SPC5746R Microcontroller
Data Sheet

Features

• This document provides electrical specifications, pin assignments, and package diagrams for the MPC5746R series of microcontroller units (MCUs).

• For functional characteristics, see the MPC5746R Microcontroller Reference Manual.

NXP reserves the right to change the production detail specifications as may be required to permit improvements in the design of its products.
1 Introduction

The MPC5746R family of 32-bit microcontrollers is the latest achievement in integrated automotive application controllers. It belongs to an expanding range of automotive-focused products designed for flexibility to support a variety of applications. The advanced and cost-efficient host processor core of the MPC5746R automotive controller family complies with the Power Architecture embedded category. It operates at speeds as high as 200 MHz and offers high-performance processing optimized for low power consumption. It capitalizes on the available development infrastructure of current Power Architecture devices and is supported with software drivers, operating systems, and configuration code to assist with users' implementations. This section contains detailed information on power considerations, DC/AC electrical characteristics, and AC timing specifications.

Note

Within this document, $V_{DD\_HV\_IO}$ refers to supply pins $V_{DD\_HV\_IO\_MAIN}$, $V_{DD\_HV\_IO\_JTAG}$, $V_{DD\_HV\_IO\_FEC}$, and $V_{DD\_HV\_IO\_MSC}$
1.1 Block diagram

**Figure 1. Core block diagram**
2 Package pinouts and signal descriptions

For package pinouts and signal descriptions, refer to the Reference Manual.
3 Absolute maximum ratings

Functional operating conditions are given in the DC electrical specifications. Absolute maximum voltages are stress ratings only, and functional operation at the maxima is not guaranteed. Stress beyond listed maxima may affect device reliability or cause permanent damage to the device.

Table 1. Absolute maximum ratings

1. Voltage is referenced to $V_{\text{SS}}$ unless otherwise noted.
2. Allowed 1.45 – 1.5 V for 60 seconds cumulative time at maximum $T_J = 150$ °C, remaining time as defined in note -1 and note -1.
3. Allowed 1.375 – 1.45 V for 10 hours cumulative time at maximum $T_J = 150$ °C, remaining time as defined in note -1.
4. 1.32 – 1.375 V range allowed periodically for supply with sinusoidal shape and average supply value below 1.275 V at maximum $T_J = 150$ °C.
5. Allowed 5.5 – 6.0 V for 10 hours cumulative time at maximum $T_J = 150$ °C, remaining time at or below 5.0 V +10%.
6. Allowed 3.6 – 4.5 V for 10 hours cumulative time at maximum $T_J = 150$ °C, remaining time at or below 3.3 V +10%. This is an internally regulated supply. Values given are for reference only.
7. The maximum input voltage on an I/O pin tracks with the associated I/P supply maximum. For the injection current condition on a pin, the voltage will be equal to the supply plus the voltage drop across the internal ESD diode from I/O pin to supply. The diode voltage varies greatly across process and temperature, but a value of 0.3V can be used for nominal calculations.
8. Relative value can be exceeded, if design measures are taken to ensure injection current limitation (parameters $I_{\text{INJD}}$ and $I_{\text{INJA}}$).
9. $V_{\text{DDHV_IO}}/V_{\text{SSHV_IO}}$ refers to supply pins and corresponding grounds: $V_{\text{DDHV_IO_MAIN}}$, $V_{\text{DDHV_IO_JTAG}}$, $V_{\text{DDHV_IO_FEC}}$, $V_{\text{DDHV_IO_MSC}}$.
10. Sum of all controller pins (including both digital and analog) must not exceed 200 mA. A $V_{\text{DDHV_IO}}$ power segment is defined as one or more GPIO pins located between two $V_{\text{DDHV_IO}}$ supply pins.
11. The average current values given in the "I/O pad current specifications* section should be used to calculate total I/O segment current.
12. Solder profile per IPC/JEDEC J-STD-020D.

4 Electromagnetic Compatibility (EMC)

EMC measurements to IC-level IEC standards are available from NXP on request.

5 Electrostatic discharge (ESD)

The following table describes the ESD ratings of the device.
All ESD testing is in conformity with CDF-AEC-Q100 Stress Test Qualification for Automotive Grade Integrated Circuits.

Device failure is defined as: "If after exposure to ESD pulses, the device does not meet the device specification requirements, which includes the complete DC parametric and functional testing at room temperature and hot temperature. Maximum DC parametrics variation within 10% of maximum specification."

### Table 2. ESD ratings

</tbody>
</table>

1. This parameter tested in conformity with ANSI/ESD STM5.1-2007 Electrostatic Discharge Sensitivity Testing
2. This parameter tested in conformity with ANSI/ESD STM5.3-1990 Charged Device Model - Component Level

### 6 Operating conditions

The following table describes the operating conditions for the device, and for which all specifications in the data sheet are valid, except where explicitly noted.

The device operating conditions must not be exceeded in order to guarantee proper operation and reliability.

**NOTE**

All power supplies need to be powered up to ensure normal operation of the device.

### Table 3. Device operating conditions

**Injection current**

<table>
<thead>
<tr>
<th>I&lt;sub&gt;IC&lt;/sub&gt;</th>
<th>DC injection current (per pin)&lt;sup&gt;18, 19, 20&lt;/sup&gt;</th>
<th>Digital pins and analog pins</th>
<th>— — 3.0 mA</th>
</tr>
</thead>
<tbody>
<tr>
<td>I&lt;sub&gt;MAXSEG&lt;/sub&gt;</td>
<td>Maximum current per power segment&lt;sup&gt;21, 22&lt;/sup&gt;</td>
<td>—</td>
<td>—80 — 80 mA</td>
</tr>
</tbody>
</table>

1. Maximum operating frequency is applicable to the computational cores and platform for the device.
2. Core voltage as measured on device pin to guarantee published silicon performance.
3. During power ramp, voltage measured on silicon might be lower. Maximum performance is not guaranteed, but correct silicon operation is guaranteed. See power management and reset management for description.
4. Maximum core voltage is not permitted for entire product life. See absolute maximum rating.
5. When internal LVD/HVDs are disabled, external monitoring is required to guarantee device operation. Failure to monitor externally supply voltage may result in erroneous operation of the device.
Operating conditions

