

PERIOD MEASUREMENT WITH ADDITIONAL TRANSITION DETECTION (PMA)

by Sharon Darley

1 Functional Overview

The PMA function detects additional transitions embedded in a series of input pulses by measuring each pulse period to a 23-bit resolution. It detects an additional transition when the current period is less than the previous period multiplied by a programmable ratio. It has two operating modes: count mode and bank mode. In count mode, the PMA function counts the number of additional transitions and compares it with a programmable maximum value before resetting the TCR2 counter and starting over with the next series of pulses. In bank mode, the TCR2 counter resets when an additional transition is detected and the flag BANK_SIGNAL is set to a non-zero value.

2 Detailed Description

The PMA function is typically used in automotive applications for detecting a reference point on a fly-wheel with regularly spaced teeth. This reference point is in the form of an additional tooth. An additional tooth causes a shorter interval between teeth, and the PMA function is able to detect this shorter interval by measuring the current period and comparing it with the previous period. The PMA function is usually used in conjunction with the PSP function. The PSP function generates an output pulse in relation to the additional tooth detected by the PMA function.

The PMA function measures the period between regularly spaced transitions for a channel that has its input connected to the same source as the clock input to TCR2. It detects an additional transition when the current period $< \text{PERIOD} * \text{RATIO}$. Thus, it is able to effectively map engine-cycle position into TCR2 counts.

When the PMA function is in count mode and detects an additional transition, it increments the parameter ADDITIONAL_COUNT. Then, it compares the new ADDITIONAL_COUNT to MAX_ADDITIONAL. If ADDITIONAL_COUNT is greater than or equal to MAX_ADDITIONAL, then the PMA function will reset TCR2 to \$FFFF, clear ADDITIONAL_COUNT, and request an interrupt.

When the PMA function is in bank mode and detects an additional transition, the TPU reads the value BANK_SIGNAL. If BANK_SIGNAL is set to a non-zero value, the PMA function will reset TCR2 to \$FFFF, clear BANK_SIGNAL, and request an interrupt. If BANK_SIGNAL is set to zero, the PMA function will not reset TCR2, but will request an interrupt. BANK_SIGNAL can be set by another function. The ITC function is ideal for this purpose.

ROLLOVER_COUNT is a parameter used to calculate a 23-bit period from the 16-bit TCR count. It increments each time the TCR count equals or exceeds \$8000 during a period measurement. At the beginning of service, REF_TIME contains the TCR1 value of the prior input capture, and the capture register contains the TCR1 value of the latest transition. On each normal transition detected (i.e., not on an additional transition), the PMA function places the elapsed time measured into PERIOD_LOW_WORD and PERIOD_HIGH_WORD, measuring a time of up to \$7EFFFF TCR1 clocks. (If the period measured is longer than \$7EFFFF, the period time is set to \$7FXXXX.)

Some transitions may be incorrect or invalid. In automotive and similar environments, noise in the system, malformed teeth on the flywheel, or incorrect adjustment of the transducer can cause extra transitions that are not a result of the flywheel teeth. To help detect these invalid transitions, the PMA supplies some noise immunity by requiring that 1) the total number of transitions just before the final additional tooth is reached does not exceed the value of TCR2_MAX_VALUE, and 2) the total number of transitions to be counted is equal to NUM_OF_TEETH. Remember that tooth count begins with zero instead of one, so the values in these two parameters will be one less than the actual number of teeth. These checks help to identify the index position. If the numbers do not match, the function assumes that the detected additional transition was invalid and responds by doing the following:

1. Indicates the error condition by setting TCR2 to the value \$80FF and the most significant byte of TCR2_VALUE to \$80 (the value \$80FF can never cause a match detection by a channel executing PSP);
2. Interrupts the CPU on each tooth (input transition);
3. Continues to increment the lower byte of TCR2_VALUE;
4. Continues to calculate the period;
5. Stores the time of the last tooth in REF_TIME.

The decision of what to do for an asynchronous condition is left up to the system programmer. The programmer may then use the force mode available in the OC or PSP functions to directly control the output channels.

The system designer must ensure that the additional transition is serviced completely (both scheduled and served) before the next normal transition occurs. If service is incomplete, errors may pass undetected. To ensure complete service, there are limitations on the parameter ratio (see description) and requirements for programming the scheduler. Some basic rules are the following:

- The PMA and PSP channels must have the same priority level.
- The PMA channel must be assigned a lower channel number than the PSP channel in order to service the PMA channel before the PSP is serviced in the case of simultaneous requests.
- The priority level of the PMA channel should be high enough to ensure service completion before the next normal transition occurs.

At PMA initialization, TCR2 is initialized to \$C0FF since the value of \$C0FF cannot cause a match detection by the channel executing PSP. On each transition detected, TCR2_VALUE is incremented, tracking TCR2, and is readable by the CPU at any time. The PMA channel is synchronized to the input whenever the additional and normal transitions occur in the expected sequence. With synchronization, TCR2 is reset to \$FFFF. TCR2 values from \$0000 to \$00FF can cause a match detection by the channels executing PSP. By setting the host sequence bit 0, the user may choose one of two operating modes: count mode or bank mode.

