i.MX 91 Applications Processor Reference Manual

Contents

Preface About This Manual....14

Chapter 1 Introduction.... 25
1.1 Overview....25
1.2 Target Applications....29
1.3 Endianness Support.... 29

Chapter 2 Memory Maps.... 30
2.1 Memory system overview....30
2.2 System memory map 30
2.3 AIPS Peripheral Bridge 1 Memory Map....41
2.4 AIPS Peripheral Bridge 2 Memory Map....52
2.5 AIPS Peripheral Bridge 3 Memory Map....64
2.6 AIPS Peripheral Bridge 4 Memory Map....69

Chapter 3 Interrupt and DMA Assignments.... 75
3.1 Overview....75
3.2 System Interrupts.... 75
3.3 DMA MUX....88

Chapter 4 Enhanced Direct Memory Access (eDMA3)....94
4.1 Chip-specific eDMA3 information.... 94
4.2 Overview....94
4.3 Functional description....97
4.4 External signals.... 102
4.5 Initialization....102
4.6 Memory map/register definition.... 114
4.7 Glossary.... 149

Chapter 5 Enhanced Direct Memory Access (eDMA4)....150
5.1 Chip-specific eDMA4 information.... 150
5.2 Overview....150
5.3 eDMA register descriptions.... 153
5.4 Functional description....196
5.5 External signals.... 201
5.6 Initialization....201
5.7 Application information.... 204
5.8 Glossary.... 211

Chapter 6 Security Overview.... 212
6.1 Overview....212
6.2 Edgelock secure enclave....212
6.3 Immutable Root of Trust (RoT)....213
6.4 Lifecycle management....213

6.5 Secure boot.... 213
6.6 Secure debug.... 213
6.7 IP protection.... 213
6.8 Secure isolation.... 214
6.9 TrustZone.... 214
6.10 Trusted resource domain control (TRDC).... 214
6.11 Block control secure (BLK_CTRL_S_AONMIX).... 215

Chapter 7 Fusemap.... 217
7.1 Overview.... 217
7.2 Boot Fusemap.... 217
7.3 Fusemap Descriptions Table.... 222
7.4 Programming Fuses.... 222

Chapter 8 Fuse Status Block (FSB).... 223
8.1 Introduction.... 223
8.2 Features.... 223
8.3 Memory map and register definition.... 223
8.4 FSB register descriptions.... 223
8.5 Functional description.... 232
8.6 APB errors.... 232
8.7 Acronyms and abbreviations.... 233

Chapter 9 System Boot.... 234
9.1 Overview.... 234
9.2 Cortex-A55 ROM Boot.... 234
9.3 Boot Modes.... 235
9.4 Boot Stages.... 236
9.5 Image Container Set.... 236
9.6 Boot Flow.... 247
9.7 Platform Initialization In ROM.... 255
9.8 Boot Devices.... 259
9.9 Serial Downloader Boot.... 273
9.10 Secure Boot.... 275
9.11 ROM API.... 275

Chapter 10 IOMUXC GPR.... 281
10.1 Overview.... 281
10.2 Memory map and register definition.... 281

Chapter 11 Arm Modules Overview.... 283
11.1 Overview.... 283

Chapter 12 ARM Cortex A55.... 285
12.1 Overview.... 285
12.2 Functional Description.... 286
12.3 External Signals.... 287

Chapter 13 SRAM Controller..... 288
13.1 Overview.....288
13.2 Functional description.....289
13.3 External signals..... 295
13.4 Initialization.....295
13.5 SRAMCTL register descriptions..... 295
13.6 Glossary..... 310

Chapter 14 Semaphores2 (SEMA42)..... 311
14.1 Overview.....311
14.2 Functional description.....312
14.3 External signals..... 315
14.4 Initialization.....315
14.5 Memory map/register definition..... 315
14.6 Glossary..... 319

Chapter 15 Trusted Resource Domain Controller (TRDC)..... 320
15.1 Chip-specific TRDC information..... 320
15.2 Overview.....328
15.3 Functional description.....329
15.4 External signals..... 332
15.5 Initialization.....333
15.6 Application information..... 333
15.7 Register descriptions..... 334

Chapter 16 System Counter (SYS_CTR).....810
16.1 Chip-specific SYS_CTR information.....810
16.2 Overview.....810
16.3 Functional description.....811
16.4 External signals 811
16.5 Initialization.....811
16.6 Application information..... 812
16.7 Programming model..... 812
16.8 Memory map and register definition..... 812

Chapter 17 System Debug.....829
17.1 Overview.....829
17.2 Functional description.....830
17.3 External Signals.....837

Chapter 18 JTAG Controller (JTAGC)..... 838
18.1 Chip-specific JTAGC information..... 838
18.2 Overview.....838
18.3 Functional description.....839
18.4 External signals..... 843
18.5 Initialization.....844
18.6 Application information..... 844
18.7 Register description.....844
18.8 Glossary..... 846

Chapter 19 External Signals and Pin Multiplexing..... 847
19.1 Overview.....847

Chapter 20 IOMUX Controller (IOMUXC)..... 848
20.1 Overview.....848
20.2 Functional description.....850
20.3 Memory Map and register definition..... 852

Chapter 21 General-Purpose Input/Output (GPIO).....1279
21.1 Chip-specific GPIO information..... 1279
21.2 Overview.....1279
21.3 Functional description.....1280
21.4 External signals 1282
21.5 Initialization.....1283
21.6 Application information..... 1283
21.7 Memory map and register definition..... 1283

Chapter 22 Clock and Power Overview..... 1304
22.1 Overview.....1304
22.2 Components of Clock and Power Management..... 1304
22.3 Power Management..... 1305
22.4 Clocks 1308

Chapter 23 Clock Controller Module (CCM)..... 1313
23.1 Overview.....1313
23.2 System Clocks.....1314
23.3 Functional description.....1323
23.4 Reset..... 1342
23.5 CCM Memory Map and Register definition.....1342

Chapter 24 General Power Controller (GPC)..... 1479
24.1 Overview.....1479
24.2 Functional description.....1480
24.3 External Signals.....1487
24.4 Initialization.....1487
24.5 Memory Map and register definition..... 1487

Chapter 25 System Reset Controller (SRC)..... 1546
25.1 Overview.....1546
25.2 Functional description.....1547
25.3 External Signals.....1553
25.4 Register access permissions.....1554
25.5 Memory Map and register definition..... 1554

Chapter 26 Battery-Backed Non-Secure Module (BBNSM)..... 1629
26.1 Chip-specific BBNSM information..... 1629
26.2 Overview.....1629
26.3 Functional description.....1631

26.4 External Signals....1634
26.5 Initialization....1635
26.6 Memory Map and register definition....1635

Chapter 27 External Memories....1647
27.1 Overview....1647
27.2 High Performance DRAM Interface (DDR)....1647
27.3 eMMC/SD/SDIO....1647
27.4 Flexible Serial Peripheral Interface....1647

Chapter 28 DDR Memory Controller (DDRC)....1648
28.1 Chip-specific DDR information....1648
28.2 Overview....1649
28.3 Functional description....1650
28.4 External signals....1670
28.5 Initialization....1672
28.6 DDRC register descriptions....1675
28.7 Glossary....1802

Chapter 29 Flexible Serial Peripheral Interface (FlexSPI)....1803
29.1 Chip-specific FLEXSPI information....1803
29.2 Overview....1804
29.3 Glossary for FlexSPI module....1806
29.4 Functional description....1807
29.5 External signals....1852
29.6 Initialization....1853
29.7 Application information....1854
29.8 Memory map and register definition....1871
29.9 AHB memory map definition....1920

Chapter 30 Ultra Secured Digital Host Controller (uSDHC)....1922
30.1 Chip-specific USDHC information....1922
30.2 Overview....1922
30.3 Functional description....1925
30.4 External signals....1956
30.5 Application information....1957
30.6 uSDHC memory map and register definition....1976
30.7 Glossary....2072

Chapter 31 CAN (FlexCAN)....2074
31.1 Chip-specific FLEXCAN information....2074
31.2 Overview....2074
31.3 Functional description....2077
31.4 External signal descriptions....2131
31.5 Initialization and application information....2131
31.6 Memory map and register definition....2132
31.7 Glossary....2240

Chapter 32 Universal Serial Bus Controller (USB)....2242

32.1 Chip-specific USB information....2242
32.2 Overview....2242
32.3 Functional description....2244
32.4 External signals....2276
32.5 Initialization....2277
32.6 Register interface....2277
32.7 Register descriptions....2280

Chapter 33 Universal Serial Bus 2.0 PHY (USB2_PHY)....2390
33.1 Overview....2390
33.2 Clock Generation....2392
33.3 Device Initialization....2392
33.4 Tuning....2392

Chapter 34 Ethernet Controller with TSN (ENET_QoS)....2393
34.1 Chip-specific ENET information....2393
34.3 Overview....2393
34.4 Functional description....2395
34.5 External signals....2508
34.6 Initialization....2510
34.7 Application Information....2512
34.8 Memory Map and register definition....2524

Chapter 35 Ethernet MAC (ENET)....3358
35.1 Chip-specific ENET information....3358
35.2 Overview....3358
35.3 Functional description....3361
35.4 External signals....3412
35.5 Initialization....3413
35.6 Memory map/register definition....3413

Chapter 36 Audio Overview....3527
36.1 Audio Overview....3527

Chapter 37 PDM Microphone Interface (PDM)....3529
37.1 Chip-specific PDM information....3529
37.2 Overview....3529
37.3 Functional description....3531
37.4 External signals....3544
37.5 Initialization....3544
37.6 Application information....3547
37.7 MICFIL register descriptions....3547

Chapter 38 Synchronous Audio Interface (SAI)....3578
38.1 Chip-specific SAI information....3578
38.2 Overview....3579
38.3 Functional description....3580
38.4 External signals....3587
38.5 Initialization....3587

38.6 Memory map and register definition..... 3588
38.7 Glossary..... 3641

Chapter 39 Audio Transceiver (SPDIF XCVR)..... 3642
39.1 Overview.....3642
39.2 Functional description.....3642
39.3 External signals..... 3646
39.4 Initialization.....3646
39.5 Application information..... 3647
39.6 Memory Map and register definition..... 3648
39.7 Glossary..... 3685

Chapter 40 Medium Quality Sound (MQS)..... 3686
40.1 Chip-specific MQS information..... 3686
40.2 Overview.....3686
40.3 Functional Description..... 3687
40.4 External Signals.....3688
40.5 Initialization.....3688
40.6 Application Information..... 3689

Chapter 41 Multimedia Overview.....3690
41.1 Multimedia Overview..... 3690

Chapter 42 LCD Interface (LCDIF)..... 3691
42.1 Chip-specific LCDIF information.....3691
42.2 Overview.....3694
42.3 Functional description.....3694
42.4 Memory Map and register definition..... 3697

Chapter 43 Image Sensing Interface (ISI)..... 3723
43.1 Chip-specific ISI information.....3723
43.2 Overview.....3723
43.3 Functional description.....3725
43.4 External signals..... 3731
43.5 Initialization and channel configuration.....3731
43.6 Application information..... 3733
43.7 ISI register descriptions..... 3735

Chapter 44 Parallel Camera Interface..... 3791
44.1 Overview.....3791
44.2 Functional Description.....3792
44.3 External Signals.....3794

Chapter 45 Low Power Inter-Integrated Circuit (LPI2C)..... 3796
45.1 Chip-specific LPI2C information..... 3796
45.2 Overview.....3796
45.3 Functional description.....3798
45.4 External signals..... 3809

45.5 Initialization....3810
45.6 Application information....3811
45.7 Memory map and registers....3811
45.8 Glossary....3865

Chapter 46 Low Power Serial Peripheral Interface (LPSPI)....3866
46.1 Chip-specific LPSPI information....3866
46.2 Overview....3866
46.3 Functional description....3868
46.4 External signals....3879
46.5 Initialization....3879
46.6 Memory map and registers....3879
46.7 Glossary....3913

Chapter 47 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)....3914
47.1 Chip-specific LPUART information....3914
47.2 Overview....3914
47.3 Functional description....3917
47.4 External signals....3933
47.5 Initialization....3934
47.6 LPUART register descriptions....3934
47.7 Glossary....3982

Chapter 48 Improved Inter-Integrated Circuit (I3C)....3983
48.1 Chip-specific I3C information....3983
48.2 Overview....3983
48.3 Functional description....3985
48.4 External signals....4000
48.5 Initialization....4000
48.6 Application information....4002
48.7 I3C register descriptions....4003
48.8 Glossary....4113

Chapter 49 Timers Overview....4115
49.1 Overview....4115

Chapter 50 Low-Power Timer (LPTMR)....4117
50.1 Chip-specific LPTMR information....4117
50.2 Overview....4117
50.3 Functional description....4118
50.4 External signals....4120
50.5 Initialization....4121
50.6 Application information....4121
50.7 Memory map and register definition....4122

Chapter 51 Low Power Periodic Interrupt Timer (LPIT)....4129
51.1 Chip-specific LPIT information....4129
51.2 Overview....4129

51.3 Functional description....4130
51.4 Initialization....4150
51.5 Memory map and registers....4151

Chapter 52 Timer/PWM Module (TPM)....4168
52.1 Chip-specific TPM information....4168
52.2 Overview....4168
52.3 Functional description....4170
52.4 External signals....4190
52.5 Initialization....4190
52.6 Application information....4191
52.7 Memory map and register definition....4192

Chapter 53 Timer (TSTMR)....4216
53.1 Chip-specific TSTMR information....4216
53.2 Overview....4216
53.3 Functional description....4216
53.4 External signals....4217
53.5 Initialization....4217
53.6 TSTMR_A memory map and register definition....4217

Chapter 54 Watchdog timer (WDOG)....4220
54.1 Chip-specific WDOG information....4220
54.2 Overview....4222
54.3 Functional description....4223
54.4 External signals....4227
54.5 Initialization....4227
54.6 Application information....4227
54.7 Memory map and register definition....4228

Chapter 55 Analog Overview....4236
55.1 Overview....4236
55.2 Analog-to-Digital Converter (ADC)....4236
55.3 Temperature Sensor....4236

Chapter 56 Trigger Mux (TRGMUX)....4238
56.1 Chip-specific TRGMUX information....4238
56.2 Overview....4238
56.3 Functional description....4239
56.4 External signals....4239
56.5 Initialization....4239
56.6 TRGMUX register descriptions....4239

Chapter 57 Analog-to-Digital Converter (SAR_ADC)....4242
57.1 Chip-specific ADC information....4242
57.2 Introduction....4243
57.3 Functional description....4245
57.4 External signals....4269
57.5 Initialization....4269

57.6 SAR_ADC register descriptions....4270

Chapter 58 Temperature Sensor (TEMPSENSOR)....4381
58.1 Chip-specific TEMPSENSOR information....4381
58.2 Overview....4381
58.3 Functional description....4382
58.4 External signals....4385
58.5 Initialization....4385
58.6 Application information....4386
58.7 Memory map and registers....4393
58.8 Glossary....4416

Chapter 59 PLLs....4417
59.1 Overview....4417
59.2 Functional description....4418
59.3 External signals....4422
59.4 Initialization....4422
59.5 Memory map and register definitions....4425

Chapter 60 OSC....4467
60.1 Overview....4467
60.2 Memory map and register definition....4467

Chapter 61 Always-on Domain, Non-secure Block Control (blk_ctrl_ns_aonmix)....4469
61.1 Introduction....4469
61.2 Features....4469
61.3 Block diagram....4470
61.4 Functional description....4470
61.5 Initialization....4471
61.6 Memory Map and register definition....4471

Chapter 62 Always-on Domain, Secure Block Control (blk_ctrl_s_aonmix)....4497
62.1 Introduction....4497
62.2 Functional description....4498
62.3 Initialization....4499
62.4 Memory Map and register definition....4499

Chapter 63 Wake-up Domain Block Control (blk_ctrl_wakeupmix)....4521
63.1 Introduction....4521
63.2 Functional description....4522
63.3 Initialization....4523
63.4 Memory Map and register definition....4523

Chapter 64 NIC Mix Block Control (blk_ctrl_nicmmix)....4541
64.1 Introduction....4541
64.2 Functional description....4542
64.3 Initialization....4542

64.4 Memory Map and register definition..... 4542

Chapter 65 DDR Mix Domain Block Control (blk_ctrl_ddrmix).....4563
65.1 Overview.....4563
65.2 Functional Description.....4563
65.3 HWFCC and SWFFC Procedure.....4564
65.4 DDR IO Retention Enter/Exit Procedure..... 4569
65.5 Memory Map and register definition..... 4576

Chapter 66 Media Mix Domain Block Control (blk_ctrl_mediamix)..... 4583
66.1 Overview.....4583
66.2 Functional description.....4584
66.3 External signals..... 4584
66.4 Initialization.....4585
66.5 Memory map and register definition..... 4585

Appendix A Release notes.....4601
A.1 About_this_manual changes..... 4601
A.2 Introduction changes.....4601
A.3 Memory Map changes.....4601
A.4 IRQ and DMA assignment changes.....4601
A.5 Enhanced Direct Memory Access (eDMA3).....4601
A.6 Enhanced Direct Memory Access (eDMA4).....4601
A.7 Security Overview changes.....4601
A.8 Fusemap changes.....4601
A.9 FSB module changes 4602
A.10 System Boot changes..... 4602
A.11 IOMUXC GPR module changes.....4602
A.12 Arm Modules Overview changes..... 4602
A.13 A55 Platform Overview changes.....4602
A.14 SRAMCTL module changes 4602
A.15 SEMA42 module changes.....4602
A.16 Trusted Resource Domain Controller (TRDC)..... 4602
A.17 System Counter (SYS_CTR).....4602
A.18 System Debug changes.....4603
A.19 JTAG Controller (JTAGC)..... 4603
A.20 External Signals changes.....4603
A.21 IOMUXC module changes..... 4603
A.22 General-Purpose Input/Output (GPIO).....4603
A.23 Clocks and Power Overview changes.....4603
A.24 CCM module changes.....4603
A.25 GPC changes.....4603
A.26 SRC module changes..... 4603
A.27 Battery-Backed Non-Secure Module (BBNSM)..... 4604
A.28 External_memory controllers.....4604
A.29 DDR Memory Controller (DDRC).....4604
A.30 Flexible Serial Peripheral Interface (FlexSPI)..... 4604
A.31 Ultra Secured Digital Host Controller (uSDHC).....4604
A.32 CAN (FlexCAN).....4605
A.33 Universal Serial Bus Controller (USB)..... 4605
A.34 fusemap changes.....4605

A.35 Ethernet Controller with TSN (ENET_QoS)..... 4605
A.36 ENET module changes..... 4605
A.37 Audio Overview changes..... 4605
A.38 PDM Microphone Interface (PDM)..... 4606
A.39 Synchronous Audio Interface (SAI)..... 4606
A.40 AUDIO_XCVR module changes 4606
A.41 Medium Quality Sound (MQS)..... 4606
A.42 Audio Overview changes..... 4606
A.43 LCD Interface (LCDIF)..... 4606
A.44 Image Sensing Interface (ISI)..... 4607
A.45 Parallel Camera Interface changes..... 4607
A.46 Low Power Inter-Integrated Circuit (LPI2C)..... 4607
A.47 Low Power Serial Peripheral Interface (LPSPI)..... 4607
A.48 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)..... 4607
A.49 Improved Inter-Integrated Circuit (I3C)..... 4608
A.50 Timers Overview changes..... 4608
A.51 Low-Power Timer (LPTMR)..... 4608
A.52 Low Power Periodic Interrupt Timer (LPIT)..... 4608
A.53 Timer/PWM Module (TPM)..... 4608
A.54 Timer (TSTMR)..... 4609
A.55 Watchdog timer (WDOG)..... 4609
A.56 Analog Overview changes..... 4609
A.57 Trigger Mux (TRGMUX)..... 4609
A.58 Analog-to-Digital Converter (SAR_ADC)..... 4609
A.59 Temperature Sensor (TEMPSENSOR)..... 4610
A.60 PLL module changes..... 4610
A.61 OSC changes..... 4610
A.62 BLK CTRL NS AONMIX..... 4610
A.63 BLK_CTRL_S_AONMIX module changes..... 4610
A.64 BLK CTRL WAKEUPMIX changes (showing internal content)..... 4610
A.65 BLK CTRL NICMIX module changes..... 4610
A.66 BLK_CTRL_DDRMIX module changes..... 4610
A.67 BLK_CTRL_MEDIAMIX module changes..... 4610

Legal information..... 4611

Preface
About This Manual

Audience

The reference manual is intended for the board-level product designers and product software developers. This manual assumes that the reader has a background in computer engineering and/or software engineering and understands the concepts of the digital system design, microprocessor architecture, input/output (I/O) devices, industry standard communication, and device interface protocols.

Organization

The reference manual describes the chip at a system level and provides an architectural overview. It also describes the system memory map, system-level interrupt events, external pins and pin multiplexing, external memory, system debug, system boot, multimedia subsystem, power management, and system security.

Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

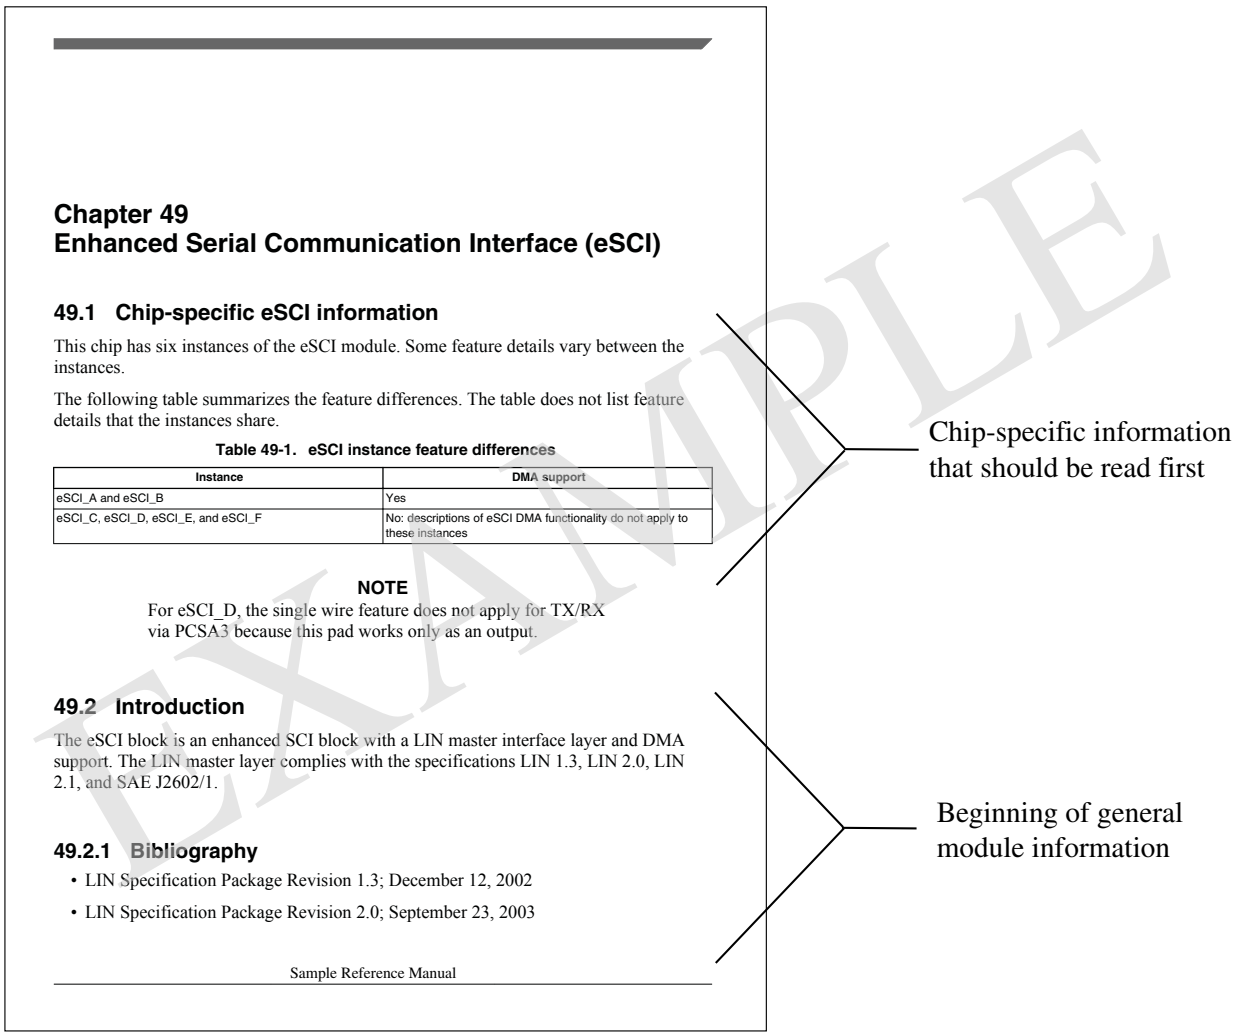
Select the paperclip icon on the left side of the PDF window to see the list of attachments.

Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No: descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

Register Access

Register Diagram Field Access Type Legend

This figure provides the interpretation of the notation used in the register diagrams for a number of common field access types:

Access type	Access description	DITA output	Effect of Write on Value	Readback Value
RW	Read/write	R / W: Mnemonic	Changes to Written Value	Current Value
RO	Read-only	R: Mnemonic / W:	No Effect	Current Value
RU	Reserved, unimplemented	R / W: Reserved	No Effect	Value Undefined
ROZ	Reserved, Read-only zero	R: 0 / W:	No Effect	Returns All Zero
ROO	Reserved, Read-only one	R: 1 / W:	No Effect	Returns All Ones
WO	Write-only	R: / W: Mnemonic	Changed to Written Value	Value Undefined
WOZ	Reserved, Write-only zero	R: / W: 0	Write Value Must Be All 0s.	Value Undefined
WOO	Reserved, Write-only one	R: / W: 1	Write Value Must Be All 1s.	Value Undefined
W0C	Write zero to clear	R: Mnemonic / W: w0c	If a Bit in the Written Value is a 0, the Corresponding Bit in the Field is Set to 0. Otherwise, the Field Bit is Not Affected.	Current Value
W1C	Write one to clear	R: Mnemonic / W: w1c	If a Bit in the Written Value is a 1, the Corresponding Bit in the Field is set to 0. Otherwise, the Field Bit is Not Affected.	Current Value
R2C	Read to clear		Value is cleared following the read operation	Current Value
ROWZ	Read-only, writes zero	R: Mnemonic / W: 0	Write Value Must Be All 0s	Current Value
ROWO	Read-only writes one	R: Mnemonic / W: 1	Write Value Must Be All 1s	Current Value
ROWU	Ready-only writes undefined	R: Mnemonic / W: —	Writes Operation Undefine	Current Value
WORZ	Write-only reads zero	R: 0 / W: Mnemonic	Changes to Written Value	Returns All Zero
WORO	Write-only reads one	R: 1 / W: Mnemonic	Changes to Written Value	Returns All Ones
WORU	Write-only reads undefined	R: — / W: Mnemonic	Changes to Written Value	Value Undefined

Figure 0. Register Field Conventions

NOTE

For reserved register fields, the software should mask off the data in the field after a read (the software can't rely on the contents of data read from a reserved field) and always write all zeros.

Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all the bits set to 1 perform the associated operation on the primary register, while the bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one-bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read-modify-write operations. When an atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

A set of SCT registers is offered for registers in many modules on this device, as described in this manual.
In a module memory map table, the suffix _SET, _CLR, or _TOG is added to the base name of the register.
For example, the CCM_ANALOG_PLL_ARM register has three other registers called CCM_ANALOG_PLL_ARM_SET, CCM_ANALOG_PLL_ARM_CLR, and CCM_ANALOG_PLL_ARM_TOG.

In the sub-section that describes one of these sets of registers, a short-hand convention is used to denote that a register has the SCT register set. There is an italicized *n* appended to the end of the short register name. Using the above example, the name used for this register is CCM_ANALOG_PLL_ARM*n*. When you see this designation, there is a SCT register set associated with the register, and you can verify this by checking it in the memory map table. The address offset for each of these registers is given in the form of the following example:

Address: 20C_8000h base + 0h offset + (4d × i), where i=0d to 3d

In this example, the address for each of the base registers and their three SCT registers can be calculated as:

Register	Address
CCM_ANALOG_PLL_ARM	20C_8000h
CCM_ANALOG_PLL_ARM_SET	20C_8004h
CCM_ANALOG_PLL_ARM_CLR	20C_8008h
CCM_ANALOG_PLL_ARM_TOG	20C_800Ch

Acronyms and Abbreviations

The table below contains acronyms and abbreviations used in this document.

Acronyms and Abbreviated Terms

Term	Meaning
ACMP	Analog Comparator
ADC	Analog-to-Digital Converter
AHB	Advanced High-performance Bus
AIPS	Arm IP Bus
ALU	Arithmetic Logic Unit
AMBA	Advanced Microcontroller Bus Architecture
APB	Advanced Peripheral Bus
ASRC	Asynchronous Sample Rate Converter
AXI	Advanced eXtensible Interface
CA/CM	Arm Cortex-A/Cortex-M
CAAM	Cryptographic Acceleration and Assurance Module
CAN	Controller Area Network
CCM	Clock Controller Module
CM7	Arm Cortex M7 Core
CPU	Central Processing Unit
CSI	CMOS Sensor Interface
CSU	Central Security Unit
CTI	Cross Trigger Interface
D-cache	Data cache
DAP	Debug Access Port
DDR	Double data rate
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory
ECC	Error correcting codes
LPSPI	Low-power SPI
EDMA	Enhanced Direct Memory Access
EIM	External Interface Module
ENET	Ethernet

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
EPIT	Enhanced Periodic Interrupt Timer
EPROM	Erasable Programmable Read-Only Memory
ETF	Embedded Trace FIFO
ETM	Embedded Trace Macrocell
FIFO	First-In-First-Out
GIC	General Interrupt Controller
GPC	General Power Controller
GPIO	General-Purpose I/O
GPR	General-Purpose Register
GPS	Global Positioning System
GPU	Graphics Processing Unit
GPV	Global Programmers View
HAB	High-Assurance Boot
I-cache	Instruction cache
I2C or I^2C	Inter-Integrated Circuit
IC	Integrated Circuit
IEEE	Institute of Electrical and Electronics Engineers
IOMUX	Input-Output Multiplexer
IP	Intellectual Property
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
LCDIF	Liquid Crystal Display Interface
LDO	Low-Dropout
LIFO	Last-In-First-Out
LRU	Least-Recently Used
LPSR	Low-Power State Retention
LSB	Least-Significant Byte

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
LUT	Look-Up Table
LVDS	Low Voltage Differential Signaling
MAC	Medium Access Control
MCM	Miscellaneous Control Module
MMC	Multimedia Card
MSB	Most-Significant Byte
MT/s	Mega Transfers per second
OCRAM	On-Chip Random-Access Memory
OCOTP	On-Chip One-Time Programmable Controller
PCI	Peripheral Component Interconnect
PCIe	PCI express
PCMCIA	Personal Computer Memory Card International Association
BPC	Basic Power Controller
PIC	Programmable Interrupt Controller
PMU	Power Management Unit
POR	Power-On Reset
PSRAM	Pseudo-Static Random Access Memory
PWM	Pulse Width Modulation
PXP	Pixel Pipeline
QoS	Quality of Service
R2D	Radians to Degrees
RISC	Reduced Instruction Set Computing
ROM	Read-Only Memory
RTOS	Real-Time Operating System
Rx	Receive
SAI	Synchronous Audio Interface

Table continues on the next page...

Table continued from the previous page...

Term	Meaning
SCU	Snoop Control Unit
SD	Secure Digital
SDIO	Secure Digital Input/Output
SDLC	Synchronous Data Link Control
SDMA	Smart DMA
SIM	Subscriber Identification Module
SNVS	Secure Non-Volatile Storage
SoC	System-on-Chip
SPBA	Shared Peripheral Bus Arbiter
SPDIF	Sony Philips Digital Interface
SPI	Serial Peripheral Interface
SRAM	Static Random-Access Memory
SRC	System Reset Controller
TFT	Thin-Film Transistor
TPIU	Trace Port Interface Unit
TSGEN	Time Stamp Generator
Tx	Transmit
TZASC	TrustZone Address Space Controller
UART	Universal Asynchronous Receiver/Transmitter
USB	Universal Serial Bus
USDHC	Ultra Secured Digital Host Controller
WDOG	Watchdog
WLAN	Wireless Local Area Network
WXGA	Wide Extended Graphics Array

Conventions

The reference manual uses the following notational conventions:

cleared / set	When a bit has a value of zero, it is said to be cleared; when it has a value of one, it is said to be set.
mnemonics	Instruction mnemonics are shown in lowercase bold.

italics	Italics indicate variable command parameters, for example, **bcctr***x*. The book titles in the text are set in italics.
15	An integer in decimal.
0x	the prefix to denote a hexadecimal number.
0b	The prefix to denote a binary number. Binary values of 0 and 1 are written without a prefix.
n'H4000CA00	The n-bit hexadecimal number.
BLK_REG_NAME	The register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (_).
BLK_REG[FIELD]	The fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.
BLK_REG[*n*]	The bit number *n* within the BLK.REG register.
BLK_REG[*l:r*]	The register bit ranges. The ranges are indicated by the left-most bit number *l* and the right-most bit number *r*, separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.
x, U	In some contexts, such as signal encodings, an unitalicized x indicates a "don't care" or "uninitialized". The binary value can be 1 or 0.
x	An italicized *x* indicates an alphanumeric variable.
n, m	Italicized *n or m* represent integer variables.
!	Binary logic operator NOT.
&&	Binary logic operator AND.
||	Binary logic operator OR.
^ or <O+>	Binary logic operator XOR. For example, A <O+> B.
|	Bit-wise OR. For example, 0b0001 | 0b1000 yields the value of 0b1001.
&	Bit-wise AND. For example, 0b0001 & 0b1000 yields the value of 0b0000.
{A,B}	Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n*+*m*)-bit value. For example, {0, REG*m* [14:0]} yeilds a 16-bit value with 0 in the most significant bit.
- or grey fill	Indicates a reserved bit field in a register. Although these bits can be written to with ones or zeros, they always read zeros.
>>	Shift right logical one position.
<<	Shift left logical one position.
<=	Assignment.
==	Compare equal.
!=	Compare not equal.
>	Greater than.
<	Less than.

Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

Numbering systems

The following suffixes identify different numbering systems:

Table 1. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

Example	Description
x and other italicized text	The italicized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period separates the elements of a hierarchy: subsystem.module.register. For example:

Table continues on the next page...

Table 2. Typographic notation (continued)

Example	Description
	• SWT.TO means that the TO register is located in the SWT module. • SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem.

Special terms

The following terms have special meanings.

Table 3. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must: • Not modify the default value of a reserved programming setting, such as the reset value of a reserved register field. • Consider undefined locations in memory to be reserved. • Not use the reset values of reserved locations documented in this manual for diagnostic purposes. They are subject to change. **NOTE** BootROM could modify the reserved bit values after reset. Please refer to the BootROM settings attachment.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

Chapter 1
Introduction

1.1 Overview

The i.MX 91 family of applications processors enables the rapid creation of new Linux®-based edge devices, such as smart home controllers, connected appliances, home entertainment, industrial and medical platforms. Emerging protocols, such as Matter™ for the smart home or the ISO 15118-20 standard for electric vehicle (EV) chargers, create inflection points for new product categories across IoT and industrial markets. Next-generation Linux-based devices based on i.MX 91 SoC will be high-performance, affordable, and secure solutions, enabling adaption to updated protocols or new standards as they are introduced. The i.MX 91 SoC's integrated EdgeLock® Secure Enclave provides security features including lifecycle management, tamper detection, secure boot and a simplified path to certifications. The i.MX 91 family features an Arm® Cortex®-A55 running at up to 1.4GHz, support for modern LPDDR4 memory to enable platform longevity, dual Gigabit Ethernet and dual USB ports, along with a rich set of peripherals targeting medical, industrial and consumer IoT market segments. Part of the EdgeVerse™ portfolio of intelligent edge solutions, the i.MX 91 family will be offered in consumer and industrial qualification and backed by NXP's product longevity program.

1.1.1 Block Diagram

The functional block diagram is shown in the figure below. This diagram provides a view of the chip's major functional components and core complexes.

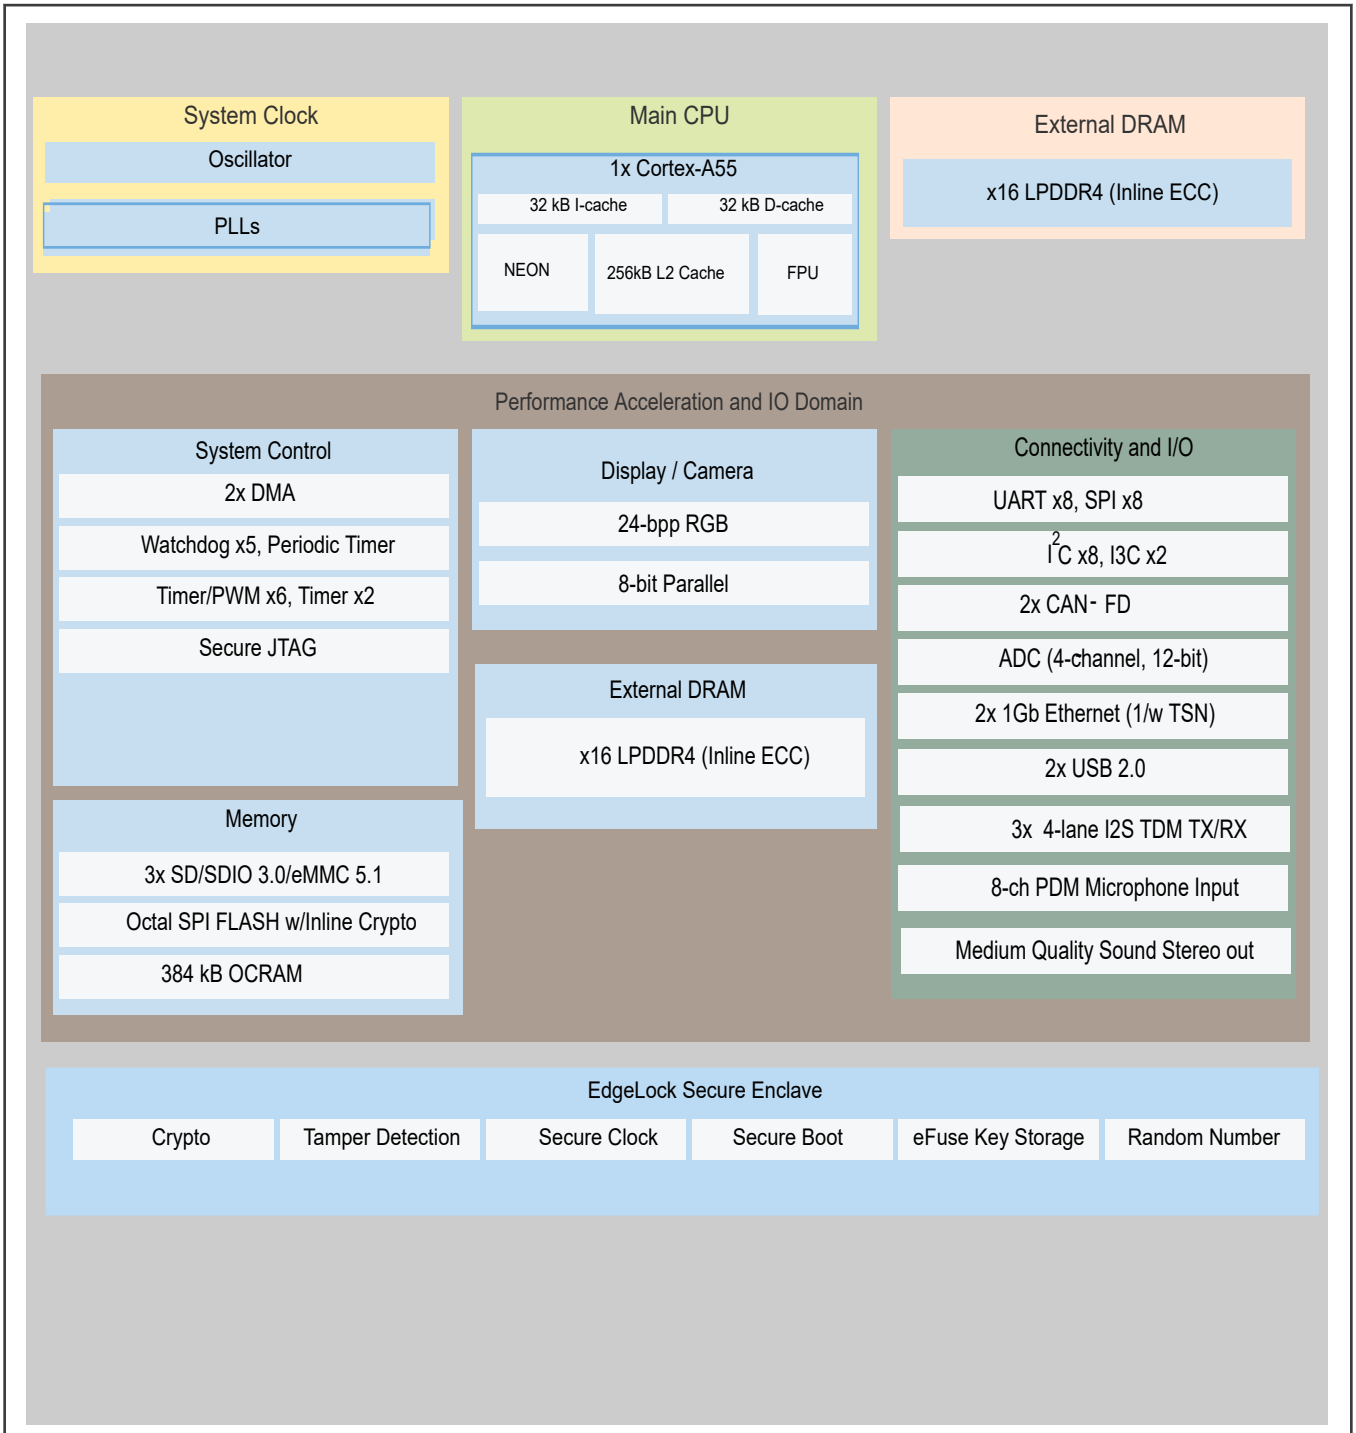

Figure 1. Simplified Block Diagram

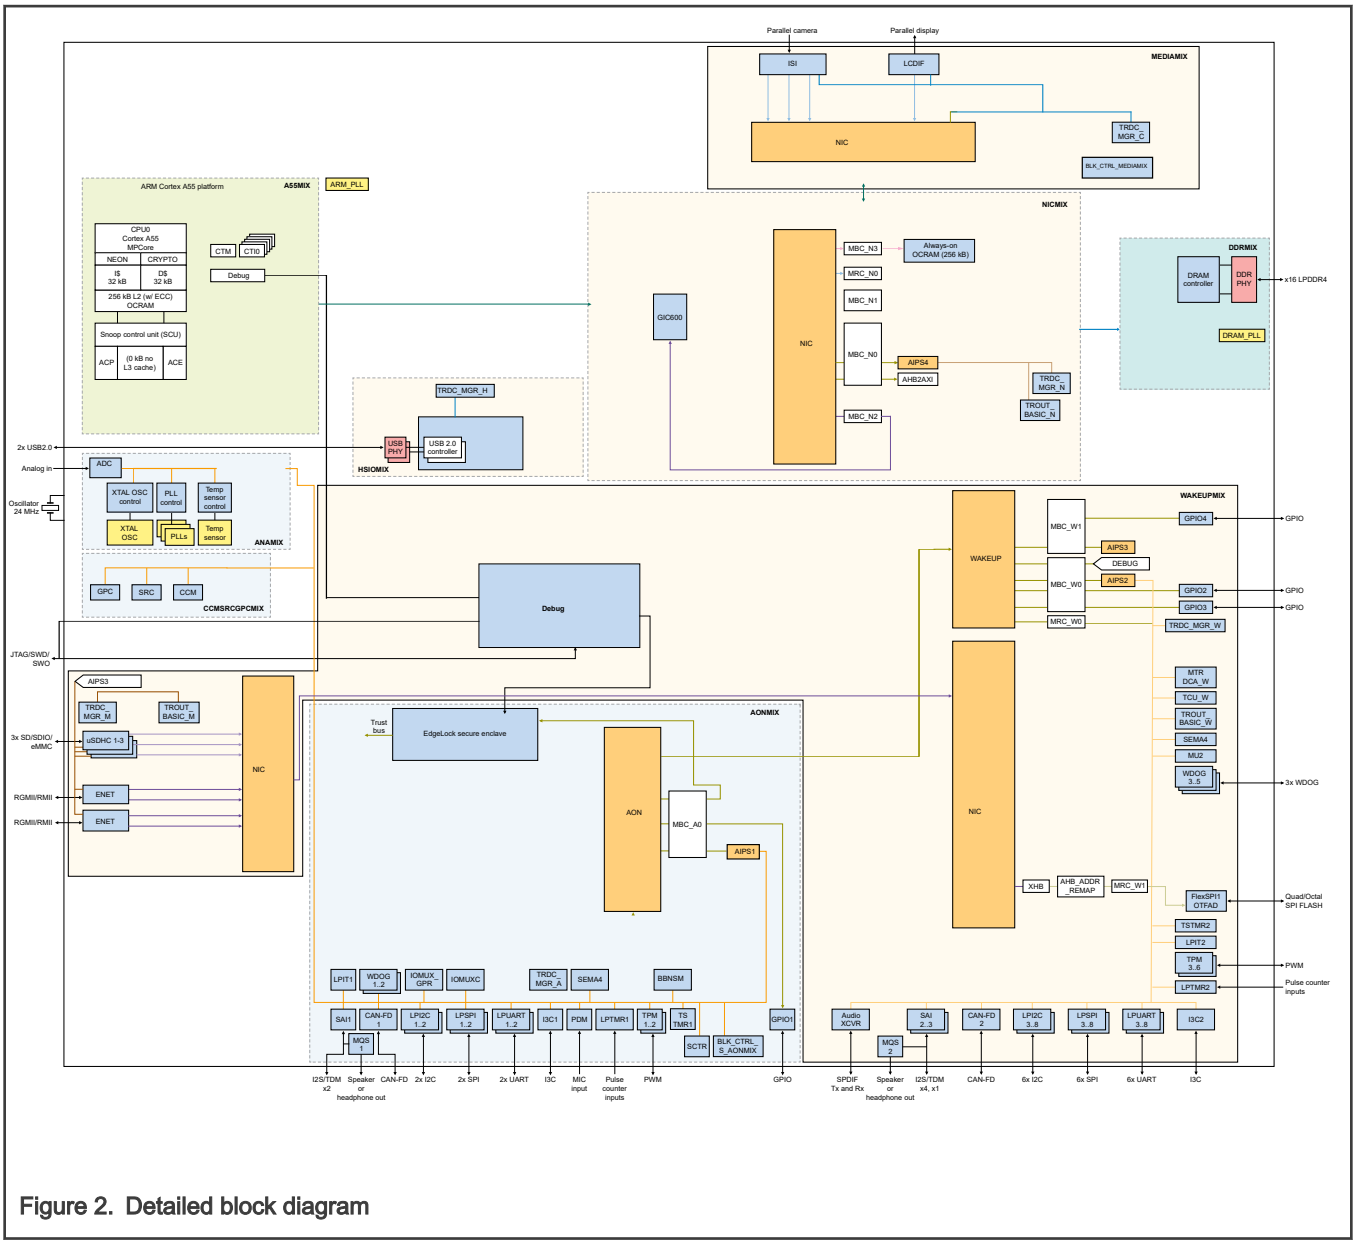

Figure 2. Detailed block diagram

1.1.2 Features

The i.MX91 processor is based on Arm Cortex®-A55 MPCore which has the following features:

Arm Cortex®-A55 MPCore cluster:

- One cluster of Cortex-A55 core
- Each core includes 32kB L1-I, 32kB L1-D and 256kB L2 cache
- Core cache protection (parity/ECC) supported

On Chip Memory:

- Boot ROM (256KB)
- 384KB of SoC-specific OCRAM

External Memory Interfaces:

- One 16-bit DRAM controller:
  - Maximum supported capacity is 2GByte
  - LPDDR4 supported.
- FlexSPI FLASH with support for XIP and support for either one Octal SPI, two Quad SPI FLASH devices

Graphics:

- LCDIF display
  - Parallel display (up to 1366x768 or 1280x800)
- ISI camera interface
  - Parallel camera

Audio:

- SPDIF supports raw capture mode that can save all the incoming bits into audio buffer.
- 3x Synchronous Audio Interface (SAI) modules supporting I2S, AC97, TDM, and Codec/DSP interfaces
- Digital microphone input, 8-channel PDM

Connectivity:

- 2x USB 2.0 dual controller with integrated PHY interfaces
- 3x Ultra Secure Digital Host Controller (uSDHC) interfaces
  - uSDHC1 with boot support for eMMC 5.1 compliance with HS400 DDR signaling to support up to 400 MB/sec
  - uSDHC2 with boot support for SD/SDIO 3.0 compliance with 200 MHz SDR signaling to support up to 100 MB/sec
  - Support for SDXC (extended capacity)
  - USDHC3 to support use cases that need simultaneous support for all three of 1x eMMC, 1x SD Card and 1x SDIO (for WIFI connectivity)
- 8x Universal asynchronous receiver/transmitter (LPUARTs) modules
- 8x LPSPI modules
- 8x I2C modules
- 2x I3C modules
- 2x CAN-FD modules
- 1x 1 Gigabit Ethernet with AVB Support (ENET)
- 1x 1 Gigabit Ethernet with AVB, QoS Support (Ethernet QoS)

Timers and PWMs:

- 2x Low Power Periodical Interrupt Timer (LPIT)
  - 4 channel
  - 4 external trigger source
  - Generic 32-bit resolution timer
  - Periodical interrupt generation
- 6x Timer/PWM module (TPM)
  - Prescaler divide-by 1, 2, 4, 8, 16, 32, 64, or 128
  - 16-bit counter, support free-running counter or modulo counter mode, counting up or down
  - Includes 6 channels that can be configured for input capture, output compare, edge-aligned PWM mode, or center-aligned PWM mode

- 2x Low-Power Timer (LPTMR)
- 5x WatchDog modules (WDOG)

GPIO and Pin Multiplexing:

- General-purpose input/output (GPIO) modules with interrupt capability
- Input/output multiplexing controller (IOMUXC) to provide centralized pad control

Analog:

- 1x 12-bit Analog Digital Converter (ADC)
- Supports SYSTEM_PLL, AUDIO_PLL, VIDEO_PLL, ARM_PLL, DRAM_PLL
- Temperature Sensor

Security:

- TRDC – Resource Domain Controller
  - Supports up to 16 resource domains
- Arm TrustZone® (TZ) architecture
- Secure and trusted access control
- Battery Backed Security Module (BBSM)
  - Monotonic counter - Secure real-time clock (RTC) - Zeroizable Master Key

System Debug:

- Arm CoreSight® debug and trace architecture
- Trace Port Interface Unit (TPIU) to support off-chip real-time trace
- Support for 5-pin (JTAG) and SWD debug interfaces

Power Management:

- One PMIC to supply all power rails.
- Temperature sensor with programmable trim points
- GPC hardware power management controller

1.2 Target Applications

The i.MX91 can be used but not limited to applications such as:

- Industrial - Air Conditioning (AC); Building Safety; Building Security; Circuit Breaker; Energy Metering; EV Charging Station; Heat Metering; Industrial HMI; Smart Lighting; Smart Power Socket and Power Switch; Solar Photovoltaic Energy Generation; Vision, Advanced Sensing and Processing Boards; Vital Sign Monitoring;
- IoT- Hearables; Smart Watch; Fleet Management; Inventory and Supply Chain Management; Home Control Panel; Home Security/Surveillance; In-Home Energy Displays; Major Connected Home Appliances; Matter Controller/Devices; Transport Ticketing; Robotic Appliance; Set-Top Boxes; Small and Medium Appliances; Audio Soundbar

1.3 Endianness Support

The chip supports only the Little Endian mode.

Chapter 2
Memory Maps

2.1 Memory system overview

This section introduces the memory architecture of the chip.

NOTE

Accessing the reserved memory regions can result in unpredictable behavior.

2.2 System memory map

The following table provides the TrustZone "Non-Secure (NS)" and "Secure (S)" world view of the system (Cortex-A) memory map. Access through the "Secure" memory region can only be performed by code with the appropriate security settings.

NOTE

The System Memory Map (used by Cortex-A cores in the chip) has TrustZone Non-Secure (NS) and Secure (S) world aliases of the address space below address 8000_0000 (hex).

Table 4. System memory map

Start address (hex)	End address (hex)	Size (KB)	Description
C000_0000 (NS)	FFFF_FFFF (NS)	1048576	DRAM (offset 1GB)
B010_0000 (NS)	BFFF_FFFF (NS)	261120	DRAM (offset continued)
B004_4000 (NS)	B00F_FFFF (NS)	752	DRAM (offset continued)
B000_0000 (NS)	B004_3FFF (NS)	272	DRAM (offset 768 MB)
A000_0000 (NS)	AFFF_FFFF (NS)	262144	DRAM (offset 512 MB)
9000_0000 (NS)	9FFF_FFFF (NS)	262144	DRAM (offset 256 MB)
8000_0000 (NS)	8FFF_FFFF (NS)	262144	DRAM (offset 0 MB)
7000_0000 (NS) 7000_0000 (S)	7FFF_FFFF (NS) 7FFF_FFFF (S)	262144	Reserved

2.3 AIPS Peripheral Bridge 1 Memory Map

The following table provides the AIPS-1 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-1 peripherals for the Non-Secure access is 0x4400_0000.

The start address of AIPS-1 peripherals for the Secure access is 0x5400_0000.

NOTE

AIPS1 Peripherals are in the AONMIX domain.

NIC Port	Size (KB)	Start Address (NS)	End Address (NS)	Start Address (S)	End Address (S)	IPS slot	Domain (MIX)
Enhanced Direct Memory Access 3 - Management Page	64	44000000	4400FFFF	54000000	5400FFFF	0	
Enhanced Direct Memory Access 3 - Channel 0 Control and Configuration	64	44010000	4401FFFF	54010000	5401FFFF	1	
Enhanced Direct Memory Access 3 - Channel 1	64	44020000	4402FFFF	54020000	5402FFFF	2

2.4 AIPS Peripheral Bridge 2 Memory Map

The following table provides the AIPS-2 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-2 peripherals for the Non-Secure access is 0x4200_0000.

The start address of AIPS-2 peripherals for the Secure access is 0x5200_0000.

NOTE

AIPS2 Peripherals are in WAKEUPMIX domain.

2.5 AIPS Peripheral Bridge 3 Memory Map

The following table provides the AIPS-3 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-3 peripherals for the Non-Secure access is 0x4280_0000.

The start address of AIPS-3 peripherals for the Secure access is 0x5280_0000.

NOTE

AIPS3 Peripherals are in the MEGAMIX domain.

2.6 AIPS Peripheral Bridge 4 Memory Map

The following table provides the AIPS-4 memory map. The peripherals have both Secure (S) and Non-Secure (NS) access possibilities. Both, Secure and Non-Secure addresses for each peripheral is provided in the table below.

The start address of AIPS-4 peripherals for the Non-Secure access is 0x4900_0000.

The start address of AIPS-4 peripherals for the Secure access is 0x5900_0000.

NOTE

AIPS4 Peripherals are in the NICMIX domain.

Chapter 3
Interrupt and DMA Assignments

3.1 Overview

This section provides information on the assignments of the interrupts and DMA.

3.2 System Interrupts

The system interrupts are routed to the Cortex-A55 Generic Interrupt Controller (GIC). The following table describes the interrupt sources.

Table 5. System Interrupt Summary

Module	IRQ	Logic	Description
-	0	-	Reserved
DAP	1	-	DAP Interrupt
-	2	OR	Reserved
-	2	OR	Reserved
-	3	OR	Reserved
	3	OR	Reserved
CA55	4	OR	CTI trigger outputs from CA55 platform (internal: nCTIIRQ[0])
	4	OR	Reserved
	5	OR	Performance Unit Interrupts from CA55 platform (internally: PMUIRQ[0])
	5	OR	Reserved
	5	OR	Performance Unit Interrupts from CA55 platform
	6	OR	ECC error with potential data corruption or loss of coherency from CA55 platform L3 Cache
	6	OR	ECC error with potential data corruption or loss of coherency from CA55 platform Core-0 L1 or L2 Cache
	6	OR	Reserved
	7	OR	1-bit or 2-bit ECC or Parity error from CA55 platform L3 Cache
	7	OR	1-bit or 2-bit ECC or Parity error from CA55 platform Core-0 L1 or L2 Cache
	7	OR	Reserved
CAN_FD1	8	OR	AONMIX CAN-FD Interrupt from busoff
	8	OR	AONMIX CAN-FD Interrupt from CAN line error
	8	OR	AONMIX CAN-FD Ored interrupts from ipi_int_MB

Table continues on the next page...

Table 5. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
	8	OR	AONMIX CAN-FD Rx warning Interrupt
	8	OR	AONMIX CAN-FD Tx warning Interrupt
	8	OR	AONMIX CAN-FD Interrupt from wake up
	8	OR	Reserved
	8	OR	Reserved
	8	OR	AONMIX CAN-FD Busoff done interrupt
	8	OR	AONMIX CAN-FD FD error interrupt
	8	OR	AONMIX CAN-FD FIFO underflow interrupt
	8	OR	AONMIX CAN-FD FIFO overflow interrupt
	8	OR	AONMIX CAN-FD FIFO watermarker interrupt
	8	OR	AONMIX CAN-FD FIFO data available interrupt
	9	OR	AONMIX CAN-FD Correctable error interrupt
	9	OR	AONMIX CAN-FD Non correctable error int host
	9	OR	AONMIX CAN-FD Non correctable error int internal
GPIO1	10	OR	AONMIX GPIO interrupt request 0
	10	OR	AONMIX GPIO async wakeup interrupt request 0
	11	OR	AONMIX GPIO interrupt request 1
	11	OR	AONMIX GPIO async wakeup interrupt request 1
I3C1	12	OR	AONMIX I3C interrupt request
	12	OR	AONMIX I3C interrupt request
LPI2C1	13	OR4[1]	AONMIX LPI2C Master interrupt
	13	OR4[1]	AONMIX LPI2C Master async interrupt
	13	OR4[1]	AONMIX LPI2C Slave interrupt
	13	OR4[1]	AONMIX LPI2C Slave async interrupt
LPI2C2	14	OR4[1]	AONMIX LPI2C Master interrupt
	14	OR4[1]	AONMIX LPI2C Master async interrupt
	14	OR4[1]	AONMIX LPI2C Slave interrupt
	14	OR4[1]	AONMIX LPI2C Slave async interrupt
LPIT1	15	OR	AONMIX LPIT global interrupt
LPSPI1	16	OR	AONMIX LPSPI interrupt
	16	OR	AONMIX LPSPI async interrupt
LPSPI2	17	OR	AONMIX LPSPI interrupt

Table continues on the next page...

Table 5. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
	17	OR	AONMIX LPSPI async interrupt
LPTMR1	18	OR	AONMIX LPTMR async interrupt
LPUART1	19	OR4[1]	AONMIX LPUART TX interrupt
	19	OR4[1]	AONMIX LPUART TX async interrupt
	19	OR4[1]	AONMIX LPUART RX interrupt
	19	OR4[1]	AONMIX LPUART RX async interrupt
LPUART2	20	OR4[1]	AONMIX LPUART TX interrupt
	20	OR4[1]	AONMIX LPUART TX async interrupt
	20	OR4[1]	AONMIX LPUART RX interrupt
	20	OR4[1]	AONMIX LPUART RX async interrupt
-	21	-	Reserved
-	22	-	Reserved
-	23	-	Reserved
-	24	-	Reserved
-	25	-	Reserved
-	26	-	Reserved
-	27	-	Reserved
Edgelock	28		AONMIX Edgelock Trust MUA RX full interrupt
	29		AONMIX Edgelock Trust MUA TX empty interrupt
	30		AONMIX Edgelock Apps Core MUA RX full interrupt
	31		AONMIX Edgelock Apps Core MUA TX empty interrupt
	32		AONMIX Edgelock Realtime Core MUA RX full interrupt
	33		AONMIX Edgelock Realtime Core MUA TX empty interrupt
	34		AONMIX Edgelock secure interrupt
	35		AONMIX Edgelock non-secure interrupt
TPM1	36	OR	AONMIX LPTPM global interrupt
	36	OR	AONMIX LPTPM async interrupt
TPM2	37	OR	AONMIX LPTPM global interrupt
	37	OR	AONMIX LPTPM async interrupt
WDOG1	38	OR	AONMIX Watchdog interrupt request. SRC reset source.

Table continues on the next page...

Table 5. System Interrupt Summary (continued)

Module	IRQ	Logic	Description
	38	OR	AONMIX Watchdog async interrupt request. SRC reset source.
WDOG2	39	OR	AONMIX Watchdog interrupt request. SRC reset source.
	39	OR	AONMIX Watchdog async interrupt request. SRC reset source.

Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The Enhanced Direct Memory Access Type 3 (eDMA3) is an AHB-based 32-bit-addressing-capable eDMA module. For the rest of the chapter, eDMA refers to the eDMA3 type. There is one instance of eDMA3 in the AON domain. This is called the eDMA3_1 instance.

4.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 31 channels

4.2.1 Block diagram

Figure 3 illustrates the components of the eDMA system, including the eDMA module (engine).

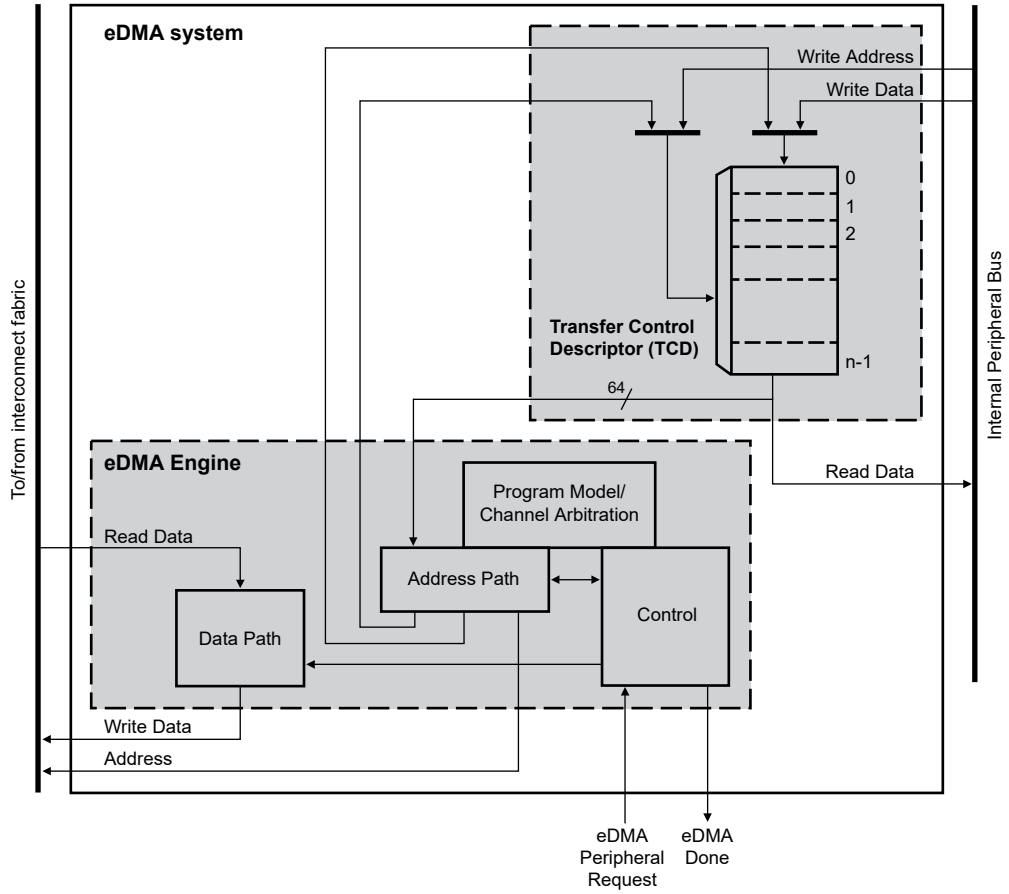

Figure 3. Block diagram

4.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 9. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all master bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 9. eDMA engine submodules (continued)

Submodule	Function
	When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus master read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 10. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

4.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 31-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers

- Connections to the crossbar switch for bus mastering the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

4.3 Functional description

The operation of eDMA is described in the following subsections.

