Generic Timer Module (GTM) Inter-Integrated Circuit (I2C) Bus Emulation

by: Inga Harris

1 Introduction

This Generic Timer Module (GTM) Inter-Integrated Circuit (I2C) Bus Emulation application note is intended to provide details of how to emulate I2C bus Serial Data (SDA) and Serial Clock (SCK) output signals using the GTM Multi-Channel Sequencer (MCS) submodule and the ARU connection Timer Output (ATOM) submodule. The assembly functions are portable to any product that has a GTM module. Porting the application code, which configures the chip and GTM, from one chip to another does require minor changes. Example code in this application note is based on the MPC5777M device. This application note should be read in conjunction with application note AN4351, “MPC57xxM Generic Timer Module (GTM) Quick Start Guide.”

2 Overview

The I2C bus was designed by Philips (now NXP Semiconductors®) in the early 1980s to allow easy communication between components that reside on the same circuit board. It is now a common communication protocol used in many embedded applications.

An I2C interface is commonly emulated in software where a dedicated hardware peripheral is not available. The solution presented in this application note emulates the interface in the GTM MCS module with only a small amount of software.
running on the chip core, which means that the emulated interface does not consume CPU bandwidth and only consumes one MCS channel with two ATOM channels.

This example is for a single-master implementation, where the MPC5777M is the single master as the I2C bus does not need to do arbitration detection. The single-master implementation is often used in chip to external EEPROM memory configurations. A multi-master system is not implemented because it is more complicated to implement all the bus timing specifications because start and stop bit detection would be needed, involving the additional of use of a TIM submodule.

The given example transmits a 7-bit address followed by 16 bits of data (divided into 8-bit bytes) with a few control bits for communication start, end, direction, and acknowledgement as shown in Table 1. The address and data information is stored in the MCS RAM at compile time for simplicity, but it could also be moved to the RAM through DMA or read by the MCS through the PSM submodule in a full application environment.

### Table 1. Message format

<table>
<thead>
<tr>
<th>START</th>
<th>Slave address</th>
<th>R/W</th>
<th>ACK</th>
<th>Data</th>
<th>ACK</th>
<th>Data</th>
<th>ACK</th>
<th>STOP</th>
</tr>
</thead>

<td>Pulse</td>
<td>Pulse</td>
<td>Pulse</td>
<td>High</td>
</tr>
</tbody>
</table>

The transmission of ADDR and DATA is controlled by the master. The SDA signal can only be changed when the SCL signal is low. When the master sets the SCL signal high, the slave samples the SDA signal.

The figure below shows an example transmission from the system:

- ADDR = 0x70
- WRITE
- DATA = 0x0114
NOTE
As this example does not require a slave to be connected to the master, the lack of the slave driving the SDA line low during the ACK clock is ignored.

3 Block Diagram
The I2C solution given in this application note uses the following GTM104 submodules:
Figure 2. GTM configuration for I2C

<table>
<thead>
<tr>
<th>Submodule</th>
<th>Purpose</th>
<th>Use case</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clock Management Unit (CMU)</td>
<td>Generates all of the clocks and counters for the GTM subsystem.</td>
<td>Controls the system clock speed from the chip level clocks.</td>
</tr>
<tr>
<td>Time Base Unit (TBU)</td>
<td>Provides a common timebase that can be used throughout the GTM subsystem.</td>
<td>TBU_TS0 uses CMU_CLK0 as source for the GTM global timebase.</td>
</tr>
<tr>
<td>Multi Channel Sequencer (MCS)</td>
<td>A generic data processing module that is connected to the ARU. It allows &quot;programs&quot; to be written to calculate complex output sequences that depend on timebase values.</td>
<td>MCS0 software state machine that calculates the timebase's values and output states for the ATOM channels.</td>
</tr>
<tr>
<td>Advanced Routing Unit (ARU)</td>
<td>Provides a mechanism for routing streams of data between data sources and transfer it to a destination. This is the heart of the GTM subsystem.</td>
<td>Complex output waveforms for the SDA and SCL as instructed by the MCS through the ARU.</td>
</tr>
<tr>
<td>ARU connected Timer Output Module (ATOM)</td>
<td>Capable of generating complex output signals through its interconnectivity with the ARU to other modules in the GTM subsystem.</td>
<td>ATOM0, channels 4 (SDA) and 5 (SCL) in SOMC mode reading values from MCS0.</td>
</tr>
</tbody>
</table>