Count Mode

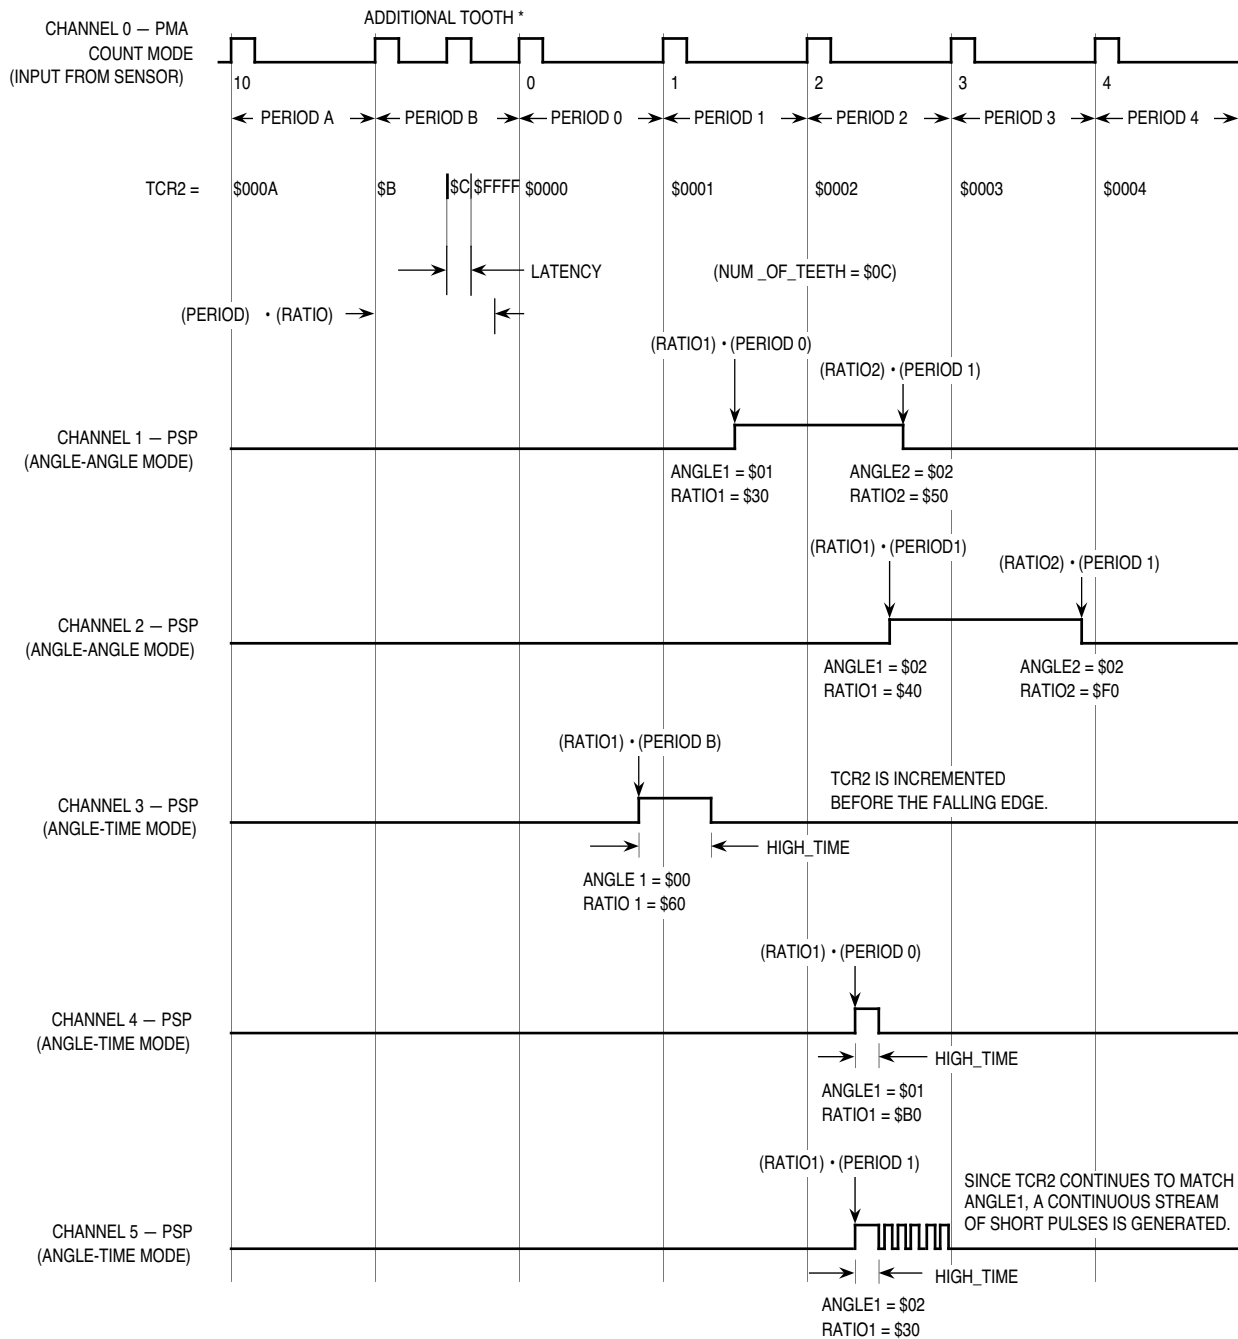

In this mode, TCR2 is set to \$FFFF after the number of additional transitions in MAX_ADDITIONAL has been identified and counted.

Bank Mode

In this mode, TCR2 is set to \$FFFF if an additional transition has been identified and BANK_SIGNAL is a non-zero value. BANK_SIGNAL can be incremented by another function such as the ITC function.

Figure 1 is an example of PMA used with a PSP function. The input to the PMA channel and the TCR2 clock input is a flywheel with teeth spaced every 30 degrees, with one additional tooth as a reference indicator. Detection of the additional tooth causes the function to set TCR2 to \$FFFF; the next tooth and input capture event advances TCR2 to \$0000, and each successive tooth advances TCR2. When the additional tooth is detected, TCR2 and TCR2_VALUE contain \$0C; therefore, NUM_OF_TEETH must also be \$0C.

Channels 4 and 5 illustrate two ways of programming a pulse using PSP angle-angle mode. Channel 4 illustrates the preferred way since it produces only one waveform. Refer to Motorola Programming Note TPUPN14/D, *Position-Synchronized Pulse Generator (PSP)* for additional information.

* ADDITIONAL TOOTH – ONE TOOTH EVERY 30° PLUS ONE TOOTH RESULTS IN A TOTAL OF 13 TEETH.

Figure 1 PMA and PSP Together

3 Function Code Size

Total TPU function code size determines what combination of functions can fit into a given ROM or emulation memory microcode space. PMA function code size is:

$$80 \mu \text{ instructions} + 6 \text{ entries} = \mathbf{86 \text{ long words}}$$

4 Function Parameters

This section provides detailed descriptions of PMA function parameters stored in channel parameter RAM. **Figure 2** shows TPU parameter RAM address mapping. **Figure 3** shows the parameter RAM assignment used by the PMA function. In the diagrams, Y = M111, where M is the value of the module mapping bit (MM) in the system integration module configuration register (Y = \$7 or \$F).

Channel Number	Base Address	Parameter Address							
		0	1	2	3	4	5	6	7
0	\$YFFF##	00	02	04	06	08	0A	—	—

Figure 3 PMA Function Parameter RAM Assignment

4.1 CHANNEL_CONTROL

CHANNEL_CONTROL contains the channel latch controls and configures the PSC, PAC, and TBS fields. A channel executing this function is configured as input. The CPU must write CHANNEL_CONTROL before initializing the function. The PSC field is “don't care” for input channels. The PAC field specifies which edge to detect. Since the TCR2 external clock input detects rising edges only, the PAC field should be configured to detect rising edges unless unusual conditions exist. The TBS field configures a channel pin as input or output and configures the time base for match/capture events. The PMA function should use TCR1 for both types of events. The following table defines the allowable data for this parameter.

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
NOT USED							TBS			PAC			PSC		

Table 1 PMA CHANNEL_CONTROL Options

TBS		PAC			PSC		Action		
8	7	6	5	4	3	2	1	0	
Input				Output					
		0	0	0	Do Not Detect Transition				—
		0	0	1	Detect Rising Edge				—
		0	1	0	Detect Falling Edge				—
		0	1	1	Detect Either Edge				—
		1	x	x	Do Not Change PAC				—
00		x	x	Input Channel				—	
0		0	0	0	Capture TCR1, Match TCR1				—
1		x	x	x	Do Not Change TBS				—

4.2 REF_TIME

REF_TIME is the time of the last transition captured. After CHANNEL_CONTROL information is used during the *Init* state, the TPU writes the captured TCR1 value into REF_TIME on each normal transition detected.

4.3 MAX_ADDITIONAL

MAX_ADDITIONAL is a byte that contains the number of additional transitions to be counted before TCR2 is set to \$FFFF. This parameter is written by the CPU before initialization and is referenced by the TPU only in count mode (host sequence bits equal 01). It cannot be set to zero and used to generate a PSP output waveform for an input pulse train with no additional teeth.