6. This LVD/HVD disabled supply voltage condition only applies after LVD/HVD are disabled by the application during the reset sequence, and the LVD/HVD are active until that point.
7. The pad are operative till 3.0V full performance. The IRC oscillator is supplied by this pin and it is setting the min voltage limit.
8. FEC will be used only in 3.3V mode. In 5V mode the segment is a general IO segment with the same characteristics of IO_MAIN.
9. MSC will be used only in 3.3V mode. In 5V mode the segment is a general IO segment with the same characteristics of IO_MAIN.
10. If XOSC is enabled via DCF_UTEST_Miscellaneous[XOSC_EN], VDD_HV_IO_JTAG must be within the operating range before RESET pin is released.
11. JTAG will be used only in 3.3V mode. In 5V mode the segment is a general IO segment with the same characteristics of IO_MAIN.
12. The startup of flash regulator and memory initialization immediately after Phase0 of reset sequence could cause a drop of the PMC supply. No LVD event will be generated as during this time the LVD monitors are not enabled.
13. VDDSTBY supply must be present before and after power up/down of the device supplies and the ramp rate should be less than 33.3 kV/s.
14. RAM retention is not guaranteed below 1.3 V, but no effect on RAM operation for voltages below 1.3 V when VDD_LV is above the minimum value.
15. For supply voltages between 3.6V and 4.5V there will be no guaranteed precision of ADC (accuracy/linearity). ADC will recover to a fully functional state when the voltage rises above 4.5V.
16. VDD_HV_ADV_SD must be higher or equal than the VDD_HV_ADV_SAR supply to guarantee full performance. It is recommended to connect the VDD_HV_ADV_SD to VDD_HV_ADV_SAR at board level.
17. Temperature Sensor and its associated Band-Gap reference are supplied by this pin. The temperature sensor performance is guaranteed only between 4.5 V and 5.5 V.
18. Full device lifetime without performance degradation.
19. I/O and analog input specifications are only valid if the injection current on adjacent pins is within these limits. See the absolute maximum ratings table for maximum input current for reliability requirements.
20. The I/O pins on the device are clamped to the I/O supply rails for ESD protection. When the voltage of the input pin is above the supply rail, current will be injected through the clamp diode to the supply rail. For external RC network calculation, assume typical 0.3 V drop across the active diode. The diode voltage drop varies with temperature. For more information, see the device characterization report.
21. Sum of all controller pins (including both digital and analog) must not exceed 200 mA. A VDD_HV_IO power segment is defined as one or more GPIO pins located between two VDD_HV_IO supply pins.
22. The average current values given in the “I/O pad current specifications” section should be used to calculate total I/O segment current.

</table>

1. Value is derived from a typical application at 200MHz, Core 0 Data and Instruction Cache On, Core 1 in Lockstep mode, typical usage for SARADC, SDADC, DMA, eTPU, eMIOS, CAN, MSC, SPI, SENT, PIT, and Flash reads.
I/O pad specification

2. This value is considering the use of the internal core regulator with an external ballast with the minimum value of $h_{FE}$ of 60.
3. Data is retained for full TB range of -40 °C to 125 °C. RAM supply switch to the standby regulator occurs when the $V_{DD\_LV}$ supply falls below 0.95V.
4. $V_{DDSTBY}$ may be supplied with a non-regulated power supply, but the absolute maximum voltage on $V_{DDSTBY}$ given in the absolute maximum ratings table must be observed.
5. The maximum value for $I_{DDSTBY\_ON}$ is also valid when switching from the core supply to the standby supply, and when powering up the device and switching the RAM supply back to $V_{DD\_LV}$
6. When the $V_{DDSTBY}$ pin is powered, the standby RAM regulator current is present on the pin, regardless if the device is in standby mode or not. No current is present on the pin when $V_{DDSTBY}$ pin is set to 0V, disabling the standby regulator.
7. Worst case usage (data trace, data overlay, full Aurora utilization).

8 I/O pad specification

The following table describes the different pad type configurations.

<table>
<thead>
<tr>
<th>Pad type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>General-purpose I/O pad</td>
<td>General-purpose I/O pads with four selectable output slew rate settings. The GPIO pads have CMOS input threshold levels.</td>
</tr>
<tr>
<td>LVDS pads</td>
<td>Low Voltage Differential Signal interface pads</td>
</tr>
<tr>
<td>Input only pads</td>
<td>These pads, which ensure low input leakage, are associated with the ADC channels. The digital inputs of these pads have CMOS, and TTL input threshold levels.</td>
</tr>
</tbody>
</table>

Note

Each I/O pin on the device supports specific drive configurations. See the signal description table in the device reference manual for the available drive configurations for each I/O pin.

1. Supported input levels vary according to pad types. Pad type "pad_sr_hv" supports only the CMOS input level, while pad type "pad_isatww_st_hv" supports TTL and CMOS levels. Refer to the I/O spreadsheet attached to the Reference Manual for the pad type of each pin.

SPC5746R Microcontroller Data Sheet, Rev. 7, 02/2020

NXP Semiconductors
2. TTL level input specifications apply to the digital inputs on the analog input pins, and not the GPIO pins on the device.
3. In a 1 ms period, assuming stable voltage and a temperature variation of ±30 °C, VIL/VIH shift is within ±50 mV. ForSENT requirement, refer to Note in the "I/O pad current specifications" section.
4. For LFAST, microsecond bus, and LVDS input characteristics, refer to dedicated communication module chapters.

The following table provides the current specifications for the GPIO pad weak pull-up and pull-down.

Table continues on the next page...
In order to ensure device reliability, the average current of the I/O on a single segment should remain below the $I_{\text{MAXSEG}}$ value given in the table "Absolute maximum ratings".

In order to ensure device functionality, the sum of the dynamic and static current of the I/O on a single segment should remain below the $I_{\text{MAXSEG}}$ value given in the table "Device operating conditions".

**Note**

The MPC5746R I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel workbook file attached to the Reference Manual.

## 9 Reset pad (PORST, RESET) electrical characteristics

The device implements a dedicated bidirectional reset pin (PORST).
NOTE

PORST pin does not require active control. It is possible to implement an external pull-up to ensure correct reset exit sequence. Recommended value is 4.7 kohm.

PORST can optionally be connected to an external power-on supply circuitry.

No restrictions exist on reset signal slew rate apart from absolute maximum rating compliance.

![Figure 6. Start-up reset requirements](image)

The following figure describes device behavior depending on supply signal on PORST:

1. PORST low pulse amplitude is too low—it is filtered by input buffer hysteresis. Device remains in current state.
2. PORST low pulse duration is too short—it is filtered by a low pass filter. Device remains in current state.
3. PORST low pulse is generating a reset:
   a) PORST low but initially filtered during at least $W_{FRST}$. Device remains initially in current state.
   b) PORST potentially filtered until $W_{NFRST}$. Device state is unknown. It may either be reset or remains in current state depending on extra condition (temperature, voltage, device).
   c) PORST asserted for longer than $W_{NFRST}$. Device is under reset.
Figure 7. Noise filtering on reset signal

1. An external 4.7 KOhm pull-up resistor is recommended to be used with the PORST and RESET pins for fast negation of the signals.
Oscillator and FMPLL

2. Strong pull-down is enabled during power up / phase0 on both pads but after that a weak pull-down is enabled on PORST and a weak pull-up is enabled on RESET.

