text{baudrate} = \frac{\text{InputCLK}}{64 \times PD \times BD}
\]

- PD (prescaler divisor) — SCP[1:0] in the SCBR register
- BD (baud rate divisor) — SCR[2:0] in the SCBR register
- The recommended XTAL frequency (for SCI) is 4.9152 MHz

**Programming the Internal Clock Generator (ICG)** shows detailed information on programming the PLL and gives several examples.
Figure 7. Distribution Clock Signals in the EY Family

The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the bus clock can be used as the clock source for the ADC.

The internal oscillator is free-running at a standard frequency of 307.2 kHz ±25% and can be trimmed to max ±5% by setting the value of TRIM register.

The ICG provides the internal clock source (ICLK), which is an integer multiple N of the internal oscillator frequency.

**Programming the Internal Clock Generator (ICG)** shows detailed information on programming the PLL and gives several examples.
The internal oscillator is free-running at a standard frequency of 307.2 kHz ±25%, and can be trimmed to max ±5% by setting the value of TRIM register.

The ICG provides the internal clock source (ICLK), which is an integer multiple N of internal oscillator frequency.

The ultra high frequency (UHF) transmit module is integrated into the RF Family MCUs. The UHF module can operate in the 315 MHz, 434 MHz, and 868 MHz industrial, scientific, and medical (ISM) bands, with on/off keying (OOK) and frequency shift keying (FSK) modulation.

**Programmable the Internal Clock Generator (ICG)** shows detailed information on programming the PLL and gives several examples.
The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the BUSCLK can be used as the clock source for the ADC. In this case, the PLL module can be used to generate the internal BUSCLK.

Baud rate for the SCI is determined by this formula:

\[
\text{baudrate} = \frac{f_{\text{CLK}}}{64 \times PD \times BD}
\]

- PD (prescaler divisor) — SCP[1:0] in the SCBR register
- BD (baud rate divisor) — SCR[2:0] in the SCBR register

**Figure 9. Distribution Clock Signals in the AB/AS/AZ/MR Families**

Programming the PLL-1 shows detailed information on programming the PLL and provides several examples.
The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the BUSCLK can be used as the clock source for the ADC. In this case, the PLL module can be used to generate the internal BUSCLK.

**Programming the PLL-2** shows detailed information on programming the PLL and provides several examples.

The MSCAN module is a communication controller implementing the CAN 2.0 A/B protocol, as defined in the BOSCH specification dated September 1991. The programmable bit rate is up to 1 Mbps.
The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the BUSCLK can be used as the clock source for the ADC. In this case, the PLL module can be used to generate the internal BUSCLK.

Baud rate for the SCI is determined by this formula:

\[
\text{baudrate} = \frac{\text{InputCLK}}{64 \times \text{PD} \times \text{BD}}
\]

- PD (prescaler divisor) — SCP[1:0] in the SCBR register
- BD (baud rate divisor) — SCR[2:0] in the SCBR register
- The Recommended clock frequency for SCI is 4.9152 MHz

**Programming the PLL-3** shows detailed information on programming the PLL and provides several examples.
The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the BUSCLK can be used as the clock source for the ADC. In this case, the PLL module can be used to generate the internal BUSCLK.

The internal RC oscillator is free-running at a typical frequency of 48 kHz and drives the SIM counter and COP module in sequence. This frequency decreases to 44 kHz with decreasing the supply voltage to 3 V.

**Programming the PLL-3** shows detailed information on programming the PLL and provides several examples.

---

**Figure 12. Distribution Clock Signals in the LJ Family**

*ADICLK is in the ADC clock register ADCLK
BCS is in the PLL control register PCTL
CKS is in the SCI baud rate register SCBR

*VALUE IS DEPENDENT ON SUPPLY VOLTAGE
The high-speed USB data rate is nominally 12 Mbps. The clock source for the USB module is the OSCXCLK. It requires a 24-MHz oscillator circuit connected to the OSC1 and OSC2 pins. This USB module supports both embedded full speed device and hub functions and contains one upstream port and four downstream ports.