4.4 NUM_OF_TEETH

NUM_OF_TEETH is one less than the total count of transitions seen by TCR2 at the time any additional transition is detected. This parameter differentiates between valid and invalid transitions. For each additional transition detected, the TPU subtracts NUM_OF_TEETH from the current tooth count in TCR2 and continues executing the function if the result is zero. If the application has multiple additional teeth separated by different numbers of normal teeth, the host CPU must update NUM_OF_TEETH once for each set, so that NUM_OF_TEETH contains the same value as TCR2 at each additional tooth. In **Figure 4**, the flywheel is divided into two segments with different numbers of teeth in each segment, so that the CPU may easily determine which half of the flywheel has the major reference tooth. At each additional tooth detected, TCR2 is compared with NUM_OF_TEETH, and an interrupt is sent to the CPU to allow the software to alternately change NUM_OF_TEETH between \$09 and \$11.

FLYWHEEL HAS TEETH EVERY 22.5°, PLUS ADDITIONAL TOOTH AT 190° AND 350°; MAX_ADDITIONAL = 2.

Figure 4 PMA NUM_OF_TEETH Example

4.5 BANK_SIGNAL

BANK_SIGNAL is a byte that contains the current value of the bank signal. A non-zero value means that BANK_SIGNAL is asserted; \$00 means that BANK_SIGNAL is negated. This parameter is referenced only in bank mode (host sequence bits equal 00). If BANK_SIGNAL is non-zero when a missing transition is detected, then TCR2 is set to \$FFFF and BANK_SIGNAL is cleared. BANK_SIGNAL is normally set by another time function, such as the ITC function, but can be set by the CPU when an outside reference determines that the next additional transition should cause TCR2 to become \$FFFF.

4.6 ADDITIONAL_COUNT

In count mode, the byte ADDITIONAL_COUNT contains the number of additional transitions detected. At initialization, this parameter is set to \$0000. Then, at each additional tooth, the PMA function compares ADDITIONAL_COUNT with the value in MAX_ADDITIONAL. If it is greater than or equal to MAX_ADDITIONAL at any additional tooth, TCR2 is set to \$FFFF and ADDITIONAL_COUNT is reset to \$0000. This parameter is used only in count mode.

4.7 ROLLOVER_COUNT

ROLLOVER_COUNT is a parameter used as a counter that increments each time the TCR count equals or exceeds \$8000 during a period measurement. This parameter is used to calculate a 23-bit period from the 16-bit TCR count and to determine if a period error (**Figure 5**) has occurred. This parameter is reset at the beginning of each measured period.

4.8 RATIO

RATIO, multiplied by the previous PERIOD, is the upper bound of time in which the next additional transition must occur. This parameter is written by the CPU and used by the TPU.

The RATIO parameter must be bounded on the upper end to ensure that no normal transition occurs within the interval $\text{PERIOD} * \text{RATIO}$. The upper bound is also limited by the requirements that 1) a match on the interval $\text{PERIOD} * \text{RATIO}$ must occur to identify the detection of an additional transition, and 2) channel service must complete for TCR2 to be reset to \$FFFF. All actions must complete before the next normal transition, which causes TCR2 to increment to \$0000. The range of RATIO is therefore \$00 to \$7F (0 to 0.99₁₀) for PMA.

4.9 TCR2_MAX_VALUE

TCR2_MAX_VALUE is a byte containing the maximum permissible value of TCR2. This parameter identifies the case when an additional transition went undetected, and TCR2 did not reset and continued incrementing. If TCR2 exceeds this value due to a normal transition instead of the expected additional transition, TCR2 is set to \$80FF, and ADDITIONAL_COUNT/BANK_SIGNAL is cleared to \$0000. This situation is recovered with re-synchronization.

4.10 PERIOD_HIGH_WORD

PERIOD_HIGH_WORD is the upper eight bits [23:16] of the last measured period. This parameter, with PERIOD_LOW_WORD, indicates the TCR1 time duration between the last two input transitions, unless the detected transition is identified as an additional transition. The maximum value in this parameter is \$007E, unless the measured period exceeds \$7EFFFF, in which case this parameter is set to \$007F. PERIOD_HIGH_WORD may be read by the CPU at any time and should be read coherently with PERIOD_LOW_WORD.

4.11 PERIOD_LOW_WORD

PERIOD_LOW_WORD is the lower 16 bits [15:0] of the last measured period. This parameter, with PERIOD_HIGH_WORD, indicates the TCR1 time duration between the last two input transitions, unless the detected transition is identified as an additional transition. PERIOD_LOW_WORD may be read by the CPU at any time and should be read coherently with PERIOD_HIGH_WORD.

4.12 TCR2_VALUE

TCR2_VALUE is incremented on each transition to track the current value of TCR2. In normal operation (i.e., when no error condition exists), the high byte of this parameter is \$00, and the low byte contains the current value of the low byte of TCR2. This low byte is therefore the current TEETH_COUNT. When an error condition is detected, the high byte contains an error code and the low byte continues incrementing at each transition detected. The error code parameter is cleared when the error condition disappears. The error codes are shown below in **Figure 5**.

ERR — Error Code	
\$00	No error
\$80	TEETH_COUNT does not match NUM_OF_TEETH on a missing transition detection, or TCR2 exceeds TCR2_MAX_VALUE.
\$C0	(Normal period) or (missing tooth period ÷ 2) exceeds \$FFFF or (PERIOD * RATIO) exceeds \$7FFF (missing tooth interval).

6 Function Configuration

The CPU initializes this time function by the following:

1. Writing parameter CHANNEL_CONTROL:
 - The pin should be configured as input, rising-edge detect, and
 - TCR1 should be used for match and capture;
2. Writing parameters MAX_ADDITIONAL, TCR2_MAX_VALUE, NUM_OF_TEETH, and RATIO to parameter RAM;
3. Writing host sequence bits 00 or 01 according to the bank or count mode desired;
4. Issuing an HSR %01 for initialization; and
5. Enabling channel servicing by assigning a high, middle, or low priority.

The TPU then executes initialization. The CPU should monitor the HSR register until the TPU clears the service request to 00 before changing any parameters or before issuing a new service request to this channel. If PMA is used in conjunction with channels executing PSP, the PMA channel should be initialized and enabled at the same time, or before, the PSP channels.

7 Performance and Use of Function

7.1 Performance

Like all TPU functions, PMA function performance in an application is to some extent dependent upon the service time (latency) of other active TPU channels. This is due to the operational nature of the scheduler. The more TPU channels are active, the more performance decreases. However, worst-case latency in any TPU application can be closely estimated. To analyze the performance of an application that appears to approach the limits of the TPU, use the guidelines given in the TPU reference manual and the information in the following table.

Table 2 PMA State Timing

State Name	Clock Cycles	RAM Accesses
S1 <i>Init</i>	16	3
S2 <i>Measure_Period</i>		
No error	58	7
Error	80	10
S3 <i>Additional_Trans</i>		
Normal transitions only	94	8
Additional transitions only — bank mode	40	5
Additional transitions only — count mode	44	6
Additional transitions not detected	8	1

7.2 Changing Mode

The host sequence bits are used to select PMA function operating mode. Change host sequence bit values only when the function is stopped or disabled (channel priority bits = %00). Disabling the channel before changing mode avoids conditions that cause indeterminate operation.

8 Function Examples

8.1 Example A

8.1.1 Description

This program demonstrates how to use the ITC, PMA, and PSP functions together to generate an output pulse in relation to an additional tooth. A common application of these functions is an angle-based automotive engine control system. A typical system is shown in **Figure 7**.