10 Oscillator and FMPLL

Two on-chip PLLs, the peripheral clock and reference PLL (PLL0), and the frequency modulated system PLL (PLL1) generate the system and auxiliary clocks from the external oscillator.

![PLL integration](image)

</table>

1. The range is selectable by UTEST miscellaneous DCF clients XOSC_LF_EN and XOSC_EN_40MHZ.
2. This value is determined by the crystal manufacturer and board design.
3. Proper PC board layout procedures must be followed to achieve specifications.
4. Crystal recovery time is the time for the oscillator to settle to the correct frequency after adjustment of the integrated load capacitor value.
5. This parameter is guaranteed by design rather than 100% tested.
6. See crystal manufacturer’s specification for recommended load capacitor (C_L) values. The external oscillator requires external load capacitors when operating from 8 MHz to 16 MHz. Account for on-chip stray capacitance (C_{S,EXTAL}/C_{S,XTAL}) and PCB capacitance when selecting a load capacitor value. When operating at 20 MHz/40 MHz, the integrated load capacitor value is selected via S/W to match the crystal manufacturer’s specification, while accounting for on-chip and PCB capacitance. The capacitance on “EXTAL” and “XTAL” by internal capacitance array is controlled by the XOSC LOAD CAP SEL field of the UTEST Miscellaneous DCF client. See the DCF Records chapter of the Reference Manual.
7. Amplitude on the EXTAL pin after startup is determined by the ALC block, i.e., the Automatic Level Control Circuit. The function of the ALC is to provide high drive current during oscillator startup, but reduce current after oscillation in order to reduce power, distortion, and RFI, and to avoid overdriving the crystal. The operating point of the ALC is dependent on the crystal value and loading conditions.
8. I_{XTAL} is the oscillator bias current out on the XTAL pin with both EXTAL and XTAL pins grounded. This is the maximum current during startup of the oscillator. The current after oscillation is typically in the 2-3 mA range and is dependent on the load and series resistance of the crystal. Test circuit is shown in the figure below.

11.2 SAR ADC

The device provides a 12-bit Successive Approximation Register (SAR) Analog-to-Digital Converter.

![Diagram of ADC characteristics and error definitions]

**Figure 10. ADC characteristics and error definitions**

---

1. Example of an actual transfer curve
2. The ideal transfer curve
3. Differential non-linearity error (DNL)
4. Integral non-linearity error (INL)
5. Center of a step of the actual transfer curve

The 1 LSB ideal is calculated as follows:

\[
1 \text{ LSB ideal} = \frac{(V_{\text{refH}} - V_{\text{refL}})}{4096} = \frac{3.3V}{4096} = 0.806 \text{ mV}
\]

The Total Unadjusted Error (TUE) is calculated as:

\[
\text{TUE} = \pm 6 \text{ LSB} = \pm 4.84 \text{ mV}
\]

</tbody>
</table>

1. $V_{DD,HV,IO} = 3.3$ V -5%,+10%, $T_J = –40$ to +150 °C, unless otherwise specified, and analog input voltage from $V_{AGND}$ to $V_{AREF}$.
2. SAR ADC performance is not guaranteed when IRC is used as clock source for PLL0 to generate SAR ADC clock.
3. AD_CK clock is always half of the ADC module input clock defined via the auxiliary clock divider for the ADC.
4. During the sample time the input capacitance $C_S$ can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within $t_{sample}$. After the end of the sample time $t_{sample}$, changes of the analog input voltage have no effect on the conversion result. Values for the sample clock $t_{sample}$ depend on programming.
5. This parameter does not include the sample time $t_{sample}$, but only the time for determining the digital result and the time to load the result register with the conversion result.
6. See the above figure.
7. Subject to change with additional -40°C characterization on final silicon version.
8. Below 4.5V, ENOB - 9.5b, THD- 60dB at $F_{in} = 125$kHz
10. Minimum and maximum values are typical +/-3%.

**NOTE**

- For spec complaint operation, do not expose clock sources, including crystal oscillator, IRC, PLL0, and PLL1 on the CLKOUT pads while the SAR ADC is converting.
- The ADC performance specifications are not guaranteed if two or more ADCs simultaneously sample the same shared channel.

### 11.3 S/D ADC

The SD ADCs are Sigma Delta 16-bit analog-to-digital converters with 333 Ksps maximum output rate.
Functional operating conditions are given in the DC electrical specifications. Absolute maximum ratings are stress ratings only, and functional operation at the maxima is not guaranteed. Stress beyond the listed maxima may affect device reliability or cause permanent damage to the device.

</tbody>
</table>

1. For input voltage above the maximum and below the clamp voltage of the input pad, there is no latch-up concern, and the signal will only be 'clipped'.
2. VINP is the input voltage applied to the positive terminal of the SD ADC.
3. VINM is the input voltage applied to the negative terminal of the SD ADC.
4. For Gain=16, SDADC Resolution is 15 bit.
5. Offset and gain error due to temperature drift can occur in either direction (+/-) for each of the SDADCs on the device.
6. Calibration of gain is possible when gain = 1. Offset Calibration should be done with respect to 0.5*V_{DD_HV_ADR_SD} for differential "differential mode" and single ended mode with negative input=0.5*V_{DD_HV_ADR_SD} "* Offset Calibration should be done with respect to 0 for "single ended mode with negative input=0". Both Offset and Gain Calibration is guaranteed for +/-5% variation of V_{DD_HV_ADR_SD}, +/-10% variation of V_{DD_HV_ADR_SD}, +/-50 C temperature variation.
7. S/D ADC is functional in the range 3.6V < V_{DD_HV_ADV_SD} < 4.5V and 3.0V < V_{DD_HV_ADR_SD} < 4.5 V, SNR parameter degrades by 9 dB.
8. Input impedance in differential mode Z_{IN} = Z_{DIFF}
9. Input impedance given at f_{ADCD,M} = 16 MHz. Impedance is inversely proportional to SDADC clock frequency. Z_{DIFF}