The ADC clock should be set to approximately 1 MHz as recommended in the data sheet.

**Programming the PLL-4** shows detailed information on programming the PLL and provides several examples.
The internal RC oscillator is free-running at a typical frequency of 24 kHz. This frequency decreases to 17 kHz with decreasing the supply voltage to 3 V.

The ADC clock should be set to approximately 1 MHz as recommended in the data sheet. Either the CGMXCLK or the BUSCLK can be used as the clock source for the ADC. In this case, the PLL module can be used to generate the internal BUSCLK.

Figure 14. Distribution Clock Signals in the SR Family
Baud rate for SCI is determined by this formula:

\[
\text{baudrate} = \frac{\text{InputCLK}}{64 \times PD \times BD}
\]

- PD (prescaler divisor) — SCP[1:0] in the SCBR register
- BD (baud rate divisor) — SCR[2:0] in the SCBR register
- The recommended clock frequency for the SCI is 4.9152 MHz

**Programming the PLL-3** shows detailed information on programming the PLL and provides several examples.
The internal oscillator is free-running at a standard frequency of 12.8 MHz. After a reset function, the TRIM register is set to $80. This provides a bus clock frequency of 3.2 MHz. The internal oscillator runs with a wide tolerance of ±25%, but it is possible to trim this to a tolerance ±5% by setting the OSCTRIM register at address $0038.

The values saved in the FLASH memory at address $FFC0 (for 5.0V supply) and $FFC1 (for 3.0V supply) by the manufacturer makes it possible to set the bus clock to 3.2 MHz ±5%. It is possible to change the bus clock in the full range from 2.4 MHz to 4.0 MHz by writing the appropriate value to the OSCTRIM register. The value of the OSCTRIM register can vary from $00 to $FF. A lower value produces a higher frequency.

**Standard Setting**

After a reset, the default setting is the internal oscillator because the clock source is running at a nominal frequency approximately 12.8 MHz. The bus-frequency is 3.2 MHz ±25% (default value of the OSCTRIM = $80). For correct functionality of ADC, the ADICLK register (address $003F) must be set to value $40.
Programming the Internal Clock Generator (ICG)

This example uses the GT Family of MCUs.

Internal clock generator (ICG) module — Used to create stable clock source (ICLK) for the MCU without using any external components.

Digitally controlled oscillator (DCO) — Generates the internal clock (ICLK). The clock period of ICLK is dependent on the digital loop filter outputs (DSTG[7:0] and DDIV[3:0]). The long-term precision of the output ICLK is restricted to the approximate range of $\pm 0.202\%$ to $\pm 0.368\%$.

Modulo N divider — Creates the low-frequency base clock (IBASE) by dividing the internal clock (ICLK) by the ICG multiplier factor N contained in the ICG multiplier register (ICGMR).

Frequency comparator — effectively compares the low-frequency base clock (IBASE) to a nominal frequency $f_{\text{nom}}$. The comparator’s outputs are fed to the digital loop filter.

Digital loop filter (DLF) — uses the outputs of the frequency comparator to adjust the internal clock (ICLK) period. DLF generates the DCO control bits (DDIV[3:0]) and the stage control bits (DSTG[7:0]), which are fed to the DCO. The DLF first concatenates the DDIV and DSTG registers and then adds or subtracts a value, depending on the relative error in the low-frequency base clock period.

Standard Setting for the GT Family

The clock generation module is set to the following values after a RESET:

- Internal clock generation with TRIM register = $80$
- In the FLASH memory at address $\text{FF80}$ and $\text{FF81}$ is the manufacturer’s recommended trim value for the 5-V supply and the 3-V supply, respectively.
- Internal bus frequency $f_{\text{Bus}} = 1.613$ MHz (25% under max $f_{\text{Bus}}$ for 3-V operation) by the setting the ICGMR register (address $\text{0037}$) to $15$.