4.3.1 Modes of operation

The eDMA operates in the following modes:

Table 11. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

4.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

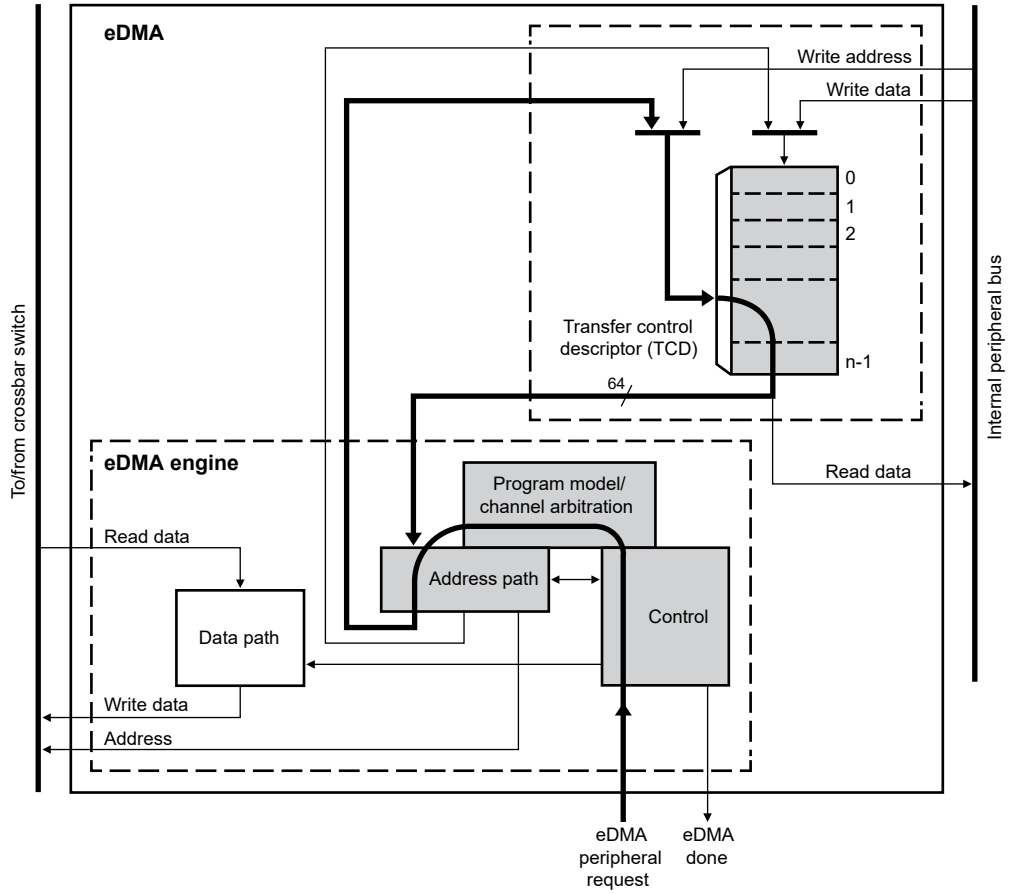

Figure 4. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

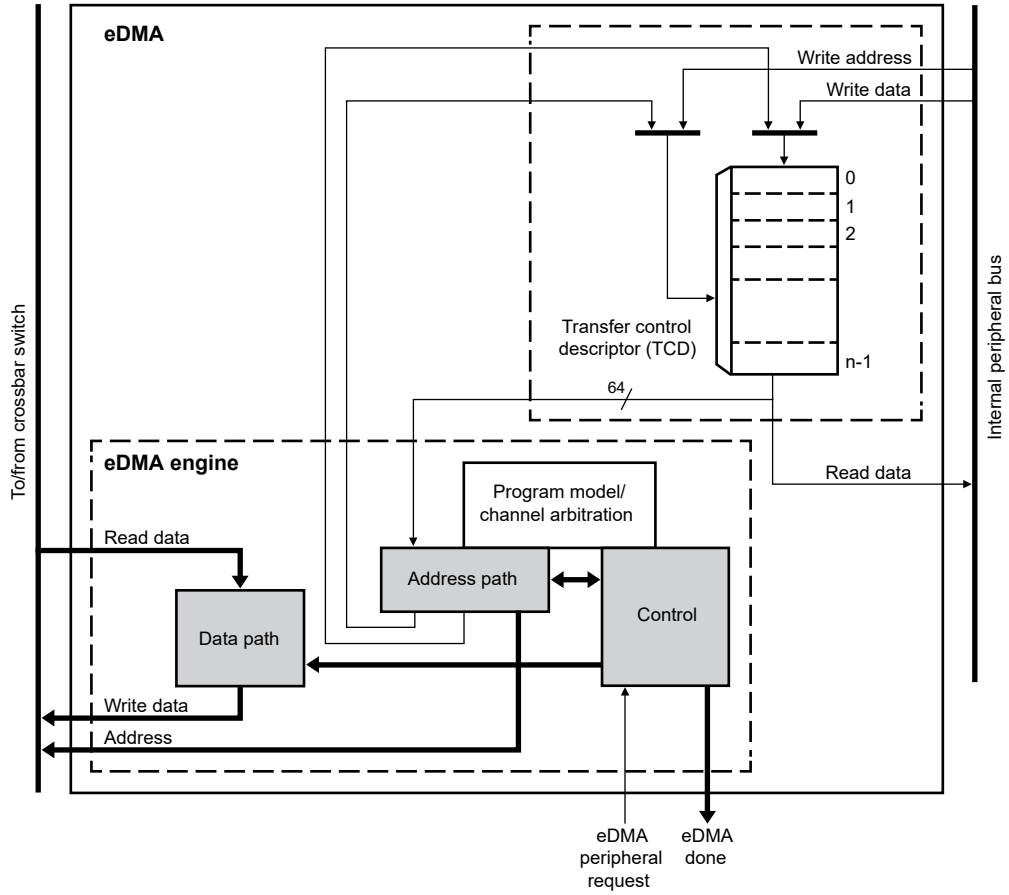

Figure 5. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

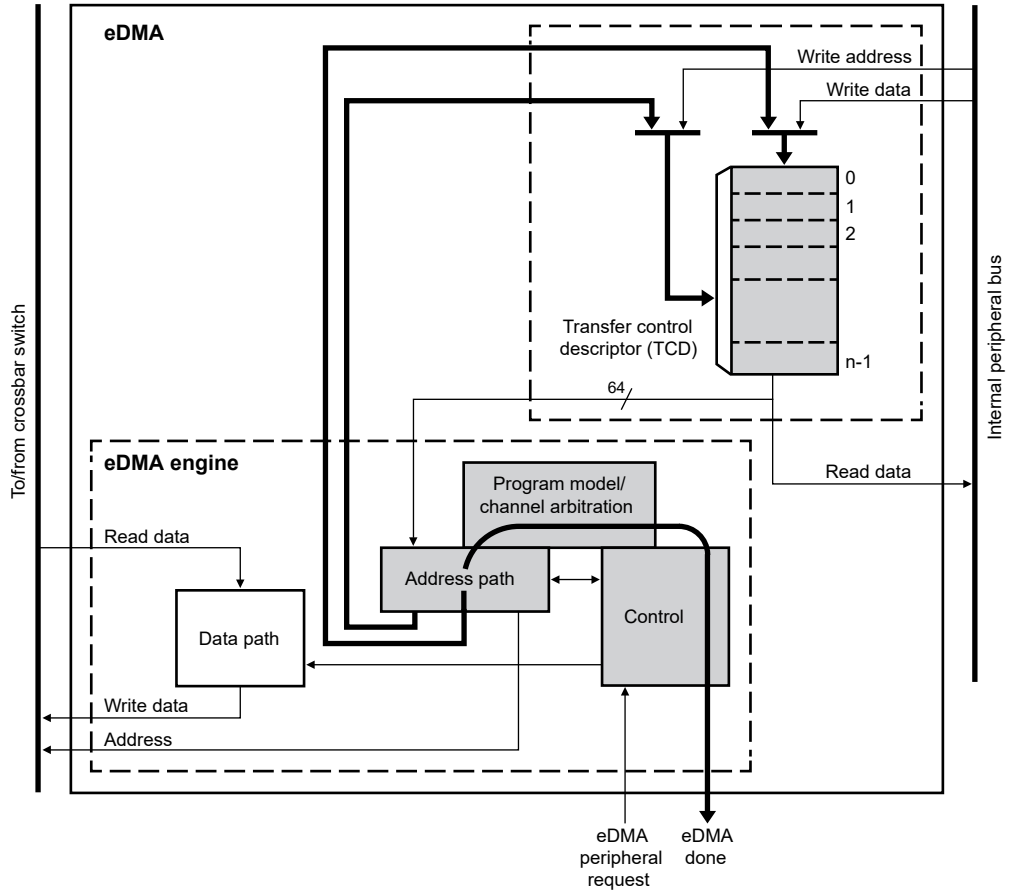

Figure 6. eDMA operation, part 3

4.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus master read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

4.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]

It can be considered a number composed of these concatenated priority levels: CHn_GRPRI : CHn_PRI[APL]

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CH_NUM)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

4.3.5 Clocking

The following table describes the clock sources:

Table 12. Clocks

Clock	Description
hclk	Clock used for the DMA engine
ipg_clk	Clock used for the DMA programming model
dma_ram_clk	Clock used for the TCD RAMs

4.3.6 Interrupts

Software can enable the interrupt for each channel for the following events:

1. The major loop is half complete (INTHALF)
2. The major loop is complete (INTMAJOR)
3. A configuration error occurs (EEI)

4.4 External signals

This module has no external signals.

4.5 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

4.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.

3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: slave device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 13, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 13. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 14. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

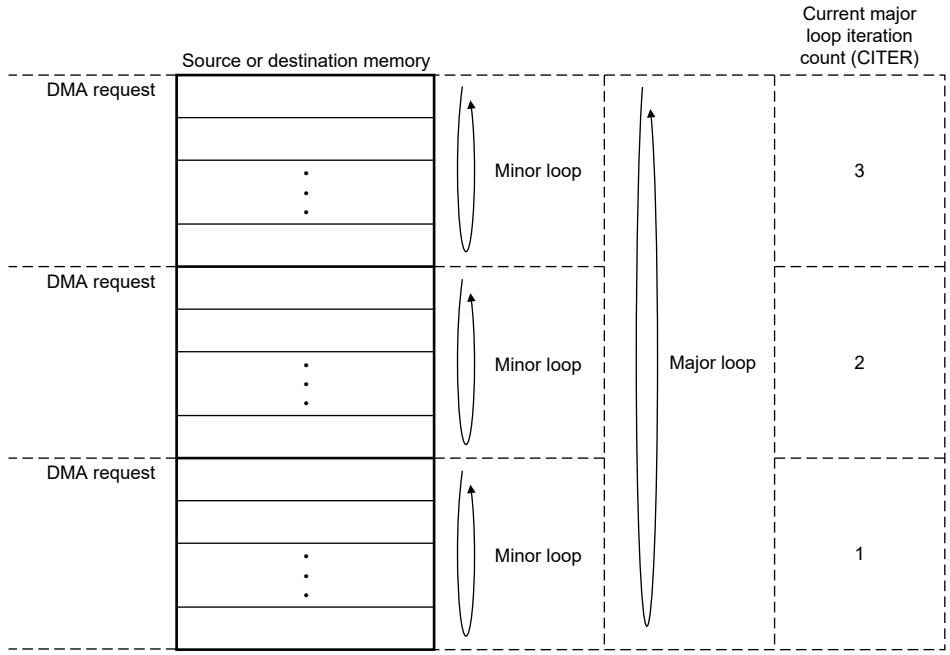

Figure 7. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

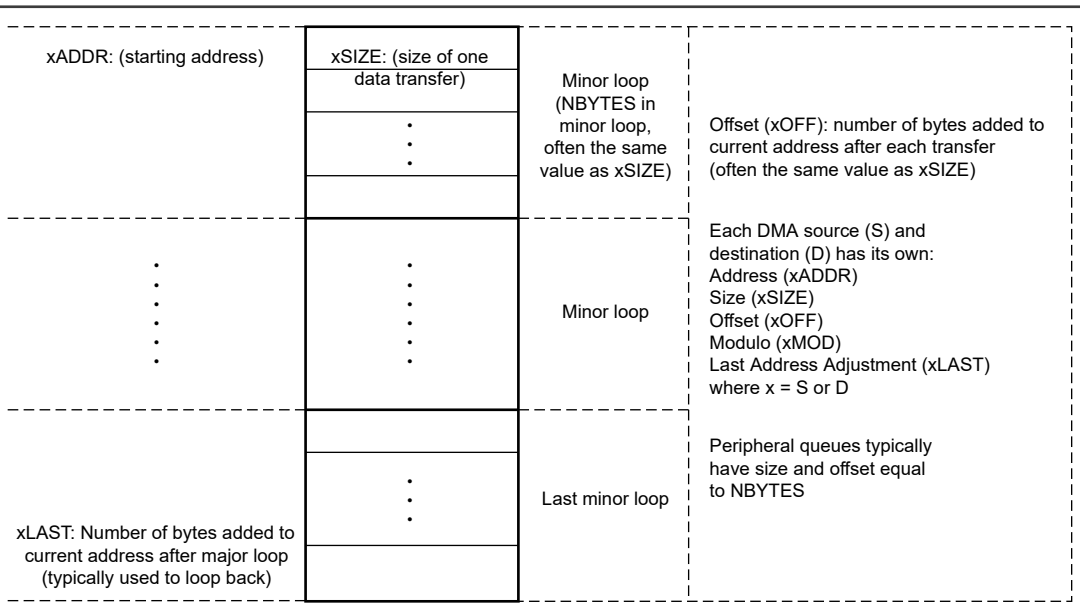

Figure 8. Memory array terms

4.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 15. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is given to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

4.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

4.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

4.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

4.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

4.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

4.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
```

```
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

4.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the slave device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.

4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
    h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

4.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 16. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

4.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

4.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

4.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

4.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

4.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
MP_CSR[GCLC] = 1
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 17. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

4.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

Steps for channel linking:

1. Set GCLC = 1
2. For linking after major loop complete:
   a. Set MAJORLINKCH = target channel number
   b. Set MAJORELINK = 1, enable the major loop link
   c. Upon major loop completion (CITER decrements to 0), the link will be made.
3. For linking on minor loop completion:
   a. Set LINKCH = target channel number
   b. Set ELINK = 1, enable the minor loop link
   c. Set the beginning iteration count to the same values; LINKCH = target channel and ELINK = 1,
   d. Upon minor loop completion (that is, after each service request except when the major loop is complete) the link will be made.

4.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

4.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

4.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[ESG] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

4.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

4.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

4.5.9 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's

service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure.

4.5.9.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.
2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the SPI is set as a master for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the SPI.
2. Ensure there is no DMA service request from the SPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

4.5.9.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

4.6 Memory map/register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See DMA TCD register descriptions for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

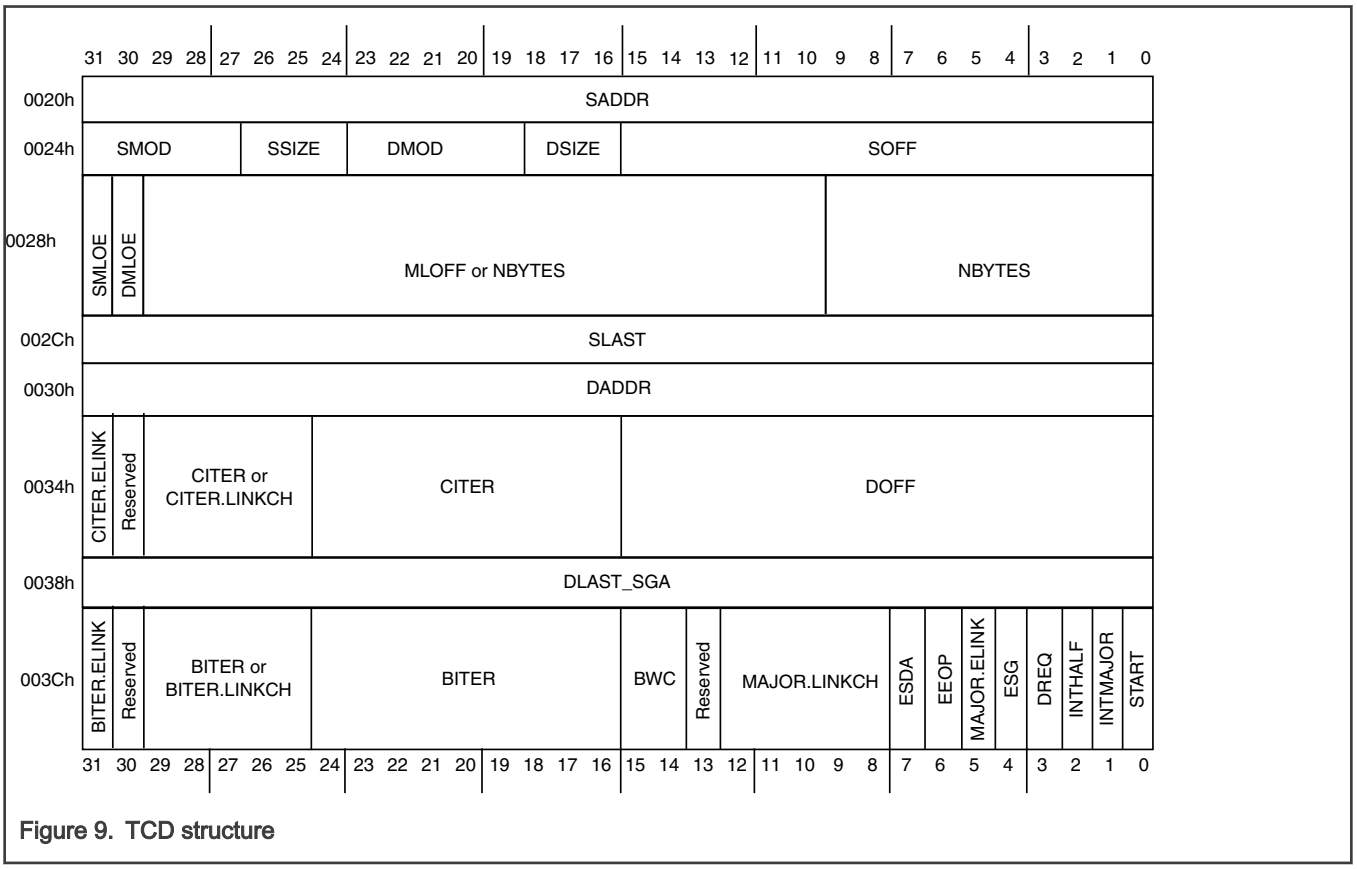

Figure 9. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

4.6.1 DMA MP register descriptions

4.6.1.1 MP memory map

EDMA3_1.MP base address: 4400_0000h

NOTE

For registers in the following table with *Protection*, see the REG_PROT details for more information.

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
0	Management Page Control (MP_CSR)	32	RW	0031_0000	Yes
4	Management Page Error Status (MP_ES)	32	R	0000_0000	No
8	Management Page Interrupt Request Status (MP_INT)	32	R	0000_0000	No

Table continues on the next page...

Table continued from the previous page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
C	Management Page Hardware Request Status (MP_HRS)	32	R	0000_0000	No
100 - 178	Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI)	32	RW	0000_0000	Yes

4.6.1.2 Management Page Control (MP_CSR)

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Offset

Register	Offset
MP_CSR	0h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W	0												0			0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31 ACTIVE	DMA Active Status 0 - eDMA is idle 1 - eDMA is executing a channel
30-29 —	Reserved
28-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0 - Normal operation 1 - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0 - Normal operation 1 - Cancel the remaining data transfer
7 GMRC	Global Master ID Replication Control **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0 - Master ID replication disabled for all channels 1 - Master ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6	Global Channel Linking Control 0 - Channel linking disabled for all channels

Table continues on the next page...

Table continued from the previous page...

Field	Description
GCLC	1 - Channel linking available and controlled by each channel's link settings
5 HALT	Halt DMA Operations This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0 - Normal operation 1 - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0 - Normal operation 1 - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0 - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1 - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0 - Debug mode disabled. When in debug mode, the DMA continues to operate 1 - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

4.6.1.3 Management Page Error Status (MP_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

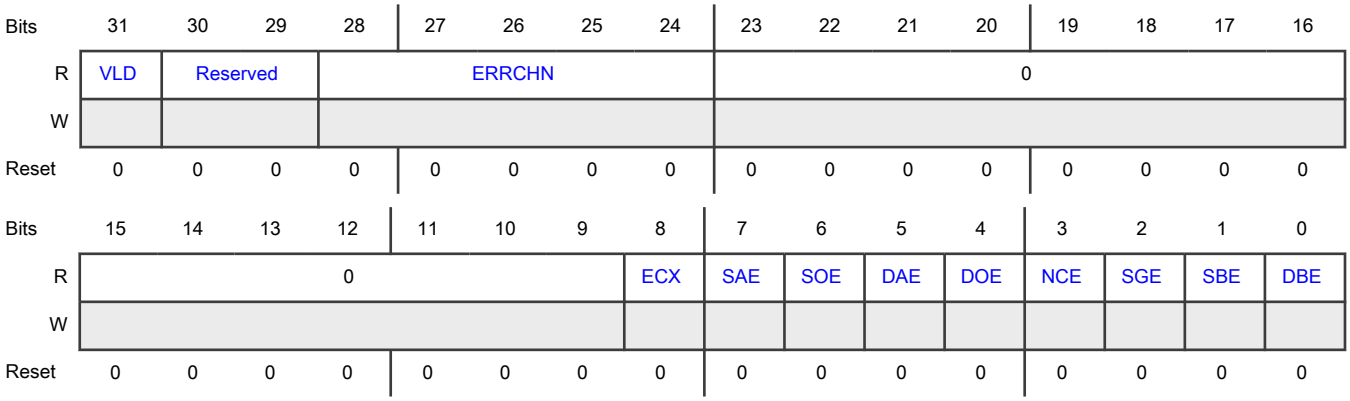
- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM
- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Offset

Register	Offset
MP_ES	4h

Diagram



Fields

Field	Description
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0 - No CHn_ES[ERR] fields are set to 1 1 - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-29 —	Reserved
28-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0 - No canceled transfers 1 - Last recorded entry was a canceled transfer by the error cancel transfer input
7	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Description
SAE	0 - No source address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0 - No source offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0 - No NBYTES/CITER configuration error 1 - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0 - No scatter/gather configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0 - No source bus error 1 - Last recorded error was a bus error on a source read
0	Destination Bus Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
DBE	0 - No destination bus error 1 - Last recorded error was a bus error on a destination write

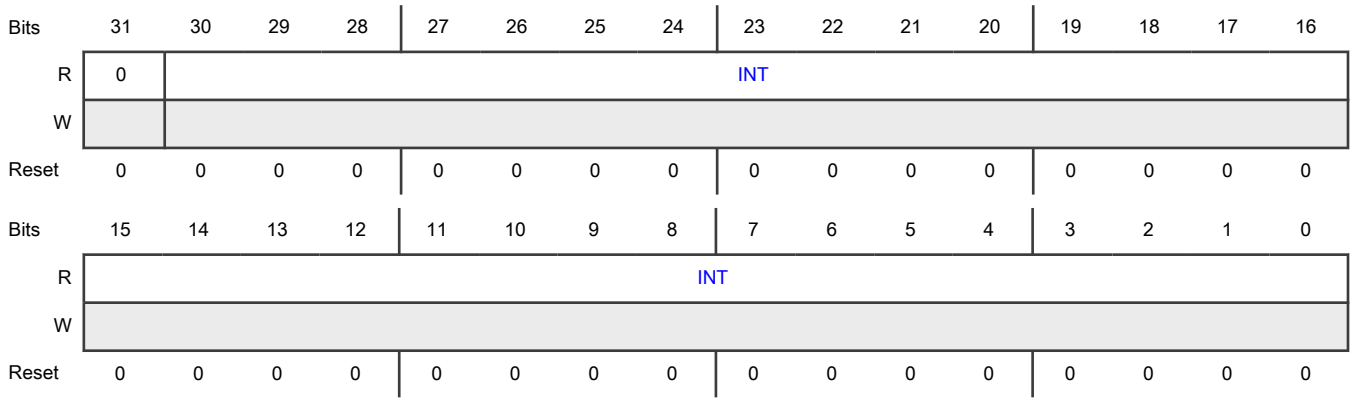
4.6.1.4 Management Page Interrupt Request Status (MP_INT)

This register shows the current state of the interrupt service requests for all eDMA channels.

Offset

Register	Offset
MP_INT	8h

Diagram



Fields

Field	Description
31 —	Reserved
30-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

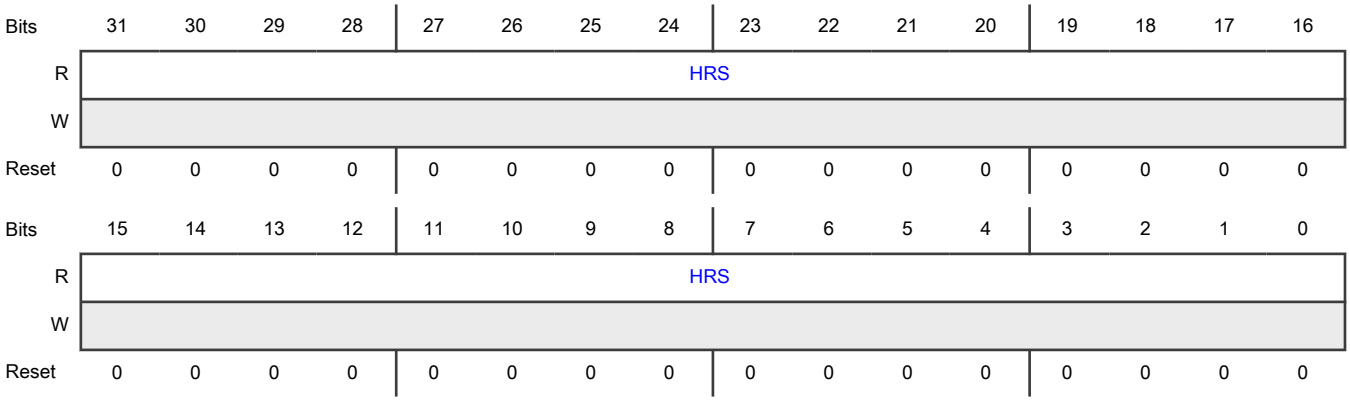
4.6.1.5 Management Page Hardware Request Status (MP_HRS)

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Offset

Register	Offset
MP_HRS	Ch

Diagram



Fields

Field	Description
31-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

4.6.1.6 Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI)

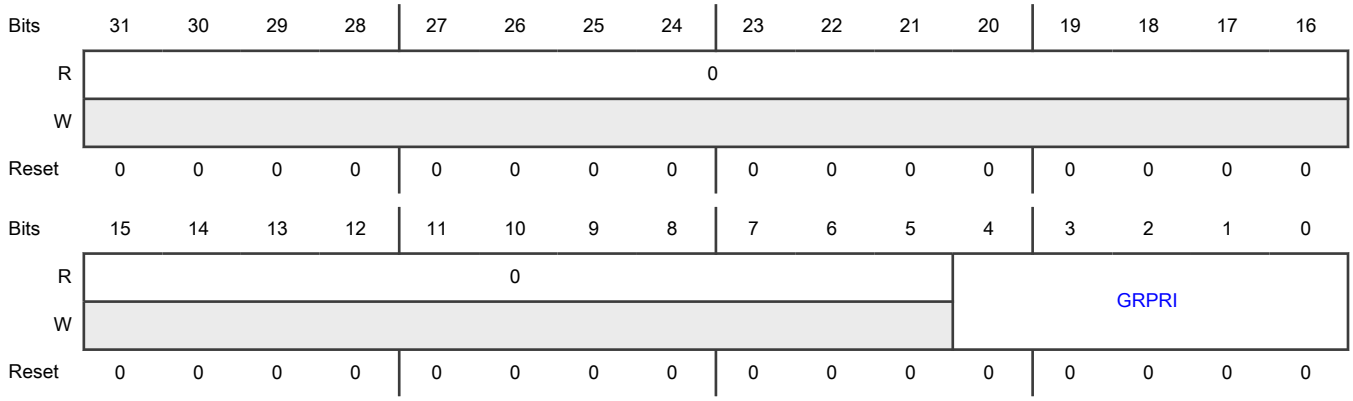
The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Offset

For n = 0 to 30:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Diagram



Fields

Field	Description
31-5 —	Reserved
4-0 GRPRI	Arbitration Group For Channel n Fixed-priority arbitration group number.

4.6.2.2 Channel Control and Status (CH0_CSR - CH30_CSR)

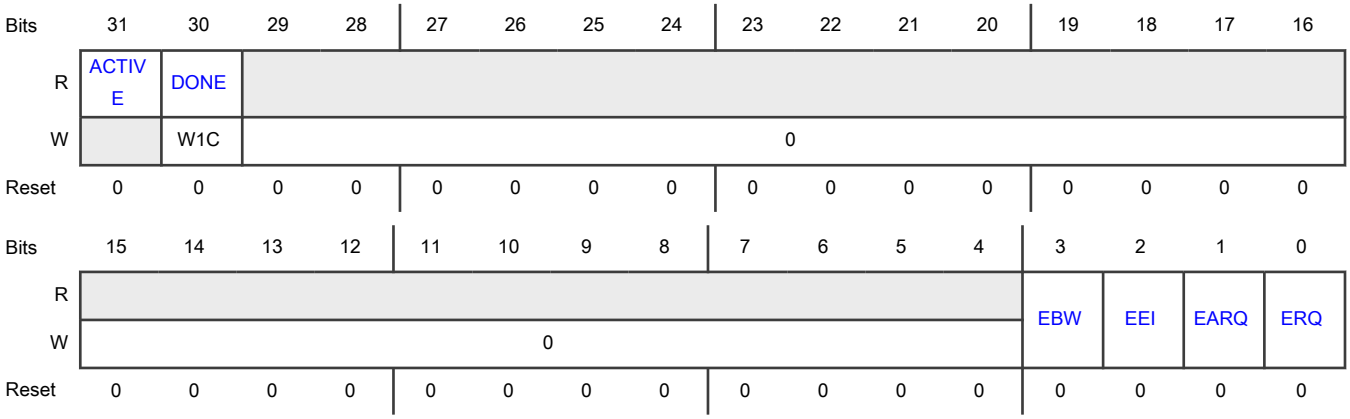
This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Offset

For n = 0 to 30:

Register	Offset
CHn_CSR	0h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0 - Buffered writes on system bus disabled. Buffered writes on system bus disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0 - Error signal for corresponding channel does not generate error interrupt 1 - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0 - Disable asynchronous DMA request for the channel 1 - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0 - DMA hardware request signal for corresponding channel disabled 1 - DMA hardware request signal for corresponding channel enabled

4.6.2.3 Channel Error Status (CH0_ES - CH30_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus master read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

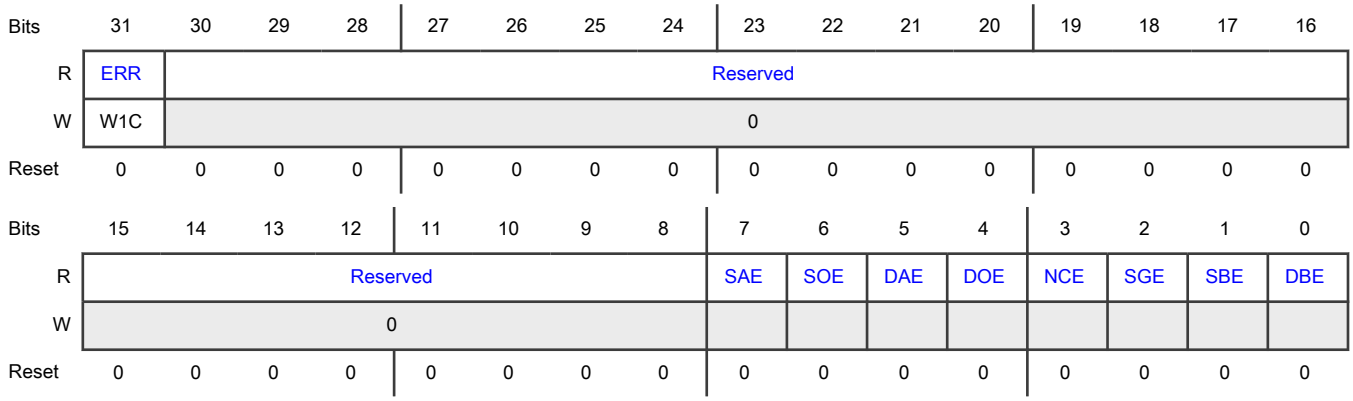
See Fault reporting and handling for more details.

Offset

For n = 0 to 30:

Register	Offset
CHn_ES	4h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 ERR	Error In Channel 0 - An error in this channel has not occurred 1 - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0 - No source address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0 - No source offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_SOFF field

Table continues on the next page...

Table continued from the previous page...

Field	Description
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination address configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0 - No destination offset configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0 - No NBYTES/CITER configuration error 1 - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0 - No scatter/gather configuration error 1 - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0 - No source bus error 1 - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0 - No destination bus error 1 - Last recorded error was bus error on destination write

4.6.2.4 Channel Interrupt Status (CH0_INT - CH30_INT)

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Offset

For n = 0 to 30:

Register	Offset
CHn_INT	8h + (n × 1_0000h)

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

4.6.2.5 Channel System Bus (CH0_SBR - CH30_SBR)

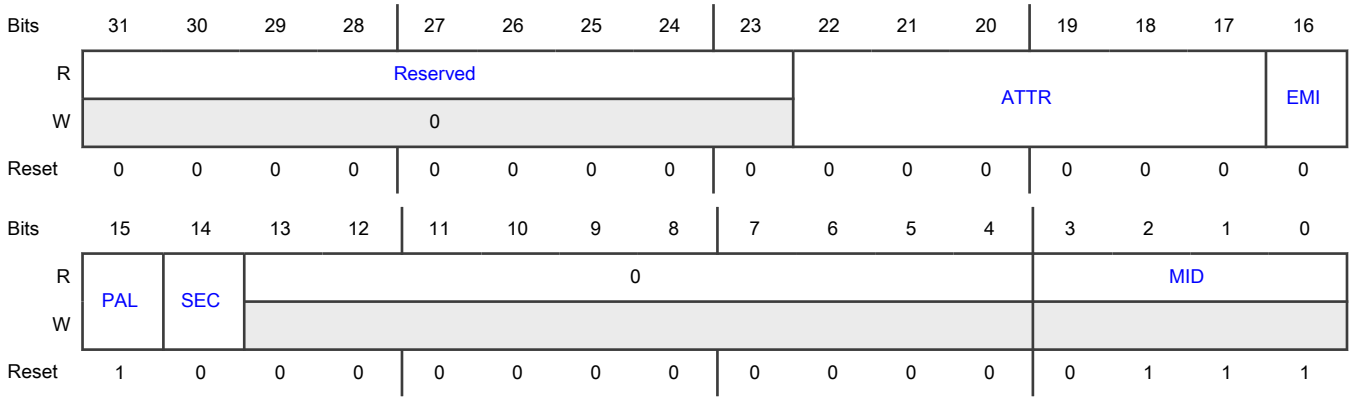
The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Offset

For n = 0 to 30:

Register	Offset
CHn_SBR	Ch + (n × 1_0000h)

Diagram



Fields

Field	Description
31-23 —	Reserved
22-17 ATTR	Attribute Output DMA's system bus attribute output value.
16 EMI	Enable Master ID Replication The eDMA master ID replication field allows the eDMA to use the same protection level and system bus ID of the master programming the eDMA's TCD. When enabled, the eDMA uses the master ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a master (for example a core) programs a TCD, its master ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Master ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0 - Master ID replication is disabled 1 - Master ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - User protection level for DMA transfers 1 - Privileged protection level for DMA transfers

Table continues on the next page...