Figure 2 also shows the Parameter Storage Module (PSM) which could be used to bring in DATA to the MCS from another peripheral in the MPC5777M device, such as an ADC or sensor. The MCS could also get its data directly from its RAM from another peripheral through DMA.
4 Chip Level Software Description

The configuration of the chip modes and clocks, and the GTM at a basic initialization is as described in AN4351. The specific configuration of the GTM submodules (TBU, ATOM, and programming of MCS RAM) is shown in Appendix B.

The MCS array, MCS0_MEM, contains both the data and the software for the I2C bus emulation. Only MCS0 channel 0 is used for the calculation; however, the channels write to two ARU ports for the SDA and SCL commands to be consumed by two ATOM channels. To start the I2C bus output after initialization, the MPC5777M core and the MCS do a handshake with the MCS's trigger mechanism as shown below. The MCS's half of the handshake can be seen in the following section describing the MCS assembly program operation.

```c
/* Start the MCS Program */
GTM_MCS_0.CH0_CTRL.R = 0x00000001; // Enable Channel 0 of MCS0

/*Check that the ATOM channels are ready, MCS_STRG is set */
while((GTM_MCS_0.STRG.R & 0x2) == 0);

/*Next Trigger for MCS to signal "Port config finished" */
GTM_MCS_0.STRG.R = 0x00000001;
```

When this handshake is complete, the MCS is running in an infinite loop.

5 MCS Software Description

The MCS's program and data must be written and pre-compiled before loading in to the MCS RAM block.

As described in the "Example 7: Writing, Compiling, and Programming MCS Code" section of the previously mentioned application note, AN4351, the structure of the assembly code includes some definitions, initialization of start addresses for each active channel, and initialization of data and stacks, followed by the subroutines themselves.

Figure 3 and Table 2 describe the general functionality of the MCS assembly code.

</tr>
</tbody>
</table>

The **Acknowledging data from slave** and **Send repeated Start bit** routines described in this application note are not used in this basic example, which does not assume that any slaves or other masters are connected to the I2C bus.

The routines can be configured to use different ARU ports and ATOM channels, to send different ARU commands, and to point to different message address spaces by altering the definitions at the start of the assembly file. This examples uses the configuration listed below.

```
.set ARU_PORT0, 0x0000
.set ARU_PORT1, 0x0001
.set PIN_HI, 0x000009
.set PIN_LO, 0x00000A
.set ATOM0_CH4, 0x0123
.set ATOM0_CH5, 0x0124
.set message_array, 0x70
```

There are also variables that are set up in the assembly code and referred to through the routine for the number of messages to be transmitted, the clock rate, and the length of the delay between messages as shown below. The clock is four times the tsk0_clock because it is used four times for each bit transmitted: three for the SCL clock timing and once for the SDA transition.
The full assembly code in the Hightec™ format is provided in Appendix A. To modify the assembly code for the CASPR-MCS assembler, refer to AN4351.

5.1 Set SDA and SCL high

The default state of the I2C bus SDA and SCL transmission lines are "pulled up" and undriven. To emulate this pre-driven state, the ATOM channels must be set to output 1.

<table>
<thead>
<tr>
<th>Step</th>

<td>ARU Read port = 0x0001</td>
<td>AWR R3 R3 ARU_PORT1</td>
</tr>
<tr>
<td>6</td>
<td>Read the ATOM channel to reactive it after the match</td>
<td>See step 4.</td>
<td>ARU Read address = 0x0123</td>
<td>ARD R0 R4 ATOM0_CH4</td>
</tr>
</tbody>
</table>

5.2 Handshake with CPU

To ensure that both the CPU and the GTM are in the initialized state and ready to start the I2C communication, a handshake routine can be used. Both the CPU and the GTM MCS have access to the STRG and CTRG registers inside the MCS memory map.