\( f_{ADCD,M} = (16 \text{ MHz} / f_{ADCD,M}) \times Z_{DIFF}, Z_{CM} (f_{ADCD,M}) = (16 \text{ MHz} / f_{ADCD,M}) \times Z_{CM}. \)
10. Input impedance in single-ended mode \( Z_{IN} = (2 \times Z_{DIFF} \times Z_{CM}) / (Z_{DIFF} + Z_{CM}) \)
11. \( V_{INTCM} \) is the Common Mode input reference voltage for the SDADC. It has a nominal value of \( \left(V_{RH_SD} - V_{RL_SD}\right) / 2 \).
12. The ±1% passband ripple specification is equivalent to 20 * log10 (0.99) = 0.873 dB.
13. Propagation of the information from the pin to the register CDR[CDATA] and flags SFR[DFEF], SFR[DFFF] is given by the different modules that need to be crossed: delta/sigma filters, high pass filter, fifo module, clock domain synchronizers. The time elapsed between data availability at pin and internal S/D module registers is given by the following formula:

\[
\text{REGISTER LATENCY} = t_{LATENCY} + 0.5f_{ADCD,S} + 2 (-1) f_{ADCD,M} + 2 (-1) f_{PBRIDGE_EX_CLK}
\]

where \( f_{ADCD,S} \) is the after-decimation ADC output data rate, \( f_{ADCD,M} \) is the modulator sampling rate and \( f_{PBRIDGE_EX_CLK} \) is the frequency of the peripheral bridge clock feeds to the ADC S/D module. The (-1) symbol refers to the number of clock cycles uncertainty (from 0 to 1 clock cycle) to be added due to resynchronization of the signal during clock domain crossing. Some further latency may be added by the target module (core, DMA, interrupt) controller to process the data received from the ADC S/D module.
14. This capacitance does not include pin capacitance, that can be considered together with external capacitance, before sampling switch.

### 12 Temperature sensor

1. Total transmitter startup time from power down to normal mode is t<sub>STRT_BIAS</sub> + t<sub>PD2NM_TX</sub> + 2 peripheral bridge clock periods. The LFAST and High-Speed Debug LFAST pad electrical characteristics are based on worst case internal capacitance values.
2. Total transmitter startup time from sleep mode to normal mode is t<sub>SM2NM_TX</sub> + 2 peripheral bridge clock periods. Bias block remains enabled in sleep mode. All LFAST and High-Speed Debug LVDS pad electrical characteristics are valid from -40 °C to 150 °C.
3. Total receiver startup time from power down to normal mode is t<sub>STRT_BIAS</sub> + t<sub>PD2NM_RX</sub> + 2 peripheral bridge clock periods.
4. Total receiver startup time from power down to sleep mode is t<sub>PD2SM_RX</sub> + 2 peripheral bridge clock periods. Bias block remains enabled in sleep mode.
5. Absolute min = 0.15 V − (285 mV/2) = 0 V
6. Absolute max = 1.6 V + (285 mV/2) = 1.743 V
7. Total internal capacitance including receiver and termination, co-bonded GPIO pads, and package contributions.

1. The 640 MHz frequency is achieved with a 10 MHz or 20 MHz reference clock. With a 26 MHz reference, the VCO frequency is 624 MHz.
2. The time from the PLL enable bit register write to the start of phase locks is maximum 2 clock cycles of the peripheral bridge clock that is connected to the PLL on the device.
3. Measured at the transmitter output across a 100 Ohm termination resistor on a device evaluation board. Refer to the figure below.

![Figure 16. LFAST output 'eye' diagram](image)

### 15 Aurora LVDS electrical characteristics

The following table describes the Aurora LVDS electrical characteristics.

All Aurora electrical characteristics are valid from -40 °C to 150 °C.

All specifications valid for maximum transmit data rate \( F_{TX} \).

</tbody>
</table>

1. All specifications valid for maximum transmit data rate $F_{TX}$.
2. The minimum value of 400 mV is only valid for differential resistance ($R_{V,L}$) = 99 ohm to 101 ohm. The differential output voltage swing tracks with the value of $R_{V,L}$.
3. Transmission line loss maximum value is specified for the maximum drive level of the Aurora transmit pad.

16 Power management PMC POR LVD sequencing

16.1 Power management electrical characteristics

The power management module monitors the different power supplies. It also generates the internal supplies that are required for correct device functionality. The power management is supplied by the $V_{DD,HV_PMC}$ supply.

16.1.1 Recommended power transistors

The following NPN transistors are recommended for use with the on-chip voltage regulator controller: ON Semiconductor™ NJD2873. The collector of the external transistor is preferably connected to the same voltage supply source as the $V_{DD,HV_PMC}$ pin.
The following table describes the characteristics of the power transistors.

</tbody>
</table>

1. See the above figure for capacitor integration.
2. Recommended X7R or X5R ceramic low ESR capacitors, ±15% variation over process, voltage, temperature, and aging.
3. Each V_DD_LV pin requires both a 47nF and 0.01µF capacitor for high-frequency bypass and EMC requirements. Remaining capacitance to meet minimum CLV requirement should be placed near the emitter of NPN ballast (if using internal regulation mode), or it should be evenly distributed across V_DD_LV pins (if using external regulation mode).
4. Each V_DD_HV_PMC pin requires both a 47nF and 0.01µF capacitor for high-frequency bypass and EMC requirements.
5. The recommended flash regulator composition capacitor is 1.5µF typical X7R or X5R, with -50% and +35% as min and max. This puts the min cap at 0.75 µF.
6. For noise filtering it is recommended to add high frequency bypass capacitors of three each 0.1 µF and three each 1nF between V_DD_HV_ADV_SAR and V_SS_HV_ADV_SAR. These capacitors need to be placed very close to the MCU pins/balls to have minimum PCB routing between pin/ball and the capacitors.
7. For noise filtering it is recommended to add a high frequency bypass capacitance of 0.1 µF between V_DD_HV_ADV_SD and V_SS_HV_ADV_SD.

16.1.3 Regulator example for the NJD2873 transistor

The bypass transistor MUST be operated out of saturation region.

Figure 18. Regulator example
16.1.4 Regulator example for the 2SCR574d transistor

![Diagram of a regulator example](image)

**Figure 19. Regulator example**

16.1.5 Device voltage monitoring

The LVD/HVDs for the device and their levels are given in the following table. Voltage monitoring threshold definition is provided in the following figure.
For $V_{DD_{LV}}$ levels, a maximum of 30 mV IR drop is incurred from the pin to all sinks on the die. For other LVD, the IR drop is estimated by multiplying the supply current by 0.5 ohm.

LVD is released after $t_{VDRELEASE}$ temporization when upper threshold is crossed, LVD is asserted $t_{VDASSERT}$ after detection when lower threshold is crossed.

HVD is released after $t_{VDRELEASE}$ temporization when lower threshold is crossed, HVD is asserted $t_{VDASSERT}$ after detection when upper threshold is crossed.