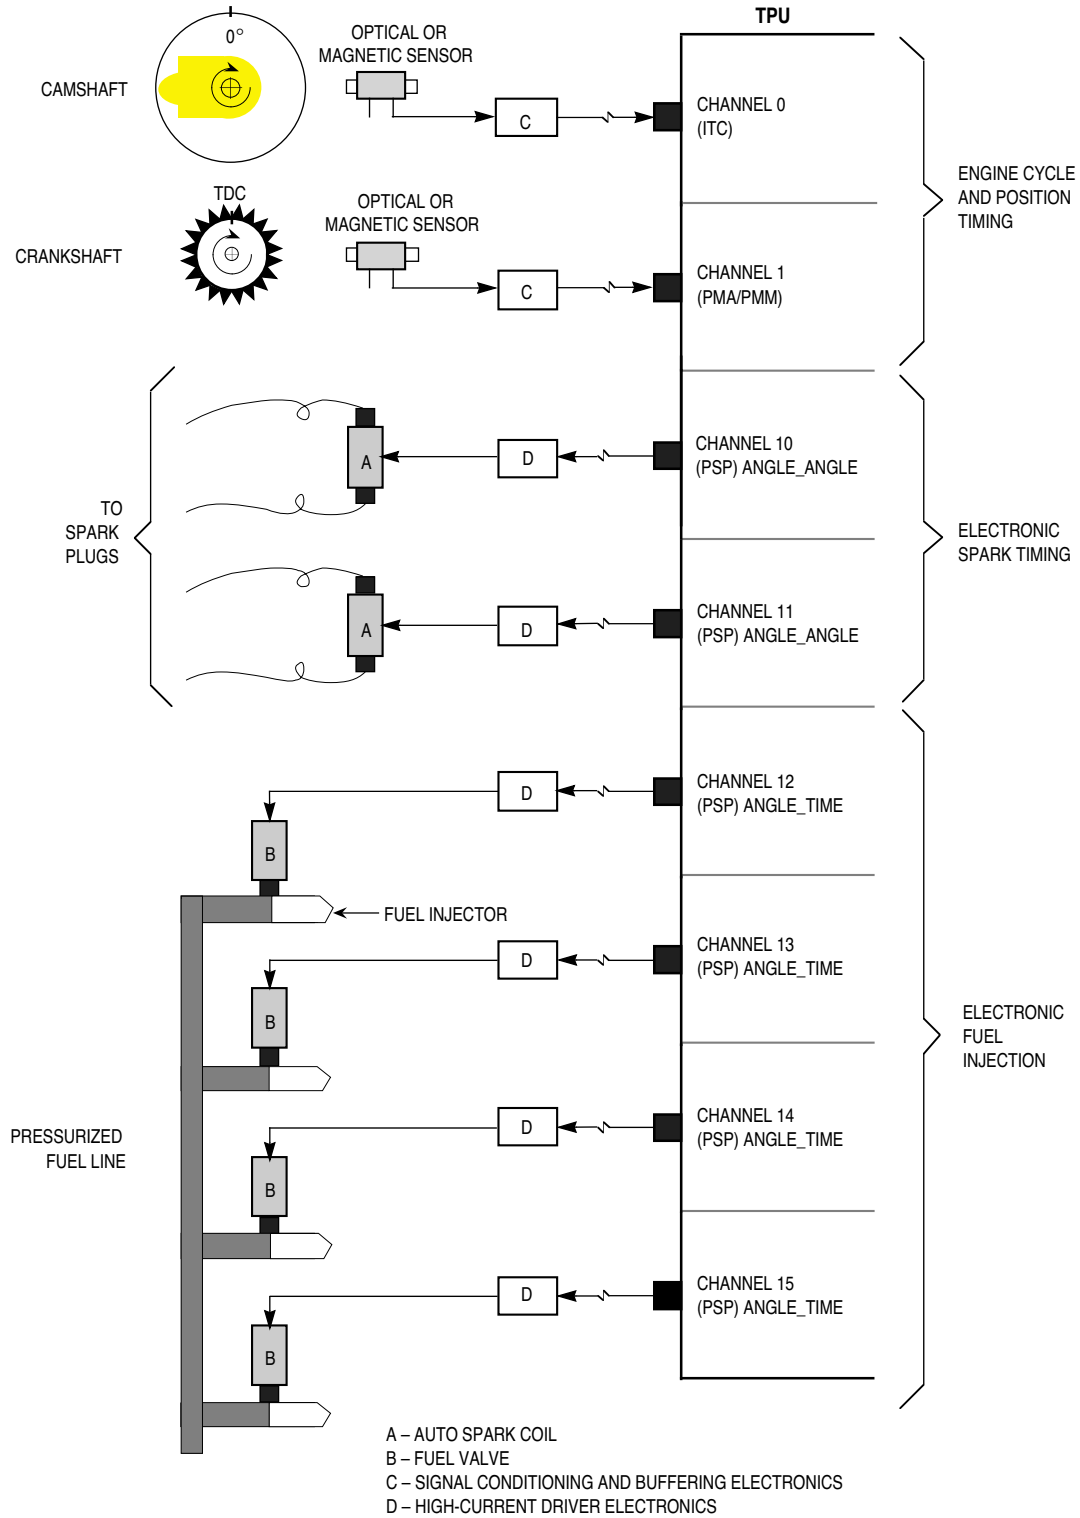

Figure 7 Engine Control Example A

Figure 7 shows that in a typical automotive engine, the camshaft works together with the flywheel to determine the timing for the ignition firing points and fuel-injection pulses. Both the camshaft and the flywheel have reference points in the form of missing or additional teeth. The PMM/PMA functions detect these reference points; the PMM function detects missing teeth, and the PMA function detects additional teeth. This example uses the PMA function to detect additional teeth.

The PMA function has two modes: count mode and bank mode. In count mode, timer TCR2 is reset to \$FFFF after the number of additional transitions in MAX_ADDITIONAL has been counted. In bank mode, timer TCR2 is reset to \$FFFF after an additional transition has been counted only if BANK_SIGNAL is a non-zero value. This example uses the bank mode.

In order to use the bank mode, either the CPU or another time function must increment the parameter BANK_SIGNAL. This example uses the ITC function on another channel to increment BANK_SIGNAL.

In this example, the PMA function is also used in conjunction with the PSP function. The PMA function determines when the additional tooth occurs, and the PSP function waits a programmable amount of time before it generates an output pulse. The PSP function has two operating modes, angle-angle and angle-time, and it generates the output pulse based on five parameters: RATIO1, RATIO2, ANGLE1, ANGLE2, and HIGH_TIME. RATIO1 and RATIO2 are 8-bit numbers that represent a decimal multiplier of the period that can range from 0 to 1.99. ANGLE1 and ANGLE2 represent reference angles. A reference angle is simply a tooth number. The teeth are numbered starting with zero after the last additional transition. HIGH_TIME specifies the time duration of the output pulse in angle-time mode. This example uses the angle-time mode, illustrated in **Figure 8**.

