1. Introduction

This document describes the estimated product lifetimes for the i.MX 6UltraLite applications processors, based on the criteria used in the qualification process.

The product lifetimes described in this document are estimates and do not represent a guaranteed lifetime for a particular product. The i.MX 6 series consists of an extensive number of processors that deliver a wide range of processing and multimedia capabilities across various qualification levels.

This document provides guidance on interpreting the i.MX 6UltraLite qualification levels in terms of the target operating frequency of the device, the maximum supported junction temperature (Tj) of the processor, and how this relates to the lifetime of a device.

Each qualification level supported (commercial, industrial, automotive) defines the number of Power-on Hours (PoH) available to the processor under a given set of conditions, such as:
• The target frequency for the application (consumer, industrial, automotive)
  – The target frequency is determined by the input voltage to the processor’s core complex (VDD_SOC_IN)
  – The use of the LDO enabled or the LDO bypass modes.
  – When using the LDO bypass mode, do not set the target voltage to the minimum specified in the datasheet. All power-management ICs have allowable tolerances. Set the target voltage higher than the minimum specified voltage to account for the tolerance of the PMIC.
  – The LDO-enabled mode uses the regulators on the i.MX 6UltraLite. These regulators are well-characterized and you may set them to output an exact minimum specified voltage. To achieve higher PoH, use the LDO-enabled mode.
  – 696 MHz can only be achieved in the LDO-enabled mode.

• The percentage of active use vs. stand-by.
  – Active use means that the processor is running in an active performance mode.
  – For the automotive tier, the performance modes are 528 MHz and 696 MHz.
  – For the commercial and industrial tiers, the performance mode is 528 MHz.
  – In the stand-by/DSM mode, the datasheet defines lower operating conditions for the VDD_SOC_IN, reducing the power consumption and the junction temperature. In this mode, the voltage and temperature are set low enough so that the effect on the lifetime calculations is negligible and treated as if the device was powered off.

• The junction temperature (Tj) of the processor.
  – The maximum junction temperature of the device is different for each tier of the product, e.g., 95 °C for the commercial tier, 105 °C for the industrial tier, and 125 °C for the automotive tier. This maximum temperature is guaranteed by the final test.
  – Ensure that your device is appropriately thermally managed and the maximum junction temperature is not exceeded.

**NOTE**

All data provided within this document are estimates for PoH, based on extensive qualification experience and testing with the i.MX 6 series.

Do not view these statistically-derived estimates as a limit to the individual device’s lifetime, nor construe them a warranty for the actual lifetime of a device. The sales and warranty terms and conditions still apply.
2. Device Qualification Level and Available PoH definitions

2.1. Commercial qualification

*Table 1* provides the number of PoH for the typical use conditions of the extended commercial devices.

<table>
<thead>

3. Combining Use Cases

In some applications, a constant operating use case cannot provide the target PoH. In this case, use multiple operating conditions. This method provides some of the benefits of running at a lower performance, while keeping the system’s ability to use the highest-performance state required by the application.

3.1. Switching between two power states with different temperatures

This scenario assumes that the system can achieve a drop in temperature by throttling back the performance, while still maintaining a constant voltage. Achieve this temperature change by changing the frequency, or by simply scaling back the load on the ARM cores and processing units. This use case is particularly useful if you want to take advantage of the full automotive temperature range of the i.MX 6UltraLite. In this scenario, the system spends 30% of its PoH at 105 °C and 70% of its PoH at 125 °C (as shown in Figure 7). Combine the two PoH values as:

$$38,700 \times 0.3 + 13,150 \times 0.7 = 20,815 \text{ PoH}$$  \hspace{1cm} \text{Eqn. 1}
3.2. Switching between two power states with different voltages

In this scenario, the system is using the 696-MHz full-power state, and the 528-MHz reduced-power state. For these calculations, it is assumed that the temperature stays constant in either mode. If the system spends 50% of its PoH at 696 MHz and 50% of its PoH at 528 MHz, combine the two PoH values (as shown in Figure 8) with the percentages:

\[ 38,700 \times 0.5 + 105,000 \times 0.5 = 71,850 \text{ PoH} \quad \text{Eqn. 2} \]
4. Revision History

*Table 4* summarizes the changes made to this document since the initial release:
