Mask Set Errata for 68HC912DG128C Mask 1L05H

digitaldna

Introduction

This mask set errata applies to the following MCU mask set:

• 1L05H

MCU Device Mask Set Identification

The mask set is identified by a 5-character code consisting of a version number, a letter, two numerical digits, and a letter, for example 0K51E. All standard devices are marked with a mask set number and a date code.

MCU Device Date Codes

Device markings indicate the week of manufacture and the mask set used. The date is coded as four numerical digits where the first two digits indicate the year and the last two digits indicate the work week. For instance, the date code "0201" indicates the first week of the year 2002.

MCU Device Part Number Prefixes

Some MCU samples and devices are marked with an SC, PC, or XC prefix. An SC prefix denotes special/custom device. A PC prefix indicates a prototype device which has undergone basic testing only. An XC prefix denotes that the device is tested but is not fully characterized or qualified over the full range of normal manufacturing process variations. After full characterization and qualification, devices will be marked with the MC or SC prefix.

Errata Summary

| Errata number | Module affected | Description | |
|------------------|--------------------|--|--|
| AR_659 | ATD | Abort in last ATDCLK of sequence does not restart | |
| AR_593 | CGM | Operation with 16MHz quartz crystals is not recommended | |
| AR_650 | CGM | XIRQ during last cycle of STOP instruction causes run away | |
| AR_644 | ECT | PA Overflow flag not set when event is concurrent with write of \$FFFF | |
| AR_526 | IIC | SCL divider has an extra clock at 8Mhz bus frequency | |
| AR_573 | IIC | IIC hold both SCL and SDA lines low when IBB bit is not busy | |
| AR_548 | IIC | Disabling IIC can glitch and corrupt IIC bus | |
| AR_646 | MSCAN | MSCAN extended ID rejected if stuff bit between ID16 and ID15 | |

Abort in last ATDCLK of sequence does not restart

ongoing conversions.

Errata Number: HC12_AR_659

Description When writing ATDCTL4 and/or ATDCTL5 during an active conversion the write is considered an abort and restart. However, when writing during the last ATDCLK of a sequence, the current conversion is aborted, but a new conversion is not started. This occurs whether the sequence is 1 or 4 or 8 conversions. Since writes to ATDCTL4 start a conversion then it is possible for successive byte writes to ATDCTL4/5 to result in this problem. This would occur if an IRQ service related to another interrupt source occurs, separating the two byte writes, and the RTI of this returns delaying the second write to occur in the last ATDCLK. Workaround The first aspect of the solution is to use word writes to ATDCTL4/5. This eliminates the possibility of other IRQ sources causing delay between writes to ATDCTL4/5. This would be the only solution required when starting the first conversion. It would also be the only solution needed when SCAN=0 if all further conversion sequences are initiated from an ATD interrupt routine. In addition, this is the only solution needed if code, in general, does not abort

The second aspect to the solution regards cases that abort conversions. The easiest solution is to toggle the S8C bit. This effectively cleans up the abort and the second write to the ATDCTL5 will perform a successful restart. Bracket this toggle sequence with SEI and CLI to prevent the second write from occurring during a last ATDCLK of a sequence.

Another method is possible using dual writes to start a conversion with a minimum of one ATDCLK period between the writes. This effectively allows the first write to abort and flush by the next write which would start (or restart) the conversion. The second write also needs to occur before another sequence complete time elapses. This method should also be prefixed by a SEI and followed by a CLI. This would prevent the case of other IRQ sources causing the same problem as well.

Operation with 16MHz quartz crystals is not recommended Errata Number: HC12_AR_593

- **Description** Interaction of the resonator and microcontroller characteristics can result in a small proportion of applications failing to start up and stabilize correctly even though typical product combinations work well under test conditions. Resonator operation should be restricted to maximum 10 MHz
- Workaround 1. Use 10 MHz (or slower) resonators and generate higher bus frequencies using the PLL module. Note: When using 10 MHz or slower resonators proper and robust operation of the oscillator circuit requires close attention to board layout to ensure correct gain margin and negative resistance margin. There is a well documented analysis technique performed to measure Negative Resistance Margin which indicates the margin for stable oscillation of the combined microcontroller and resonator. However, an alternative approach is to include gain margin analysis. Since a negative resistance margin optimization cannot include all process, temperature, and voltage variance of the microcontroller, it is possible that the components chosen for the optimum negative resistance point may not yield acceptable component values for gain margin. In this case a compromise between the negative resistance margin and gain margin is desired. However option 2 (below) may be necessary should this remain unachievable.
 - 2. The EXTAL pin input accepts frequencies greater than 10 MHz. In this case, use of an external quartz oscillator module or other source of externally generated clocks at the desired frequency, up to the 16 MHz specification, will allow the MCU to function correctly.

XIRQ during last cycle of STOP instruction causes run away Errata Number: HC12_AR_650

Description If an XIRQ interrupt occurs during the execution of the STOP instruction with the control bit DLY=0 (located in the INTCR register), the CPU may not run the software code as designed.

MSE912DG128C_1L05H

Workaround

- 1. Set the delay control bit DLY=1 so that a delay will be imposed prior to coming out of STOP.
- 2. If using XIRQ with a stable external clock and DLY=0, contact Motorola Applications Department for a detailed workaround.

PA Overflow flag not set when event is concurrent with write of \$FFFF Errata Number: HC12_AR_644

Description When the value \$FFFF is written to PACA or PACB and, at the same time, an external clocking pulse is applied to the PAC, the pulse accumulator may overflow from \$FFFF to \$0000, but the pulse accumulator overflow flag [PAFLG,PBFLG] is not set. Same situation may happen with 8-bit pulse accumulators PAC1 and PAC3.

Workaround The input capture function for the subject channel be enabled prior to writing a value to the PACA or PACB. Write to the pulse accumulator register. Then do one NOP (to allow the input capture to update the interrupt flag) followed by a read of the input capture interrupt flag to see if it set. If yes, a check must be made for a missing pulse accumulator event. Steps for software workaround to see if event happens while writing to PAC:

- 1. Enable Input Capture on same pin as the pulse accumulator (and same type of event).
- 2. Clear the appropriate CxF in the timer interrupt flag register.
- 3. Read PAC and store as "Old PAC".
- 4. Calculate desired PAC value and write it to the PAC.
- 5. Execute 1 NOP.
- 6. Read CxF in the timer interrupt flag register.

If flag is not set, done (no events happened while writing to the PAC).

If flag is set read PAC

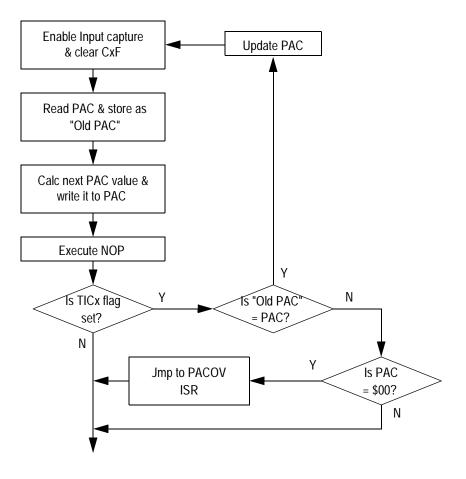

If "Old PAC" = PAC, then update PAC (event happened while writing to PAC and the PAC did not capture it). Note, if the updated PAC value is \$00 jump to PACOV ISR.

If "Old PAC" does not equal PAC, does PAC = \$00 ?

If yes, jump to PACOV ISR.

If no, done (event happened while writing to the PAC and PAC captured it). Read CxF in the timer interrupt.

SCL divider has an extra clock at 8Mhz bus frequency Errata Number: HC12_AR_526

Description At maximum system frequency, the IIC bus rate slows down as much as 5%.

Workaround Communication rate will be adjusted automatically to slower rate.

IIC hold both SCL and SDA lines low when IBB bit is not busy Errata Number: HC12_AR_573

| Description | If SCL line is pulled low when generating a start signal the device will lock up. | | | | | |
|---|---|---|---|------|--|--|
| Workaround | | - | neither the IBB nor IBAL bits a bled and reenabled with the IB | | | |
| Disabling IIC can glit | ch and corrupt IIC bus | | Errata Number: HC12_AR_548 | | | |
| Description | | | EN bit in IBCR register, the S if PORTIB bits 6 and 7 are ze | | | |
| Workaround | Set PORTIB bits 6 and 7 to c | one prior to cleari | ng IBEN bit in IBCR register. | | | |
| MSCAN extended ID rejected if stuff bit between ID16 and ID15 Errata Number: HC12_AR_646 | | | | | | |

g. 10000011111

When an affected ID is received, an incorrect value is compared to the 2nd byte of the filter (IDAR1 and IDAR5, plus IDAR3 and IDAR7 in 16-bit mode). This incorrect value is the shift register contents before ID15 is shifted in (i.e. right shifted by 1).

Workaround If the problematic IDs cannot be avoided, the workaround is to mask certain bits with IDMR1 (and IDMR5, plus IDMR3 and IDMR7 in 16-bit mode).

Example 2: to receive the message IDs

IDMR1 etc. must be 1xxx xxx1, i.e. ID20 and ID15 must be masked.

In general, using IDMR1 etc. 1111 xxx1, i.e. masking ID20,19,18,SRR,15, hides the problem