Standard Setting for EY, KX, and RF Families

The clock generation module is set to the following values after a RESET:

- Internal clock generation with TRIM register = $80$
- Internal bus frequency $f_{\text{Bus}} = 1.613$ MHz (25% under max $f_{\text{Bus}}$ for 3-V operation) by the setting the ICGMR register (address $\text{0037}$) to $15$. 

For More Information On This Product, Go to: www.freescale.com
Programming the PLL-1

This example uses the AB Family of MCUs.

The following instruction shows how to program the PLL.

1. Choose the desired bus frequency $f_{\text{Busdes}}$.
2. Calculate the desired VCO frequency:

\[
f_{\text{CLKdes}} = 4 \times f_{\text{Busdes}}
\]

3. Choose the partial PLL reference frequency $f_{\text{RCLK}}$.
4. Select the VCO frequency multiplier, $N$:

\[
N = \text{round}\left(\frac{f_{\text{CLKdes}}}{f_{\text{RCLK}}}\right)
\]

**NOTE:** The *round* function means that the real number should be rounded to the nearest whole number.

5. Calculate and verify the adequacy of the VCO and bus frequencies $f_{\text{VCLK}}$ and $f_{\text{Bus}}$:

\[
f_{\text{VCLK}} = N \times f_{\text{RCLK}}
\]

\[
f_{\text{Bus}} = \frac{f_{\text{VCLK}}}{4}
\]

6. Select the linear VCO multiplier $L$:

\[
L = \text{round}\left(\frac{f_{\text{VCLK}}}{f_{\text{nom}}}\right) \quad \text{where } f_{\text{nom}} = 4.9152 \text{ MHz}.
\]

7. Calculate and verify the adequacy of the VCO programmed center-of-range frequency $f_{\text{VRS}}$.

\[
f_{\text{VRS}} = (L) \cdot f_{\text{nom}}
\]

8. Verify and choose $N$ and $L$ by comparing $f_{\text{VCLK}}$ to $f_{\text{VRS}}$ and $f_{\text{CLKdes}}$: For proper operation, $f_{\text{VCLK}}$ must be within the application's tolerance of $f_{\text{CLKdes}}$, and $f_{\text{VRS}}$ must be as close as possible to $f_{\text{VCLK}}$.
9. Program the PLL registers (in Figure 16) accordingly:
   – In the upper four bits of the PLL programming register (PPG)($001E), program the binary equivalent of N.
   – In the lower four bits of the PLL programming register (PPG), program the binary equivalent of L.

**CAUTION:** Exceeding the recommended maximum bus frequency or VCO frequency can cause damage to the MCU.

To set the desired bus frequency, you must program the content of several PLL registers. They are shown in Figure 16.

---

**Figure 16. PLL Registers for the HC908AB/AS/AZ/MR Families**
Standard Settings

MCU default after reset function:

- External crystal element 4.9152 MHz
- Internal bus frequency of 7.3728 MHz
- For ADC, it is recommended setting ADCLK register ($003A) to $70
- For SCI, baud rate scale is from 600 to 76.800 bps (for setting: PD = 1 and BD is set from 1 to 128) in the SCBR register ($0019)
  - For [SCBR] = $00 baud rate is 76.8 kbps
  - For [SCBR] = $02 baud rate is 19.2 kbps
  - For [SCBR] = $03 baud rate is 9.6 kbps

Programming the PLL-2

This example uses the GZ Family of MCUs.

The following instruction shows how to program the PLL.

1. Choose the desired bus frequency $f_{Busdes}$
2. Calculate the desired VCO frequency:

$$V_{CLKdes} = 4 \times f_{Busdes}$$

3. Choose the partial PLL reference frequency $f_{RCLK}$. Typically the reference crystal is 1 to 8 MHz.
4. Select the VCO frequency multiplier, $N$:

$$N = \text{round} \left( \frac{f_{VCLKdes}}{f_{RCLK}} \right)$$

**NOTE:** The round function means that the real number should be rounded to the nearest whole number.

5. Calculate and verify the adequacy of the VCO and bus frequencies $f_{VCLK}$ and $f_{Bus}$:

$$f_{VCLK} = N \times f_{RCLK}$$

$$f_{Bus} = \frac{f_{VCLK}}{4}$$
6. Select the VCO’s power-to-two range multiplier E, according to Table 1:

**Table 1. VCO Range Multiplier**

<table>
<thead>
<tr>
<th>Frequency range</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>$0 &lt; f_{VCLK} &lt; 8$ MHz</td>
<td>0</td>
</tr>
<tr>
<td>$8$ MHz $\leq f_{VCLK} &lt; 16$ MHz</td>
<td>1</td>
</tr>
<tr>
<td>$16$ MHz $\leq f_{VCLK} &lt; 32$ MHz</td>
<td>2</td>
</tr>
</tbody>
</table>

**NOTE:** Do not program E to a value of 3.

7. Select a VCO linear range of multiplier L, where $f_{\text{nom}} = 71.4$ kHz

$$L = \text{round} \left( \frac{f_{\text{VCLK}}}{2^E \times f_{\text{nom}}} \right)$$

8. Calculate and verify the adequacy of the VCO programmed center-of-range frequency $f_{\text{VRS}}$. The center-of-range frequency is the midpoint between the minimum and maximum frequencies attainable by the PLL.

$$f_{\text{VRS}} = (L \times 2^E) f_{\text{nom}}$$

for proper operation:

$$\left| f_{\text{VRS}} - f_{\text{VCLK}} \right| \leq \frac{f_{\text{nom}} \times 2^E}{2}$$

9. Verify and choose N, E, and L by comparing $f_{\text{VCLK}}$ to $f_{\text{VRS}}$ and $f_{\text{VCLKdes}}$. For proper operation, $f_{\text{VCLK}}$ must be within the application’s tolerance of $f_{\text{VCLKdes}}$, and $f_{\text{VRS}}$ must be as close as possible to $f_{\text{VCLK}}$.

10. Program the PLL registers accordingly:
    - In the VPR bits of the PLL control register (PCTL), program the binary equivalent of E.
    - In the PLL multiplier select register low (PMSL) and the PLL multiplier select register high (PMSH), program the binary equivalent of N.
    - In the PLL VCO range select register (PMRS), program the binary equivalent of L.

**NOTE:** Exceeding the recommended maximum bus frequency of VCO frequency can cause damage to the MCU.
In the programming of the PLL registers there are two exceptions:

- A 0 value for N is interpreted exactly the same as a value of 1.
- A 0 value for L disables the PLL and prevents its selection as the source for the base clock.

<table>

</table>
Programming the PLL-3

This example uses the GP Family of MCUs.

The following instruction shows how to program the PLL.

1. Choose the desired bus frequency $f_{\text{Busdes}}$.

2. Calculate the desired VCO frequency:

$$f_{\text{VCLKdes}} = 4 \times f_{\text{Busdes}}$$

3. Choose the practical PLL (crystal) reference frequency $f_{\text{RCLK}}$, and the reference clock divider $R$. Typically the reference crystal is 32.768 kHz and $R = 1$.

Frequency errors to the PLL are corrected at the rate of $f_{\text{RCLK}}/R$. For stability and lock time reduction this rate must be as fast as possible. The VCO frequency must be an integer multiple of this rate.

The relationship between the VCO frequency and the reference frequency is:

$$f_{\text{VCLK}} = \frac{2^P N}{R} f_{\text{RCLK}}$$

where $P$ and $N$ are integers.

4. Select a VCO frequency multiplier $N$:

$$N = \text{round}\left(\frac{R \times f_{\text{VCLKdes}}}{f_{\text{RCLK}}}\right)$$

Reduce $N/R$ to the lowest possible $R$.