</table>

1. POR085_c and POR096_c threshold are untrimmed value, before the completion of the power-up sequence. All other LVD/HVD thresholds are provided after trimming.
2. LV internal supply levels are measured on device internal supply grid after internal voltage drop.
3. LV external supply levels are measured on the die size of the package bond wire after package voltage drop.

16.1.6 Power up/down sequencing

The following shows the constraints and relationships for the different power supplies.

Figure 21. Device supply relation during power-up/power-down sequence
Each column indicates that the corresponding supply is 0 and the other supplies are UP. For example, the "Amps" cell in the "$V_{DD\_HV\_ADV\_SD}=0$" column shows that when $V_{DD\_HV\_ADR\_SD}$ supply is 0 and all other supplies are UP, this supply has a current in Amp flowing into $V_{DD\_HV\_ADR\_SD}$.

# 17 Flash memory specifications

## 17.1 Flash memory program and erase specifications

**NOTE**

All timing, voltage, and current numbers specified in this section are defined for a single embedded flash memory within an SoC, and represent average currents for given supplies and operations.

Table 30 shows the estimated Program/Erase times.

</table>

1. Program times are actual hardware programming times and do not include software overhead. Block program times assume quad-page programming.
2. Typical program and erase times represent the median performance and assume nominal supply values and operation at 25 °C. Typical program and erase times may be used for throughput calculations.
4. Plant Programing times provide guidance for timeout limits used in the factory.
5. Typical End of Life program and erase times represent the median performance and assume nominal supply values. Typical End of Life program and erase values may be used for throughput calculations.

17.2 Flash memory Array Integrity and Margin Read specifications

<td>Margin Read time for sequential sequence on 256 KB block.</td>
<td>893.01</td>
<td>—</td>
<td>1,339.5</td>
<td>μs</td>
</tr>
</tbody>
</table>

1. Array Integrity times need to be calculated and is dependent on system frequency and number of clocks per read. The equation presented require Tperiod (which is the unit accurate period, thus for 200 MHz, Tperiod would equal 5e-9) and Nread (which is the number of clocks required for read, including pipeline contribution. Thus for a read setup that requires 6 clocks to read with no pipeline, Nread would equal 6. For a read setup that requires 6 clocks to read, and has the address pipeline set to 2, Nread would equal 4 (or 6 - 2).)

2. The units for Array Integrity are determined by the period of the system clock. If unit accurate period is used in the equation, the results of the equation are also unit accurate.

</tbody>
</table>

1. \( t_{CYC} \) is system clock period.
2. Achieving the absolute minimum TCK cycle time may require a maximum clock speed (system frequency / 8) that is less than the maximum functional capability of the design (system frequency / 4) depending on the actual peripheral frequency being used. To ensure proper operation TCK frequency should be set to the peripheral frequency divided by a number greater than or equal to that specified here.
3. This is a functionally allowable feature. However, it may be limited by the maximum frequency specified by the Absolute minimum TCK period specification.
4. This value is TDO propagation time 36ns + 4ns setup time to sampling edge.
5. This may require a maximum clock speed (system frequency / 8) that is less than the maximum functional capability of the design (system frequency / 4) depending on the actual system frequency being used.
6. This value is TDO propagation time 16ns + 4ns setup time to sampling edge.
7. Timing includes TCK pad delay, clock tree delay, logic delay and TDO output pad delay.

</table>

1. Startup time is defined as the time taken by LVDS current reference block for settling bias current after its pwr\_down (power down) has been deasserted. LVDS functionality is guaranteed only after the startup time.
2. Startup time is defined as the time taken by LVDS transmitter for settling after its pwr\_down (power down) has been deasserted. Here it is assumed that current reference is already stable (see Bias start-up time). LVDS functionality is guaranteed only after the startup time.
3. Startup time is defined as the time taken by LVDS receiver for settling after its pwr_down (power down) has been deasserted. Here it is assumed that current reference is already stable (see Bias start-up time). LVDS functionality is guaranteed only after the startup time.

18.2 **DSPI timing with CMOS and LVDS**

DSPI in TSB mode with LVDS pads can be used to implement Micro Second Channel bus protocol.

DSPI channel frequency support is shown in Table 39. Timing specifications are shown in Table 40, Table 41, Table 42, Table 43, Table 44.

<table>
<thead>
<tr>

</tbody>
</table>
1. Maximum usable frequency can be achieved if used with fastest configuration of the highest drive pads.
2. Maximum usable frequency does not take into account external device propagation delay.

18.2.1 DSPI master mode full duplex timing with CMOS and LVDS pads

The values presented in these sections are target values. A complete performance characterization of the pads (in all configuration combinations) is required before the final specifications can be released.

18.2.1.1 DSPI CMOS master mode – classic timing

All output timing is worst case and includes the mismatching of rise and fall times of the output pads.

**NOTE**

In Table 40, all output timing is worst case and includes the mismatching of rise and fall times of the output pads.

</table>

1. All timing values for output signals in this table are measured to 50% of the output voltage.
2. Timing is guaranteed to same drive capabilities for all signals, mixing of pad drives may reduce operating speeds and may cause incorrect operation.
3. N is the number of clock cycles added to time between PCS assertion and SCK assertion and is software programmable using DSPI_CTARx[PSSCK] and DSPI_CTARx[CSSCK]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, N is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
4. $t_{SYS}$ is the period of DSPI_CLKn clock, the input clock to the DSPI module. Maximum frequency is 100 MHz (min $t_{SYS} = 10$ ns).
5. \( M \) is the number of clock cycles added to time between SCK negation and PCS negation and is software programmable using DSPI_CTARx[PASC] and DSPI_CTARx[ASC]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, \( M \) is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).

6. \( t_{SDC} \) is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.

7. PCSx and PCSS using same pad configuration.

8. Input timing assumes an input slew rate of 1 ns (10% - 90%) and uses TTL voltage thresholds.

9. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.

---

**Figure 30. DSPI CMOS master mode – classic timing, CPHA = 0**
18.2.1.2 DSPI CMOS master mode – modified timing

All output timing is worst case and includes the mismatching of rise and fall times of the output pads.

**NOTE**

In Table 41, all output timing is worst case and includes the mismatching of rise and fall times of the output pads.

</table>

1. All timing values for output signals in this table are measured to 50% of the output voltage.
2. N is the number of clock cycles added to time between PCS assertion and SCK assertion and is software programmable using DSPI_CTARx[PSSCK] and DSPI_CTARx[CSSCK]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, N is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
3. t<sub>SYS</sub> is the period of DSPI_CLKn clock, the input clock to the DSPI module. Maximum frequency is 100 MHz (min t<sub>SYS</sub> = 10 ns).
4. M is the number of clock cycles added to time between SCK negation and PCS negation and is software programmable using DSPI_CTARx[PASC] and DSPI_CTARx[ASC]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, M is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
5. t<sub>SDC</sub> is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.
6. Input timing assumes an input slew rate of 1 ns (10% - 90%) and LVDS differential voltage = ±100 mV.
7. P is the number of clock cycles added to delay the DSPI input sample point and is software programmable using DSPI_MCR[SMPL_PT]. The value must be 0, 1 or 2. If the baud rate divide ratio is /2 or /3, this value is automatically set to 1.
8. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.