Figure 8 PSP Angle-Time Mode

8.1.2 Hardware Setup

This example requires two input pulse trains. The input to the TCR2 clock pin and the TPU channel executing the PMA function is a series of pulses with additional transitions. This pulse train is from a flywheel in an automobile engine. In this example, the flywheel has 36 teeth and one additional tooth (37 teeth total). Thus, the teeth are spaced evenly to accommodate 36 teeth, but an additional tooth is placed after the 36th tooth. The flywheel rotates twice for every one rotation of the camshaft. When the flywheel rotates to top dead center and reaches an additional tooth, the engine compresses and fires the spark plugs. After the flywheel makes a second revolution and the camshaft finishes making its first full rotation, the additional tooth is reached again. This time, the engine releases exhaust. The cycle repeats. Thus, the 36-tooth flywheel with one additional tooth behaves the same as a 72-tooth flywheel with two additional teeth. The reference points on the camshaft keep track of which half of the cycle is currently taking place.

The input pulse train to the channel executing the ITC function consists of high and low transitions from the camshaft. During one additional tooth, this pulse is low, and during the next additional tooth, the pulse is high. This pulse causes BANK_SIGNAL to increment from zero to one during every other additional tooth.

See **Figure 9** for an illustration of the two input waveforms.

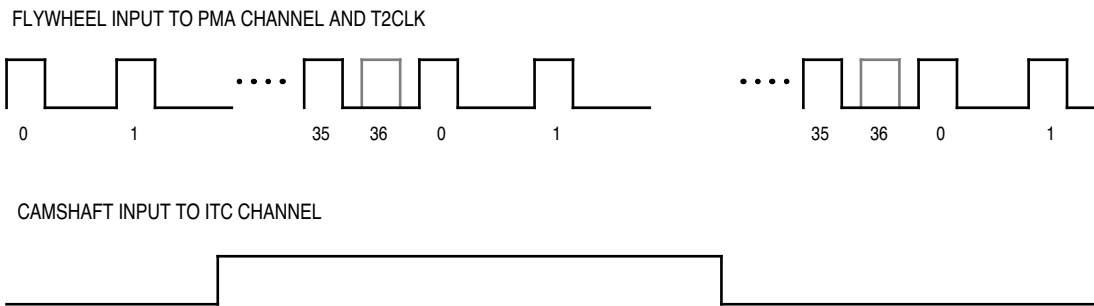

Figure 9 Input Waveforms for Example A

The TPU is set up with the functions needed to generate the PSP output pulse: the ITC function on channel 3, the PMA function on channel 4, and the PSP function on channel 5. The ITC function on channel 3 is connected to the camshaft. It is set up so that each time it detects a rising transition, it increments the PMA parameter BANK_SIGNAL, thus forcing it to a non-zero value to allow timer TCR2 to reset to \$FFFF. The PMA function on channel 4 is connected to the flywheel to detect additional teeth. The PSP function is not physically connected to any of the other channels, but its parameter PERIOD_ADDRESS points to the PMA parameter PERIOD_LOW_WORD. In addition, the TCR2 clock input is connected to the flywheel. See **Figure 10** for an illustration of the hardware setup.

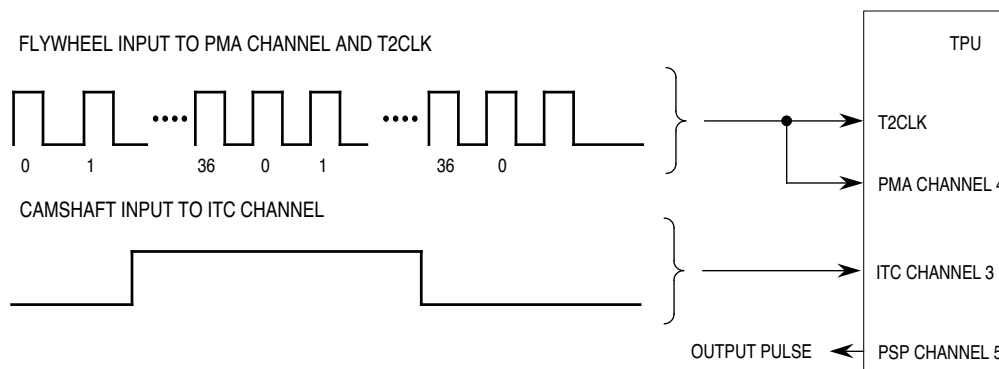

Figure 10 Example A Hardware Setup

8.1.3 Initialization

Set up channel 3 as ITC counting rising edges from the camshaft. Set up channel 4 as PMA, detecting additional teeth. Set up channel 5 in PSP angle-time mode. The pulse generated will look like the illustration shown on channel 4 in **Figure 1**.

For the ITC channel, the host sequence field bits are 01, continual with no links. The parameter MAX_COUNT is set to one. On every rising edge, the parameter TRANS_COUNT will count one edge. When this happens, the TPU will reset TRANS_COUNT to zero and increment the high byte of the RAM location pointed to by BANK_ADDRESS. In this case, that byte is BANK_SIGNAL for the PMA function.

The host sequence field bits for the PMA channel are 00, additional tooth bank mode. When the PMA function operates in the bank mode, TCR2 will not reset to \$FFFF when an additional tooth is reached unless the parameter BANK_SIGNAL is set to a non-zero value.

8.2 Program Code for CPU32-Based Microcontrollers

This program was assembled using the IASM32 assembler available from P&E Microcomputer Systems with the M68332 In-Circuit Debugger. It was run on an M68332EVS and BCC.

        ;BANK_SIGNAL
        move.w   #$01,(PRAM3_2).l ;MAX_COUNT = 1

```

8.2.2 PMA Initialization for Channel 4

MAX_ADDITIONAL is a don't care value since bank mode is used.

NUM_OF_TEETH is the number that is compared to the current TCR2 count in TCR2_VALUE when an additional tooth is detected. These numbers must match or else an error code will appear in ERROR. The program NUM_OF_TEETH each time an additional tooth is detected. Since the TPU begins counting with zero instead of one, NUM_OF_TEETH is first set to 36 instead of 37. NUM_OF_TEETH alternates between 36 and 73 (\$24 and \$49) at each additional tooth.

RATIO, multiplied by the previous period, is the upper bound of time in which the next additional transition must occur. This parameter is written by the CPU and used by the TPU.

The `RATIO` parameter must be bounded on the upper end to ensure that no normal transition occurs within the interval `PERIOD * RATIO`. The upper bound is also limited by the requirements that 1) a match on the interval `PERIOD * RATIO` must occur to identify the detection of an additional transition, and

2) channel service must complete for `TCR2` to be reset to `$FFFF`. All actions must complete before the next normal transition, which causes `TCR2` to increment to `$0000`. The range of ratio is therefore `$00` to `$7F` (0_{10} to 0.99_{10}) for PMA. In this case, `$60` is used.

`TCR2_MAX_VALUE` contains the maximum permissible value of `TCR2`. `TCR2` resets to `$FFFF` when the final additional tooth is reached so that the tooth count can begin again at zero. If an additional transition goes undetected and `TCR2` continues incrementing past `TCR2_MAX_VALUE`, then the error code `$80` is set in `ERROR`, and `BANK_SIGNAL` is cleared to zero. Since the maximum number of teeth to be counted before the final additional tooth is reached and `TCR2` is reset is 73, set `TCR2_MAX_VALUE` to 72 (`$48`), since the TPU begins numbering with zero.

Since the `NUM_OF_TEETH` parameter alternates between 36 and 73, interrupt the program each time an additional transition is detected. Start the interrupt routine at the label `INT` by storing the address of `INT` in the appropriate vector address location. For this example, the base vector number `$80` is chosen. This number is stored in the `TICR` register. The actual interrupt vector number is calculated by concatenating the channel number with the base vector number. Thus, the interrupt vector number is `$84`, since channel 4 is used. The vector address (where the starting address of the interrupt routine is stored) is calculated as four times the vector number plus the value in the vector base register. In this case, since this program was developed on an M68332 BCC, the vector base register is initialized to `$400` by `CPU32Bug`. The vector address is therefore $4 * \$84 + \400 , which is equal to `$610`.

The interrupt level must be set to a non-zero value in the `TICR`. The interrupt level chosen determines the priority given to this interrupt. Level 7 is the highest priority, and level 1 is the lowest. This example uses level 6. Once an interrupt level has been chosen, bits [10:8] in the CPU status register must be modified to allow recognition of that level interrupt. These bits must be set to a number that is lower than the interrupt level number. Interrupts at the same level or lower than the number in the CPU status register will be masked out and will not be recognized by the CPU. In addition, the interrupt arbitration (`IARB`) field in the `TPUMCR` must be set to a non-zero value between `$0` and `$F`. Otherwise, a spurious interrupt may occur. If two or more interrupts on the same level request an interrupt at the same time, the `IARB` value determines which interrupt will be recognized first.