5. If $N < N_{\text{max}}$, use $P = 0$. If $N > N_{\text{max}}$, choose $P$ using this table

\[
\begin{array}{c|c}
\text{Current N value} & \text{P} \\
\hline
0 < N \leq N_{\text{max}} & 0 \\
N_{\text{max}} < N \leq N_{\text{max}} \times 2 & 1 \\
N_{\text{max}} \times 2 < N \leq N_{\text{max}} \times 4 & 2 \\
\end{array}
\]
Then re-calculate N:

\[ N = \text{round} \left( \frac{R \times f_{VCLK\text{des}}}{f_{RCLK} \times 2^P} \right) \]

6. Calculate and verify the adequacy of the VCO and bus frequencies \( f_{VCLK} \) and \( f_{Bus} \)

\[ f_{VCLK} = (2^P \times N/R) \times f_{RCLK} \]

\[ f_{BUS} = \frac{f_{VCLK}}{2^P \times 4} \]

7. Select the VCO’s power-to-two range multiplier \( E \), according to Table 4.

8. Select a VCO linear range of multiplier \( L \), where \( f_{\text{nom}} = 38.4 \text{ kHz} \).

\[ L = \text{round} \left( \frac{f_{VCLK}}{2^E \times f_{\text{nom}}} \right) \]

9. Calculate and verify the adequacy of the VCO programmed center-of-range frequency \( f_{VRS} \). The center-of-range frequency is the midpoint between the minimum and maximum frequencies attainable by the PLL.

\[ f_{VRS} = (L \times 2^E) f_{\text{nom}} \]

for proper operation:

\[ |f_{VRS} - f_{VCLK}| \leq \frac{f_{\text{nom}} \times 2^E}{2} \]

10. Verify and choose \( P, R, N, E \) and \( L \), by comparing \( f_{VCLK} \) to \( f_{VRS} \) and \( f_{VCLK\text{des}} \). For proper operation, \( f_{VCLK} \) must be within the application’s tolerance of \( f_{VCLK\text{des}} \), and \( f_{VRS} \) must be as close as possible to \( f_{VCLK} \).

### Table 4. VCO Range Multiplier

**NOTES:**

1. When AUTO = 0, PLLIE is forced clear and is read-only.
2. When AUTO = 0, PLLF and LOCK read as clear.
3. When AUTO = 1, ACQ is read-only.
4. When PLLON = 0 or VRS7:VRS0 = $0, BCS is forced clear and is read-only.
5. When PLLON = 1, the PLL programming register is read-only.
6. When BCS = 1, PLLON is forced set and is read-only.

Figure 17. PLL Registers of the HC908GR/GP/LJ/SR Families
If a crystal element of frequency 32.768 kHz is in use, desired bus frequency is 8 MHz, it is necessary to set these values in the respective registers:

- $A2 to address $0036 (PCTL register) — P, E
- $80 to address $0037 (PBWC register) — Auto BW
- $F4 to address $0039 (PMSL register) — N
- $D0 to address $003A (PMRS register) — L
- $70 to address $003E (ADCLK register)

If a crystal element of frequency 32.768 kHz is in use, desired bus frequency is 4 MHz, it is necessary to set these values in the respective registers:

- $A1 to address $0036 (PCTL register) — P,E;
- $80 to address $0037 (PBWC register) — Auto BW
- $7A to address $0039 (PMSL register) — N
- $D0 to address $003A (PMRS register) — L
- $50 to address $003E (ADCLK register)
Programming the PLL-4

This example uses the LD Family of MCUs.

In this family, the PLL is used to generate output frequency CGMVCLK in integer multiples of the crystal reference OSCXCLK. The base selector circuit (the software controlled circuit) selects either CGMVCLK or OSCXCLK as the clock source DCLK1 for the sync processor. The sync processor derives other display clocks from DCLK1.

The basic setting of relevant PLL registers is shown in Table 6.

</tbody>
</table>

HVOCR[1:0] — These two bits determine the prescaler of the PLL reference clock in the CGM module. When HVOCR[1:0] = 11, the prescaler is 2; for other values the prescaler is 3.

The relevant PLL registers are shown in Figure 18.

LD Family default settings after a reset:
- External crystal element 24 MHz
- Internal bus frequency of 6.0 MHz
- Sync processor use the CGMXCLK (frequency of external crystal element) as a reference to generate sync composition (video mode is 640 x 480).