Table continued from the previous page...

Field	Description
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - Nonsecure protection level for DMA transfers 1 - Secure protection level for DMA transfers
13-4 —	Reserved
3-0 MID	Master ID This field controls the DMA's master ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the master ID of the core or other master writing the channel's security attributes, TCD*n*_SBR[SEC].

4.6.2.6 Channel Priority (CH0_PRI - CH30_PRI)

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH30_GRPRI).

The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

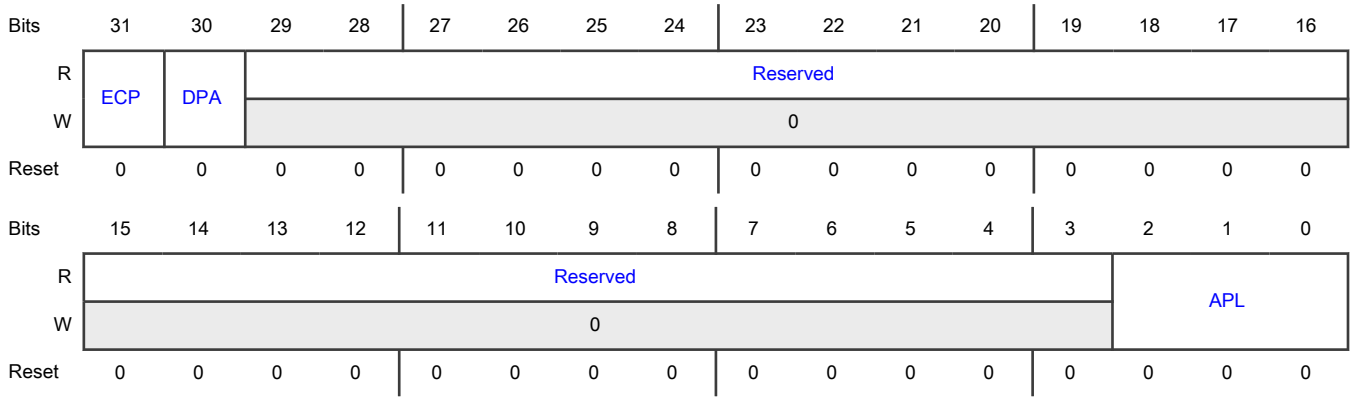
When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Offset

For n = 0 to 30:

Register	Offset
CHn_PRI	10h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 ECP	Enable Channel Preemption 0 - Channel cannot be suspended by a higher-priority channel's service request 1 - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0 - Channel can suspend a lower-priority channel 1 - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

4.6.2.7 TCD Source Address (TCD0_SADDR - TCD30_SADDR)

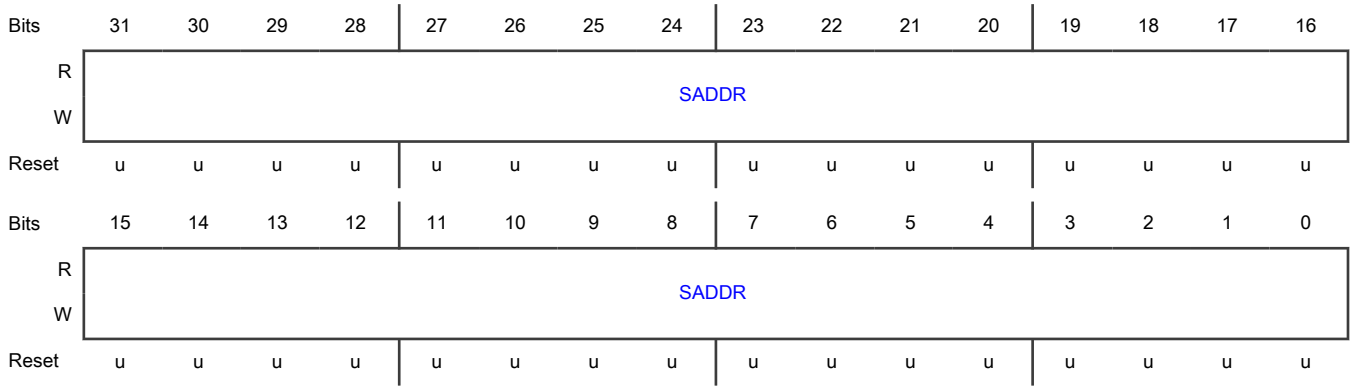
This register contains the address for the read transactions.

Offset

For n = 0 to 30:

Register	Offset
TCDn_SADDR	20h + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 SADDR	Source Address Memory address pointing to the source data.

4.6.2.8 TCD Signed Source Address Offset (TCD0_SOFF - TCD30_SOFF)

This register contains the sign-extended value added to Source Address register after each read transaction.

Offset

For n = 0 to 30:

Register	Offset
TCDn_SOFF	24h + (n × 1_0000h)

Fields

Field	Description
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000 - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - 16-byte 101 - 32-byte 110 - 64-byte 111 - Reserved
7-3	Destination Address Modulo

Field	Description
DMOD	See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

4.6.2.10 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD30_NBYTES_MLOFFNO)

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

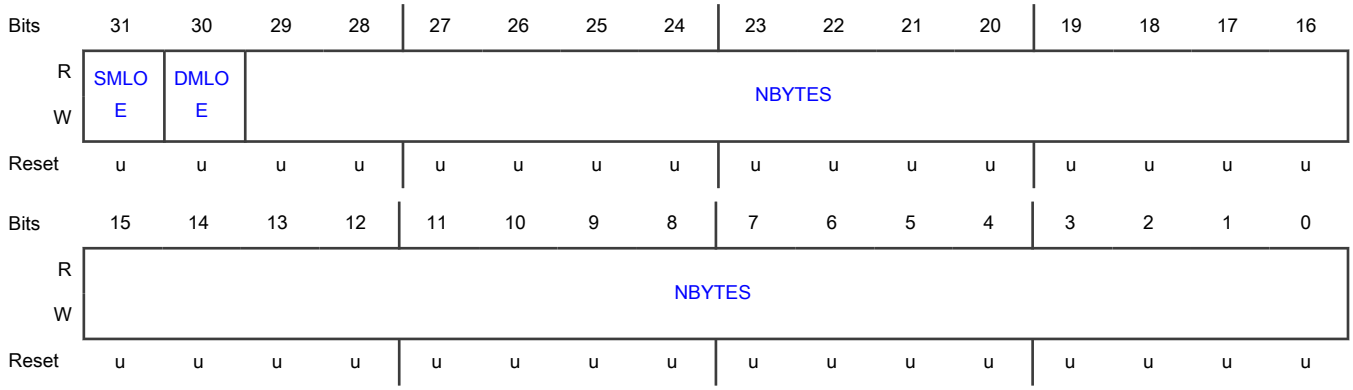
- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Offset

For n = 0 to 30:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 - Minor loop offset not applied to SADDR 1 - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 - Minor loop offset not applied to DADDR 1 - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

4.6.2.11 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD30_NBYTES_MLOFFYES)

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

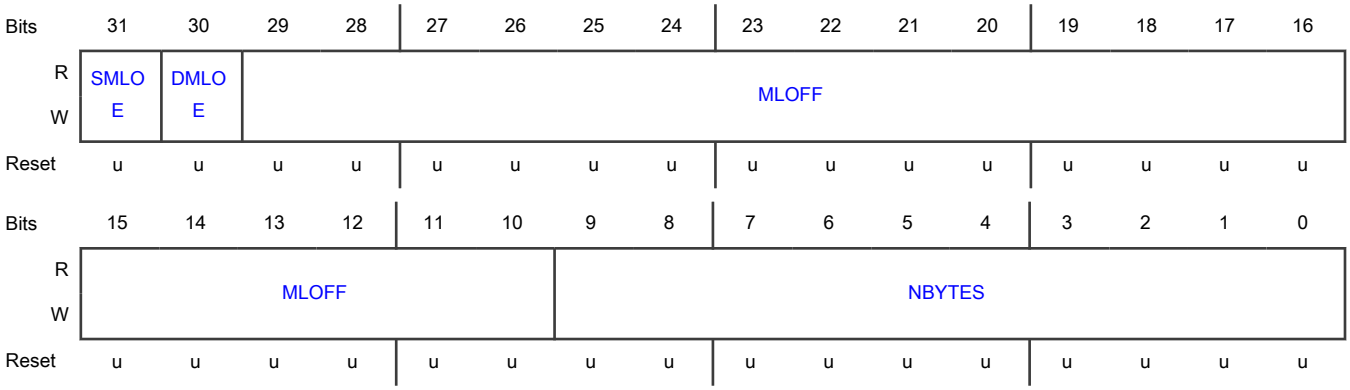
- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Offset

For n = 0 to 30:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1_0000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0 - Minor loop offset not applied to SADDR

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0 - Minor loop offset not applied to DADDR 1 - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

4.6.2.12 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD30_SLAST_SDA)

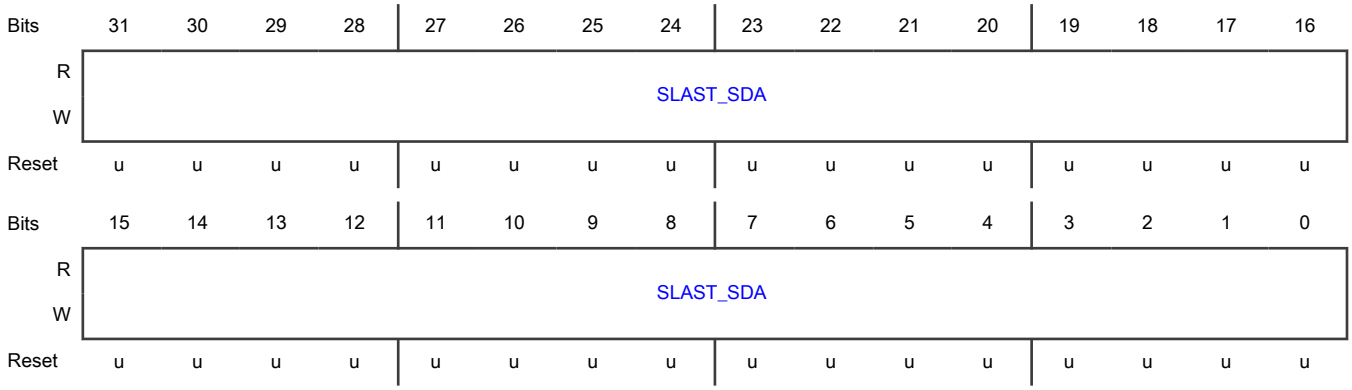
This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Offset

For n = 0 to 30:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

4.6.2.13 TCD Destination Address (TCD0_DADDR - TCD30_DADDR)

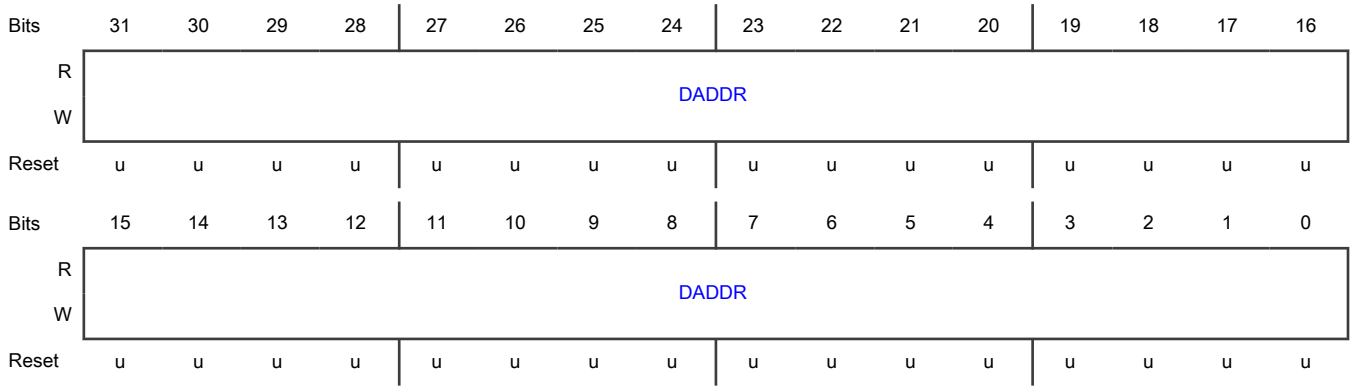
This register contains the address for the write transactions.

Offset

For n = 0 to 30:

Register	Offset
TCDn_DADDR	30h + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 DADDR	Destination Address Memory address pointing to the destination data.

4.6.2.14 TCD Signed Destination Address Offset (TCD0_DOFF - TCD30_DOFF)

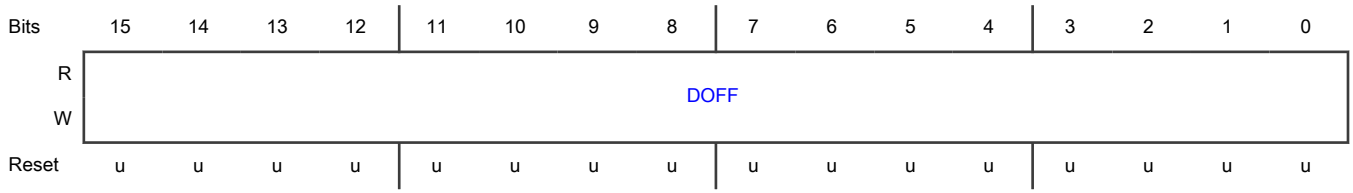
This register contains the sign-extended value added to Destination Address register after each write transaction.

Offset

For n = 0 to 30:

Register	Offset
TCDn_DOFF	34h + (n × 1_0000h)

Diagram



Fields

Field	Description
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

4.6.2.15 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD30_CITER_ELINKNO)

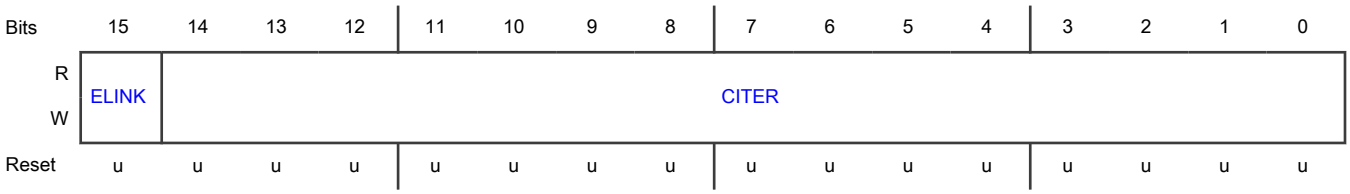
If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1_0000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

4.6.2.16 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD30_CITER_ELINKYES)

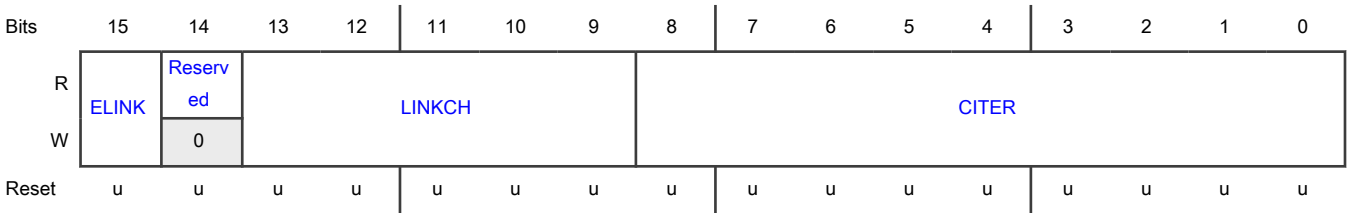
If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1_0000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
14 —	Reserved
13-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

4.6.2.17 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD30_DLAST_SGA)

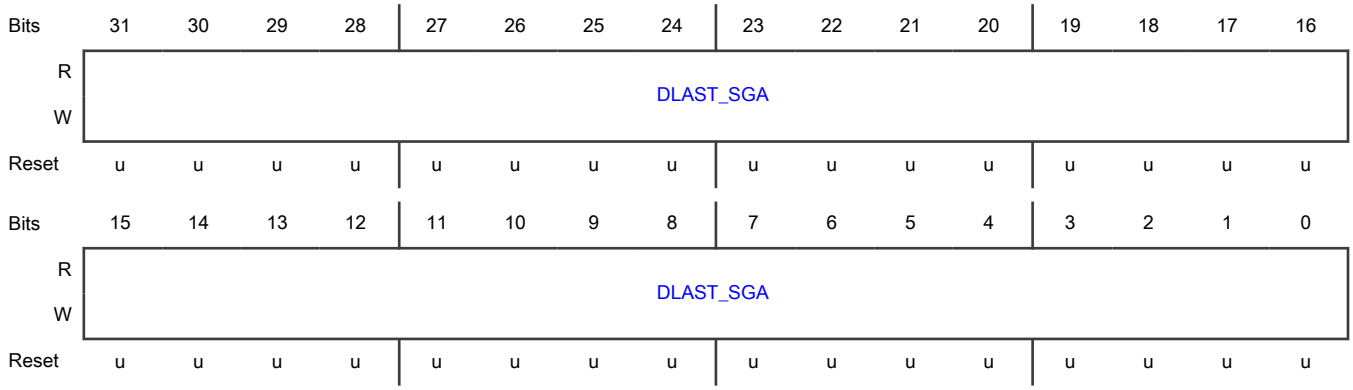
This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Offset

For n = 0 to 30:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1_0000h)

Diagram



Fields

Field	Description
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

4.6.2.18 TCD Control and Status (TCD0_CSR - TCD30_CSR)

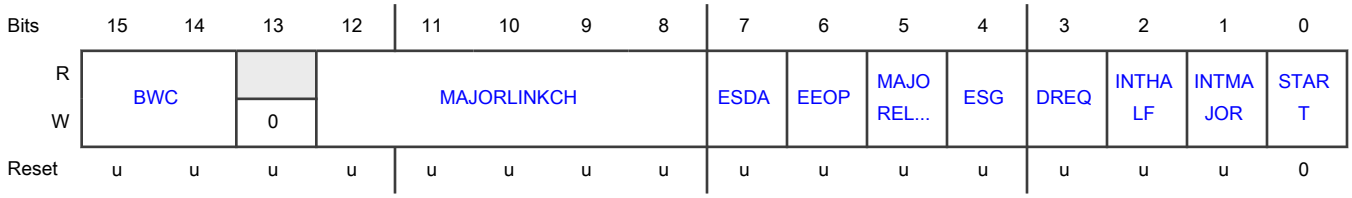
This register is used to enable optional features.

Offset

For n = 0 to 30:

Register	Offset
TCDn_CSR	3Ch + (n × 1_0000h)

Diagram



Fields

Field	Description
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00 - No eDMA engine stalls 01 - Reserved 10 - eDMA engine stalls for 4 cycles after each R/W 11 - eDMA engine stalls for 8 cycles after each R/W
13 —	Reserved
12-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0 - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0 - End-of-packet operation disabled 1 - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0 - Channel-to-channel linking disabled 1 - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0 - Current channel's TCD is normal format 1 - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0 - No operation. Channel's ERQ field not affected 1 - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Description
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0 - Halfway point interrupt disabled 1 - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0 - End-of-major loop interrupt disabled 1 - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0 - Channel not explicitly started 1 - Channel explicitly started via a software-initiated service request

4.6.2.19 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD30_BITER_ELINKNO)

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Offset

For n = 0 to 30:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1_0000h)

Chapter 5
Enhanced Direct Memory Access (eDMA4)

5.1 Chip-specific eDMA4 information

Table 18. Reference links to related information

Topic	Related module	Reference
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

“The Enhanced Direct Memory Access Type 4 (eDMA4) is an AXI-based 32-bit-addressing-capable eDMA module. For the rest of the chapter, eDMA refers to the eDMA4 type. There is one instance of eDMA4 in the Wakeup domain. This is called the eDMA4_2 instance.

5.2 Overview

eDMA is a highly programmable data-transfer engine that performs complex data transfers with minimal intervention from a host processor. You can use it in applications where the data size to be transferred is statically known and not defined within the transferred data.

The eDMA microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing TCDs for each of the 64 channels

5.2.1 Block diagram

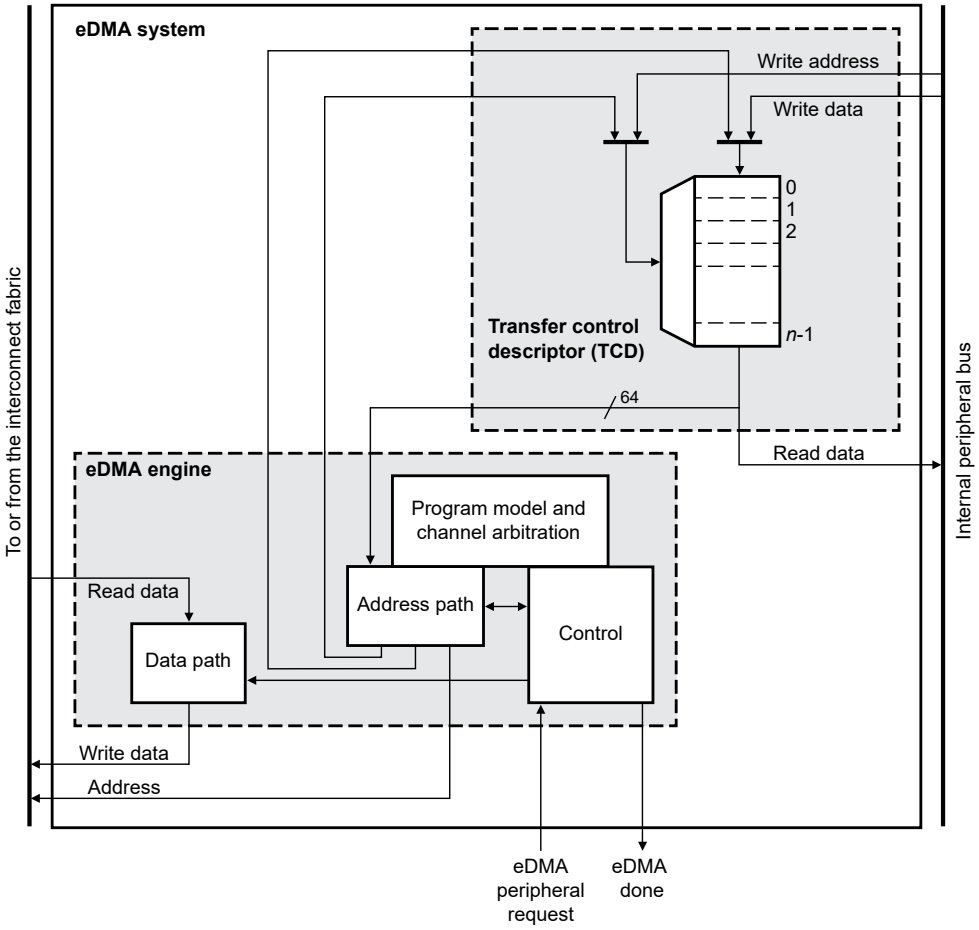

Figure 10. Block diagram

5.2.2 Block parts

eDMA is partitioned into two major modules: the eDMA engine and the TCD local memory.

Table 19 shows the submodules that the eDMA engine is partitioned into.

Table 19. eDMA engine submodules

Submodule	Function
Address path	Implements registered versions of the following channel TCDs: • Primary channel • Secondary (preempt) channel Additionally, this submodule manages all controller bus-address calculations. All channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher-priority channel activation is asserted when the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless a higher-priority channel preempts it. This provides a mechanism (enabled by CH0_PRI[ECP]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

Table continues on the next page...

Table 19. eDMA engine submodules (continued)

Submodule	Function
	When you select a channel to execute, the contents of its TCD are read from local memory and loaded into the address path channel *x* registers for a normal start and into channel *y* registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for TCD*n*[SADDR], TCD*n*[DADDR], and TCD*n*[CITER] back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading TCD*n*_CITER, and a possible fetch of the next TCD*n* from memory as part of a scatter/gather operation.
Data path	Implements the bus controller read/write datapath. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the two-stage pipelined internal bus. The address path submodule represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
Program model and channel arbitration	Implements the first section of the eDMA programming model and channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via the control logic).
Control	Describes the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the small-size data are required for each reference of the larger size. For example, if the source size references 16-bit data and the destination is 32-bit data, two reads are performed followed by a one 32-bit write.

Table 20 shows further partitioning of the TCD local memory.

Table 20. Transfer control descriptor memory

Submodule	Description
Memory controller	Implements the required dual-ported controller, managing accesses from the eDMA engine and references from the internal peripheral bus. If there are simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

5.2.3 Features

- Facilitates data movement through dual-address transfers read from source, write to destination plus a write-only initialization mode:
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- Supports 64-channel implementation that performs complex data transfers with minimal intervention from a host processor:
  - Internal data buffer, used as temporary storage to support large multibyte transfers
  - Connections to the interconnect fabric for bus mastering the data movement
- Supports a TCD that is organized to support two-deep, nested transfer operations:
  - 32-byte TCD stored in local memory for each channel

  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Initializes channel activation through one of the following methods:
  - Explicit software initiation
  - Initiation through channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Supports fixed-priority and round-robin channel arbitration
- Reports channel completion reported through programmable interrupt requests:
  - One interrupt per channel, which can be asserted after the completion of a major iteration count
  - Programmable error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Provides programmable support for the scatter/gather DMA processing
- Provides support for complex data structures

eDMA uses *n* for reference to the channel number.

5.3 eDMA register descriptions

The eDMA's programming model is partitioned into three parts:

- The first part defines the number of registers providing the overall control functions: the management page.
- The second part corresponds to the channel (CH) control, status, and configuration.
- The third part corresponds to the local TCD memory.

5.3.1 TCD memory

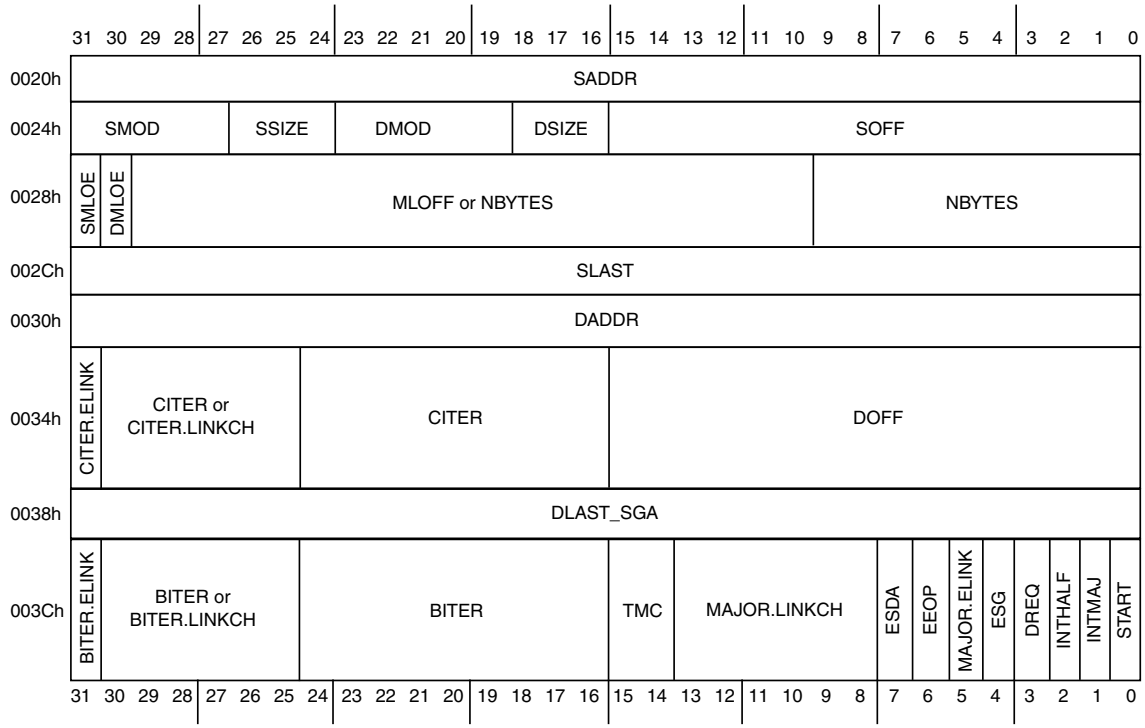
Each channel requires a 32-byte TCD for defining the desired data movement operation. The local memory stores the channel descriptors in a sequential order: channel 0, channel 1, ... channel 63.

This table provides a 32-bit view of the eDMA memory map.

5.3.2 TCD initialization

The TCD memory is in an unknown state after reset. Only the TCD START bit is initialized to 0. Before activating a channel, you must initialize its TCD with the appropriate transfer profile.

5.3.3 TCD structure



5.3.3.1 Reserved memory and bit fields

- Reading reserved bits in a register returns the value of zero.
- Writes to reserved bits in a register are ignored.
- Reading or writing to a reserved memory location generates a bus error.

5.3.4 DMA MP register descriptions

5.3.4.1 MP memory map

EDMA4_2.MP base address: 4200_0000h

NOTE

For registers in the following table with *Protection*, see the REG_PROT details for more information.

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
0	Management Page Control (CSR)	32	RW	0040_0000	No
4	Management Page Error Status (ES)	32	R	0000_0000	No
8	Management Page Interrupt Request Status Register - Low (INT_LOW)	32	R	0000_0000	No

Table continues on the next page...

Table continued from the previous page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)	Protection
C	Management Page Interrupt Request Status Register-High (INT_HIGH)	32	R	0000_0000	No
10	Management Page Hardware Request Status Register - Low (HRS_LOW)	32	R	0000_0000	No
14	Management Page Hardware Request Status Register - High (HRS_HIGH)	32	R	0000_0000	No
100 - 1FC	Channel Arbitration Group (CH0_GRPRI - CH63_GRPRI)	32	RW	0000_0000	No

5.3.4.2 Management Page Control (CSR)

Defines the basic operating configuration of DMA.

Arbitration uses a two-tier priority system: group and channel priority. Each channel is assigned a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed-priority, and you can configure it to use a selective round-robin scheme for specified channels within each priority group.

For fixed-priority arbitration, select the highest-priority channel requesting service in the highest-priority arbitration group to execute. The channel priority registers assign the relative priorities within each arbitration group (see Channel Priority (CH0_PRI - CH63_PRI)). All channels with a nonzero value in Channel Priority (CH0_PRI - CH63_PRI) use fixed-priority arbitration.

When you enable round-robin arbitration, any channel with its channel priority set to 0 does not have a priority. The channels requesting service are cycled through (from high to low channel number) without considering the relative priority within the same priority group. Any channel with a nonzero value in Channel Priority (CH0_PRI - CH63_PRI) automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH63_GRPRI).

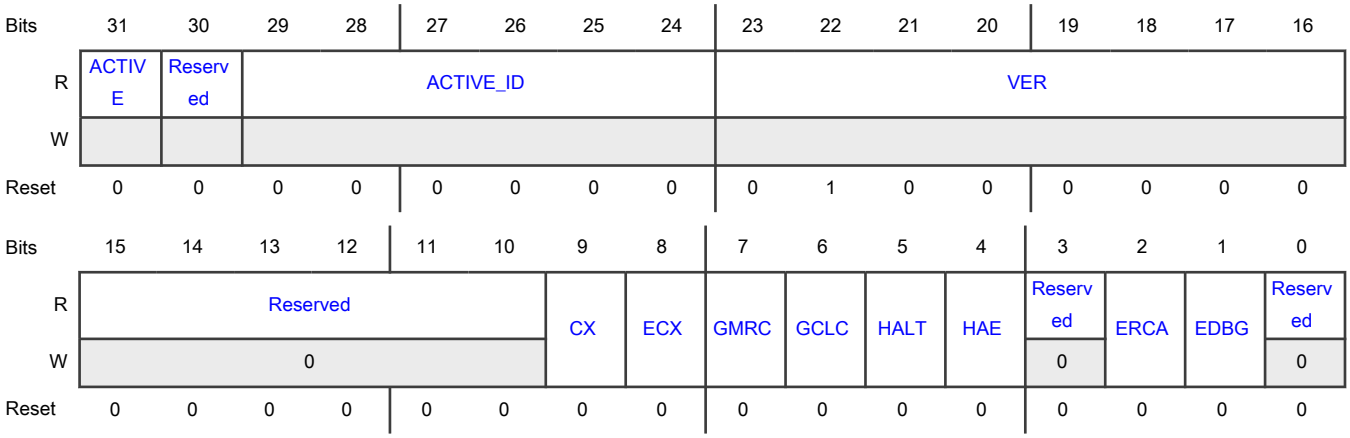
NOTE

For correct operation, perform changes to ERCA, GCLC, and GMRC when the DMA channels are inactive; that is, when ACTIVE is 0.