1. All timing values for output signals in this table are measured to 50% of the output voltage.
2. N is the number of clock cycles added to time between PCS assertion and SCK assertion and is software programmable using DSPI_CTARx[PSSCK] and DSPI_CTARx[CSSCK]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, N is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
3. t<sub>SYS</sub> is the period of DSPI_CLKn clock, the input clock to the DSPI module. Maximum frequency is 100 MHz (min t<sub>SYS</sub> = 10 ns).
4. M is the number of clock cycles added to time between SCK negation and PCS negation and is software programmable using DSPI_CTARx[PASC] and DSPI_CTARx[ASC]. The minimum value is 2 cycles unless TSB mode or Continuous SCK clock mode is selected, in which case, M is automatically set to 0 clock cycles (PCS and SCK are driven by the same edge of DSPI_CLKn).
5. t<sub>SDC</sub> is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.
6. Input timing assumes an input slew rate of 1 ns (10% - 90%) and LVDS differential voltage = ±100 mV.
7. P is the number of clock cycles added to delay the DSPI input sample point and is software programmable using DSPI_MCR[SMPL_PT]. The value must be 0, 1 or 2. If the baud rate divide ratio is /2 or /3, this value is automatically set to 1.
8. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.
18.2.1.4 DSPI master mode – output only

For Table 43:
• All DSPI timing specifications apply to pins when using LVDS pads for SCK and SOUT and CMOS pad for PCS with pad driver strength as defined. Timing may degrade for weaker output drivers.
• TSB = 1 or ITSB = 1 automatically selects MTFE = 1 and CPHA = 1.

Table 43. DSPI LVDS master timing - output only - timed serial bus mode TSB = 1 or ITSB = 1, CPOL = 0 or 1, continuous SCK clock

|    |        | after SCK CPHA = 1\(^5\) |                        | Strong      | 50 pF  | -11.0 | — | ns |
|    |        | |                      | Medium      | 50 pF  | -15.0 | — | ns |

1. All timing values for output signals in this table are measured to 50% of the output voltage.
2. Timing is guaranteed to same drive capabilities for all signals, mixing of pad drives may reduce operating speeds and may cause incorrect operation.
3. With TSB mode or Continuous SCK clock mode selected, PCS and SCK are driven by the same edge of DSPI_CLKn. This timing value is due to pad delays and signal propagation delays.
AC specifications

4. \( t_{SDC} \) is only valid for even divide ratios. For odd divide ratios the fundamental duty cycle is not 50:50. For these odd divide ratios cases, the absolute spec number is applied as jitter/uncertainty to the nominal high time and low time.

5. SOUT Data Valid and Data hold are independent of load capacitance if SCK and SOUT load capacitances are the same value.

Figure 38. DSPI LVDS and CMOS master timing – output only – modified transfer format
MTFE = 1, CHPA = 1

18.2.2 DSPI CMOS slave mode

NOTE
DSPI slave operation is only supported for a single master and single slave on the device. Timing is valid for that case only.

1. Input timing assumes an input slew rate of 1 ns (10% - 90%) and uses TTL / Automotive voltage thresholds.
2. All timing values for output signals in this table, are measured to 50% of the output voltage. All output timing is worst case and includes the mismatching of rise and fall times of the output pads.

Figure 39. DSPI Slave Mode - Modified transfer format timing (MFTE = 0/1) — CPHA = 0
18.3 FEC timing

The FEC supports the 10/100 Mbps MII, 10/100 Mbps MII-lite, and the 10 Mbps-only 7-wire interface.

18.3.1 MII-lite receive signal timing (RXD[3:0], RX_DV, RX_ER, and RX_CLK)

The receiver functions correctly up to a RX_CLK maximum frequency of 25 MHz $+1\%$. There is no minimum frequency requirement. The system clock frequency must be at least equal to or greater than the RX_CLK frequency.

All timing specifications are referenced from RX_CLK = 1.4 V to the valid input levels.

<table>
<thead>
<tr>
<th>Spec</th>
<th>Characteristic</th>
<th>Value</th>
<th>Unit</th>

<td>RX_CLK period</td>
</tr>
<tr>
<td>M4</td>
<td>RX_CLK pulse width low</td>
<td>35% - 65%</td>
<td>RX_CLK period</td>
</tr>
</tbody>
</table>
18.3.2 MII-lite transmit signal timing (TXD[3:0], TX_EN, TX_ER, TX_CLK)

The transmitter functions correctly up to a TX_CLK maximum frequency of 25 MHz +1%. There is no minimum frequency requirement. The system clock frequency must be at least equal to or greater than the TX_CLK frequency.

The transmit outputs (TXD[3:0], TX_EN, TX_ER) can be programmed to transition from either the rising or falling edge of TX_CLK, and the timing is the same in either case. This option allows the use of non-compliant MII PHYs.

All timing specifications are referenced from TX_CLK = 1.4 V to the valid output levels.

Table 47. MII-lite transmit signal timing

<table>
<thead>
<tr>
<th>Spec</th>

18.3.4 MII-lite serial management channel timing (MDIO and MDC)

The FEC functions correctly with a maximum MDC frequency of 2.5 MHz.

**NOTE**

All timing specifications are referenced from MDC = 1.4 V (TTL levels) to the valid input and output levels, 0.8 V and 2.0 V (TTL levels). For 5 V operation, timing is referenced from MDC = 50% to 2.2 V/3.5 V input and output levels.

Figure 45. RMII-lite serial management channel timing diagram

18.3.6 RMII receive signal timing (RXD[1:0], CRS_DV)

The receiver functions correctly up to a REF_CLK maximum frequency of 50 MHz +1%. There is no minimum frequency requirement. The system clock frequency must be at least equal to or greater than the RX_CLK frequency, which is half that of the REF_CLK frequency.

All timing specifications are referenced from REF_CLK = 1.4 V to the valid input levels.

Figure 46. RMII receive signal timing diagram

18.3.7 RMII transmit signal timing (TXD[1:0], TX_EN)

The transmitter functions correctly up to a REF_CLK maximum frequency of 50 MHz + 1%. There is no minimum frequency requirement. The system clock frequency must be at least equal to or greater than the TX_CLK frequency, which is half that of the REF_CLK frequency.

