32-bit Linear Quadrature
Decoder TPU Function Set
(32LQD)

By Milan Brejl, Ph.D.

Freescale Semiconductor, Inc.

Functional Overview

32-bit Linear Quadrature Decoder (32LQD) TPU Function Set is useful for decoding position, direction and velocity information from encoder signals in motion control systems. The 32-bit Position Counter (PC) is particularly useful for linear motor systems. The function set consists of 3 TPU functions:

- 32-bit Linear Quadrature Decoder (32LQD)
- Home Channel for 32-bit Linear Quadrature Decoder (32LQD_Home)
- Velocity Support for 32-bit Linear Quadrature Decoder (32LQD_VS)

The 32-bit Linear Quadrature Decoder uses two input channels to decode a pair of out-of-phase encoder signals and produce a resulting 32-bit bidirectional position counter for the CPU. An additional input channel can also be used to indicate a “home” position. When the position is reached, appropriate actions are taken. For accurate velocity measurement, Velocity Support can be added.

Figure 1 illustrates the functionality.

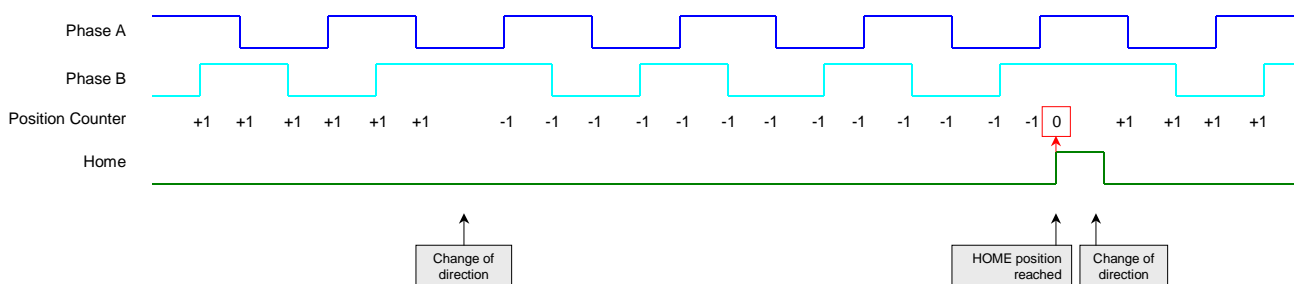

Figure 1. Signals processed by 32LQD TPU function set and corresponding PC value

Function Set Configuration

The 32LQD is the main function of the set. It can be used either alone, with one of the supporting functions, or with both of them. There are no restrictions on channel numbers – any function can run on any channel.

Table 1 shows the configuration options and restrictions.

Table 1. 32LQD TPU function set configuration options and restrictions

TPU function	Optional/Mandatory	How many channels	Assignable channels
32LQD	mandatory	2	any 2 channels: Phase A and Phase B
32LQD_home	optional	1 or more	any
32LQD_VS	optional	1 or more	any

The two out of phase encoder signals are called Phase A (primary channel) and Phase B (secondary channel). The Host Sequence (HSQ) bit 0 is used to determine to which channel Phase A is connected and to which Phase B is connected. The HSQ is also used for other configuration options – refer to the detailed function descriptions.

Table 2 shows an example of configuration. The Phase A encoder signal is connected to channel 0 and Phase B to channel 1. TCR2 clock is selected for all timing operations and the Home channel reacts to low-high transitions.

Table 2. Example of configuration

Channel	TPU function	HSQ	Priority
0	32LQD	10	high
1	32LQD	11	high
2	32LQD_home	00	middle
15	32LQD_VS	10	middle

In this configuration, when no other functions run on the same TPU, the 32LQD can receive and process input transitions at a rate of up to 540 kcounts per second at 40MHz IMB clock. When 32LQD_home and 32LQD_VS are not used, the 32LQD running standalone can count edges at a rate of up to 800 kcounts per second at 40MHz IMB clock. This is equivalent to a 1024-pulse encoder speed of more than 11,700 rpm.