Offset

Register	Offset
CSR	0h

Diagram



Fields

Field	Description
31 ACTIVE	DMA Active Status Indicates whether eDMA is executing a channel. 0 - Idle 1 - Executing
30 —	Reserved
29-24 ACTIVE_ID	Active Channel ID Indicates the active channel ID.
23-16 VER	eDMA Version Indicates the eDMA version.
15-10 —	Reserved
9 CX	Cancel Transfer Cancels the remaining data transfer. If this field is 1, it stops the executing channel and forces the minor loop to finish. The transfer cancelation takes effect after the last write of the current read/write sequence. The field becomes 0 after the cancel is honored. This cancel retires the channel normally as if the minor loop is completed. 0 - Normal operation 1 - Cancel transfer
8 ECX	Cancel Transfer with Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Cancels the remaining data transfer (similar to CX) and treats the transfer cancelation as an error condition, updates the Error Status register (DMA*n*_ES), and generates an optional error interrupt. If this field is 1, it stops the executing channel and forces the minor loop to finish. The transfer cancelation takes effect after the last write of the current read/write sequence. This field becomes 0 after the cancelation is honored. 0 - Normal operation 1 - Cancel transfer
7 GMRC	Global Master ID Replication Control Specifies whether the master ID replication is available. If this field is 1, the master ID replication is available and is controlled by the configuration of CH0_SBR[EMI] for each channel. **NOTE** If master ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0 - Not available 1 - Available
6 GCLC	Global Channel Linking Control Specifies whether channel linking is available and controlled by each channel's link settings. 0 - Disable 1 - Available
5 HALT	Halt DMA Operations Specifies whether DMA operations are halted. If this field is 1, it stalls the start of any new channels. The channels in execution are allowed to complete. Channel execution resumes when you write 0 to this field. 0 - Normal operation 1 - Halt
4 HAE	Halt after Error Specifies whether the operation halts after an error. If this field is 1, an error causes HALT to become 1. Subsequently, all service requests are ignored until HALT becomes 0. 0 - Normal operation 1 - Halt
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
2 ERCA	Enable Round-Robin Channel Arbitration Enables round-robin channel arbitration. If this field is 0, round-robin channel arbitration is disabled and fixed-priority arbitration is used for channel selection within each group. If this field is 1, round-robin channel arbitration is enabled and is used for channel selection within each group. 0 - Disable 1 - Enable
1 EDBG	Enable Debug Enables Debug mode. If this field is 0, Debug mode is disabled. When in Debug mode, DMA continues to operate. If this field is 1, Debug mode is enabled. When in Debug mode, DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system exits Debug mode or when this field becomes 0. 0 - Disable 1 - Enable
0 —	Reserved

5.3.4.3 Management Page Error Status (ES)

Provides information concerning the last recorded channel error, which can be caused by:

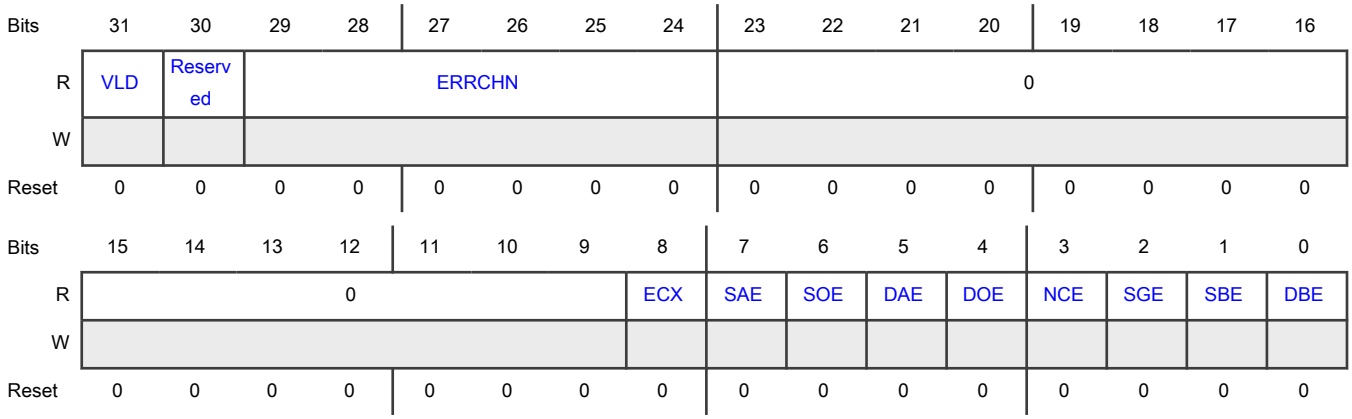
- An illegal setting in TCD.
- An error termination to a bus controller read or write cycle.
- An uncorrectable error occurring when the chip is accessing the TCD SRAM.
- A cancel transfer with error request made through the corresponding cancel transfer bit or input signal.

After an error condition occurs, you must initialize the errant channel's TCD as it is in an incomplete state after an error. See Fault reporting and handling for details.

Offset

Register	Offset
ES	4h

Diagram



Fields

Field	Description
31 VLD	Valid Indicates the logical OR of all ERR status bits. If this field is 1, it indicates that at least one ERR bit is set, indicating an existing valid error that has not been cleared. 0 - No bits are set 1 - At least one bit is set
30 —	Reserved
29-24 ERRCHN	Error Channel Number or Canceled Channel Number Indicates the channel number of the last recorded error or last recorded error canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled Indicates whether the last recorded entry is a canceled transfer by the error cancel transfer input. The ECX operation is a management page function. When this operation is used, the targeted channel's Channel Error Status (CH0_ES - CH63_ES) register reports an unspecified error (only ERR becomes 1). The management page has a complete view of the error condition. 0 - No canceled transfers 1 - Canceled transfers
7 SAE	Source Address Error Indicates whether the last recorded error is a configuration error detected in TCD Source Address (TCD0_SADDR - TCD63_SADDR), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Error detected
6 SOE	Source Offset Error Indicates whether the last recorded error is a configuration error detected in TCD Signed Source Address Offset (TCD0_SOFF - TCD63_SOFF), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected 1 - Error detected
5 DAE	Destination Address Error Indicates whether the last recorded error is a configuration error detected in TCD Destination Address (TCD0_DADDR - TCD63_DADDR), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
4 DOE	Destination Offset Error Indicates whether the last recorded error is a configuration error detected in TCD Signed Destination Address Offset (TCD0_DOFF - TCD63_DOFF), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
3 NCE	NBYTES or CITER Configuration Error Indicates whether NBYTES or CITER configuration error occurred. If this field is 1, the last recorded error is NBYTES equal to zero or a CITER not equal to BITER. Also, the last recorded error is a configuration error detected in TCD*n*_NBYTES or TCD*n*_CITER fields. The configuration error on TCD*n*_NBYTES occurs when TCD*n*_NBYTES is not configured as an integer multiple of TCD0_ATTR[SSIZE] and TCD0_ATTR[DSIZE]. The configuration error on TCD*n*_CITER occurs when TCD*n*_CITER[CITER] is equal to zero or when TCD*n*_CITER[CITER] is not equal to TCD*n*_BITER[ELINK]. 0 - No error detected 1 - Error detected
2 SGE	Scatter/Gather Configuration Error Indicates whether a scatter/gather configuration error is detected. If this field is 1, the last recorded error is a configuration error detected in TCD0_DLAST_SGA[DLAST_SGA]. This field is checked at the beginning of a scatter/gather operation after major loop completion if you enable TCD0_CSR[ESG]. TCD*n*_DLAST_SGA is not on a 32-byte boundary. 0 - No error detected 1 - Error detected
1	Source Bus Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
SBE	Indicates whether the last recorded error is a bus error on a source read. 0 - No error 1 - Error
0 DBE	Destination Bus Error Indicates whether the last recorded error is a bus error on a destination write. 0 - No error 1 - Error

5.3.4.4 Management Page Interrupt Request Status Register - Low (INT_LOW)

This register shows the current state of the interrupt service request for all eDMA channels.

Offset

Register	Offset
INT_LOW	8h

Diagram

Fields

Field	Description
31-0 INT	Interrupt Request Status for channels 31 - 0 The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion . The eDMA channel interrupt requests are routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit in the channel’s interrupt request register, CHn_INT, thus negating the interrupt request.

Table continues on the next page...

Field	Description
	• 0 - An interrupt request for the corresponding channel is not present. • 1 - An interrupt request for the corresponding channel is present.

5.3.4.5 Management Page Interrupt Request Status Register- High (INT_HIGH)

This register shows the current state of the interrupt service request for all eDMA channels.

Offset

Register	Offset
INT_HIGH	Ch

Fields

Field	Description
31-0 INT	Interrupt Request Status for channels 63-32 The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt on data transfer completion . The eDMA channel interrupt requests are routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit in the channel's interrupt request register, CHn_INT, thus negating the interrupt request. • 0 - An interrupt request for the corresponding channel is not present. • 1 - An interrupt request for the corresponding channel is present.

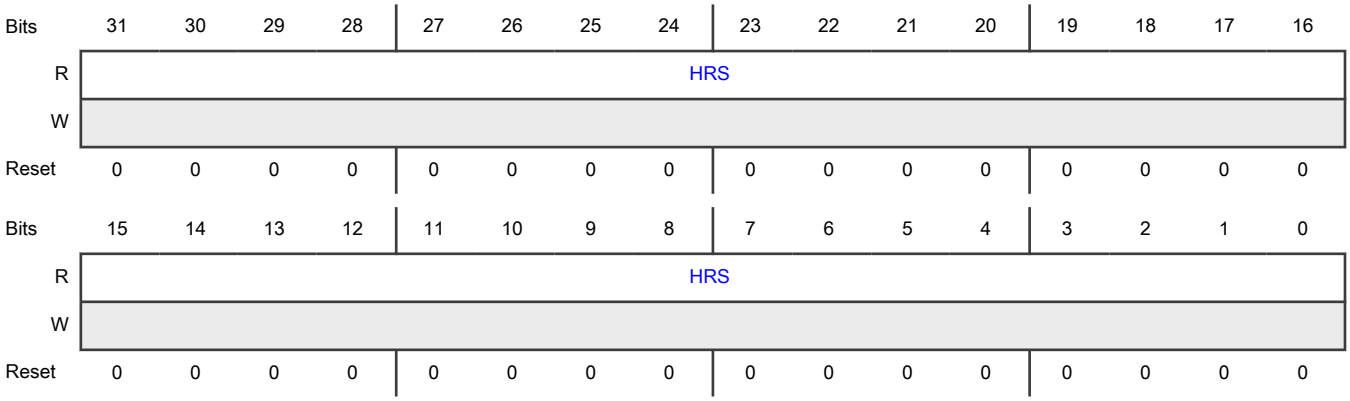
5.3.4.6 Management Page Hardware Request Status Register - Low (HRS_LOW)

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by the eDMA's arbitration logic.

Offset

Register	Offset
HRS_LOW	10h

Diagram



Fields

Field	Description
31-0 HRS	Hardware Request Status for channels 31 - 0 The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and channel is free, the HRS bit is automatically cleared by hardware. 0000_0000_0000_0000_0000_0000_0000_0000 - A hardware service request for the channel is not present 0000_0000_0000_0000_0000_0000_0000_0001 - A hardware service request for channel 0 is present

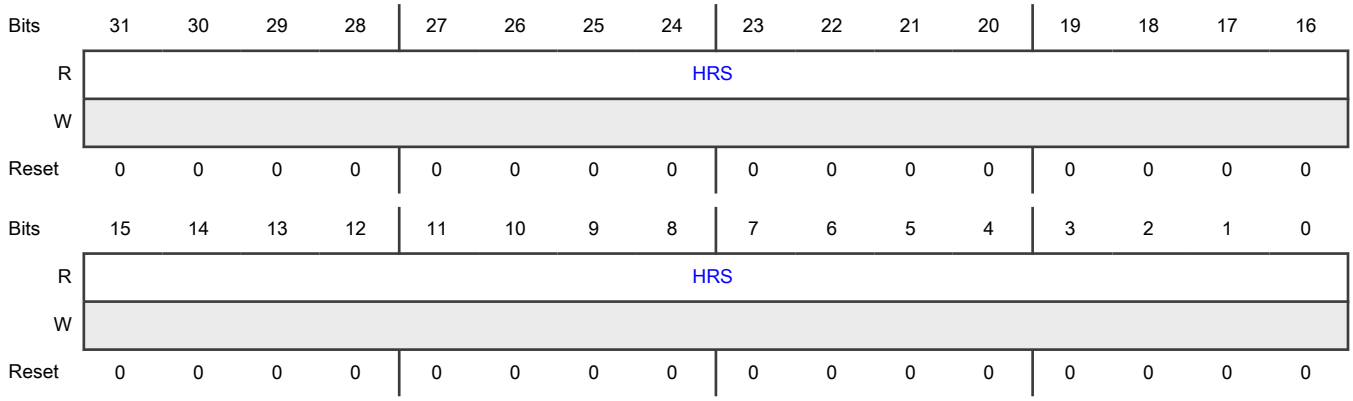
5.3.4.7 Management Page Hardware Request Status Register - High (HRS_HIGH)

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by the eDMA's arbitration logic.

Offset

Register	Offset
HRS_HIGH	14h

Diagram



Fields

Field	Description
31-0 HRS	Hardware Request Status for channels 63-32 The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. After the request is completed and channel is free, the HRS bit is automatically cleared by hardware. 0000_0000_0000_0000_0000_0000_0000_0000 - A hardware service request for the channel is not present 0000_0000_0000_0000_0000_0000_0000_0001 - A hardware service request for channel 0 is present

5.3.4.8 Channel Arbitration Group (CH0_GRPRI - CH63_GRPRI)

Defines the arbitration group associated with each channel.

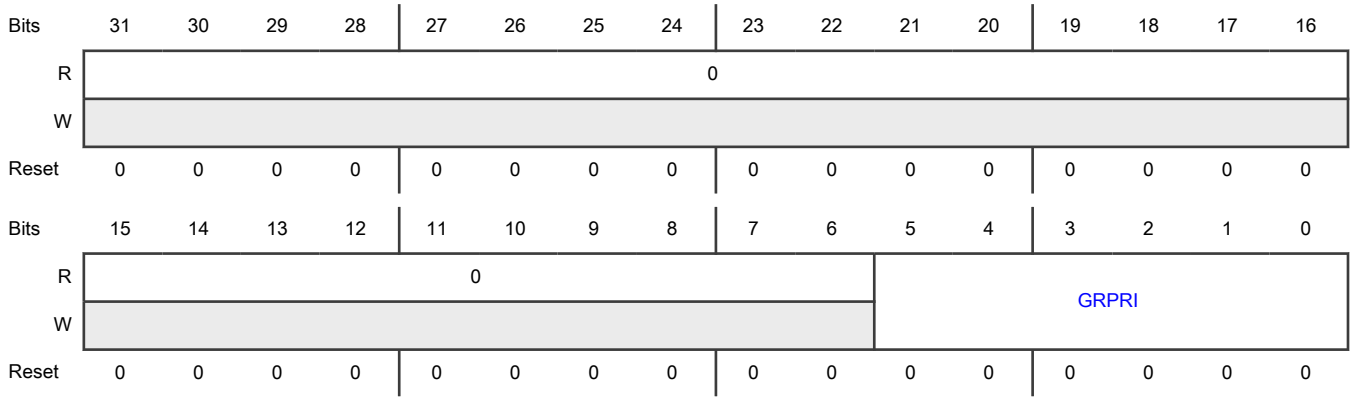
The arbitration group priorities are evaluated by a numeric value from the highest group number to the lowest using the fixed-priority group arbitration scheme; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, Channel Priority (CH0_PRI - CH63_PRI) determines the highest priority channel.

Offset

For n = 0 to 63:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Diagram



Fields

Field	Description
31-6 —	Reserved
5-0 GRPRI	Arbitration Group Per Channel Specifies the fixed-priority arbitration group number.

5.3.5.2 Channel Control and Status (CH0_CSR - CH63_CSR)

Provides channel control and status.

The DMA hardware request input signal must be asserted and ERQ must be 1 before a channel's hardware service request is accepted. The state of ERQ does not affect a channel's service request made explicitly through software or channel linking. The state of ERQ does not affect the channel's START field.

EARQ does not affect DMA operations. If this field is 1, this field allows ERQ to propagate out of DMA to the power controller. When 0, this field masks ERQ to the power controller.

EEI enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

DONE indicates whether the channel has completed the major loop. If enabled, eDMA generates an interrupt request corresponding to this completed channel.

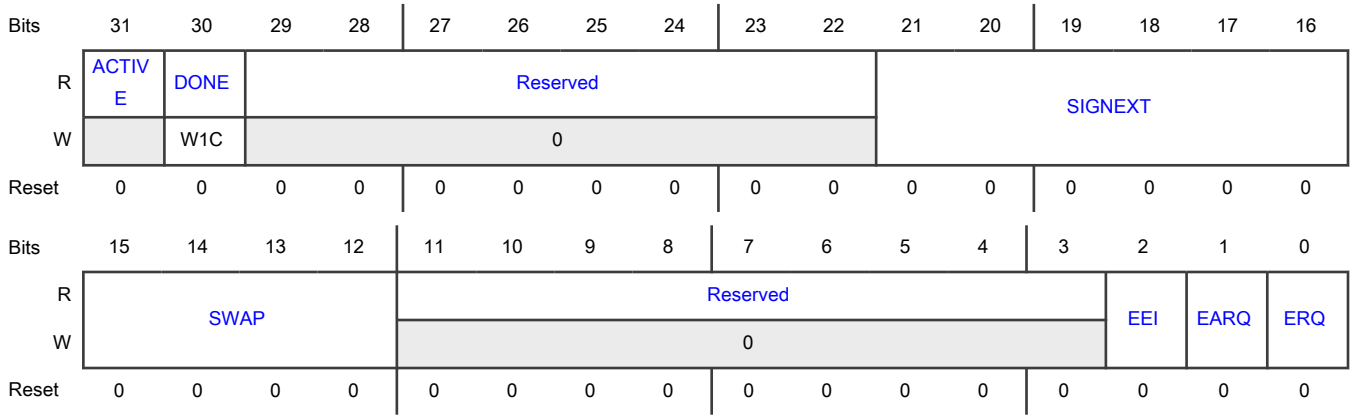
ACTIVE indicates whether the channel is selected by arbitration and is executing the prescribed transfers. Except for dynamic channel linking, you must not modify TCD when a channel is active.

Offset

For n = 0 to 63:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Diagram



Fields

Field	Description
31 ACTIVE	Channel Active Indicates whether the channel is currently in execution. This field becomes 1 when channel service begins; eDMA writes 0 to it when the minor loop completes or when any error condition is detected.
30	Channel Done

Table continues on the next page...

Table continued from the previous page...

Field	Description
DONE	Indicates whether eDMA has completed the major loop. The eDMA engine sets this flag when the CITER count reaches 0. You or hardware can clear the flag when the channel is activated. **NOTE** Clear this flag to write 1 to MAJORELINK. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not done 1 - Done When writing 0 - No effect 1 - Clear the flag
29-22 —	Reserved
21-16 SIGNEXT	Sign Extension Specifies whether the data written on each transaction is sign extended at the bit specified in this field. 00_0000 - Sign extension disabled 00_0001 - Nonzero value specifying the sign extend bit position
15-12 SWAP	Swap Size Swaps data elements within the specified transfer. The swapping occurs with respect to the specified transfer size (TCD0_ATTR[SSIZE] or TCD0_ATTR[DSIZE]). 0000 - Disabled 0001 - Read with 8-bit swap 0010 - Read with 16-bit swap 0011 - Read with 32-bit swap 0100-1000 - Reserved 1001 - Write with 8-bit swap 1010 - Write with 16-bit swap 1011 - Write with 32-bit swap 1100-1111 - Reserved
11-3	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
2 EEI	Enable Error Interrupt Specifies whether the assertion of the error signal for the corresponding channel generates an error interrupt request. 0 - Do not generate 1 - Generate
1 EARQ	Enable Asynchronous DMA Request Enables asynchronous DMA request for the channel. 0 - Disable 1 - Enable
0 ERQ	Enable DMA Request Enables DMA hardware request for the corresponding channel. Disable the channel's hardware service request at the source prior to writing 0 to this field for the corresponding channel. 0 - Disable 1 - Enable

5.3.5.3 Channel Error Status (CH0_ES - CH63_ES)

Provides information concerning the last recorded channel error. Channel errors can occur because of the following:

- An illegal setting in TCD
- An error termination to a bus master read or write cycle

ERR signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by configuring the appropriate fields in this register. The outputs of this register are enabled by the contents of CH0_CSR[EEI], and then logically summed across all channels to form an error interrupt request, which can be routed to the interrupt controller.

During execution of the interrupt-service routine associated with any DMA errors, it is your responsibility to clear the appropriate field, negating the error-interrupt request. The normal DMA channel completion indicators (setting the TCD DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected. The contents of ERR can also be polled because a nonzero value indicates the presence of a channel error regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing 1 to ERR clears the channel's error status. Writing 0 has no effect on the channel's current error status.

An unspecified error, where only ERR becomes 1 indicates any of the following:

- A transfer is canceled with an error

Management Page Error Status (ES) has a full view of the error condition.

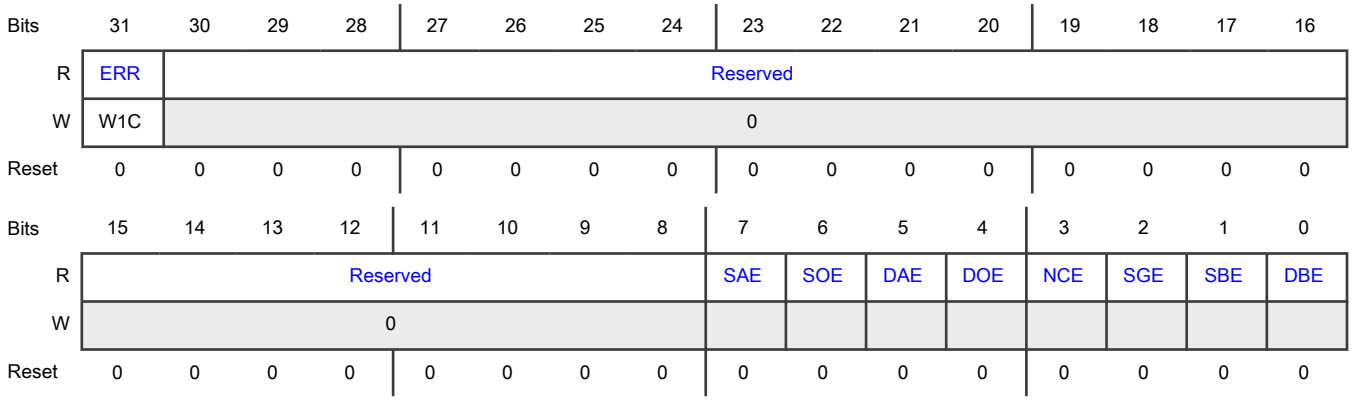
See Fault reporting and handling for details.

Offset

For n = 0 to 63:

Register	Offset
CHn_ES	4h + (n × 1000h)

Diagram



Fields

Field	Description
31 ERR	Error in Channel Indicates whether an error occurred in this channel. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not occurred 1 - Occurred When writing 0 - No effect 1 - Clear the flag
30-8 —	Reserved
7 SAE	Source Address Error Indicates whether the last recorded error is a configuration error detected in TCD Source Address (TCD0_SADDR - TCD63_SADDR), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected 1 - Error detected
6 SOE	Source Offset Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Indicates whether the last recorded error is a configuration error detected in TCD Signed Source Address Offset (TCD0_SOFF - TCD63_SOFF), which is inconsistent with TCD0_ATTR[SSIZE]. 0 - No error detected 1 - Error detected
5 DAE	Destination Address Error Indicates whether the last recorded error is a configuration error detected in TCD Destination Address (TCD0_DADDR - TCD63_DADDR), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
4 DOE	Destination Offset Error Indicates whether the last recorded error is a configuration error detected in TCD Signed Destination Address Offset (TCD0_DOFF - TCD63_DOFF), which is inconsistent with TCD0_ATTR[DSIZE]. 0 - No error detected 1 - Error detected
3 NCE	NBYTES/CITER Configuration Error Indicates whether NBYTES or CITER configuration error occurred. If this field is 1, the last recorded error is a configuration error detected in TCD*n*_NBYTES or TCD*n*_CITER fields. The configuration error on TCD*n*_NBYTES occurs when TCD*n*_NBYTES is not configured as an integer multiple of TCD0_ATTR[SSIZE] and TCD0_ATTR[DSIZE]. The configuration error on TCD*n*_CITER occurs when TCD*n*_CITER[CITER] is equal to zero or when TCD*n*_CITER[CITER] is not equal to TCD*n*_BITER[ELINK]. 0 - No error occurred 1 - Error occurred
2 SGE	Scatter/Gather Configuration Error Indicates whether a scatter/gather configuration error is detected. If this field is 1, the last recorded error is a configuration error detected in TCD0_DLAST_SGA[DLAST_SGA]. This field is checked at the beginning of a scatter/gather operation after major loop completion, if you enable TCD0_CSR[ESG]. TCD*n*_DLASTSGA is not on a 32-byte boundary. 0 - No error detected 1 - Error detected
1 SBE	Source Bus Error Indicates whether the last recorded error is a bus error on a source read. 0 - No error 1 - Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 DBE	Destination Bus Error Indicates whether the last recorded error is a bus error on a destination write. 0 - No error 1 - Error

5.3.5.4 Channel Interrupt Status (CH0_INT - CH63_INT)

Indicates the presence of an interrupt request for the channel.

Depending on the appropriate field setting in TCDs, the eDMA engine generates an interrupt on data transfer completion. The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, you must clear the appropriate bit to negate the interrupt request.

Offset

For n = 0 to 63:

Register	Offset
CHn_INT	8h + (n × 1000h)

Fields

Field	Description
31-1 —	Reserved
0 INT	Interrupt Request Indicates whether the interrupt request for the corresponding channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field behaves differently for register reads and writes. When reading 0 - Cleared 1 - Active When writing 0 - No effect 1 - Clear the flag

5.3.5.5 Channel System Bus (CH0_SBR - CH63_SBR)

Places identification and protection information on the system bus interface for eDMA.

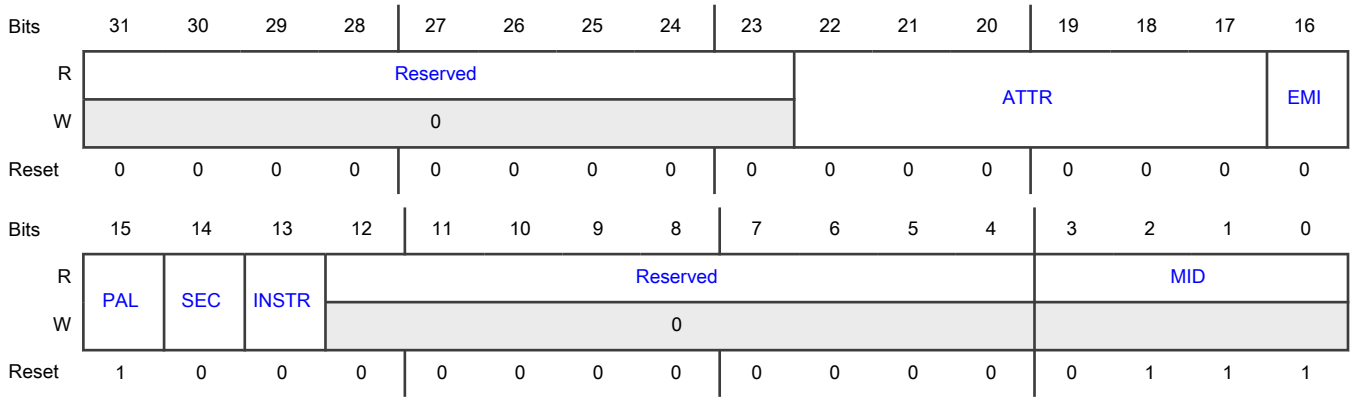
ATTR outputs the register values onto the system bus interface for further decoding by the security system.

Offset

For n = 0 to 63:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Diagram



Fields

Field	Description
31-23 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
22-17 ATTR	Attribute Output Specifies the DMA's system bus attribute output value.
16 EMI	Enable Master ID Replication Enables master ID replication. This field allows eDMA to use the same protection level and system bus ID of the master programming eDMA's TCD. When you enable this field, eDMA uses the master ID and protection level stored in SBR registers instead of eDMA's default values. When a master, for example a core, programs a TCD, its master ID is captured when TCD*n*_CSR control is written. The protection and security levels are captured when CH*n* _SBR security attributes are written. A scatter/gather operation does not affect Channel System Bus (CH0_SBR - CH63_SBR). You can write to this field only if CSR[GMRC] = 1; otherwise, this field is forced to 0. **NOTE** If you disable master ID replication, the nonsecure, privileged protection level for DMA transfers is used. 0 - Disable 1 - Enable
15 PAL	Privileged Access Level DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH *n* _SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - User protection level for DMA transfers 1 - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other master writing the channel's system bus register; CH *n* _SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0 - Nonsecure protection level for DMA transfers 1 - Secure protection level for DMA transfers
13 INSTR	Instruction/Data Access DMA's transactions type on the system bus when the channel is active. 0 - Data access for DMA transfers

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Instruction access for DMA transfers
12-4 —	Reserved
3-0 MID	Master ID Indicates the DMA master ID on the system bus when the channel is active. **NOTE** When you enable EMI, the ID captured in this field reflects the master ID of the core or another master writing the channel's control attributes (TCD Control and Status (TCD0_CSR - TCD63_CSR)).

5.3.5.6 Channel Priority (CH0_PRI - CH63_PRI)

Defines the unique priorities associated with each channel within the same channel group.

Channel grouping is programmed through the group priority registers, CH*n*_GRPRI. The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Program the channel priorities with unique values; otherwise, channel numbers with the same nonzero value are selected based on the higher channel number having the higher priority. If more than one channel in a group has an arbitration priority level value of 0, then CSR[ERCA] is used to determine the arbitration scheme for all channels with APL = 0 within a group. When round-robin channel arbitration is enabled (CSR[ERCA] = 1), all channels with APL = 0 within a group use a round-robin arbitration scheme that rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group. When fixed-priority channel arbitration is enabled (CSR[ERCA] = 0), channels with APL = 0 are selected based on the higher channel number having higher priority.

Offset

For n = 0 to 63:

Register	Offset
CHn_PRI	10h + (n × 1000h)

1. See bit field description.

Fields

Field	Description
31 ECP	Enable Channel Preemption Specifies whether the channel can be temporarily suspended by a service request from a higher priority channel. 0 - Do not suspend 1 - Suspend temporarily
30 DPA	Disable Preempt Ability Specifies whether the channel can suspend any other channel, regardless of channel priority. 0 - Can suspend a lower-priority channel 1 - Cannot suspend any other channel
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Specifies the channel priority level for arbitration within the assigned arbitration group.

5.3.5.7 Channel Multiplexor Configuration (CH0_MUX - CH63_MUX)

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by another channel, a mux configuration of 0 (SRC = 0) will be written.

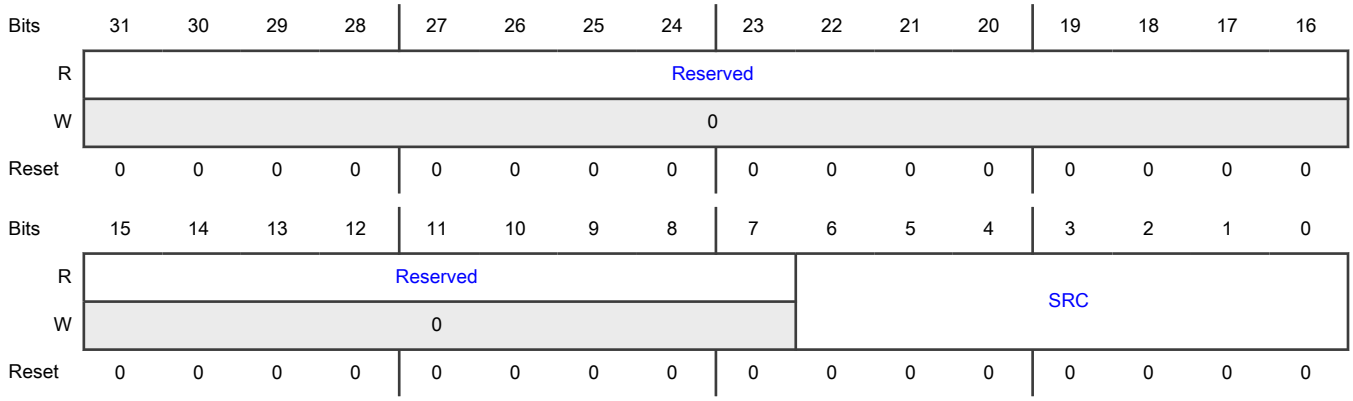
All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Offset

For n = 0 to 63:

Register	Offset
CHn_MUX	14h + (n × 1000h)

Diagram



Fields

Field	Description
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

5.3.5.8 Memory Attributes (CH0_MATTR - CH63_MATTR)

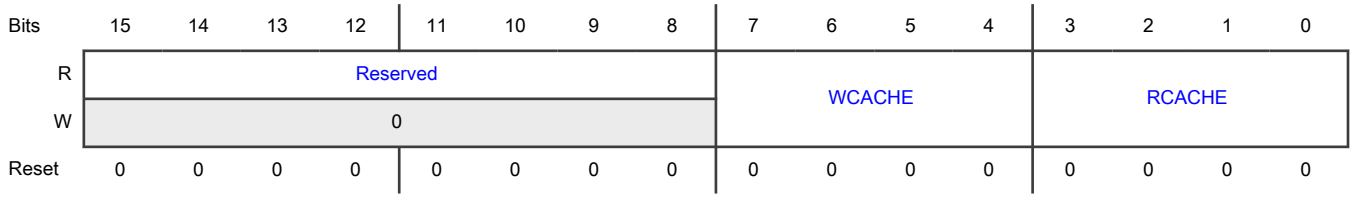
Defines a set of transaction attributes for memory and peripherals. The cache attributes specify how a transaction progresses through the system and how they are handled.