The transmit outputs (TXD[1:0], TX_EN) can be programmed to transition from either the rising or falling edge of REF_CLK, and the timing is the same in either case. This options allows the use of non-compliant RMII PHYs.

All timing specifications are referenced from REF_CLK = 1.4 V to the valid output levels.

20 Thermal characteristics

The following tables describe the thermal characteristics of the device.

Junction temperature is a function of die size, on-chip power dissipation, package thermal resistance, mounting side (board) temperature, ambient temperature, air flow, power dissipation or other components on the board, and board thermal resistance.

**Table 56. Thermal characteristics for the 144-pin LQFP package**

20.1 General notes for specifications at maximum junction temperature

An estimation of the chip junction temperature, $T_J$, can be obtained from this equation:

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where:

- $T_A =$ ambient temperature for the package (°C)
- $R_{\theta JA} =$ junction to ambient thermal resistance (°C/W)
- $P_D =$ power dissipation in the package (W)

The junction to ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. Unfortunately, there are two values in common usage: the value determined on a single layer board and the value obtained on a board with two planes. For packages such as the PBGA, these values can be different by a factor of two. Which value is closer to the application depends on the power dissipated by other components on the board. The value obtained on a single layer board is appropriate for the tightly packed printed circuit board. The value obtained on the board with the internal planes is usually appropriate if the board has low power dissipation and the components are well separated.

When a heat sink is used, the thermal resistance is expressed in the following equation as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$
where:

- \( R_{\theta JA} \) = junction to ambient thermal resistance (°C/W)
- \( R_{\theta JC} \) = junction to case thermal resistance (°C/W)
- \( R_{\theta CA} \) = case to ambient thermal resistance (°C/W)

\( R_{\theta JC} \) is device related and cannot be influenced by the user. The user controls the thermal environment to change the case to ambient thermal resistance, \( R_{\theta CA} \). For instance, the user can change the size of the heat sink, the air flow around the device, the interface material, the mounting arrangement on printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device.

To determine the junction temperature of the device in the application when heat sinks are not used, the Thermal Characterization Parameter (\( \Psi_{JT} \)) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using this equation:

\[
T_J = T_T + (\Psi_{JT} \times P_D)
\]

where:

- \( T_T \) = thermocouple temperature on top of the package (°C)
- \( \Psi_{JT} \) = thermal characterization parameter (°C/W)
- \( P_D \) = power dissipation in the package (W)

The thermal characterization parameter is measured per JESD51-2 specification using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by cooling effects of the thermocouple wire.

¹Sample PD
²Sample ED
1. "PD" refers to a production device, orderable in quantity.
2. "ED" refers to an emulation device, orderable in limited quantities. An emulation device (ED) is for use during system
development only and is not to be used in production. An ED is a Production PD chip combined with a companion chip to
form an Emulation and Debug Device (ED) and includes additional RAM memory and debug features. EDs are provided
“as is” without warranty of any kind. In the event of a suspected ED failure, NXP agrees to exchange the suspected failing
ED from the customer at no additional charge, however NXP will not analyze ED returns.

<tr>
<td></td>
<td></td>
<td>• Added IVDDA.</td>
</tr>
</tbody>
</table>

In section Input pad specifications:

- In Table 7:
  - Added footnote that supported input levels vary according to pad types.
  - Corrected VILTTL Min and Max values.
  - Corrected VIHAUTO, VILCMOS_H and VILCMOS Min value.

- In Table 8:
  - Modified IWPUI Min values for condition Vin = VIH = 0.65 * VDD_HV_IO.
  - Modified IWPDI Min values for condition Vin = VIL = 0.35 * VDD_HV_IO.
  - Removed the "Analog Input Leakage and Pull-Up/Down DC electrical characteristics" table and the preceding introductory paragraph to be moved to the ADC input description section.

In section Output pad specifications, Table 9, changed VOH and VOL specs to two separate specs for 3V pads and 5V pads respectively. Corrected VOH Min and VOL Max values.

In section I/O pad current specifications:

- Added I/O Current Consumption tables.

Added section Reset pad (PORST, RESET) electrical characteristics.

In section Oscillator and FMPLL:

- In Table 13, removed PLL0_PHI0 single period jitter row.
- In Table 15:
  - Modified footnote for CS_EXTAL and CS_XTAL.
  - Modified gm (Oscillator Transconductance) spec.
  - Removed VHYS.

In section ADC modules, revised the subsection structure and titles:

- Added section ADC input description with content moved from the "Input pad specifications" section.
- Section "Input impedance and ADC accuracy" renamed to Input equivalent circuit and ADC conversion characteristics with all content except Figure 11 and Table 19 removed.
- Removed erroneous section "SAR ADC electrical specification".

In section SAR ADC, Table 19:

- Added footnote ("SAR ADC performance is not guaranteed...") to fCK symbol.
- Changed tsample specification min value to 250 ns (was 275).
- Added footnote to OFS and GNE. Changed OFS and GNE min and max values.
- Removed "Input (singe ADC channel)".
- Removed injection row for "Input (double ADC channel)".
- SNR, THD, SINAD, and ENOB specifications: changed frequency condition to 50 kHz (was 125 kHz).
- Changed SNR Min values.
- Added footnote to ENOB.
- Added IDD_VDDA, IDD_VDDR, and VBG_REF parameters.

In section S/D ADC, Table 20:

- For VIN_PK2PK parameter second and third rows, changed VSS in Conditions to VDD.
- For fADCD_M specification, removed sampling frequency footnote from parameter.
- Added footnote to RESOLUTION value.
- For IGAINT specification added footnote to parameter and added new row with more detailed "After calibration" conditions.
- Moved footnote "S/D ADC is functional in the range..." from the Zin to the SNR parameters.