The description of the assembly routine that runs inside of the GTM is described below in Table 4.

<table>
<thead>
<tr>
<th>Step</th>
<th>Operation</th>
<th>Description</th>
<th>Code Snippet</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Set the Channel 1 trigger</td>
<td>Set the trigger bit to indicate the routine has started to the CPU</td>
<td>MOVL STRG 0x000002</td>
</tr>
<tr>
<td>2</td>
<td>Load R0 with 1</td>
<td>—</td>
<td>MOVL R0 0x000001</td>
</tr>
</tbody>
</table>

Table continues on the next page...
Table 4. Handshake with CPU (continued)

<table>
<thead>
<tr>
<th>Step</th>
<th>Operation</th>
<th>Description</th>
<th>Code Snippet</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Wait until bit 0 of the STRG register is same as R0</td>
<td>Wait until the CPU signals back that the handshake was seen</td>
<td>WURM R0 STRG 0x0001</td>
</tr>
<tr>
<td>4</td>
<td>Load R3 with the current timebase value</td>
<td>—</td>
<td>MOV R3 TBU_TS0</td>
</tr>
<tr>
<td>5</td>
<td>Load R0 with 25,000</td>
<td>—</td>
<td>MOV R0 0x0061A8</td>
</tr>
<tr>
<td>6</td>
<td>Add R0 and R3 in R0</td>
<td>—</td>
<td>ADD R0 R3</td>
</tr>

</tr>
<tr>
<td>8</td>
<td>Clear the triggers</td>
<td>—</td>
<td>MOVL CTRG 0x000003</td>
</tr>
</tbody>
</table>

The code below is the CPU’s side of the handshake code.

```c
/*Check that the ATOM channels are ready, MCS_STRG is set */
while((GTM_MCS_0.STRG.R & 0x2) == 0);

/*Next Trigger for MCS to signal "Port config finished" */
GTM_MCS_0.STRG.R = 0x00000001;
```

5.3 Send Start bit

Before any message contents can be transmitted on the I2C bus, the start condition needs to be issued on the bus. A start bit is a high-to-low transmission on the SDA line while the SCL is high.

Table 5. Load message and send start bit

### 5.4 Send repeated Start bit

During an I2C transmission there is often the need to send a command and then immediately read back an answer. This has to be done without the risk of another device interrupting this atomic operation. The I2C protocol defines a repeated start condition. After having sent the address byte (address and read/write bit), the master may send any number of bytes followed by a stop condition. Instead of sending the stop condition it is also allowed to send another start condition again, followed by an address (and of course including a read/write bit) and more data.

### 5.5 Send message

The message to be transmitted consists of 3 bytes: 7 bits of address, 1 bit R/W, and 2 bytes of data.

The messages in this example are stored in the MCS RAM in the format 0x00aadddd, where 'aa' is the address and the R/W bit, and 'dddd' is the 16-bit data. For example, 0x00e00114 is the address 0x70, with the R/W clear (indicating a write), the high byte data is 0x01, with the low byte data is 0x14 as shown in Figure 1.

As the message is transmitted MSB first, the message in memory must be shifted to get the bits out in the correct order.

The routine is designed to be run multiple times for each message, it preserves and moves the bits around so that each major and minor loop transmits the correct byte, and bit, in the correct order, using the MCS channel's R0 and R5 registers as illustrated in Figure 5.

Figure 4 shows the flow of the assembly routine that is executed to calculate the ATOM and timing of the ATOM channels for each byte. This routine is run once for each byte: ADDR and R/W, high DATA, and low DATA.

5.7 Acknowledging data from slave

An I2C slave releases the SDA line (high) while the master provides a pulse on the clock line after transmitting (slave)/receiving (master) the last bit of the byte.

Step 2 is the only step that is different from the routine described in Acknowledgement from slave.

Table continues on the next page...
5.9 MCS delay routine

A delay routine is a useful code snippet to have for any software development. In this example, a delay is used to create a time space between messages.

The MCS has direct access to the TBU timestamp counter and also has a "wait until register match" instruction, WURM, which can be used to hold the MCS program counter for a predetermined amount of time or to wait until a trigger event from another channel occurs. WURM suspends the MCS channel until the two registers (with a bit mask) match.

\[
\text{WURM A B C}
\]

Wait until \( A = (B \& C) \)

A commonly used delay routine often involves a variable "duration" that is decremented in a loop, until it is zero. Within that loop, a known finite time can be included by using a wait operation.

In the example given in this application note, the "duration" variable is stored in the MCS RAM with other data such as the clock frequency and message loop counter at address 0x6C (0xFA = 250 in this particular case).

The timebase value is read and the match value is set at 2,500 clocks after "now." If the GTM TBU is running from an 80 MHz clock, the delay is 31.25 µs around each loop, 7.8125 ms in total.

delay:

\[
\begin{align*}
\text{MOV} & \quad R3 & \text{TBU\_TS0} & \text{# Load timestamp to R3} \\
\text{MRD} & \quad R4 & 0x006C & \text{# Load loop counter to R4} \\
\text{ATUL} & \quad R4 & 0x000000 & \text{# Is R4 Zero?} \\
\text{JBS} & \quad \text{STA} & Z & \text{exit} & \text{# If R4 is Zero jump to exit} \\
\text{MOVL} & \quad R0 & 0x0009C4 & \text{# Load R0 with 2,500} \\
\end{align*}
\]
continue: ADD R3 R0  # Add R0 to the Timebase saved in R3
    WURM R3 TBU_TSO 0xFFFF  # Wait until the timebase matches R3
    SUBL R4 0x000001  # Decrement the loop counter in R4
    JBC STA Z continue  # If not zero continue
exit: RET  # Exit subroutine

Appendix A Core Code to Initialize the GTM for I2C

The C code below configures the TBU, the ATOM channels, and then loads the MCS software and message array into MCS RAM memory and the handshake with the MCS itself.