Offset

For n = 0 to 63:

Register	Offset
CHn_MATTR	18h + (n × 1000h)

Diagram



Fields

Field	Description
15-8 —	Reserved
7-4 WCACHE	Write Cache Attributes Defines the attributes associated with a write transaction. • [7] 0b: no write allocate; 1b: write-allocate • [6] 0b: no read allocate; 1b: read-allocate • [5] 0b: non-cacheable; 1b: cacheable • [4] 0b: non-bufferable; 1b: bufferable
3-0 RCACHE	Read Cache Attributes Defines the attributes associated with a read transaction. • [3] 0b: no write allocate; 1b: write-allocate • [2] 0b: no read allocate; 1b: read-allocate • [1] 0b: non-cacheable; 1b: cacheable • [0] 0b: non-bufferable; 1b: bufferable

5.3.5.9 TCD Source Address (TCD0_SADDR - TCD63_SADDR)

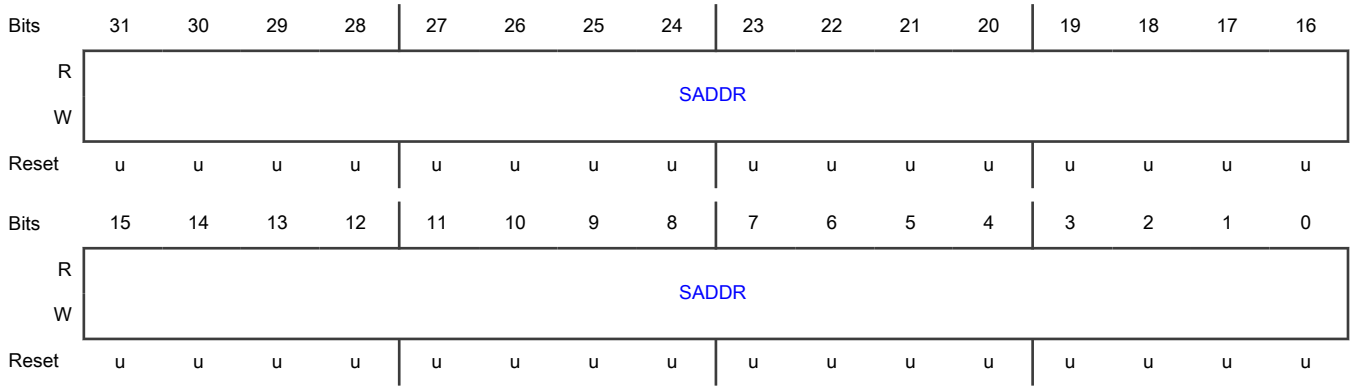
Contains the address for the read transactions.

Offset

For n = 0 to 63:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Diagram



Fields

Field	Description
31-0 SADDR	Source Address Specifies the memory address pointing to the source data.

5.3.5.10 TCD Signed Source Address Offset (TCD0_SOFF - TCD63_SOFF)

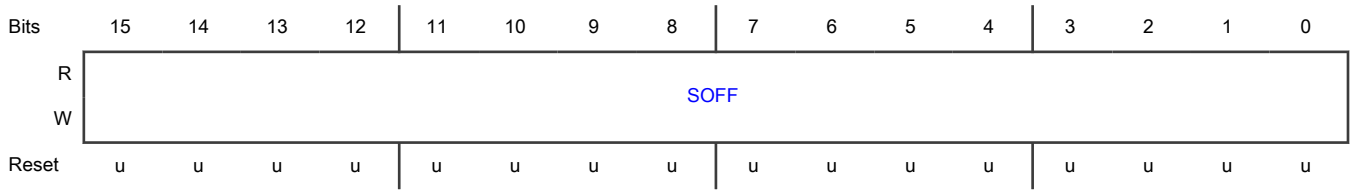
Specifies the sign-extended value added to TCD0_SADDR[SADDR] after each read transaction.

Offset

For n = 0 to 63:

Register	Offset
TCDn_SOFF	24h + (n × 1000h)

Diagram



Fields

Field	Description
15-0 SOFF	Source Address Signed Offset Specifies the sign-extended offset that applies to the current source address to form the next-state value as each source read completes.

5.3.5.11 TCD Transfer Attributes (TCD0_ATTR - TCD63_ATTR)

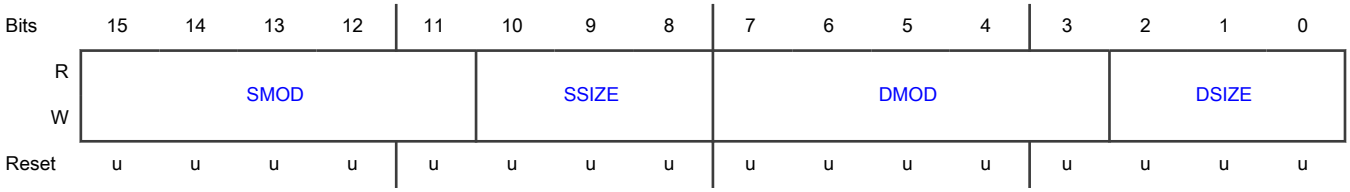
Specifies the size and option modulo addressing information for source and destination addresses.

Offset

For n = 0 to 63:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Diagram



Fields

Field	Description
15-11 SMOD	Source Address Modulo Specifies whether the source address modulo feature is enabled for any nonzero value [1-31]. This field defines a specific address range specified to be the value after you perform the TCD0_SADDR[SADDR] + TCD0_SOFF[SOFF] calculation on the original register value. Writing 1 to this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue must start at a 0-modulo-size address and you must set this field to an appropriate value for the queue, freezing the desired number of the upper address bits. The value that you program for this field specifies the number of lower address bits it allows to change. For a circular queue application, TCD0_SOFF[SOFF] is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000 - Disable 0_0001 - Enable
10-8 SSIZE	Source Data Transfer Size Specifies the size of each read transaction on the system bus. **NOTE** NBYTES must be an integer multiple of the source transfer size. 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - 16-byte

Table continues on the next page...

Table continued from the previous page...

Field	Description
	101 - 32-byte 110 - 64-byte 111 - 128-byte
7-3 DMOD	Destination Address Modulo Specifies the destination address modulo. See SMOD for more information.
2-0 DSIZE	Destination Data Transfer Size Specifies the size of each write transaction on the system bus. **NOTE** NBYTES must be an integer multiple of the destination transfer size. 000 - 8-bit 001 - 16-bit 010 - 32-bit 011 - 64-bit 100 - 16-byte 101 - 32-byte 110 - 64-byte 111 - 128-byte

5.3.5.12 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO)

Defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCD Source Address (TCD0_SADDR - TCD63_SADDR)) or destination address (TCD Destination Address (TCD0_DADDR - TCD63_DADDR)) upon minor loop completion, which happens when the channel has finished the service request and has transferred NBYTES. When you enable minor loop offsets, the minor loop offset value (MLOFF) is added to the final source address (TCD*n*_SADDR), to the final destination address (TCD*n*_DADDR), or to both prior to the address being written back to TCD. If the major loop is complete, the minor loop offset is ignored, and the major loop address offsets (TCD*n*_SLAST_SDA and TCD*n*_DLAST_SGA) are used to compute the next TCD*n*_SADDR and TCD*n*_DADDR values.

When you enable minor loop mapping (SMLOE or DMLOE = 1), TCD*n* word2 is redefined. A portion of TCD*n* word2 is used to specify following fields:

- A source enable field (SMLOE) must be applied to the source address (TCD*n*_SADDR) after minor loop completion, to specify the minor loop offset.
- A destination enable field (DMLOE) must be applied to the destination address (TCD*n*_DADDR) after minor loop completion, to specify the minor loop offset.
- A sign-extended minor loop offset value (MLOFF)

The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either of the two minor loop offsets are enabled (SMLOE or DMLOE = 1), NBYTES is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE and DMLOE = 0), NBYTES is a 30-bit vector.

One of the two register profiles (TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO) or TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)) defines the number of bytes to transfer per request. You can select the register depending on whether the source or destination minor loop mapping is enabled.

TCD word 2 is defined when SMLOE and DMLOE are 0. If either SMLOE or DMLOE is 1, see the description of TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)).

NOTE

NBYTES must be an integer multiple of the source transfer size and the destination transfer size.

Offset

For n = 0 to 63:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address (SADDR) after minor loop completion. 0 - Do not apply 1 - Apply
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address (DADDR) after minor loop completion. 0 - Do not apply 1 - Apply

Table continues on the next page...

Table continued from the previous page...

Field	Description
29-0 NBYTES	Number of Bytes to Transfer Per Service Request Specifies the number of bytes to be transferred for each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the byte transfer count is transferred. This is normally an indivisible operation and you cannot halt the operation. However, you can stall the operation using the bandwidth control field, or through preemption. After the byte count is exhausted, SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is completed, additional processing is performed.

5.3.5.13 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES)

Defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCD Source Address (TCD0_SADDR - TCD63_SADDR)) or destination address (TCD Destination Address (TCD0_DADDR - TCD63_DADDR)) upon minor loop completion, which happens when the channel has finished the service request and has transferred NBYTES. You can enable minor loop offsets by either writing 1 to SMLOE or to DMLOE.

SMLOE specifies MLOFF that must be applied to the source address (TCD*n*_SADDR) upon minor loop completion. DMLOE specifies MLOFF that must be applied to the destination address (TCD*n*_DADDR) upon minor loop completion. If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCD*n*_SLAST_SDA and TCD*n*_DLAST_SGA) are used to compute the next TCD*n*_SADDR and TCD*n*_DADDR values.

When the minor loop offset overlay is enabled (either SMLOE or DMLOE = 1), TCD*n*_NBYTES_* is redefined. A portion of TCD*n*_NBYTES_* is used to specify the sign extended minor loop offset value (MLOFF). The same offset value (MLOFF) is used for both source and destination minor loop offsets. When enabled, the minor loop offset must be aligned to the transfer size of the source or destination it is associated with. When either of the two minor loop offsets are enabled (SMLOE or DMLOE is 1), NBYTES is reduced to 10 bits. When both minor loop offsets are disabled (SMLOE and DMLOE are 0), NBYTES is a 30-bit vector.

One of the two register profiles (TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES) or TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO)), defines the number of bytes to transfer per request. You can use the register depending on whether the source or destination minor loop mapping is enabled.

TCD*n*_NBYTES is defined when either of the two minor loop offsets are enabled (SMLOE or DMLOE = 1); see TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD63_NBYTES_MLOFFYES) for more information. If SMLOE and DMLOE = 0, see TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD63_NBYTES_MLOFFNO).

NOTE

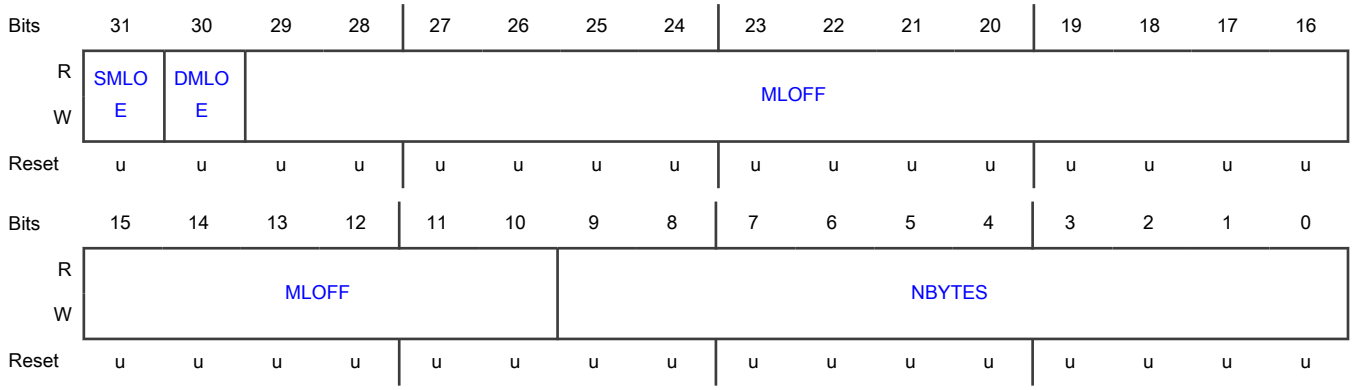
NBYTES must be an integer multiple of the source transfer size and the destination transfer size.

Offset

For n = 0 to 63:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Diagram



Fields

Field	Description
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address (SADDR) after minor loop completion. 0 - Do not apply 1 - Apply
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address (DADDR) after minor loop completion. 0 - Do not apply 1 - Apply
29-10 MLOFF	Minor Loop Offset Represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes, if SMLOE or DMLOE = 1.
9-0 NBYTES	Number of Bytes to Transfer Per Service Request Specifies the number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes are performed until the minor byte transfer count is transferred. This is an indivisible operation and you cannot halt the operation. However, you can stall the operation by using the bandwidth control field, or through preemption. After the minor count is exhausted, SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed.

5.3.5.14 TCD Last Source Address Adjustment and Store DADDR Address (TCD0_SLAST_SDA - TCD63_SLAST_SDA)

Specifies the value added to the source address after the major loop completes.

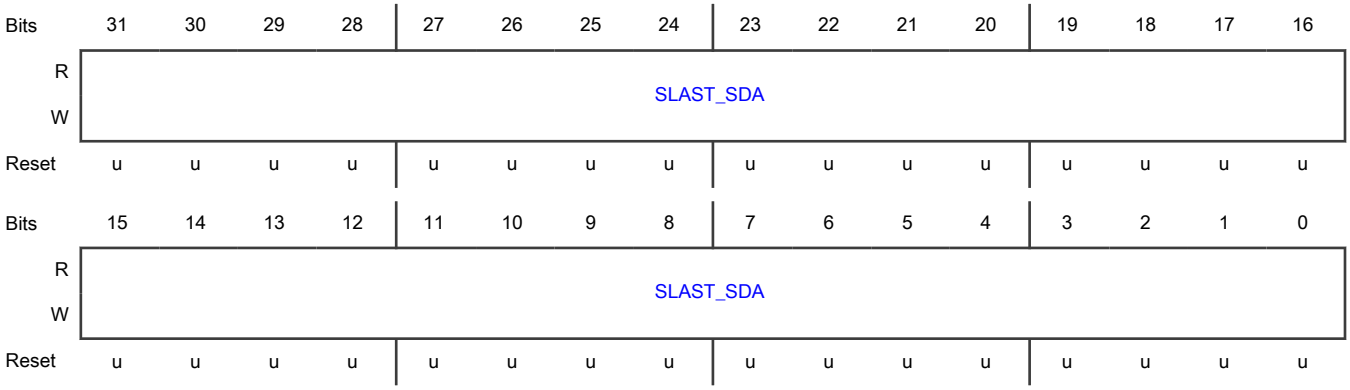
Provides a pointer to memory for storing the final destination address when the store destination address option is enabled.

Offset

For n = 0 to 63:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Diagram



Fields

Field	Description
31-0 SLAST_SDA	Last Source Address Adjustment and Store DADDR Address Specifies the last source address adjustment or the system memory address for the destination address (DADDR) storage. When TCD0_CSR[ESDA] = 0, then: • Adjustment value is added to the source address after the completion of the major iteration count. You can use this value to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses the two's-complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is stored in system memory. By saving the final destination address in system memory through the ESDA feature, you can compute the size of a variable destination data buffer by subtracting the beginning DADDR from the final saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. • The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because eDMA forces the lower two address bits of SLAST_SDA to 0 when ESDA is enabled. eDMA performs this write operation when the major loop is complete; that is, when the major iteration count (CITER) decrements to 0.

5.3.5.15 TCD Destination Address (TCD0_DADDR - TCD63_DADDR)

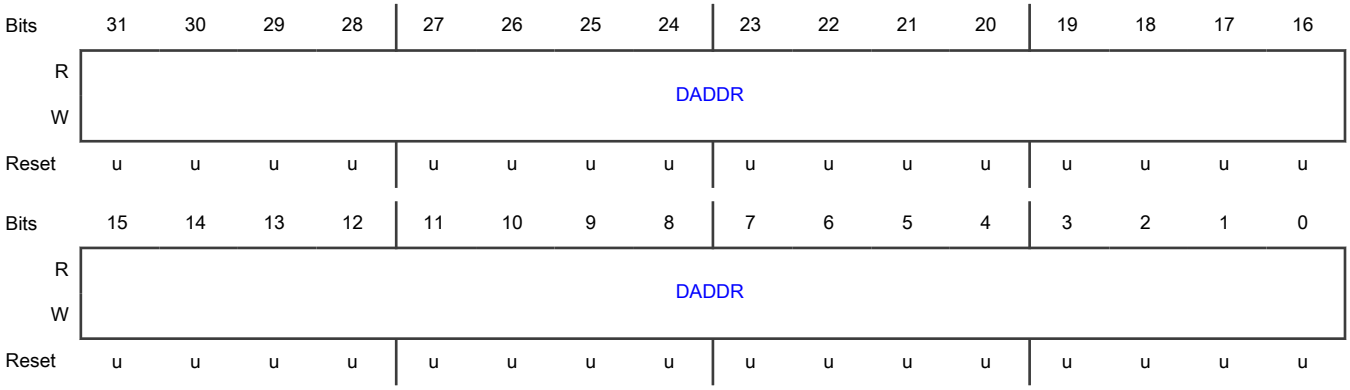
Specifies the address for write transactions.

Offset

For n = 0 to 63:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Diagram



Fields

Field	Description
31-0 DADDR	Destination Address Specifies the memory address pointing to the destination data.

5.3.5.16 TCD Signed Destination Address Offset (TCD0_DOFF - TCD63_DOFF)

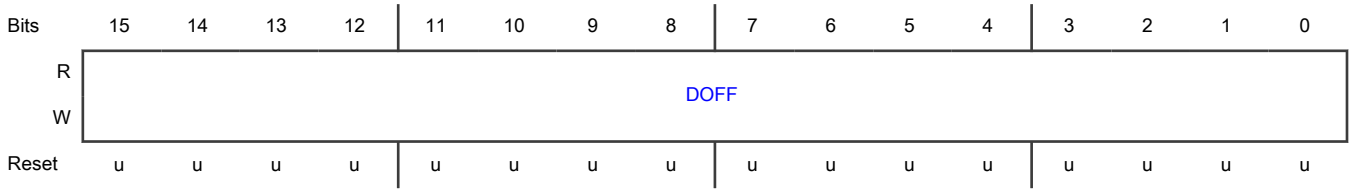
Specifies the sign-extended value added to TCD0_DADDR[DADDR] after each write transaction.

Offset

For n = 0 to 63:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Diagram



Fields

Field	Description
15-0 DOFF	Destination Address Signed Offset Specifies the sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

5.3.5.17 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD63_CITER_ELINKNO)

Allows channel-to-channel linking and specifies the current major iteration count.

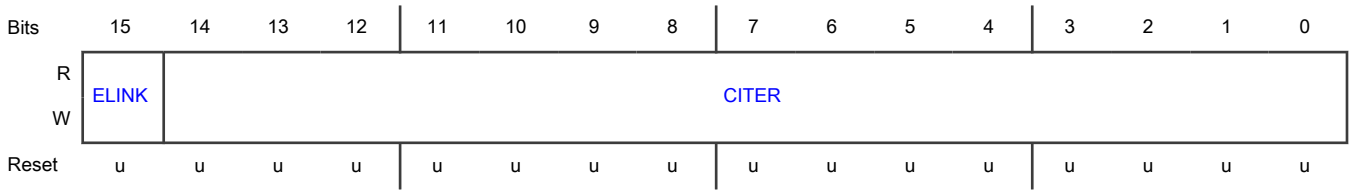
If TCD*n*_CITER[ELINK] is 0, the CITER field is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Channel-to-Channel Linking after Minor Loop Completion Enables linking to another channel as the channel completes the minor loop, defined by LINKCH. The link target channel initiates a channel service request through an internal mechanism that writes 1 to TCD0_CSR[START] of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported. 0 - Disable 1 - Enable
14-0 CITER	Current Major Iteration Count Represents the current major loop count (9-bit (ELINK = 1) or 15-bit (ELINK = 0)) for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations, for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading CITER from BITER. **NOTE** • When you initially load CITER, you must set this to the same value as that contained in BITER for proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). • If the channel is configured to execute a single service request, the initial values of the BITER and CITER fields must be 0001h.

5.3.5.18 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD63_CITER_ELINKYES)

Allows channel-to-channel linking and specifies the minor loop link channel number and current major iteration count.

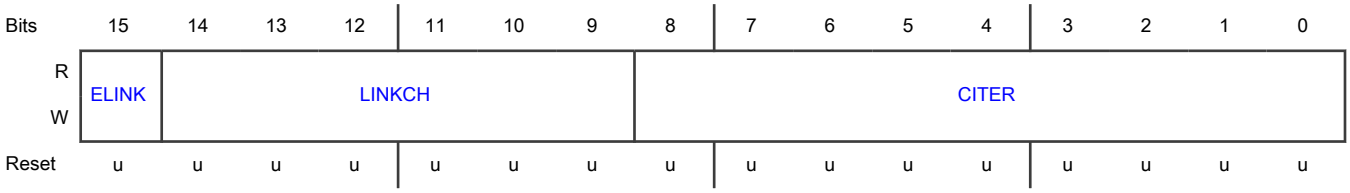
If TCD*n*_CITER[ELINK] is 1, the CITER field is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Enable Channel-to-Channel Linking on Minor-Loop Complete Enables linking to another channel as the channel completes the minor loop, defined by LINKCH. When enabled, an internal mechanism sets TCD0_CSR[START] of the specified channel (LINKCH) after minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking. **NOTE** This field must be equal to BITER[ELINK]; otherwise, a configuration error is reported. 0 - Disable 1 - Enable
14-9 LINKCH	Minor Loop Link Channel Number Specifies the minor loop link channel number. When channel-to-channel linking is enabled (ELINK = 1), after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by this field by writing 1 to that channel's TCD0_CSR[START].
8-0 CITER	Current Major Iteration Count Represents the current major loop count (9-bit (ELINK = 1) or 15-bit (ELINK = 0)) for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations (for example, final source and destination address calculations, optionally generating an interrupt to signal channel completion before reloading CITER from BITER). **NOTE** • When you initially load CITER, you must set this to the same value as that contained in BITER for proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). • If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0001h.

5.3.5.19 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD63_DLAST_SGA)

Specifies the value added to the destination address when the major loop is complete.

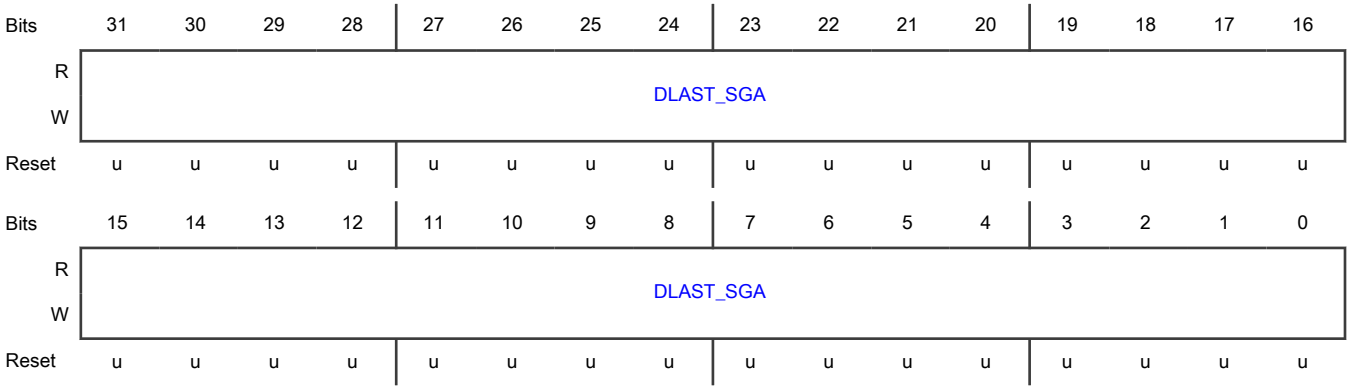
Provides a pointer to memory for fetching a TCD to reprogram the channel, if the scatter/gather option is enabled.

Offset

For n = 0 to 63:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Diagram



Fields

Field	Description
31-0 DLAST_SGA	Final Destination Address Adjustment and Scatter/Gather Address Specifies the destination final address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather). If TCD0_CSR[ESG] = 0, then: • Adjustment value is added to the destination address at the completion of the major iteration count. You can use this value to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses the two's-complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo-32-byte region containing the next TCD to be loaded into this channel, which is reloaded after the major iteration count completes. The scatter/gather address must be 0-modulo-32-byte, otherwise a configuration error is reported.

5.3.5.20 TCD Control and Status (TCD0_CSR - TCD63_CSR)

Provides status and control of TCD. It also enables optional features.

Offset

For n = 0 to 63:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Description
15-14 TMC	Transfer Mode Control Specifies the direction in which DMA transfers data. For normal data movement operation, Read/Write mode reads from the source address and writes to the destination address. For Read-Only mode, data is read from the source address and discarded. You can use Read-Only mode for calculating the CRC values on a block of memory. For Write-Only mode, the source address is read once and all subsequent writes to the destination use the data from the first and only read. You may use Write-Only mode to initialize a block of memory to a specific value. 00 - Read/Write 01 - Read-Only 10 - Write-Only 11 - Reserved
13-8 MAJORLINKCH	Major Loop Link Channel Number Specifies the major loop link channel number. If MAJORELINK = 0, you cannot perform any channel-to-channel linking, or chaining after the major loop counter is exhausted. If MAJORELINK is not 0, after the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by writing 1 to that channel's START.
7 ESDA	Enable Store Destination Address Enables the store destination address to system memory operation. This field enables writing the destination address (DADDR) to the address pointed to by TCD0_SLAST_SDA[SLAST_SDA] as the channel completes the major loop through either CITER decrementing to zero or, by receiving an enabled end-of-packet signal. When SDA = 1, TCD0_SLAST_SDA[SLAST_SDA] contains the write pointer instead of the final source address offset. The value written to the system memory specified by SLAST_SDA has the following possibilities: • For a normal successful transfer, the value is the last DADDR value prior to the DLAST_SGA offset that an enabled scatter/gather operation applies or overwrites. You can also compute this value using the TCD information. • For a transfer that EOP ends early, the value written to the memory is the last destination address written with the last good read data before EOP was issued.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Disable 1 - Enable
6 EEOP	Enable End-of-Packet Processing Enables the end-of-packet hardware input signal. When this field is 1, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel and to treat the shutdown as major loop completed. Additionally, the end-of-packet signal from supported peripherals is accepted. If this field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA saved destination address) minus the software-saved initial address (DADDR) reflects the total amount of data transferred. For this calculation, the destination offset, DOFF, must match the natural boundary of the destination transfer size, DSIZE. For example, if DSIZE = 32-bit, DOFF = 4. 0 - Disable 1 - Enable
5 MAJORELINK	Enable Channel-to-Channel Linking on Major Loop Complete Enables linking to another channel (as the channel completes the major loop), defined by MAJORLINKCH. The link target channel initiates a channel service request through an internal mechanism that writes 1 to START of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to become 0 when you write to it while TCD*n*_CSR[DONE] is 1. Write to this field and MAJORLINKCH at the same time when attempting a dynamic channel link. 0 - Disable 1 - Enable
4 ESG	Enable Scatter/Gather Processing Specifies the current channel's TCD format. This field enables scatter/gather processing in the current channel as the channel completes the major loop. If this field is 1, the eDMA engine uses TCD0_DLAST_SGA[DLAST_SGA] as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as TCD into the local memory. TCD0_DLAST_SGA[DLAST_SGA] provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution. **NOTE** Any changes made to this field while the channel is executing are not recognized until the next time the channel is activated. 0 - Normal format 1 - Scatter/gather format
3	Disable Request

Table continues on the next page...

Table continued from the previous page...

Field	Description
DREQ	Clears CH0_CSR[ERQ] after major loop completion, thus disabling hardware service requests. If this field is 0, no operation is carried out. The channel's ERQ {H,L} bit is not affected. If this field is 1, the channel's ERQ {H,L} bit becomes 0 when the major loop is complete. Also, the eDMA hardware automatically clears the corresponding ERQ field when the current major iteration count reaches 0. 0 - No operation 1 - Clear ERQ
2 INTHALF	Interrupt Enable after Major Counter is Half Complete Enables half-point interrupt. If this field is 1, the channel generates an interrupt request by writing 1 to the appropriate bit in INT when CITER reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use this field. Use INTMAJOR instead. 0 - Disable 1 - Enable
1 INTMAJOR	Interrupt Enable after Major Iteration Count Completion Enables end-of-major loop interrupt. If this field is 1, the channel generates an interrupt request by writing 1 to the appropriate bit in INT when CITER reaches zero. 0 - Disable 1 - Enable
0 START	Channel Start Specifies whether the channel is explicitly started through a software-initiated service request. If this field is 1, it indicates that the channel is requesting service. The eDMA hardware automatically writes 0 to this field after the channel begins execution. 0 - Do not start 1 - Start

5.3.5.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD63_BITER_ELINKNO)

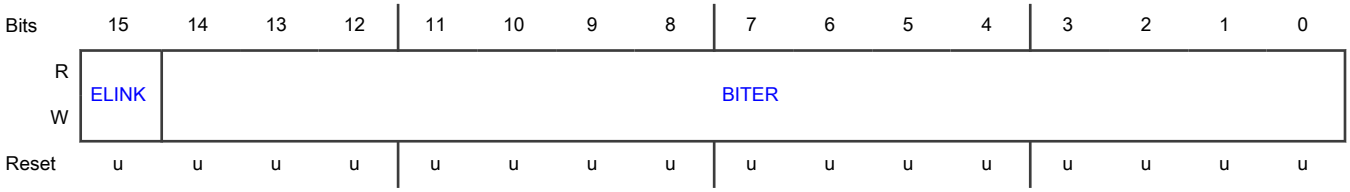
Allows channel-to-channel linking and specifies the major iteration count. If TCD*n*_BITER[ELINK] = 0, TCD*n*_BITER is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Channel-to-Channel Linking after Minor Loop Completion Enables linking to another channel (after the channel completes the minor loop), defined by BITER[LINKCH]. The link target channel initiates a channel service request through an internal mechanism that writes 1 to TCD0_CSR[START] of the specified channel. If you disable the channel linking, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking. **NOTE** When you load TCD, this field must be set equal to the corresponding CITER; otherwise, a configuration error is reported. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. 0 - Disable 1 - Enable
14-0 BITER	Starting Major Iteration Count Specifies the starting major iteration count. When you first load TCD, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. **NOTE** When you load TCD, this field must be set equal to the corresponding CITER field for the proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). When the major iteration count is exhausted, the contents of this field are reloaded into CITER. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0001h.

5.3.5.22 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD63_BITER_ELINKYES)

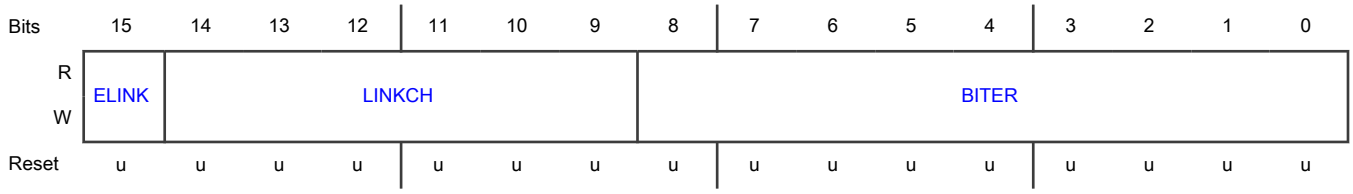
Allows channel-to-channel linking and specifies the link channel number and the starting major iteration count. If TCD*n*_BITER[ELINK] = 1, TCD*n*_BITER is defined as explained in this register.

Offset

For n = 0 to 63:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Diagram



Fields

Field	Description
15 ELINK	Channel-to-Channel Linking after Minor Loop Completion Enables linking to another channel (as the channel completes the minor loop), defined by BITER[LINKCH]. The link target channel initiates a channel service request through an internal mechanism that writes 1 to TCD0_CSR[START] of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed to support MAJORELINK channel linking. **NOTE** When you load TCD, this field must be equal to the corresponding CITER; otherwise, a configuration error is reported. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. 0 - Disable 1 - Enable
14-9 LINKCH	Link Channel Number Specifies the link channel number. If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field, by writing 1 to that channel's TCD0_CSR[START].

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When the major iteration count is exhausted, the contents of this field are reloaded into CITER.
8-0 BITER	Starting Major Iteration Count Specifies the starting major iteration count. When you load TCD, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be equal to the value in the CITER field. When the major iteration count is exhausted, the contents of this field are reloaded into CITER. **NOTE** When you load TCD, this field must be set equal to the corresponding CITER for proper operation of the optional interrupt (see TCD0_CSR[INTHALF]). When the major iteration count is exhausted, the contents of this field are reloaded into CITER. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0001h.

5.4 Functional description

The eDMA operation is described in the following subsections.

5.4.1 Modes of operation

Table 21. Modes of operation

Mode	Description
Normal	eDMA transfers data between a source and destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in TCD. The minor loop is the sequence of read/write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode through CSR: • When you write 0 to CSR[EDBG], eDMA continues to operate. • When you write 1 to CSR[EDBG], eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operating until the channel retires.

5.4.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in Figure 11, the first segment involves channel activation. This figure shows the assertion of the eDMA peripheral request signal to request service for channel *n*. When you activate the channel, TCD0_CSR[START] follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, and then into the program model and channel arbitration. In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD

memory is accessed, and the required descriptor is read from the local memory and loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64-bit wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

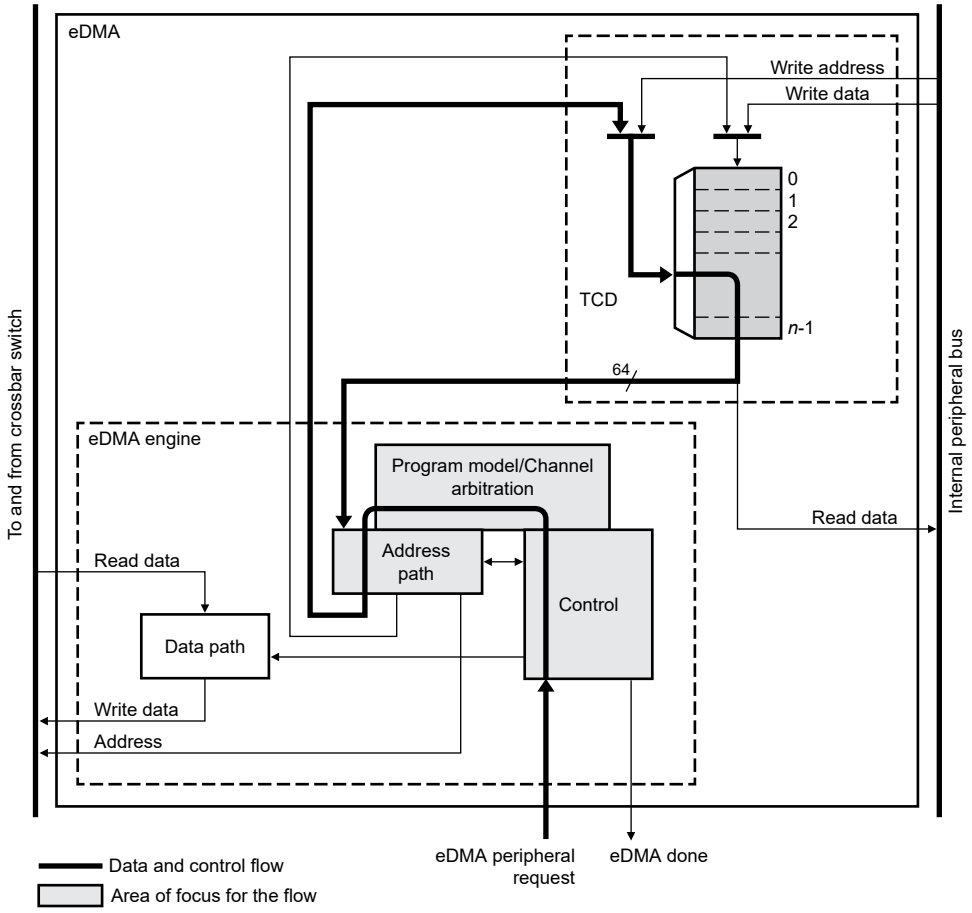


Figure 11. eDMA operation, part 1

Figure 12 illustrates the second part of the data flow to perform the data movement, from the source read to the destination write. The modules associated with the data flow include the address path, data path, and control block.

The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read or destination write processing continues until the byte count, NBYTES, is transferred.

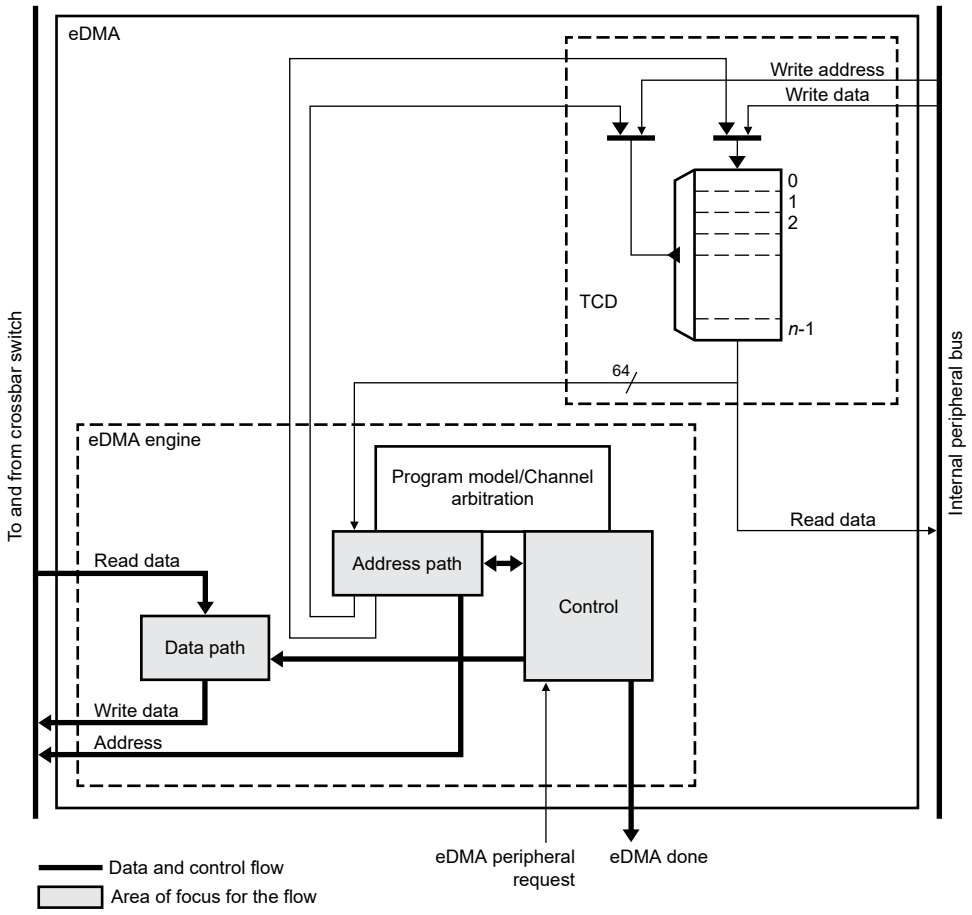

Figure 12. eDMA operation, part 2

After NBYTES of data is moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to some fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of BITER into CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). Updates to the TCD memory and the assertion of an interrupt request are shown in Figure 13.

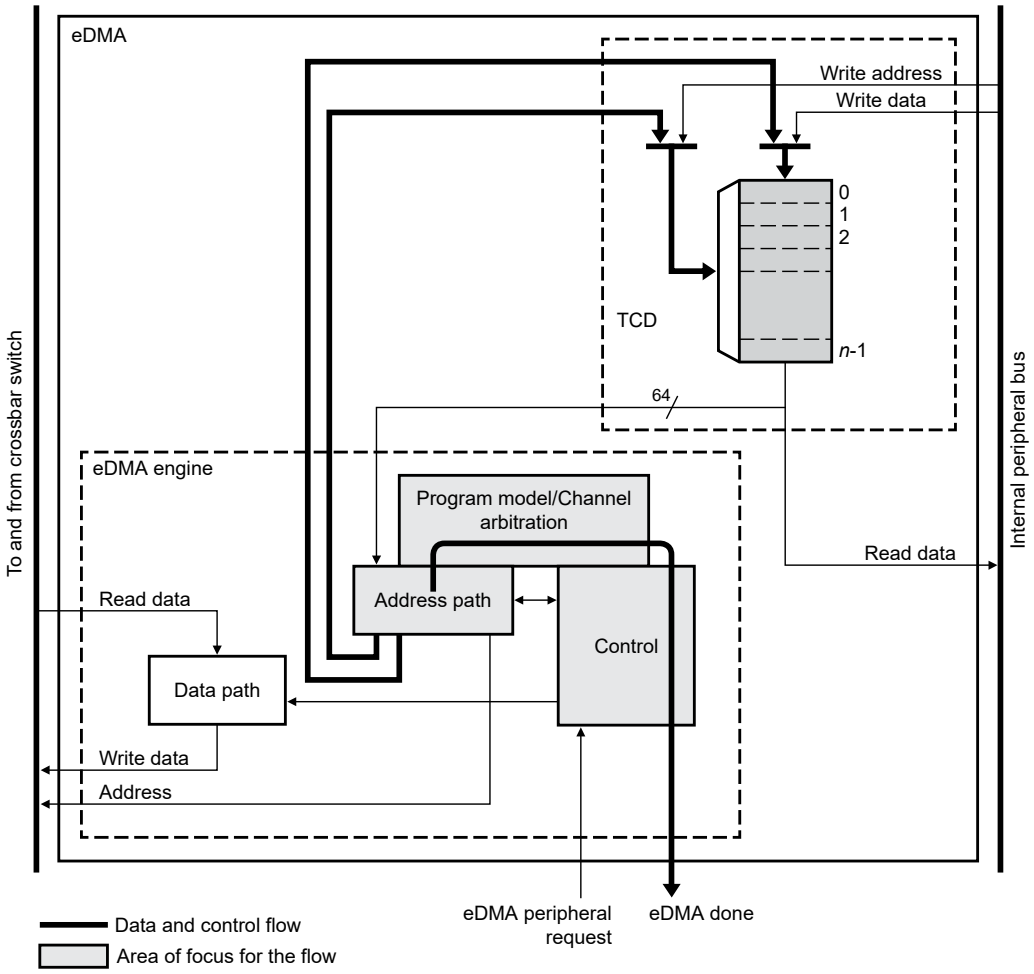

Figure 13. eDMA operation, part 3

5.4.3 Fault reporting and handling

Channel errors are reported in CH0_ES and can be caused by either of the following:

- A configuration error, which is an illegal setting in TCD
- An active channel canceled via a "cancel transfer with error" software request
- An error termination to a bus controller read or write cycle

eDMA reports a configuration error when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represents an inconsistent state. Following are the possible causes of a configuration error:

- The addresses and offsets are aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes are configured to the natural boundary of the programmed transfer size respectively.
- If you enable a scatter/gather operation after the channel completion, a configuration error is reported (if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary).
- If you enable the minor loop channel linking after the channel completion, a configuration error is reported when the link is attempted (if TCD*n*_CITER[ELINK] is not equal to TCD*n*_BITER[ELINK]).

NOTE

To aid in debug, write 1 to CSR[HAE]. After an error condition occurs, eDMA is halted after the error is recorded. eDMA remains halted and does not process any channel service requests. After the error is fixed, you can enable the eDMA by writing 0 to CSR[HALT].

If enabled, all configuration error conditions (except the scatter/gather and minor-loop link errors) report as the channel activates and asserts an error interrupt request, in case it is enabled. A scatter/gather configuration error is reported when the scatter/gather operation begins on major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

When a system bus read or write is terminated with an error, the data transfer is stopped, and the appropriate bus error flag is set. In this case, the eDMA engine updates the state of the channel's TCD with the current source address, destination address, and the current iteration count at the point of the fault. When a system bus error occurs, the channel terminates the processing. Due to the pipeline effect, when eDMA receives a bus error, it does not abort the transfer in progress. Bus errors are imprecise. The source and destination addresses stored in TCD, after a bus error occurs, may not be the addresses that caused the error.

You may cancel a transfer by using CSR[CX]. When a cancel transfer request is recognized, the DMA engine stops processing the channel. Transactions in flight are allowed to complete. If you cancel a transfer on the last sequence of a major or minor loop, the canceled request is discarded, and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except that ES is updated with the canceled channel number, and CSR[ECX] becomes 1. TCD of a canceled channel contains the source and destination addresses of the last transfer saved in TCD. If you want to restart the channel, you must reinitialize TCD because the aforementioned fields no longer represent the original parameters. When the error cancel transfer mechanism cancels a transfer, the channel number is loaded into ES[ERRCHN], and ES[ECX] and ES[VLD] become 1. In addition, it can generate an error interrupt if enabled.

NOTE

The cancel transfer request allows you to stop a large data transfer when you no longer need the full data transfer. CSR[CX] does not abort the channel. It stops the transferring of data and then retires the channel through its normal shutdown sequence. The cancel transfer is an imprecise operation. You must handle the context of the cancel. Depending on whether an interrupt is required or not, you must enable or disable the interrupt before the cancel request. You must clean up TCD because the complete transfer did not occur.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states, and the transaction to the system bus has a pipeline effect), and the appropriate channel field in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into ES. When an error is detected the following major loop indicators remain unaffected:

- Setting of CH0_CSR[DONE]
- Possible assertion of an interrupt request

After the error status is updated, the eDMA engine continues to operate by servicing the next appropriate channel. A channel that experiences an error condition is automatically disabled from hardware service requests. If an error terminates a channel, CH0_CSR[ERQ] becomes 0, preventing continuous errors from a peripheral's service request.

The fields in ES represent error indicators that are sticky and cannot be cleared. They show the last recorded error until DMA is reset. You can use ES[VLD] to determine whether a new error condition exists. ES[VLD] is the logical OR of each channel's CH0_ES[ERR]. After you resolve all the errors and clear all the error interrupt bits, ES[VLD] becomes 0, but the cause of the last error is still indicated.

5.4.4 Channel preemption

eDMA uses a priority vector value to determine the highest-priority channel requesting service.

The priority vector is a combination of:

- The channel's group priority, CH0_GRPRI[GRPRI]
- The channel's priority level, CH0_PRI[APL]

- The channel number

Priority vector = ((CH*n*_GRPRI << 8) + (CH*n*_PRI[APL] << 5) + CHn_*)

A channel requesting service with the highest-priority vector value receives the next execution slot, which is available:

- Immediately if eDMA is idle.
- When an active channel retires.
- When valid preemption conditions exist.

NOTE

Preemption is strictly priority based and is not bound by a specific group number as defined by CH*n*_GRPRI.

Write 1 to CH0_PRI[ECP] to enable channel preemption on a per-channel basis. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel completes all its minor loop data transfers, the preempted channel restores and resumes execution. After the restored channel completes one read or write sequence, it is again eligible for preemption. If any higher priority channel requests service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot preempt again.

You can disable the channel's ability to preempt another channel by writing 1 to CH0_PRI[DPA]. When you disable a channel's preempt ability, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower priority channel's CH*n*_PRI[ECP] being 1. This allows a pool of low priority, large data-moving channels to define. You can configure the low-priority channels not to preempt each other, therefore preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel. When you enable Round-Robin Channel Arbitration mode (CSR[ERCA] = 1), any channel with a priority level equal to zero (CH*n*_PRI[APL] = 0), has the preemption disabled and does not preempt another channel.

5.4.5 Clocking

This module has no clocking considerations.

5.4.6 Interrupts

This module has no interrupts.

5.5 External signals

This module has no external signals.

5.6 Initialization

The following sections discuss eDMA initialization and programming considerations.

5.6.1 Initialization procedure

Table 22. Initialization steps

Step	Purpose	Programming	Notes
1	Specify the configuration other than default.	Write to CSR.	—
2	Specify the priority levels to channel or group for a configuration other than default.	Write the channel priority levels to CH0_PRI and group priority levels to CH0_GRPRI.	—
3	Enable error interrupts if needed.	Write 1 to CH0_CSR[EEI].	—

Table continues on the next page...

Table 22. Initialization steps (continued)

Step	Purpose	Programming	Notes
4	Request service for each channel.	Write the 32-byte TCD for each channel.	—
5	Enable hardware service requests.	Write 1 to CH0_CSR[ERQ].	—
6	Request a channel service through software.	Write 1 to TCD0_CSR[START].	—
7	Request a channel service through hardware.	Target device asserts its eDMA peripheral request signal.	—

5.6.2 Channel selection

After any of the channel requests service, select a channel for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 23, for the selected channel into its internal address path module.

As TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, as defined by TCD0_SADDR, to the destination, as defined by TCD0_DADDR, continue until the number of bytes specified by TCD*n*_NBYTES are transferred.

When the transfer is complete, write the eDMA engine's local TCD*n*_SADDR, TCD*n*_DADDR, and TCD*n*_CITER back to the main TCD memory and perform any minor loop channel linking, if enabled. If the major loop is exhausted, further postprocessing is performed, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 23. TCD*n*_CSR field descriptions

Field	Description
START	Control field to start channel explicitly when using a software-initiated DMA service (hardware clears it automatically)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable the storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable the interrupt when the major loop is half complete
INTMAJOR	Control field to enable the interrupt when the major loop completes

Table 24. CH*n*_CSR field description

Field	Description
ACTIVE	Status field indicating the channel is in execution
DONE	Status field indicating major loop completion (you clear it when a channel begins execution)

Table continues on the next page...

Table 24. CH*n*_CSR field description (continued)

Field	Description
EEI	Control field to enable error interrupts
EARQ	Control field to enable an external, asynchronous wake-up event with the ERQ field
ERQ	Control field to enable hardware service requests

5.6.3 Multi-loop iterations

Figure 14 shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, allowing one level of minor loop DMA preemption. The beginning iteration count (BITER) specifies the number of minor loops in a major loop.

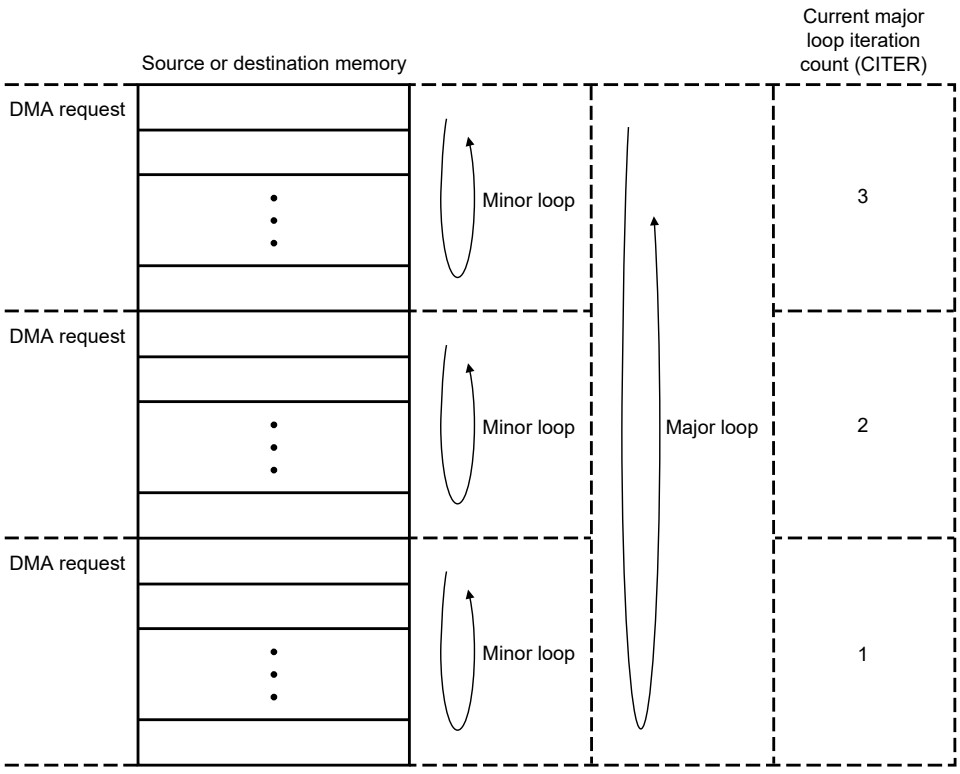

Figure 14. Example of multiple loop iterations

5.6.4 Memory array terms

Figure 15 shows the memory array terms and how the TCD settings interrelate.

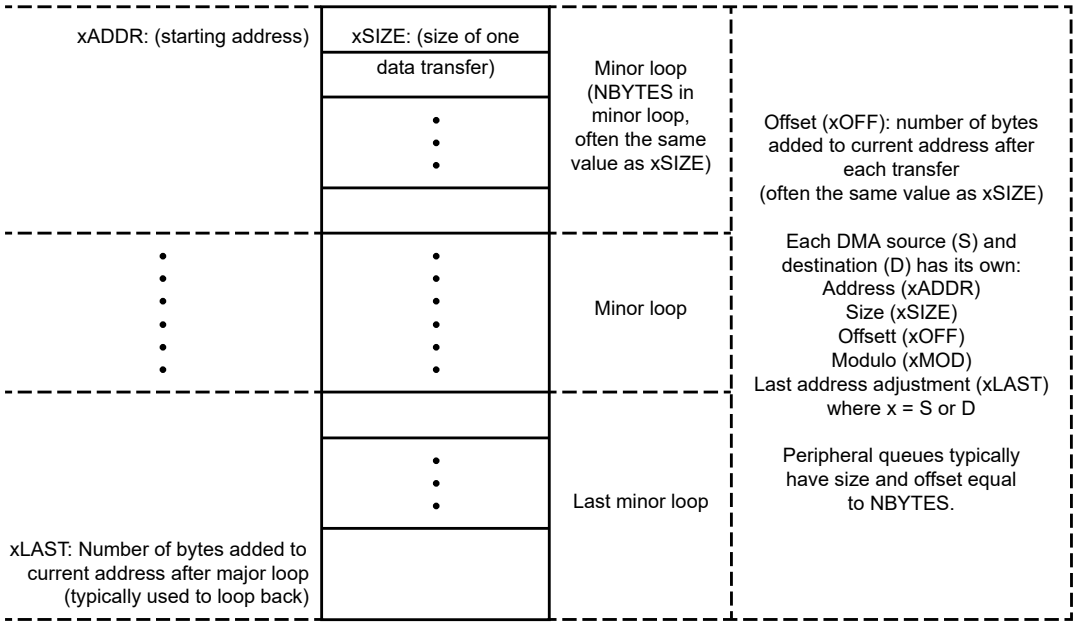

Figure 15. Memory array terms

5.7 Application information

The following sections discuss eDMA application information.

5.7.1 eDMA arbitration

eDMA uses a layered arbitration scheme consisting of multiple priority levels. It uses a fixed-priority arbitration scheme with an optional, round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

1. Highest arbitration group priority: Each channel is assigned an arbitration group through CH0_GRPRI. Priority is given to the highest value (31 is the highest possible value) down to the lowest value (0 being the default).
2. Channel priority: Each channel is assigned a channel priority level through CH0_PRI. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (7 being the highest possible value) down to the lowest value (0 being the default). Channel priorities within each arbitration group do not have to be unique. If multiple channels have the same channel priority level, the channel number is used to determine priority as defined in channel number.
3. Channel number: When two or more channels have the same arbitration group and channel priority, the channel number (CH_NUM) is used to determine the highest priority. Priority is given to the highest channel number. The lowest priority is channel 0. The channel numbers are static and you cannot change them in the programmer's model.
4. Lowest: When you enable round-robin, any channel configured for the round-robin operation has the lowest priority within an arbitration group. When you enable round-robin by writing 1 to CSR[ERCA], channels with a channel priority of zero (CH_PRI = 0) use round-robin arbitration, which rotates the channel selection among the channel's requesting service with CH_PRI = 0 within the arbitration group. Any nonzero channel within the arbitration group continues to use fixed-priority arbitration, and if requesting service, selects over any round-robin channels.

For fixed arbitration, you can consider the overall priority as a number composed of three concatenated priority levels (CH_GRPRI:CH_PRI:CH_NUM). The largest number has the highest priority and the lowest number has the lowest priority.

When you enable round-robin arbitration, channels are serviced in an order, per priority group (CH_GRPRI:0:X). Within a priority group, all channels with their channel priority set to zero are cycled through from the highest to lowest channel number.

The round-robin scheme can be overridden by a nonzero channel priority value (any channel with a nonzero CH*n*_PRI value automatically has a higher priority over the round-robin scheme).

5.7.2 Programming errors

eDMA performs various tests on TCD to verify consistency in the descriptor data.

The channel number causing the error is recorded in ES. If you do not remove the error source before the next activation of the problem channel, the error is detected and recorded again. Writing 1 to CSR[HAE] halts the DMA and prevents the recurrence of the error.

5.7.3 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

5.7.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If you program eDMA in a way that the channels with a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower priority group is serviced if there is at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that require immediate service.

5.7.3.2 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request is serviced. Lower priority groups are serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest nonzero channel priority. For all channels with a channel priority programmed to 0, the highest channel number requesting service is selected, rotating to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower priority channels.

This scenario can lead to the same bandwidth consumption problem as indicated in Fixed-group arbitration, fixed-channel arbitration, but all channels in the highest priority group are serviced. Service latency is short on the highest priority group, but can become potentially longer as the group priority decreases.

5.7.4 Performing DMA transfers

This section presents examples on how to perform DMA transfers with eDMA.

5.7.4.1 Single request

To perform a simple transfer of *n* bytes of data with one activation, write 1 to the major loop (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after you acknowledge the channel service request and select the channel to execute. After the transfer is complete, CH0_CSR[DONE] becomes 1 and an interrupt generates, if properly enabled.

The following TCD entry (see Code Listing 1) is configured to transfer 16 bytes of data. eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port at 1000h. The destination memory has a 32-bit port at 2000h. Program the address offsets in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their initial values.

This generates the following event sequence:

1. You must write 1 to TCD0_CSR[START] to request channel service.
2. Arbitration selects the channel for servicing.
3. The eDMA engine writes 0 to CH0_CSR[DONE] and TCD*n*_CSR[START], and 1 to CH0_CSR[ACTIVE].
4. The eDMA engine reads channel TCD data from the local memory to internal register file.
5. The source-to-destination transfers are executed as follows:

a. Data is continuously read from the source addresses by issuing read transactions and adjusting the source address through the source address-offset after each transaction.

b. Data is continuously written to the destination addresses after sufficient data is buffered. Adjust the destination address through the destination address offset after each transaction.

6. The eDMA engine writes 1000h to TCD*n*_SADDR, 2000h to TCD*n*_DADDR, and 1 to TCD*n*_CITER(TCD*n*_BITER).
7. The eDMA engine writes 0 to CH*n*_CSR[ACTIVE], 1 to CH*n*_CSR[DONE], and 1 to CH0_INT[INT].
8. The channel retires and eDMA goes idle or services the next channel.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 1000h
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 2000h
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (You must write to this field after all other fields are initialized.)
All other TCDn fields = 0
```

Code Listing 1. Single request

5.7.4.2 Multiple requests

Code Listing 2 shows the transfer of 32 bytes through two hardware requests but is otherwise the same as the previous example (see Single request). The only fields that change are the major loop iteration count and final address offsets. Program eDMA for two iterations of the major loop transferring 16 bytes per iteration. After you enable the channel's hardware requests through CH0_CSR[ERQ], the target device initiates channel service requests.

This generates the following sequence of events:

1. First hardware, that is, eDMA peripheral, requests for channel service.
2. Arbitration selects the channel for servicing.
3. The eDMA engine writes 0 to CH0_CSR[DONE] and TCD0_CSR[START], and 1 to CH0_CSR[ACTIVE].
4. The eDMA engine reads channel TCD*n* data from the local memory to the internal register file.
5. The source to destination transfers are executed as follows:

   a. Data is continuously read from the source addresses by issuing read transactions and adjusting the source address through the source address offset value after each transaction.

   b. Data is continuously written to the destination addresses after sufficient data is buffered. Adjust the destination address through the destination address offset after each transaction.
6. The eDMA engine writes 1010h to TCD*n*_SADDR, 2010h to TCD*n*_DADDR, and 1 to TCD*n*_CITER.
7. The eDMA engine writes 0 to CH*n*_CSR[ACTIVE].
8. The channel retires → one iteration of the major loop. eDMA goes idle or services the next channel.
9. The second hardware, that is, eDMA peripheral, requests channel service.
10. Arbitration selects the channel for servicing.

11. The eDMA engine writes 0 to CH*n*_CSR[DONE] and TCD*n*_CSR[START], and 1 to CH*n*_CSR[ACTIVE].
12. The eDMA engine reads the channel TCD data from the local memory to the internal register file.
13. The source to destination transfers are executed as follows:
    a. Data is continuously read from the source addresses by issuing read transactions and adjusting the source address through the source address offset value after each transaction.
    b. Data is continuously written to the destination addresses after sufficient data is buffered. Adjust the destination address through the destination address offset after each transaction.
14. The eDMA engine writes 1000h to TCD*n*_SADDR, 2000h to TCD*n*_DADDR, and 2 to TCD*n*_CITER(TCD*n*_BITER).
15. The eDMA engine writes 0 to CH*n*_CSR[ACTIVE], and 1 to CH*n*_CSR[DONE] and CH0_INT[INT].
16. The channel retires → major loop complete. eDMA goes idle or services the next channel.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

Code Listing 2. Multiple request

5.7.4.3 Using the modulo feature

The modulo feature of eDMA provides the ability to implement a circular data queue in which the queue's size is a power of 2. MOD is a 5-bit field for the source and destination in TCD, and it specifies which lower address bits increment from their original value after the address plus offset calculation. All upper address bits remain the same as their original value. When you write 0 to this field, it disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

Table 25 shows how to specify the transfer addresses based on the MOD field setting. A circular buffer is created where the address wraps to the original value while the 28 upper address bits (1234_567*x*h) retain their original value. In this example, the source address is set to 1234_5670h, the offset is set to 4 bytes, and MOD is set to 4, allowing for a 2^4 byte (16-byte) size queue.

Table 25. Modulo example

Transfer number	Address
1	1234_5670h
2	1234_5674h
3	1234_5678h
4	1234_567Ch
5	1234_5670h
6	1234_5674h

5.7.5 Monitoring TCD status

This section discusses how to monitor eDMA status.

5.7.5.1 Testing for minor loop completion

There are two methods to test minor loop completion when using software-initiated service requests. First is to read TCD*n*_CITER and test for a change. You may extract another method from Table 26. The second method is to test TCD0_CSR[START] and CH0_CSR[ACTIVE]. The minor-loop-complete condition is indicated by both fields reading zero after you write 1 to TCD*n*_CSR[START]. Only polling CH*n*_CSR[ACTIVE] can be inconclusive because you can miss the active status while the channel execution is of shorter duration.

The CH*n*_CSR and TCD*n*_CSR status fields execute the following sequence (as shown in Table 26) for a software-activated channel.

Table 26. Settings for software-activated channel

Stage	TCD*n*_CSR and CH*n*_CSR			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request through software.
2	0	1	0	Channel is executing.
3a	0	0	0	The channel is idle after completing its minor loop.
3b	0	0	1	The channel is idle after completing its major loop.

The best method to test for minor-loop completion when using eDMA (that is, peripheral, initiated service requests), is to read TCD*n*_CITER and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence (as shown in Table 27) for a hardware-activated channel.

Table 27. Settings for hardware-activated channel

Stage	TCD*n*_CSR and CH*n*_CSR			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request through hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	The channel is idle after completing its minor loop.
3b	0	0	1	The channel is idle after completing its major loop.

For both the activation types, the major-loop-completion status is explicitly indicated through CH0_CSR[DONE].

TCD0_CSR[START] becomes 0 automatically when the channel begins execution regardless of how the channel activates.

5.7.5.2 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher priority request becomes active. When you enable the round-robin channel arbitration mode, all the channels with their channel priority set to zero lose their preempt ability. Channel priorities of zero are treated as equal, that is, constantly rotating, when round-robin arbitration mode is enabled.

CH0_CSR[ACTIVE] remains 1 for the preempted channel throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If you write 1 to two CH*n*_CSR[ACTIVE] fields simultaneously in the global TCD map, a higher priority channel actively preempts a lower priority channel.

5.7.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel writes 1 to TCD0_CSR[START] of another channel (or itself), initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs after the minor loop (or one iteration of the major loop). TCD*n*_CITER[ELINK] determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. After the major loop is exhausted, only the major loop channel link fields are used to determine whether a channel link should be created. For example, the initial fields listed in Code Listing 3 execute as:

1. Minor loop done → write 1 to TCD12_CSR[START]
2. Minor loop done → write 1 to TCD12_CSR[START]
3. Minor loop done → write 1 to TCD12_CSR[START]
4. Minor loop done, major loop done→ write 1 to TCD7_CSR[START]