Table 3 shows another example of configuration where the functions of Standard Space Vector Modulation TPU function set (svmStd) run together with 32LQD functions on one TPU. This configuration enables the 32LQD to receive and process input transitions at a rate of up to 363 kcounts per second

at 40MHz IMB clock. This is equivalent to a 1024-pulse encoder speed of more than 5,300 rpm. The Space Vector Modulation PWM frequency can be set up to 12.8 kHz to enable the maximum rpm. If the PWM frequency is set to 16 kHz the encoder pulses can be processed at a rate of 272 kcounts per second, that is equivalent to 3,900 rpm with a 1024-pulse encoder. If the PWM frequency is set to 20 kHz the encoder pulses can be processed at a rate of 181 kcounts per second, that is equivalent to 2,600 rpm with a 1024-pulse encoder.

Table 3. Example of configuration

Channel	TPU function	Priority
0	svmStd_top	middle
1	svmStd_top	middle
2	svmStd_top	middle
3	svmStd_bottom	middle
4	svmStd_bottom	middle
5	svmStd_bottom	middle
6	32LQD	high
7	32LQD	high
8	32LQD_home	low
10	svmStd_sync	low
12	32LQD_VS	low
15	svmStd_fault	middle

Table 4 shows the TPU function code sizes.

Table 4. TPU function code sizes

TPU function	Code size
32LQD	40 μ instructions + 8 entries = 48 long words
32LQD_home	10 μ instructions + 8 entries = 18 long words
32LQD_VS	19 μ instructions + 8 entries = 27 long words

- Configuration Order** The CPU configures the TPU as follows.
1. Disables the channels by clearing the two channel priority bits on each channel used (not necessary after reset).
 2. Selects the channel functions on all used channels by writing the function numbers to the channel function select bits.
 3. Initializes function parameters. The parameters PC_init_LOWER, and PC_init_UPPER, CORR_PIN_PTR_A and CORR_PIN_PTR_B must be set before initialization. The parameter VS_period must be set if Velocity Support channel is used.
 4. Set the HSQ (Host Sequence) bits to determine which channel is Phase A and which is Phase B and to select other function options.
 5. Issues an HSR (Host Service Request) type %10 to both of the 32LQD channels to initialize position counting. Issues an HSR type %10 to the 32LQD_home and 32LQD_VS channels, if used.
 6. Enables servicing by assigning high, middle or low priority to the channel priority bits. Both Phase A and Phase B channels should be assigned the same priority.

NOTE: *A CPU routine that configures the TPU can be generated automatically using the MPC500_Quick_Start Graphical Configuration Tool.*

Detailed Function Description

32-bit Linear Quadrature Decoder (32LQD)

The 32LQD operates on two channels and processes the incoming out-of-phase encoder signal. As a result of this processing, the bidirectional 32-bit Position Counter (PC) gets a value that reflects the position of a motion system. The PC value is incremented or decremented by 1 on each transition of Phase A or Phase B input channels – see [Figure 2](#). On initialization, the PC is set to a 32-bit PC_init value entered by the CPU.

Figure 2. 32-bit Linear Quadrature Decoder

Two function modes are offered:

- TCR1 clock selected
- TCR2 clock selected

The mode selection is done by HSQ bit 1. The HSQ bit 0 is used to determine which channel is Phase A and which is Phase B – see [Table 5](#). The user has to select Phase A on one channel and Phase B on the other, and the same mode on both channels.

The function offers interpolation support for very slow quadrature signals. The parameters LastEdgeT and ActualT are updated on a Host Service Request HSR = 11. The LastEdgeT then has the value of last incoming edge time in TCR clocks and the ActualT has the current value of the TCR clock.

The CPU program should use 32-bit reads/writes of 32-bit parameters (PC, PC_init) to ensure their coherency. It can also use a 32-bit read of LastEdgeT and ActualT for coherency.

GET_TIME	8	3
EDGE	36	9

NOTE: Execution times do not include the time slot transition time (TST = 10 or 14 IMB clocks)

Figure 3. 32LQD timing

Figure 4. 32LQD state diagram

Noise Immunity

The input signals can be disturbed by an impulse noise. The TPU hardware rejects short input pulses of less than a configurable number of IMB clocks. Longer pulses are processed by TPU. Furthermore the function itself uses a pin history to reject any short error pulse that is long enough to get through the hardware filter, but not long enough to last from the actual transition time to the time that the TPU services the channel. Even longer error pulses are counted on both edges resulting a net error of zero on the PC. See examples of error pulses processing on [Figure 5](#).