<tr>
<td></td>
<td></td>
<td>• Changed statement on status of doc at the bottom of the page.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Removed &quot;Preliminary&quot; and &quot;Non-Disclosure Agreement required&quot; from footers on each page.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In section <strong>Electromagnetic Compatibility (EMC)</strong> removed content of entire section and replaced it with statement: &quot;EMC measurements to IC-level IEC standards are available from Freescale on request.&quot;</td>
</tr>
</tbody>
</table>
|          |        | In section **Operating conditions**:
|          |        | • In Table 3
|          |        | • For VDD_HV_PMC, removed the two footnotes. |
|          |        | • For VDDSTBY, added statement on ramp rate to footnote. |
|          |        | • For VSTBY_BO, removed Min value and added Max value. |
|          |        | In section **DC electrical specifications**:
|          |        | • In Table 5
|          |        | • IDD_LV spec:
|          |        | • MPC5746R/MPC5745R Max value changed to 700 mA. |
|          |        | • MPC5743R/MPC5742R Max value changed to 610 mA. |
|          |        | • IDDSTBY_ON TA=40°C and TA=85°C values updated. |
|          |        | • IVDDA values updated. |
|          |        | In section **I/O pad specification**, Table 6 Description for Input only pads, removed reference to "Automotive" input. |
|          |        | In section **Input pad specifications**, Table 7 removed VIHAUTO, VILAUTO, VHYSAUTO, and VDRFTAUTO specs and references to "Automotive" input in footnotes. |
|          |        | In section **Output pad specifications**:
|          |        | • In Table 9, removed footnote for tR_F spec Parameter about transition time maximum value approximation formula. |
|          |        | In section **Reset pad (PORST, RESET) electrical characteristics**:
|          |        | • In Table 12
|          |        | • Changed specs for VIH, VIL, and VHYS to VIH Reset, VIL Reset, and VHYS Reset respectively. |
|          |        | • Added specs for VIH PORST, VIL PORST, VHYS PORST. |
|          |        | • Generally added Conditions and updated spec values. In the Conditions column, changed all instances of "3.0 V" to "3.5 V". |
|          |        | In section **Oscillator and FMPLL**:
|          |        | • In Table 13, for ΔPLL0LTJ spec, modified long term jitter Min and Max values. |
|          |        | • In Table 16, values updated. |
|          |        | • In Table 17, added spec for dTRIM (IRC software trimming step). |
|          |        | In section **ADC input description**:
|          |        | • In Table 18
|          |        | • RPUPD 5KΩ spec Max value changed to 8.8KΩ. |
|          |        | In section **Input equivalent circuit and ADC conversion characteristics**:

<tr>
<td></td>
<td></td>
<td>• In VBG_REF row's Conditions, added &quot;INPSAMP=0xFF&quot;</td>
</tr>
</tbody>
</table>
|          |        | • Added NOTE "For spec complaint operation, do not expose clock sources, including crystal oscillator, IRC, PLL0, and PLL1 on the CLKOUT pads while the SAR ADC is converting."
|          |        | • Added NOTE: "The ADC performance specifications are not guaranteed if two or more ADCs simultaneously sample the same shared channel". |
|          |        | In section S/D ADC:    |
|          |        | • In Table 20:         |
|          |        | • For THD_DFF333 _GAIN = 16, updated Min value. |
|          |        | • For IADV_D, updated Max value. |
|          |        | In section LFAST and MSC /DSPI LVDS interface electrical characteristics: |
|          |        | • After table Table 24 added NOTE "For optimum LVDS performance, it is recommended to set the neighbouring GPIO pads to use Weak Drive". |
|          |        | In section Device voltage monitoring: |
|          |        | • In Table 29:         |
|          |        | • For LVD_core_hot, LVD_HV, and LVD_IO specs, removed the untrimmed Rising voltage and Falling voltage rows. |
|          |        | • For LVD_core_hot, changed Mask Opt. value to "No". |
|          |        | In section Regulator example for the 2SCR574d transistor, figure "Regulator example", changed "5V or Vcollector" to "3.3V or Vcollector". |
|          |        | In section DSPI CMOS master mode – classic timing, Table 40: |
|          |        | • Changed tSDC spec's Condition SCK drive strength from "0 pF" to "0 to 50 pF". |
|          |        | • In tSUI and tHI specs' footnote, removed reference to "Automotive" thresholds. |
|          |        | In section DSPI CMOS master mode – modified timing, Table 41: |
|          |        | • Changed tSDC spec's Condition SCK drive strength from "0 pF" to "0 to 50 pF". |
|          |        | • In tSUI and tHI specs' footnote, removed reference to "Automotive" thresholds. |
|          |        | In section DSPI master mode – output only, Table 44, changed tSDC spec's Condition SCK drive strength from "0 pF" to "0 to 50 pF". |
|          |        | Added section eMIOS timing. |
|          |        | In section Ordering information, Table 60: |
|          |        | • Updated Part Numbers. |
|          |        | • Updated Emulation device footnote. |
| 4        | 03/2016| In section Block diagram, Figure 2: |
|          |        | • "DECIM" changed to "DECFILTER". |
|          |        | • "SIPI" changed to "Zipwire". |
|          |        | • I/O lines added to Zipwire, SIUL2, REACM, eTPU, eMIOS, IGF, and XOSC. |
|          |        | In section Absolute maximum ratings table "Absolute maximum ratings", removed IOMAX spec and added IMAXSEG Spec. |
|          |        | In section Operating conditions table “Device operating conditions”:
|          |        | • For the FEC I/O supply voltage, MSC I/O supply voltage, and JTAG I/O supply voltage specs, removed the LVD enabled/disabled distinction. |
|          |        | • Added footnote to IMAXSEG. |
|          |        | In section I/O pad current specifications: |

Table continues on the next page...
Table 61. Revision history (continued)

<table>
<thead>
<tr>
<th>Revision</th>
<th>Date</th>
<th>Description of changes</th>
</tr>
</thead>
</table>
| 5        | 10/2016| - Modified the descriptions in the two paragraphs after the tables.  
- Removed the third paragraph after the tables and the first Note.  
- Added section DSPI CMOS slave mode.  
- In section Ordering information table "Ordering Information", changed Part Numbers for the 176 LQFP PD and the ED.  |
|          |        | 5                     |
|          |        | 6                     |
|          |        | 6                     |
|          | 05/2017| Changed Freescale to NXP throughout the datasheet.  
- In Ordering information added rows for SPC5746RK1MLU3, SPC5745RK1MMT5 and SPC5743RK1MLU5.  
- In Table 3 added footnote in $V_{DD_HV_PMC}$  
- In Table 28 for the rowset C_HV_FLA changed the Minimum and Typical values.  |
|          | 01/2020| In Table 20 :  
- Changed the condition of $\delta_{GROUP}$ from "Within pass band – Tclk is $f_{ADCD_M}$/2" to "Within pass band – Tclk is 2/$f_{ADCD_M}$.  
- In the footnote of $t_{LATENCY}$ changed the Register Latency formula from "$\text{REGISTER LATENCY} = t_{LATENCY} + 0.5/f_{ADCD_S} + 2 (\sim+1)/f_{ADCD_M} + 2(\sim+1)/f_{PBRIDGEx_CLK}$ where $f_{ADCD_S}$ is the frequency of the sampling clock, $f_{ADCD_M}$ is the frequency of the modulator" to "$\text{REGISTER LATENCY} = t_{LATENCY} + 0.5/f_{ADCD_S} + 2 (\sim+1)/f_{ADCD_M} + 2(\sim+1)/f_{PBRIDGEx_CLK}$.  |
