32 kHz watch circuits with EEPROM

FEATURES

• 32 kHz oscillator, amplitude regulated with excellent frequency stability
• High immunity of the oscillator to leakage currents
• Time calibration electrically programmable and reprogrammable (via EEPROM)
• A quartz crystal is the only external component required
• Very low current consumption; typically 170 nA
• Detector for silver-oxide or lithium battery voltage levels
• Indication for battery end-of-life
• Stop function for accurate timing
• Power-on reset for fast testing
• Various test modes for testing the mechanical parts of the watch and the IC.

GENERAL DESCRIPTION

The PCA16xx series devices are CMOS integrated circuits specially suited for battery-operated, quartz-crystal-controlled wrist-watches, with bipolar stepping motors.

FUNCTIONAL DESCRIPTION AND TESTING

Motor pulse
The motor pulse width ($t_P$) and the cycle times ($t_T$) are given in Chapter “Available types”.

Voltage level detector
The supply voltage is compared with the internal voltage reference $V_{LIT}$ and $V_{EOL}$ every minute. The first voltage level detection is carried out 30 ms after a RESET.

Lithium mode
If a lithium voltage is detected ($V_{DD} \geq V_{LIT}$), the circuit will operate in the lithium mode. The motor pulse will be produced with a 75% duty factor.

Silver-oxide mode
If the voltage level detected is between $V_{LIT}$ and $V_{EOL}$, the circuit will operate in silver-oxide mode.

Battery end-of-life (1)
If the battery end-of-life is detected ($V_{DD} \leq V_{EOL}$), the motor pulse will be produced without chopping. To indicate this condition, bursts of 4 pulses are produced every 4 s.

Power-on reset
For correct operation of the Power-on reset the rise time of $V_{DD}$ from 0 V to 2.1 V should be less than 0.1 ms. All resettable flip-flops are reset. Additionally the polarity of the first motor pulse is positive: $V_{M1} - V_{M2} \geq 0 \text{ V}$.

Customer testing
An output frequency of 32 Hz is provided at RESET (pin 8) to be used for exact frequency measurement. Every minute a jitter occurs as a result of time calibration, which occurs 90 to 150 ms after disconnecting the RESET from $V_{DD}$.

Connecting the RESET to $V_{DD}$ stops the motor pulses leaving them in a HIGH impedance 3-state condition and a 32 Hz signal without jitter is produced at the TEST pin. A debounce circuit protects accidental stoppages due to mechanical shock to the watch ($t_{DEB} = 14.7$ to 123.2 ms).

Connecting RESET to $V_{SS}$ activates Tests 1 and 2 and disables the time calibration.

Test 1, $V_{DD} > V_{EOL}$: Normal function takes place except the voltage detection cycle ($t_V$) is 125 ms and the cycle time ($t_{T1}$) is 31.25 ms. At pin TEST a minute signal is available at 8192 times its normal frequency.

Test 2(2), $V_{DD} < V_{EOL}$: The voltage detection cycle ($t_V$) is 31.25 ms and the motor pulse period ($t_{T2}$) = 31.25 ms. Test and reset mode are terminated by disconnecting the RESET pin.

Test 3, $V_{DD} > 5.1 \text{ V}$: Motor pulses with a time period of $t_{T3} = 31.25 \text{ ms}$ and $n \times 122 \mu\text{ s}$ are produced to check the contents of the EEPROM. At pin TEST the motor pulse period signal ($t_T$) is available at 1024 times its normal frequency. The circuit returns to normal operation when $V_{DD} < 2.5 \text{ V}$ between two motor pulses.

(1) Only available for types with a 1 s motor pulse.

(2) Only applicable for types with the battery end-of-life detector.
Time calibration

Taking a normal quartz crystal with frequency 32768kHz, frequency deviation ($\Delta f/f$) of $\pm 15 \times 10^{-6}$ and $C_L = 8.2$ pF; the oscillator frequency is offset (by using non-symmetrical internal oscillator input and output capacitances of 10 pF and 15 pF) such that the frequency deviation is positive-only. This positive deviation can then be compensated for to maintain time-keeping accuracy.

Once the positive frequency deviation is measured, a corresponding number 'n' (see Table 1) is programmed into the device’s EEPROM. This causes n pulses of frequency 8192 Hz to be inhibited every minute of operation, which achieves the required calibration.

The programming circuit is shown in Fig.2. The required number n is programmed into EEPROM by varying $V_{DD}$ according to the steps shown in Fig.3, which are explained below:

1. The positive quartz frequency deviation ($\Delta f/f$) is measured, and the corresponding values of n are found according to Table 1.

2. $V_{DD}$ is increased to 5.1 V allowing the contents of the EEPROM to be checked from the motor pulse period $t_{T3}$ at nominal frequency.

3. $V_{DD}$ is decreased to 2.5 V during a motor pulse to initialize a storing sequence.

4. The first $V_{DD}$ pulse to 5.1 V erases the contents of EEPROM.

5. When the EEPROM is erased a logic 1 is at the TEST pin.

6. $V_{DD}$ is increased to 5.1 V to read the data by pulsing $V_{DD}$ n times to 4.5 V. After the n edge, $V_{DD}$ is decreased to 2.5 V.

7. $V_{DD}$ is increased to 5.1 V to store n bits in the EEPROM.

8. $V_{DD}$ is decreased to 2.5 V to terminate the storing sequence and to return to operating mode.

9. $V_{DD}$ is increased to 5.1 V to check writing from the motor pulse period $t_{T3}$.

10. $V_{DD}$ is decreased to the operation voltage between two motor pulses to return to operating mode.

(Decreasing $V_{DD}$ during the motor pulse would restart the programming mode).

The time calibration can be reprogrammed up to 100 times.

Note
1. Connecting the battery with reversed polarity does not destroy the circuit, but in this condition a large current flows, which will rapidly discharge the battery.

HANDLING
Inputs and outputs are protected against electrostatic discharges in normal handling. However, to be totally safe, it is advisable to take handling precautions appropriate to handling MOS devices. Advice can be found in “Data Handbook IC16, General, Handling MOS Devices”.

CHARACTERISTICS
V_{DD} = 1.55 V; V_{SS} = 0 V; f_{osc} = 32.768 kHz; T_{amb} = 25 °C; crystal: R_S = 20 kΩ; C_1 = 2 to 3 fF; C_L = 8 to 10 pF; C_0 = 1 to 3 pF; unless otherwise specified.
Immunity against parasitic impedance = 20 MΩ from one pin to an adjacent pin.

SOLDERING

Introduction
There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our “IC Package Databook” (order code 9398 652 90011).

Reflow soldering
Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

Wave soldering
Wave soldering techniques can be used for all SO packages if the following conditions are observed:

• A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
• The longitudinal axis of the package footprint must be parallel to the solder flow.
• The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Repairing soldered joints
Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

Limiting values

Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.

Application information

Where application information is given, it is advisory and does not form part of the specification.

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