Figure 5. Noise immunity

Home Channel for 32-bit Linear Quadrature Decoder (32LQD_home)

The 32LQD_home function monitors an input signal, which indicates a “HOME-position” of the motion system with a pulse. The function can be configured to react on either a low-high transition, a high-low transition or either transition. This way the user can select whether the HOME-signal is of positive or negative polarity and the action to be taken when the HOME-position is either reached, left or both. Three function modes are offered based on these options:

- Detection of low-high transition
- Detection of high-low transition
- Detection of any transition

The mode selection is done by HSQ bits – see [Table 9](#).

When the specified action happens the 32LQD_home function resets the 32-bit Position Counter to its initialization value (PC_init_UPPER, PC_init_LOWER) and generates a channel interrupt.

Velocity Support for 32-bit Linear Quadrature Decoder (32LQD_VS)

The 32LQD_VS runs on an unconnected TPU channel. The function periodically measures the difference of the 32LQD 32-bit Position Counter (PD – Position Difference) and the exact time corresponding to it (TD – Time Difference). The Time Difference slightly varies from the period of measurement (VS_period). The Time Difference is calculated as the difference between the time of the last transition counted and the time of the transition preceeding the first one counted. It is illustrated on **Figure 8**.

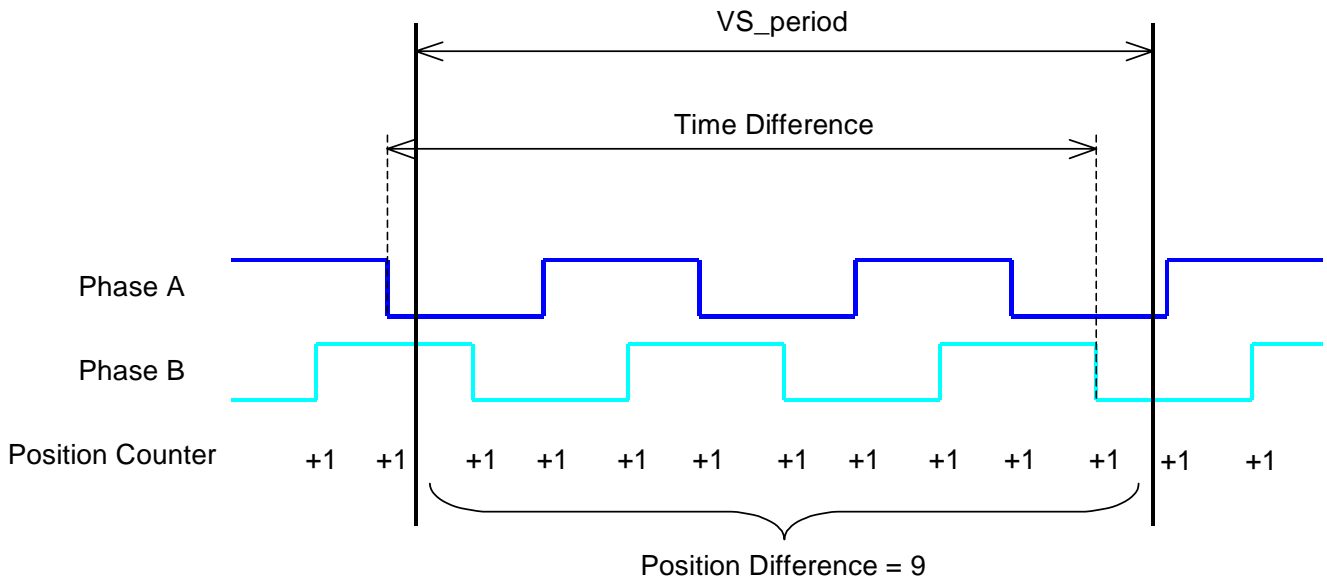

Figure 8. Velocity Support

The Time Difference and Position Difference values can be used by the CPU program to calculate the exact velocity of the motion system.

The function can use either the TCR1 or the TCR2 clock for VS_period measurement. Two function modes are offered based on this options:

- TCR1 clock selected
- TCR2 clock selected

The mode selection is done by the HSQ bits – see **Table 13**. **The selected clock must be the same as is used by the main function 16QD.**