```

move.w    #$0004,(PRAM4_0).l;Channel control, detect rising edge
move.w    #$0024,(PRAM4_1).l;NUM_OF_TEETH=36

andi.w    #$F5ff,SR          ;allow interrupts on level 6 and above

```

8.2.3 PSP Initialization for Channel 5 in Angle-Time Mode

Since the PSP is initialized in angle-time mode, the parameters that form the output pulse are determined as follows:

1. The hightime is specified in `HIGH_TIME`. For this example, it is `$100`.
2. The rising edge is determined by three parameters: `ANGLE1`, `RATIO1`, and `PERIOD_ADDRESS`. `ANGLE1` is a `TCR2` tooth number. Remember that teeth are numbered starting with zero after the additional transition. `PERIOD_ADDRESS` points to the PMA parameter `PERIOD_LOW_WORD`, which contains the period of the input to `TCR2`. `RATIO1` is an 8-bit multiplier that ranges from `$00` to `$FF` (0 to 1.99). The rising edge of the output waveform is offset from `TCR2 = ANGLE1 by PERIOD * RATIO1`.

3. The falling edge occurs at the end of HIGH_TIME.

```

move.w    #$4a01,(PRAM5_0).l ;period address points to period
                                ;low word of PMA, Channel control is a don't care value

move.w    #$0010,(CIER).l ;enable interrupt for channel 4
finish    bra      finish

```

8.2.4 Interrupt Handling Routine for PMA

The processor will be interrupted each time an additional tooth is detected, and the interrupt routine alternates NUM_OF_TEETH between 36 (\$24) and 73 (\$49). Because the processor does not know at which tooth it starts counting, it takes a few interrupts (typically about four) to achieve synchronization. Until synchronization is achieved, an error code will appear in ERROR at each interrupt. Thus, until ERROR clears for the first time, keep NUM_OF_TEETH at 36. Then, each time an interrupt is received thereafter, alternate NUM_OF_TEETH between 36 and 73.

```

ldd      #$01
std      PRAM3_2          ;MAX_COUNT = 1

```

8.3.3 PMA Initialization for Channel 4

MAX_ADDITIONAL is a don't care value since the program uses bank mode.

NUM_OF_TEETH is the number that is compared to the current TCR2 count in TCR2_VALUE when a missing tooth is detected. These numbers must match or else an error code will appear in ERROR. The program changes NUM_OF_TEETH at each missing tooth. Since the TPU begins counting with zero instead of one, NUM_OF_TEETH is first set to 36 instead of 37.

RATIO, multiplied by the previous period, is the upper bound of time in which the next additional transition must occur. This parameter is written by the CPU and used by the TPU.

The RATIO parameter must be bounded on the upper end to ensure that no normal transition occurs within the interval PERIOD * RATIO. The upper bound is also limited by the requirements that 1) a match on the interval PERIOD * RATIO must occur to identify the detection of an additional transition, and 2) channel service must complete for TCR2 to be reset to \$FFFF. All actions must complete before the next normal transition, which causes TCR2 to increment to \$0000. The range of ratio is therefore \$00 to \$7F (0 to 0.99₁₀) for PMA. In this case, \$60 is used.

TCR2_MAX_VALUE contains the maximum permissible value of TCR2. TCR2 resets to \$FFFF when the last additional tooth is reached so that the count can begin again with zero. If an additional transition goes undetected and TCR2 continues incrementing past TCR2_MAX_VALUE then the error code \$80 is set in ERROR, and BANK_SIGNAL is cleared to zero. Since the maximum number of teeth to be counted before the last tooth is reached and TCR2 is reset is 73, set TCR2_MAX_VALUE to 72 (\$48), since the TPU begins numbering with zero.

Since the NUM_OF_TEETH parameter alternates between 36 and 73, interrupt the program each time an additional transition is detected. Start the interrupt routine at the label INT by storing the address of INT in the appropriate vector address location. For this example, the base vector number \$80 is chosen. This number is stored in the TICR register. The actual interrupt vector number is calculated by concatenating the channel number with the base vector number. Thus, the interrupt vector number is \$84, since channel 4 is used. The vector address (where the starting address of the interrupt routine is stored) is calculated as two times the vector number. In this case, the vector address is 2 * \$84, which is equal to \$108.

The interrupt level must be set to a non-zero value in the TICR. The interrupt level chosen determines the priority given to this interrupt. Level 7 is the highest priority, and level 1 is the lowest. This example uses level 6. Once an interrupt level has been chosen, bits [6:4] in the CPU status register must be modified to allow recognition of that level interrupt. These bits must be set to a number that is lower than the interrupt level number. Interrupts at the same level or lower than the number in the CPU status register will be masked out and will not be recognized by the CPU. In addition, the interrupt arbitration (IARB) field in the TPUMCR must be set to a non-zero value between \$0 and \$F. Otherwise, a spurious interrupt may occur. If two or more interrupts on the same level request an interrupt at the same time, the IARB value determines which interrupt will be recognized first.

