This document describes the estimated product lifetimes for the i.MX 6SoloLite applications processor based on the criteria used in the qualification process.

The product lifetimes described here are estimates and do not represent a guaranteed lifetime for a particular product.

1 Introduction

The i.MX 6 series consists of an extensive number of processors that deliver a wide range of processing and multimedia capabilities across various qualification levels.

This document is intended to provide users with guidance on how to interpret the different i.MX 6SoloLite qualification levels in terms of the target operating frequency of the device, the maximum supported junction temperature (Tj) of the processor, and how this relates to the lifetime of the device.
Introduction

Each qualification level supported (Commercial and Extended Commercial) defines a number of power-on hours (PoH) available to the processor under a given set of conditions, such as:

- The target frequency for the application (commercial and extended commercial).
  
  a) The target frequency is determined by the input voltage to the processor’s core complex (VDD_ARM_IN).
  
  b) The use of LDO-enabled or LDO-bypass mode.
     
     - When using LDO-bypass mode, the target voltage should not be set to the minimum specified in the datasheet. All power management ICs have allowable tolerances. The target voltage must be set higher than the minimum specified voltage to account for the tolerance of the PMIC. The tolerance assumed in the calculations in this document is +/-25mV.
     
     - LDO-enabled mode uses the regulators on the i.MX 6 series. These regulators are well characterized and can be set to output the exact minimum specified voltage. Longer power-on-hours can be achieved using LDO-enabled mode.

- The percentage of active use vs. standby.
  
  a) Active use means that the processor is running at an active performance mode.
     
     - For the commercial and extended commercial tiers, there are two available performance modes: 996 MHz and 792 MHz.
  
  b) In standby/DSM mode the datasheet defines lower operating conditions for VDD_ARM_IN, VDD_SOC_IN and VDD_PU_IN, reducing power consumption and junction temperature. In this mode, the voltage and temperature are set low enough so that the effect on the lifetime calculations is negligible and treated as if the device were powered off.

- The junction temperature (Tj) of the processor.
  
  a) The maximum junction temperature of the device is different for each tier of the product, e.g. 95°C for commercial and 105°C extended commercial. This maximum temperature is guaranteed by final test.
  
  b) Users must ensure that their device is appropriately thermally managed such that the maximum junction temperature is not exceeded.

All data provided within this document are estimates for PoH that are based on extensive qualification experience and testing with the i.MX 6 series. These statistically derived estimates should not be viewed as a limit on an individual device’s lifetime, nor should they be construed as a guarantee by Freescale as to the actual lifetime of the device. Sales and warranty terms and conditions still apply.
2 Device qualification level and available PoH

2.1 Commercial qualification

Table 2 provides the number of PoH for the typical use conditions for the commercial device.

</tbody>
</table>

Figure 1 and Figure 2 establish guidelines for estimating PoH as a function of CPU frequency and junction temperature. PoH can be read directly off of the charts below to determine the necessary trade-offs to be made to CPU frequency and junction temperature to increase the estimated PoH of the device.
2.2 Extended commercial qualification

Table 2 provides the number of PoH for the typical use conditions for the extended commercial device.

<table>
<thead>
<tr>
<th>Case</th>

3 Combining use cases

In some applications a constant operating use case cannot deliver the target PoH. In this case, it is advantageous to use multiple operating conditions. This method provides some of the lifetime benefits of running at a lower performance use case, while keeping the ability of the system to use the highest performance state dictated by the application’s demands.

Scenario 1: Switching between two power states with different voltages.

In this scenario, the system is using a 996 MHz full power state, and a 792 MHz reduced power state. It is assumed for these calculations that the temperature stays constant in either mode. If the system spends 50% of its power-on-time at 996 MHz and 50% of its power-on-time at 792 MHz, the two POH (read from Figure 5) can be combined with using those percentages: $61,500 \times 0.5 + 23,000 \times 0.5 = 42,250$ PoH.

![Figure 5. Multiple power state use case](image)
Combining use cases

**Scenario 2: Switching between two power states with different temperatures**

This scenario assumes that the system can achieve a drop in temperature by throttling back in performance while still maintaining a constant voltage. This temperature change may be able to be achieved by changing the frequency or by simply scaling back the loading on the ARM cores or processing units. This use case is particularly useful for customers who need to take advantage of the full extended commercial temperature range of the i.MX 6 series. In this scenario, the system spends 30% of its power-on-hours at 90°C and 70% of its power-on hours at 105°C (as read off the chart in *Figure 6*). The two POH can be combined as such: $41,500 \times 0.3 + 23,000 \times 0.7 = 28,550$ PoH.

![Figure 6. Multiple temperature use case](image)
Scenario 3: Using three or more power states.
This scenario shows how this strategy can be extended to more than two power states. While this example only has three power states, there is no limit to the actual number of power states that can be combined. The power states that are being used in this scenario are 792 MHz (at 104°C) and 996 MHz (at 92°C). Each state will be used equally one third of the time. These power states can be combined as such: 

\[ 61,500 \times 0.34 + 41,500 \times 0.33 + 23,000 \times 0.33 = 42,195 \, \text{PoH} \]