The MCS software is compiled in to a binary file and loaded into the MCS RAM as described in AN4351. The MCS message array is given as an array of integers and copied into RAM at the specified location so that it is easier to manipulate without the need to reassemble the MCS software each time.

```c
unsigned int * dest, src;
extern int __MCS0_ADDR; /* Label of location of the raw data set in the linker */
void memcpy_swap_word(unsigned int *, unsigned int *, signed int);
void I2C()
{
    int i;
    gtm_ptr p;

    // Configure TBU
    GTM_TBU.CH0_CTRL.R = 0x00000000;// Select CMU_CLK0
    GTM_TBU.CHEN.R = 0x00000002;// Switch on TBU0

    /*******************************************************************************
    *ATOM0 CH5 = SCL
    *ATOM0 CH4 = SDA
    ******************************************************************************/

    /* Program MCS. First check whether the RAM RESET is complete. 
    WAIT until RAM_RST == 0, wait RAM Reset after startup. */
    while(GTM_MCS_0.CTRL.R == 0x00010000);

    GTM_ATOM_0.CH5_RDADDR.R = MCS0_WRADDR0;  // used for reading
    GTM_ATOM_0.CH4_RDADDR.R = MCS0_WRADDR1;  // used for reading
    GTM_ATOM_0.CH5_CTRL.R = 0x00000009;  // SOMC, ARU_EN=1, SL=0
    GTM_ATOM_0.CH4_CTRL.R = 0x00000009;  // SOMC, ARU_EN=1, SL=0

    /*ATOM0 CH4 + CH5 switch on*/
    GTM_ATOM_0.AGC_OUTEN_CTRL.R = 0x00000A00;
    GTM_ATOM_0.AGC_ENDIS_CTRL.R = 0x00000A00;
    GTM_ATOM_0.AGC_FUPD_CTRL.R = 0x00000000;
    GTM_ATOM_0.AGC_INT_TrIG.R = 0x00000000;
    GTM_ATOM_0.AGC_GLB_CTRL.R = 0xAAAA0001;// Host Trigger to start ATOM

    // load raw bin data in to MCS0 RAM = 0xFFD38000
    dest = (int)&MCS0_MEM; /* CPU view of the address of the MCS memory space */
    src = (int)&__MCS0_ADDR; /* Label of location of the raw data set in the linker */
    memcpy_swap_word(dest, src, 270);
    p = &MCS0_MEM + 0x1C;
    for(i=0;i<=67;i++)
    {
        /* Copying the content of the array mcs0i2c_messages[i] into MCS0 RAM0 */
        p[i]=mcs0i2c_messages[i];
    }

    /* Start the MCS Program */
    GTM_MCS_0.CH0_CTRL.r = 0x00000001;  // Enable Channel 0 of MCS module 0

    /*Check if the Channel program is ready and MCS_STRG is set, then start configure the Ports. 

    Generic Timer Module (GTM) Inter-Integrated Circuit (I2C) Bus Emulation, Rev 1, 3/2014
    Freescale Semiconductor, Inc. 
    */
WAIT until STRG == 0x00000002
MCS --> ATOM Output finished when STRG == h#00000002 */
while((GTM_MCS_0.STRG.R & 0x2) == 0); // STRG != 2

/* Next Trigger for MCS to signalize "Port config finished" */
GTM_MCS_0.STRG.R = 0x00000001; // Port configuration finished, MCS running

/* Now the MCS is running in an infinite loop. */
}

/*END of function I2C()*/

void memcpy_swap_word(unsigned int * dst, unsigned int * src, signed int size)
{
    while (size-- > 0)
    {
        *dst++ = SWAPW(*src);
        src++;
    }
}

Below is the I2C message array used in this example.

int mcs0i2c_messages[68] = {0x00e00101, 0x00e00102, 0x00e00104, 0x00e00108, 0x00e00110, 0x00e00112, 0x00e00114, 0x00e00116, 0x00e00118, 0x00e00120, 0x00e00122, 0x00e00124, 0x00e00126, 0x00e00128, 0x00e00130, 0x00e00132, 0x00e00134, 0x00e00136, 0x00e00138, 0x00e00140, 0x00e00142, 0x00e00144, 0x00e00146, 0x00e00148, 0x00e00150, 0x00e00152, 0x00e00154, 0x00e00156, 0x00e00158, 0x00e00160, 0x00e00162, 0x00e00164, 0x00e00166, 0x00e00168, 0x00e00170, 0x00e00172, 0x00e00174, 0x00e00176, 0x00e00178, 0x00e00180, 0x00e00182, 0x00e00184, 0x00e00186, 0x00e00188, 0x00e00190, 0x00e00192, 0x00e00194, 0x00e00196, 0x00e00198, 0x00e001a0, 0x00e001a2, 0x00e001a4, 0x00e001a6, 0x00e001a8, 0x00e001b0, 0x00e001b2, 0x00e001b4, 0x00e001b6, 0x00e001b8, 0x00e001c0, 0x00e001c2, 0x00e001c4, 0x00e001c6, 0x00e001c8, 0x00e001d0, 0x00e001d2, 0x00e001d4, 0x00e001d6, 0x00e001d8, 0x00e001e0, 0x00e001e2, 0x00e001e4, 0x00e001e6, 0x00e001e8, 0x00e001f0, 0x00e001f2, 0x00e001f4, 0x00e001f6, 0x00e001f8, 0x00e001fa, 0x00e001fc, 0x00e001fe};

The Hi9tect assembler generates the binary in the little endian, whereas the MPC57xx is big endian. The endianness can be swapped using the following macro.

#define SWAPW(w)\
{((w & 0xff) << 24) | ((w & 0xff00) << 8)\
| ((w & 0xff0000) >> 8) | ((w & 0xff000000) >> 24)) /* change endianness */