```

8.3.4 PSP Initialization for Channel 5 in Angle-Time Mode

Since the PSP is initialized in angle-time mode, the parameters that form the output pulse are determined as follows:

1. The hightime is specified in HIGH_TIME. For this example, it is \$100.
2. The rising edge is determined by three parameters: ANGLE1, RATIO1, and PERIOD_ADDRESS. ANGLE1 is a TCR2 tooth number. Remember that teeth are numbered starting with zero after the missing transition. PERIOD_ADDRESS points to the PMA parameter PERIOD_LOW_WORD, which contains the period of the input to TCR2. RATIO1 is an 8-bit multiplier that ranges from \$00 to \$FF (0 to 1.99). The rising edge of the output waveform is offset from $TCR2 = ANGLE1$ by $PERIOD * RATIO1$.
3. The falling edge occurs at the end of HIGH_TIME.

```

ldd      #$4a01
std      PRAM5_0          ;period address points to period low word

std      CIER            ;enable interrupt for channel 4
finish   bra      finish

```

8.3.5 Interrupt Handling Routine for PMA

The processor will be interrupted each time an additional tooth is detected, and the interrupt routine alternates NUM_OF_TEETH between 36 (\$24) and 73 (\$49). Because the processor does not know at which tooth it starts counting, it takes a few interrupts (typically about four) to achieve synchronization. Until synchronization is achieved, an error code will appear in ERROR at each interrupt. Thus, until ERROR clears for the first time, keep NUM_OF_TEETH at 36. Then, each time an interrupt is received thereafter, alternate NUM_OF_TEETH between 36 and 73.

```

```

8.4 Example B

8.4.1 Description

This example uses the PMA function in the count mode. It produces an output pulse on the PSP channel after every additional tooth. To wait for two or more teeth to pass before producing an output pulse, NUM_OF_TEETH must be changed in an interrupt routine such as was done in Example A.

In the count mode, the ITC channel that changes BANK_ADDRESS between one and zero is not needed. TCR2 will automatically reset to \$FFFF at each additional tooth and generate an output pulse because ADDITIONAL_COUNT will match MAX_ADDITIONAL.

8.4.2 Software Initialization

Set up channel 4 for the PMA function, detecting additional teeth. Set up channel 5 in PSP angle-time mode. The pulse generated will look like the one shown on channel 1 in **Figure 1**.

The host sequence field bits for the PMA channel are 01, additional tooth count mode. When the PMA function operates in the count mode and MAX_COUNT is set to one, TCR2 will reset to \$FFFF at each missing tooth. The interrupt routine from Example A is not needed since a PSP output pulse is generated after every additional tooth, and the NUM_OF_TEETH remains constant.

8.4.3 Hardware Setup

This example requires one input pulse train. The input to the TCR2 clock pin and the TPU channel executing the PMA function is a series of pulses with additional transitions. This pulse train is from a flywheel in an automobile engine. In this example, the flywheel has 36 evenly-spaced teeth and 1 additional tooth (37 teeth total).

See the first waveform in **Figure 9** for an illustration of this one input waveform.

The TPU is set up with the functions needed to generate the PSP output pulse: the PMA function on channel 4 and the PSP function on channel 5. The PMA function on channel 4 is connected to the flywheel to detect additional teeth. The PSP function is not physically connected to any of the other channels, but its parameter PERIOD_ADDRESS points to the PMA parameter PERIOD_LOW_WORD. In addition, the TCR2 clock input is connected to the flywheel. See **Figure 11** for an illustration of the hardware setup.

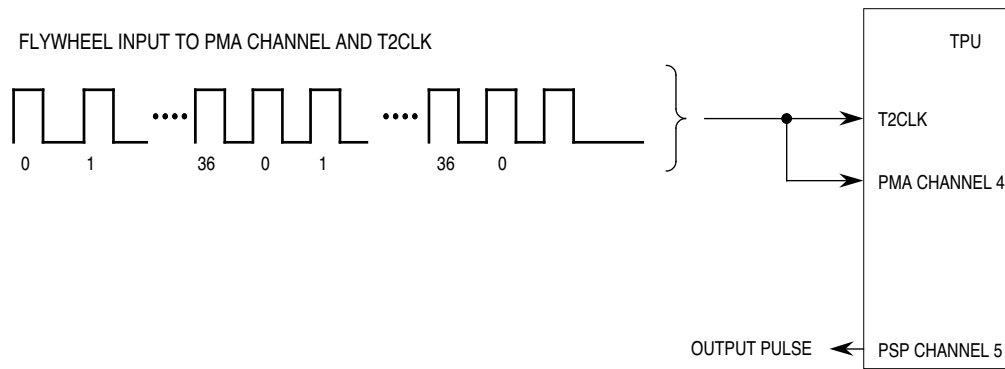

Figure 11 Hardware Setup for Example B

8.5 Program Code for CPU32-Based Microcontrollers

This program was assembled using the IASM32 assembler available from P&E Microcomputer Systems with the M68332 In-Circuit Debugger. It was run on an M68332EVS and BCC.

For this example, use the same equates used for Example A.

Set up channel 4 in PMA count mode, counting additional teeth.

Set up channel 5 in PSP angle-angle mode

```

8.6 Program Code for CPU16-Based Microcontrollers

This program was assembled on the IASM16 Assembler available with the ICD16 In-Circuit Debugger from P&E Microcomputer Systems and was run on an MC68HC16Y1EVB.

Set up channel 4 in PMA count mode, counting additional teeth.

Set up channel 5 in PSP angle-angle mode

8.6.1 Initialization

The following code is included to set up the reset vector (\$00000 – \$00006). It may be changed for different systems.

```

ORG      $0000      ;put the following reset vector information
                        ;at address $00000 of the memory map
DW       $0000      ;zk=0, sk=0, pk=0
DW       $0200      ;pc=200 -- initial program counter
DW       $3000      ;sp=3000 -- initial stack pointer
DW       $0000      ;iz=0 -- direct page pointer
org      $0400      ;begin program at memory location $0400

```

The following code initializes and configures the system including the software watchdog and system clock. It was written to be used with an EVB.

```

9 Function Algorithm

The PMA function consists of three states, which are described in the following paragraphs. The following description is provided as a guide only, to aid understanding of the function. The exact sequence of operations in microcode may be different from that shown, in order to optimize speed and code size.

TPU microcode source listings for all functions in the TPU function library can be downloaded from the Motorola Freeware bulletin board. Refer to *Using the TPU Function Library and TPU Emulation Mode* (TPUPN00/D) for detailed instructions on downloading and compiling microcode.

9.1 State 1: *Init*

Condition: HSR1, HSR0, M/TSR, LSR, Pin, Flag0 = 01xxxx.

Match Enable: Don't Care

Summary:

This state is entered as a result of HSR%01. The channel is configured to detect a specified transition at the pin and the particular time base to be used for match and capture events. (In general, TCR1 should be used for both match and capture).

TCR2 and TCR2_VALUE are set to \$C0FF (since a previous period longer than \$FFFF is assumed). ROLLOVER_COUNT is set to \$80 (a long previous period is assumed).

Algorithm:

```
Configure channel latches via CHANNEL_CONTROL
Negate flag0
ROLLOVER_COUNT = $80
    /* a longer than $FFFF previous period is set */
TCR2 = $C0FF
TCR2_VALUE = $C0FF
ADDITIONAL_COUNT = 0
```

9.2 State 2: *Measure_Period*

Condition: HSR1, HSR0, M/TSR, LSR, Pin, Flag0 = 001xx0.

Match Enable: Don't Care

Summary:

This state is entered as a result of a match or a normal transition detection, when flag0 equals zero. With a match, ROLLOVER_COUNT is incremented. With a transition, PERIOD is updated, and TCR2_VALUE low byte (TEETH_COUNT) is incremented.

If TCR2 exceeds TCR2_MAX_VALUE, indicating an error condition, then TCR2 is set to \$80FF and the high byte of TCR2_VALUE is set to \$80. A search for the additional transition is initiated if the measured period is less than or equal to \$FFFF TCR1 counts; if the period is greater, TCR2 is set to \$C0FF and the high byte of TCR2_VALUE is set to \$C0. In either error condition, an interrupt is asserted to the CPU.

Algorithm:

```
If MRL = 1 then {
INCR_ROLLOVER:                                     /* address label */
    If ROLLOVER_COUNT - $FF then {
        ROLLOVER_COUNT = ROLLOVER_COUNT + 1
    }
    If (TDL = 0) then {
        If (ROLLOVER_COUNT > 1) then {
            If (TCR2_VALUE(15) = 0) then {
                /* issue period error */
                TCR2 = $C0FF
                TCR2_VALUE (high) = $C0
                Assert interrupt request
                Generate a match on ERT + $8000
            }
        }
    }
}
```

```

Negate MRL /* this match has been handled */
Negate channel flag0, flag1
If host sequence bit 0 = 0 then { /* bank mode */
    BANK_SIGNAL = $00
}
Else { /* count mode */
    ADDITIONAL_COUNT = $00
}
Else {
    Generate a match on ERT + $8000
    Negate MRL /* this match has been handled */
}
}
}
If TDL = 1 then {
NEW_PER: /* address label */
/* see Figure 12. Period Time Calculation. */

PERIOD_TIME (14:0) = ERT - REF_TIME
PERIOD_TIME (22:15) = ROLLOVER_COUNT /* update period parameters */

PERIOD_LOW_WORD = PERIOD_TIME [15:0]
PERIOD_HIGH_WORD = PERIOD_TIME [22:16] /* upper bits zero */
REF_TIME = ERT
ROLLOVER_COUNT = 0
Negate TDL
TCR2_VALUE (low) = TCR2_VALUE (low) + 1
If TCR2 (low) > TCR2_MAX_VALUE then {
    TCR2 = $80FF
    TCR2_VALUE (high) = $80
    Generate a match on ERT + $8000
    Assert interrupt request
    Negate MRL /* this match has been handled */
    Negate channel flag0, flag1
    If host sequence bit 0 = 0 then { /* bank mode */
        BANK_SIGNAL = $00
    }
    Else { /* count mode */
        ADDITIONAL_COUNT = $00
    }
}
Else {
    If (PERIOD_TIME ≥ $10000) then { /* Period error*/

        If (TCR2_VALUE(15) = 0) then { /* issue period error */

            TCR2 = $C0FF
            TCR2_VALUE(high) = $C0
            Assert interrupt request
            Generate a match on ERT + $8000
            Negate MRL /* this match has been handled */
            Negate channel flag0, flag1
            If host sequence bit 0 = 0 then { /* bank mode */
                BANK_SIGNAL = $00
            }
            Else { /* count mode */

```

1. In count mode (host sequence bit 0 equals one):
 - If (TCR2 - NUM_OF_TEETH), indicating an error condition, then TCR2 is set to \$80FF, the TCR2_VALUE high byte is set to \$80, the low byte is incremented, and ADDITIONAL_COUNT is set to \$0000; or else,
 - If (TCR2 = NUM_OF_TEETH) then ADDITIONAL_COUNT is incremented, and if (ADDITIONAL_COUNT ≥ MAX_ADDITIONAL), then TCR2 is set to \$FFFF, TCR2_VALUE is set to \$00FF, and ADDITIONAL_COUNT is cleared.
2. In bank mode (host sequence bit 0 equals zero):
 - If (TCR2 - NUM_OF_TEETH), indicating an error condition, then TCR2 is set to \$80FF, the TCR2_VALUE high byte is set to \$80, the low byte is incremented, and BANK_SIGNAL is set to \$00; or else,
 - If (TCR2 = NUM_OF_TEETH) and if (BANK_SIGNAL - \$00) (reference has been passed), then TCR2 is set to \$FFFF, TCR2_VALUE is set to \$00FF, and BANK_SIGNAL is set to \$00.

Algorithm:

```

Negate channel flag0
If (TDL = 1) and (MRL = 0) then {                                     /* additional transition detected */
  Negate TDL
  TCR2_VALUE (low) = TCR2_VALUE (low) + 1
  If TCR2 (low) - NUM_OF_TEETH then {
    TCR2 = $80FF
    TCR2_VALUE (high) = $80
    Generate a match on ERT + $8000
    Assert interrupt request
    Negate MRL                                                         /* this match has been handled */
    Negate channel flag0, flag1
    If host sequence bit 0 = 0 then {                                   /* bank mode */
      BANK_SIGNAL = $00
    }
    Else {                                                             /* count mode */
      ADDITIONAL_COUNT = $00
    }
  }
}
Else {
  If (host sequence bit 0 = 0) and (BANK_SIGNAL - $00) then {
    TCR2 = $FFFF
    TCR2_VALUE = $00FF
    BANK_SIGNAL = $00
    Assert interrupt request
  }
  If (host sequence bit 0 = 1) then {
    ADDITIONAL_COUNT = ADDITIONAL_COUNT + 1
    If (ADDITIONAL_COUNT ≥ MAX_ADDITIONAL) then {
      TCR2 = $FFFF
      TCR2_VALUE = $00FF
      ADDITIONAL_COUNT = $00
      Assert interrupt request
    }
  }
}
Prepare a match on REF_TIME + $8000
Negate MRL                                                         /* this match has been handled */
}
If (MRL = 1) and (TDL = 0) then {                                     /* no additional transition detected */
  Prepare a match on REF_TIME + $8000
  Negate MRL                                                         /* this match has been handled */
}

```

```

}
If (MRL = 1) and (TDL = 1) then {                               /* no additional transition detected */
    If (ERT - REF_TIME ≥ $8000) then {
        Goto INCR_ROLLOVER                                       /* calculate new period */
    }
    Goto NEW_PER                                                 /* calculate new period */
}
                                                                    /* EXPLANATION:

```

This state is entered as a result of one of the following conditions:

MRL = 0; TDL = 1:

An additional transition has been detected. Set TCR2 to \$FFFF, prepare a match on REF_TIME + \$8000, and wait for the next transition and/or rollover period.

MRL = 1; TDL = 0:

No additional transition, prepare a match on REF_TIME + \$8000, wait for the next transition and/or rollover period.

MRL = 1; TDL = 1:

No additional transition. Calculate new period. Increment ROLLOVER_COUNT if the last transition time minus REF_TIME is greater than \$8000. */

The table below shows the PMA state transitions listing the service request sources and channel conditions from current state to next state. **Figure 13** illustrates the flow of PMA states, including the initialization and immediate update states.

Table 3 PMA State Transition Table

Current State	HSR	M/TSR	LSR	Pin	Flag0	Next State
All States	01	—	—	—	—	S1 Init
S1 Init	00	1	—	—	0	S2 Measure_Period
S2 Measure_Period	00	1	—	—	0	S2 Measure_Period
	00	1	—	—	1	S3 Additional_Trans
S3 Additional_Trans	00	1	—	—	0	S2 Measure_Period
	00	1	—	—	1	S3 Additional_Trans
Unimplemented Conditions	11	—	—	—	—	—
	10	—	—	—	—	—
	00	0	1	—	—	—

NOTES:

1. Conditions not specified are "don't care."
2. HSR = Host service request
 LSR = Link service request
 M/TSR = Either a match or transition (input capture) service request occurred (M/TSR = 1) or neither occurred (M/TSR = 0).