```
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = Ch
TCDn_CITER[CITER] value = 4h
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 7h
```

Code Listing 3. Channel linking

After you enable minor loop linking (TCD*n*_CITER[ELINK] = 1), TCD*n*_CITER[CITER] uses a 9-bit vector to form the current iteration count. When you disable minor loop linking (TCD*n*_CITER[ELINK] = 0), TCD*n*_CITER[CITER] uses a 15-bit vector to form the current iteration count. Fields associated with TCD*n*_CITER[LINKCH] are concatenated onto the CITER value to increase the range of CITER.

NOTE

TCD*n*_CITER[ELINK] and TCD*n*_BITER[ELINK] must be equal; else, a configuration error is reported. CITER and BITER vector widths must be equal to calculate the major loop, halfway done interrupt point.

Table 28 summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD at the end of a loop.

Table 28. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at the end of minor loop	TCD*n*_CITER[ELINK]	Enables channel-to-channel linking on minor loop completion (current iteration)
	TCD*n*_CITER[LINKCH]	Links channel number when linking at the end of minor loop (current iteration)
Link at the end of major loop	TCD0_CSR[MAJORELINK]	Enables channel-to-channel linking on major loop completion
	TCD0_CSR[MAJORLINKCH]	Links channel number when linking at the end of major loop

5.7.7 Dynamic channel linking

Dynamic channel linking is the process of writing 1 to TCD0_CSR[MAJORELINK] and TCD0_CSR[MAJORLINKCH] during channel execution. These fields are read from the TCD profile at the end of channel execution. This allows you to enable the feature during channel execution. When attempting a dynamic channel link, you must write to TCD*n*_CSR[MAJORELINK] and TCD*n*_CSR[MAJORLINKCH] in a single write transaction (that being a write size of at least 16 bits to TCD0_CSR).

Because you can change the configuration during execution, it requires a coherency model. Consider a scenario where you attempt to execute a dynamic channel link by writing 1 to TCD*n*_CSR[MAJORELINK] at the same time when the eDMA engine is retiring the channel. TCD*n*_CSR[MAJORELINK] is 1 in the programmer's model, but it is unclear whether the actual link was made before the channel retired.

When you execute a dynamic channel link request, NXP recommends using the following coherency model:

1. Write 1 to TCD*n*_CSR[MAJORELINK].
2. Read TCD*n*_CSR[MAJORELINK].
3. Test the TCD*n*_CSR[MAJORELINK] request status:
   - If TCD*n*_CSR[MAJORELINK] = 1, the dynamic link attempt is successful.
   - If TCD*n*_CSR[MAJORELINK] = 0, the attempted dynamic link does not succeed (the channel is retiring already).

The TCD local memory controller forces TCD*n*_CSR[MAJORELINK] to become 0 on any writes to a channel's TCD*n*_CSR after that channel's CH0_CSR[DONE] becomes 1, indicating that the major loop is complete.

NOTE

Write 0 to CH*n*_CSR[DONE] before writing to TCD*n*_CSR[MAJORELINK]. The eDMA engine automatically writes 0 to CH*n*_CSR[DONE] after a channel begins execution.

5.7.8 Suspend or resume a DMA channel with active hardware service requests

DMA allows you to move data from memory or peripheral registers to another location in memory or peripheral registers without CPU interaction. After you configure DMA and peripherals and they are active, it is rare to suspend a peripheral's service request dynamically. In this scenario, there are restrictions to disable a DMA hardware service request. Follow a specific procedure for coherency. This section provides guidance on how to coherently suspend and resume a DMA channel when a target module triggers the DMA.

5.7.8.1 Suspend an active DMA channel

Perform the following procedure to suspend an active DMA channel:

1. Stop the DMA service request at the peripheral.
2. Read back the appropriate register in the peripheral to confirm that the service request is disabled.
3. Check HRS to ensure that there is no suspended service request to the DMA channel.
4. Write 0 to CH0_CSR[ERQ] on the appropriate DMA channel to disable the hardware service request.

For example, assume the SPI is set as the controller for transmitting data through a DMA service request when DSPI_TXFIFO has an empty slot. DMA transfers the next command and data to the TXFIFO upon the request. If you require to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the source by writing 0 to DSPI_RSER[TFFF_RE]. Confirm that DSPI_RSER[TFFF_RE] is 0.
2. Ensure that there is no DMA service request from the SPI by verifying that HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by writing 0 to CH0_CSR[ERQ]. If a service request is present, wait until the request is processed and HRS becomes 0.

5.7.8.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by writing 1 to CH0_CSR[ERQ].
2. Enable the DMA service request at the peripheral.

5.8 Glossary

TCD	Transfer control descriptor

Chapter 6
Security Overview

6.1 Overview

By controlling access to the device as well as providing trusted computing environment, this chip offers various security features and tools that allow customers to protect their assets.

Some of the basic features include:

- Secure boot ensuring that only authentic entity is allowed to access the device or execute code on it.
- Secure debug allowing customers to securely develop and debug software while the device is at manufacturing or deployed in the field.
- Secure lifecycle management guaranteeing that security mechanisms are enforced, and device reaches its highest security level after it has been deployed or returned to NXP for failure analysis.
- Hardware Security Module (HSM) and cryptographic services ensuring that cryptographic keys remain hidden from the application in all circumstances.

This chapter explains the main purpose and features of security-relevant SoC components:

- EdgeLock secure enclave (ELE) acts as a Root of Trust for platform security. It manages the SoC lifecycle, enforces secure boot, controls debug access, and provides full key management and key isolation from the rest of SoC.
- Trusted Resource Domain Controller (TRDC) is essential in enabling isolation between various processes running within the SoC. It is used to define and enforce separation between security critical and other processes by introducing the notion of domain IDs, as well as enforcing the trusted execution environment defined by ARM TrustZone.
- On-the-Fly AES Decryption (OTFAD) protects the confidentiality of code stored in external memory using AES in CTR mode. The key used for decryption is securely handled by ELE and delivered to OTFAD using a dedicated private bus, ensuring that the key is not observable by any application running on the SoC. OTFAD supports up to four independent memory contexts, each having a unique 128-bit decryption key.
- Battery Backed Secure Memory (BBSM) is used as a non-volatile storage of security parameters including general purpose registers, run-time counter with a wake-up alarm, monotonic counters, as well as tamper detection inputs.

6.2 Edgelock secure enclave

The Edgelock Secure Enclave (ELE) supports the following features:

- SoC Life cycle management
- Cryptographic services
- Key Management
- Runtime Root of Trust
- One Time programmable Fuse controller
- Authenticated Debug with multiple debug domains
- Clock Frequency Monitoring

The ELE has a 32-bit bus with access to the SoC. The Edgelock secure enclave has multiple MU instances, and private buses to connect to security components outside EdgeLock Enclave such as BBSM, and FlexSPI's OTFAD.

6.3 Immutable Root of Trust (RoT)

As defined by Trusted Computing Group, “an Immutable Root of Trust (RoT) is expected to remain identical across all devices within a set of device models based on a defined threat model. It is also expected not to change across time and, therefore, will behave the same during each device’s lifespan.”

Immutable RoT consists of truly immutable hardware logic, including analog and digital logic, read-only memory and one-time programmable memory. It is essential for guaranteeing any security feature, including secure boot, secure debug, life-cycle management, and a number of others. In this device, immutable RoT is embedded in the ELE boot ROM (immutable boot loader) and it relies on the ELE hardware cryptographic accelerators for its function.

6.4 Lifecycle management

During its lifespan, a typical device finds itself in various places around the world. It is manufactured in a semiconductor factory, tested and packaged in silicon manufacturer facilities, sold to various distributors, sold further to the Original Equipment Manufacturer (OEM), assembled, tested and provisioned by their Contract Manufacturers and, finally, delivered to the end-customer. In the case of failure, a device is returned to OEM or even back to the silicon manufacturer for further failure analysis.

Device life cycle state is used to reflect the actual state of the device, which is further used to instruct the device on how exactly to protect the assets a device hosts during specific time. For example, when a device is being tested at a silicon manufacturer facility and no OEM or end-customer assets have been provisioned, then access to the device, in terms of debug or test, is less restrictive than when a device is with the end-customer.

Life cycle state is monotonic, meaning it can only always be increased. Immutable RoT is in charge of life cycle management and it enforces device access policies accordingly.

6.5 Secure boot

Secure boot ensures authenticity, integrity and confidentiality of the device boot loader, firmware, and other software during the boot process and ensures that the intended secure life-cycle state is reached. SHA with ECDSA or RSA with different key lengths are available to guarantee authenticity and integrity of the firmware image. AES-based memory encryption can be used to provide code/data confidentiality while the firmware image is stored in external memory. ELE as an immutable RoT is in charge of enforcing secure boot and it does so according to the policies defined by the life-cycle state.

See i.MX 91 Applications Processor Security Reference Manual for more details about secure boot.

6.6 Secure debug

Secure debug is the process used to securely access external jtag debug, following the policy defined by the life-cycle state. When a debugger wants to debug a device, they indicate that through the jtag interface.

One of two mechanisms can be selected:

- password match based mechanism for SoC debug and SoC TrustZone debug
- asymmetric signed message based debug enablement

NXP recommends using the asymmetric signed message based mechanism as it has better security compared to the password based mechanism.

6.7 IP protection

IP protection is a set of mechanisms used to protect confidentiality and integrity of valuable code and data stored on the device. During secure update, the firmware image is encrypted using AES. While at rest and during secure boot, the firmware image is encrypted and stored in external memory. Up to four independent memory contexts available through OTFAD using a unique 128-bit key per context.

6.8 Secure isolation

ELE guarantees run-time key isolation from any process running on the rest of SoC. In addition, Arm TrustZone capable Cortex A55, in combination with the Trusted Resource Domain Controller (TRDC), enables secure isolation during run-time.

6.9 TrustZone

Trustzone (TZ) is a feature on the Cortex A55, which provides segmentation of memory arrays and peripherals into either Secure (S) or Non-Secure (NS).

The TrustZone® security architecture is supported. For on-chip RAM, all of OCRAM have TrustZone® access control support. One region with configurable address range of the OCRAM can be set to TZ access only. The Trustzone memory region protection of DRAM is supported through TRDC.

The majority of system initiators in the SoC do not natively support TrustZone (and more specifically, do not support a concept of AxPROT[0] indicating controllable privileged vs normal access or AxPROT[1] indicating non-secure vs TrustZone secure access). Therefore, the TRDC DAC provides controls to override IP initiator's AxPROT[1:0] inputs to the subsystem NICs. However, initiators which do have concept of these AxPROT[1:0] signals, do not have their signals overridden by the TRDC DAC.

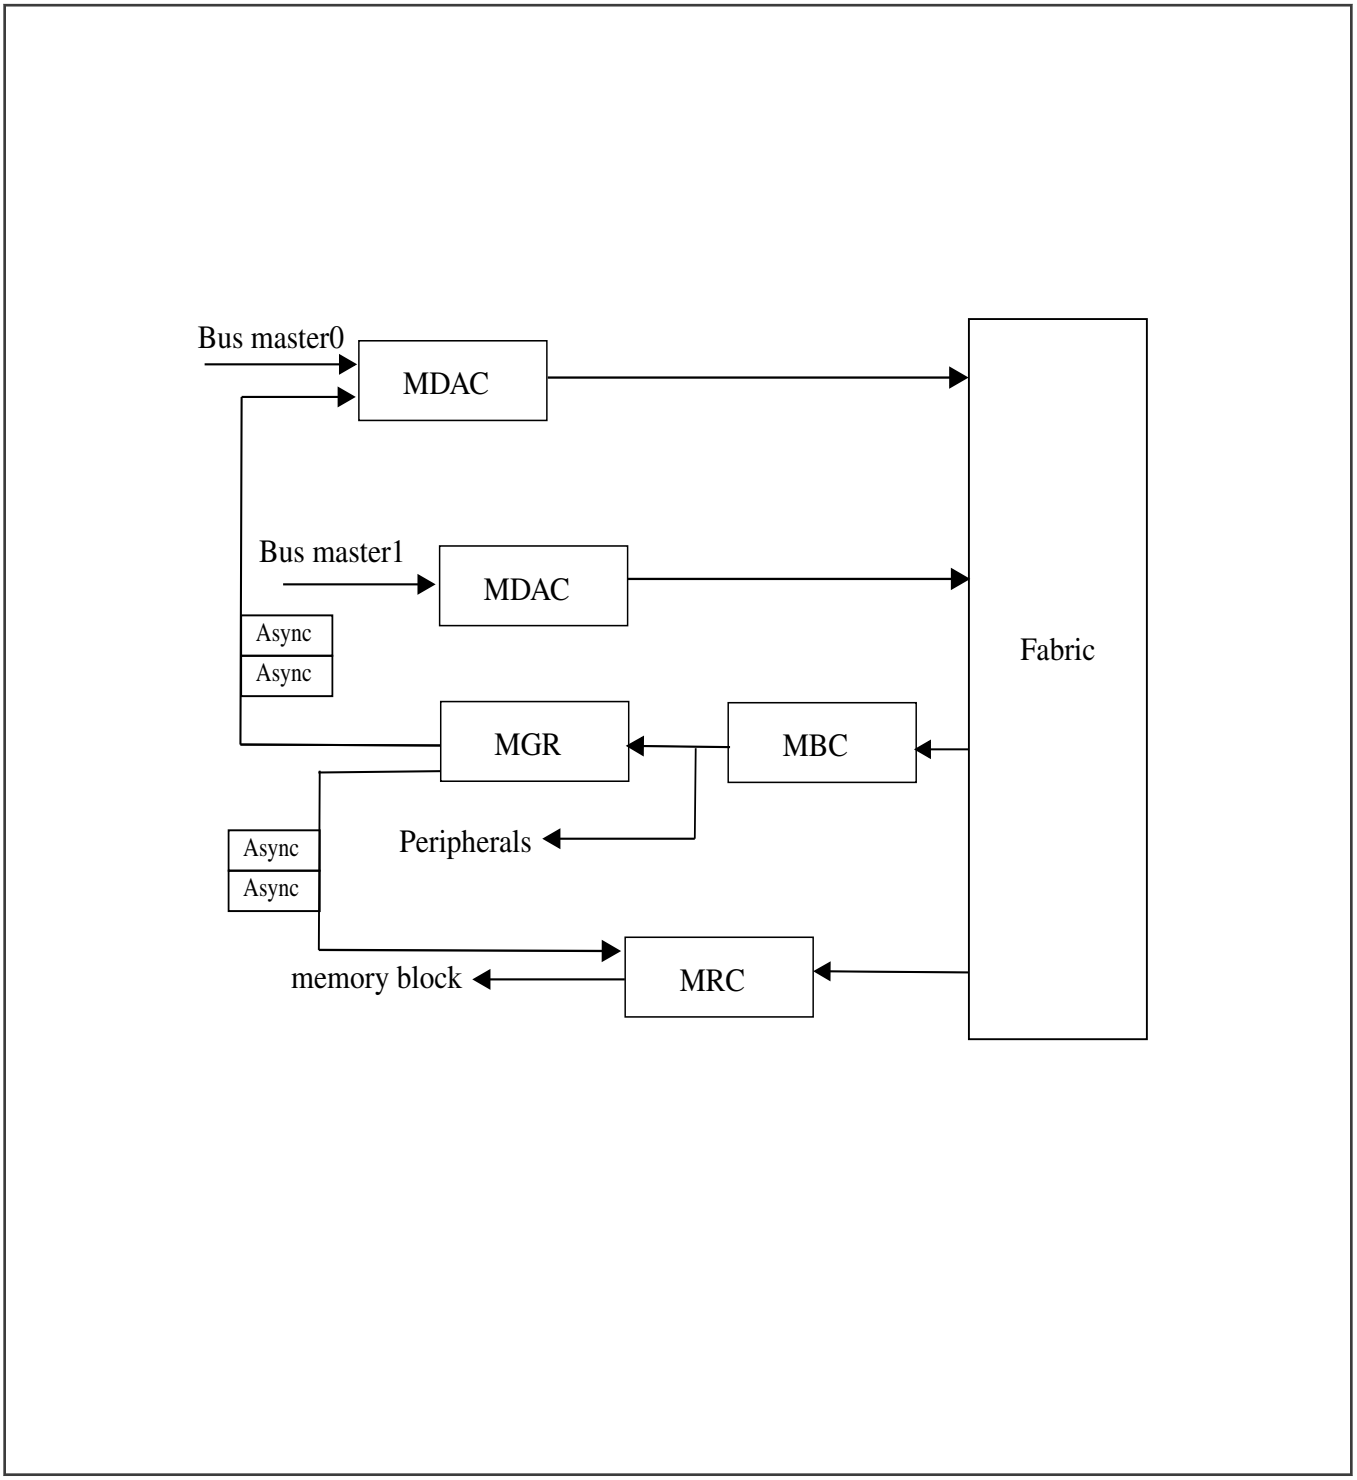
6.10 Trusted resource domain control (TRDC)

The chip uses a domain based resource control architecture for the memory/peripheral resource sharing and isolation between the Cortex®-A55 platform and other bus masters. A key feature of this architecture is that it must be possible for either Cortex-A55 platform to program the resource domain control access lists to implement a customer-defined policy. Another key feature is that any peripheral can be assigned to any domain. The TRDC supports multiple regions with flexible access permission control for each memory space.

A core complex should not rely on TRDC and should use the internal MMU for memory management. In addition, initiators like Cortex-A55, that implement the DSU architecture, do support AxPROT internally, but do not drive AxPROT[2] and AxPROT[0] on the system bus. For Cortex-A55, after boot, it is recommended to use the internal MMU for access control.

For more details please refer Chip-specific TRDC information.

6.10.1 TRDC components



For more details please refer Chip-specific TRDC information.

6.11 Block control secure (BLK_CTRL_S_AONMIX)

The chip includes a block called BLK_CTRL_S_AONMIX which contains assorted configuration controls that can potentially have security implications. The BLK_CTRL_S_AONMIX registers are reset only by when ELE is reset. These registers can only be accessed by TrustZone Secure World.

BLK_CTRL_S_AONMIX has the following functions:

- Cortex-A GIC Interrupt Masking.
- WDOG Timer output masking for combined watchdog timer SoC output pin.

Chapter 7
Fusemap

7.1 Overview

This section details the various fuses and their associated configuration settings. This chapter also describes various modes and the selection of the required boot devices.

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers must not attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

7.1.1 Bank redundancy

Fuses can generally only be set from 0 to 1 and the most common failure is a 1 appearing as a 0. The simplest mechanism to verify these failures is redundancy. Redundancy is when two bits are OR'd together so that if either is set, then the output value is a 1.

In case of fuses protected by redundancy, only 16 of the 32 bits are available (bits 15:0 are automatically copied to 31:16) and checked on read. This allows for multiple programming operations on a word, so bits can be configured at different times.

NOTE

In shadow registers, the inverted version of [15:0] will show in [31:16]. In the fuse array, [31:16] is the same as [15:0].

NOTE

The monotonic array requires redundancy, as it’s programmed individually

7.1.2 Lock bits

There are three kinds of lock bits, write lock, overwrite lock and read lock. If a word attribute of read / write / over-write lock is not set, then it can be read sensed, programmed and the shadow registers can be overwritten.

The write lock bits are used by the controller to control writing/programming of the fuse bits. A set of fuse words used for the same function can be write locked using a single fuse bit. If the fuse write lock is set, it indicates that the associated fuse bits can no longer be updated.

Read lock bits are a specific set of fuses that give you the ability to block bus access to specific words. When a fuse is read locked, it will be loaded to shadow registers during boot, but won't be readable via bus access.

Over-write lock bits are used to disable the feature of allowing SW to write to the shadow registers, enabling emulation of the function without committing to the fuse value.

Please refer the attached spreadsheet for the chip fusemap descriptions.

7.2 Boot Fusemap

This section describes the various modes and the selection of the required boot devices. The device select is specified by the BOOT_CFG0[3:0] fuses. Please refer i.MX 91 Applications Processor Reference Manual for more details.

Table 29. Boot device select (Cortex-A55 Boot Core)

7.3 Fusemap Descriptions Table

Please refer the attached spreadsheet for the chip fusemap descriptions.

7.4 Programming Fuses

This section provides an overview on how to read and program eFuses. The OTP memory is part of the security subsystem and is controlled by the ELE. The ELE Firmware provides API functions which are used to interact with OCOTP CTRL block. Please refer the EdgeLock Enclave (ELE) API Reference Guide for more information.

Chapter 8
Fuse Status Block (FSB)

8.1 Introduction

The Fuse and Status block (FSB) is an interface to allow the SoC to directly read select public fuses and ELE status information.

FSB also provides SOC with write access to some of the OCOTP status registers.

8.2 Features

The FSB includes the following features:

- Allow the SoC to read certain fuses and status registers
- Fuse values can be read from APB register interface
- FSB provides read/write access to OCOTP registers that hold status of fuse accesses

8.3 Memory map and register definition

This section includes the FSB module memory map and detailed descriptions of all registers.

FSB does not by itself generate bus errors on accesses to its register space. However, FSB will return a bus error it might get from OCOTP on accesses to fuse and OCOTP status registers. Unsupported accesses or accesses to reserved space are ignored or return 0.

8.4 FSB register descriptions

8.4.1 FSB memory map

FSB1 base address: 4751_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	FSB Version ID Register (VERID)	32	R	0202_0001
1C	FSB Status Register (FSB_STATUS)	32	R	0000_0000
64	Access Count Register (ACCESS_COUNT)	32	RW	0000_0000
1000	Fuse Status Register (FUSE_STAT)	32	RW	0000_0000
1004	Fuse Event Register (FUSE_EVNT)	32	RW	0000_0000
1008	Fuse Interrupt Enable Register (FUSE_INT_EN)	32	RW	0000_0000
100C	Fuse Interrupt Register (FUSE_INT)	32	R	0000_0000
8000 - 87FC	Fuse Value Registers (FUSE0 - FUSE511)	32	R	0000_0000

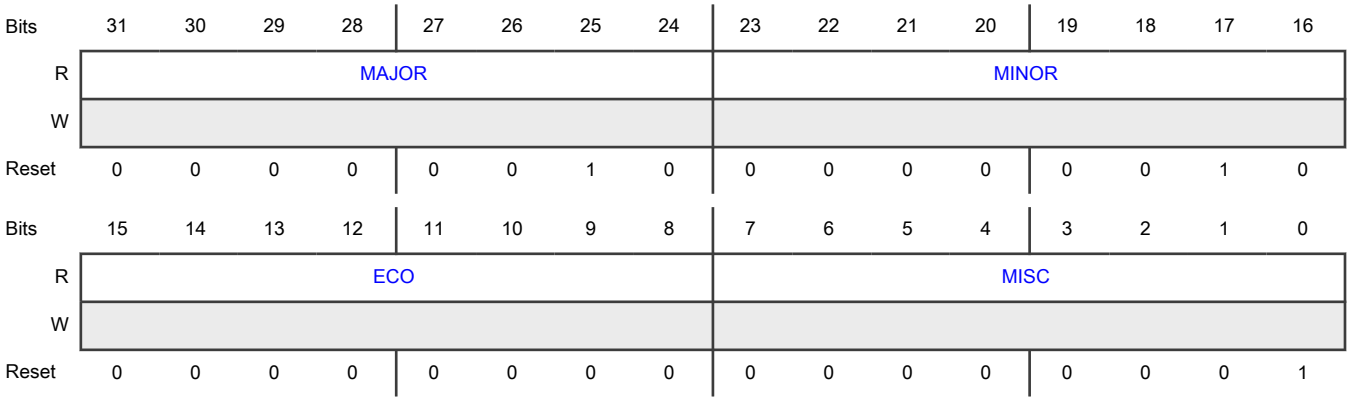
8.4.2 FSB Version ID Register (VERID)

This register records the specific version of the FSB module in the chip.

Offset

Register	Offset
VERID	0h

Diagram



Fields

Field	Description
31-24 MAJOR	Major Version Number This read only field returns the major version number.
23-16 MINOR	Minor Version Number This read only field returns the minor version or revision number. Starting with minor version 2, FSB supports OCOTP status register space in addition to the fuse space and enables write transfers in these areas of the address map.
15-8 ECO	ECO Version Number This read only field returns the ECO version number.
7-0 MISC	Feature Specification This read only field returns the status of various configuration options indicating features present in this instance of FSB. xxxx_xxx1 - Support for stopped transfers to OCOTP fuse space on the FSB target APB is enabled.

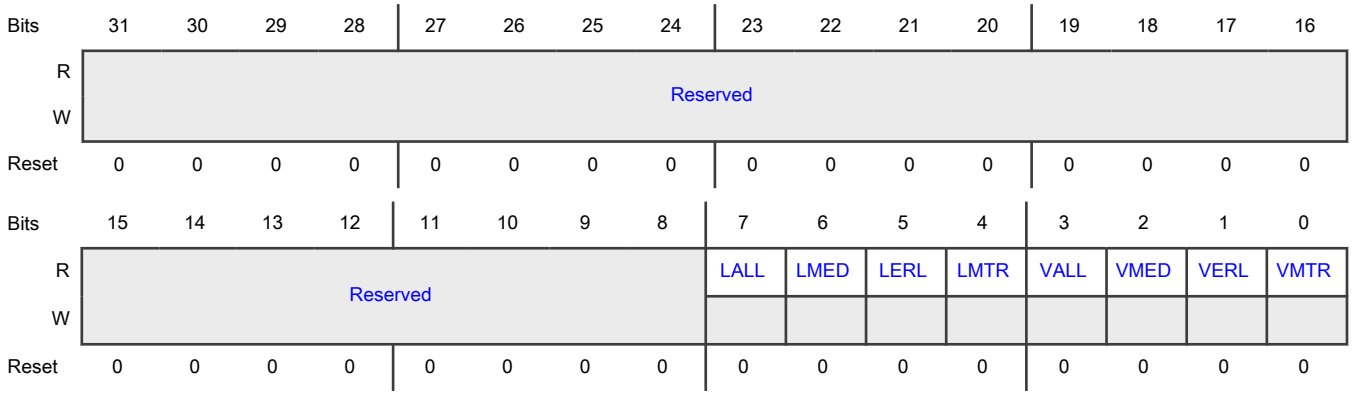
8.4.3 FSB Status Register (FSB_STATUS)

FSB status. For now the only status is whether or not fuse values are loaded and valid. At reset, the fuse values will not be valid. FSB does not gate accesses to OCOTP shadow RAM based on the state of these bits.

Offset

Register	Offset
FSB_STATUS	1Ch

Diagram



Fields

Field	Description
31-8 —	Reserved
7 LALL	All fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
6 LMED	Medium fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
5 LERL	Early fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
4 LMTR	MTR Trim fuses loaded. The fuse values are loaded and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
3 VALL	All fuses valid. The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
2 VMED	Medium fuses valid. The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
1 VERL	Early fuses valid. The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.
0	MTR Trim fuses valid.

Table continues on the next page...

Table continued from the previous page...

Field	Description
VMTR	The fuse values are valid and can be read by the SoC. At boot, fuses may take some clock cycles to be available for SW to read.

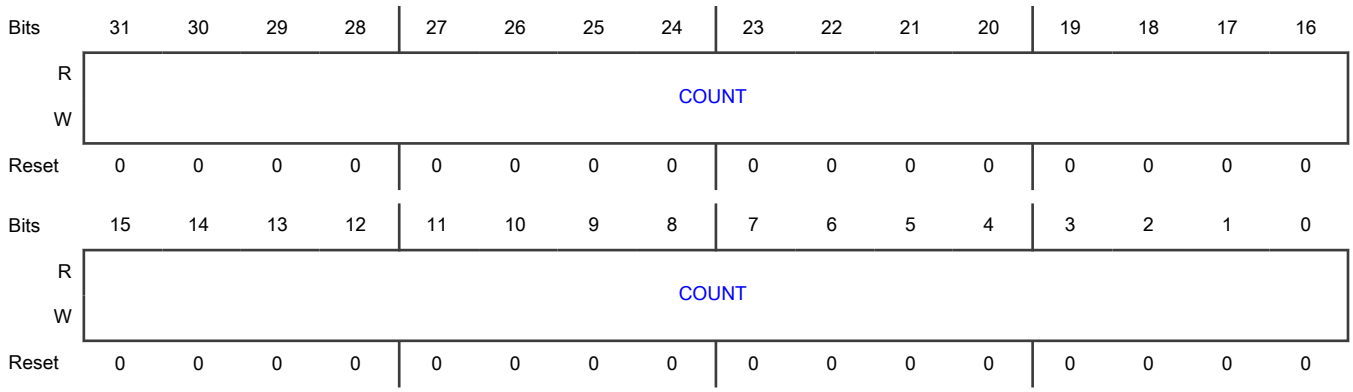
8.4.4 Access Count Register (ACCESS_COUNT)

This register contains a count of the number of times an FSB register has been accessed.

Offset

Register	Offset
ACCESS_COUNT	64h

Diagram



Fields

Field	Description
31-0 COUNT	Access Count Register. Each time an FSB is read or written, this register will increment. Writing a value to this register will set a new starting value. Writing a new value takes precedence over incrementing this register.

8.4.5 Fuse Status Register (FUSE_STAT)

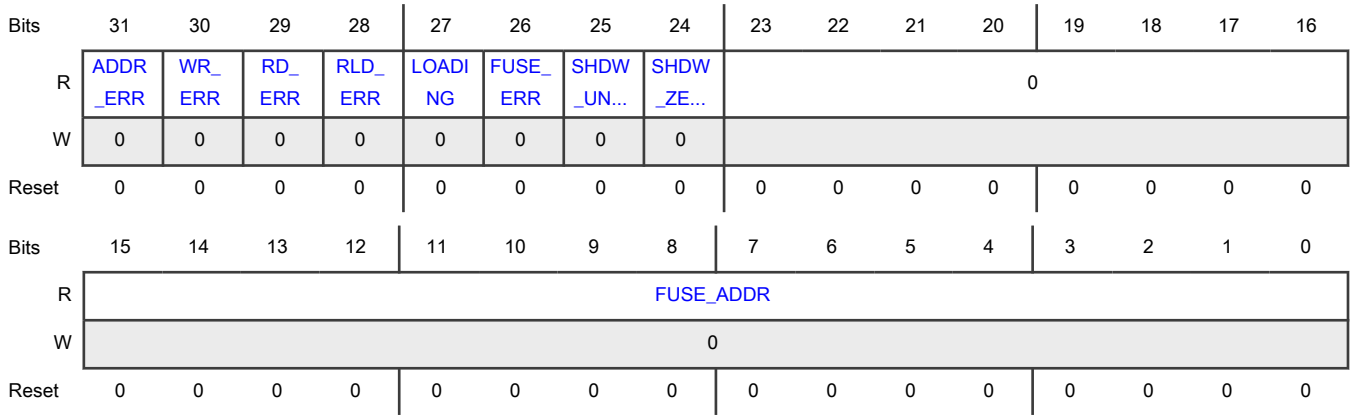
Reports the status and address of the last fuse shadow read. Writing to this register will clear the register contents.

If the fuse shadow read reports a RD_ERR or RLD_ERR then the Shadow Loading, Fuse Error, Unprogrammed, Zeroized, ECC and RED status bits will be 0 regardless of the actual fuse status.

Offset

Register	Offset
FUSE_STAT	1000h

Diagram



Fields

Field	Description
31 ADDR_ERR	Address error High if the last fuse shadow read used an illegal address, including: • Writing to a fuse shadow • Accessing an address that is not 32-bit aligned • Accessing fuse which does not have a shadow in RAM • The Shadow RAM entry is not accessible from the FSB APB • The `soc_apb_fsb_access_disable` is asserted to disable FSB access • The SRAM controller FSM is in an error state preventing access to the SRAM
30 WR_ERR	Write Error Attempted to write a shadow RAM entry
29 RD_ERR	Read error High if the last fuse shadow read attempted to read a shadow that was read protected
28 RLD_ERR	Reload error High if the last fuse shadow was read during a Fuse Shadow Reload before it's section (early, mid or late) had finished loading and the Reload Control register setting for that fuse section is set to BLOCK
27 LOADING	Shadow loading High if the last fuse shadow was read while the shadow was still loading from the fusebox. This prevents the ECC and Fuse Errors from being determined
26 FUSE_ERR	Fuse error High if the last fuse shadow read reported a serious error when the shadow was loaded from the fusebox. This includes: • Uncorrected Fuse ECC multi-bit error

Table continues on the next page...

Table continued from the previous page...

Field	Description
	• Corrected Fuse RED multi-bit error • Transfer error from the fusebox This will also be high if the fuse shadow read reported a multi-bit error
25 SHDW_UNPROG	Shadow unprogrammed High if the last fuse shadow read was unprogrammed
24 SHDW_ZERO	Shadow zeroized High if the last fuse shadow read was zeroized
23-16 —	Reserved
15-0 FUSE_ADDR	Fuse address The address offset of the last fuse shadow read for which the status applies. Note that the 2 lsb will always be zero because the fuse address = fuse number left shifted by 2.

8.4.6 Fuse Event Register (FUSE_EVNT)

Accumulates the status from fuse shadow reads. Bits are set when the corresponding status bit is set and cleared by writing a '1' to the event bit.

Offset

Register	Offset
FUSE_EVNT	1004h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31 ADDR_ERR	Address error Set if a shadow read used an illegal address, including: • Writing to a fuse shadow • Accessing an address that is not 32-bit aligned • Accessing fuse which does not have a shadow in RAM • The Shadow RAM entry is not accessible from the FSB APB • The `soc_apb_fsb_access_disable` is asserted to disable FSB access • The SRAM controller FSM is in an error state preventing access to the SRAM Write '1' to clear.
30 WR_ERR	Write Error Attempted to write a shadow RAM entry. Write '1' to clear.
29 RD_ERR	Read error Set if a fuse shadow read attempted to read a shadow that was read protected. Write '1' to clear.
28 RLD_ERR	Reload error Set if a fuse shadow was read during a Fuse Shadow Reload before it's section (early, mid or late) had finished loading and the Reload Control register setting for that fuse section is set to BLOCK. Write '1' to clear.
27 LOADING	Shadow loading Set if a fuse shadow was read while the shadow was still loading from the fusebox. This prevents ECC and Fuse Error from being determined. Write '1' to clear.
26 FUSE_ERR	Fuse error Set if a fuse shadow read reported a serious error when the shadow was being loaded from the fusebox. This includes: • Uncorrected Fuse ECC multi-bit error • Corrected Fuse RED multi-bit error • Transfer error from the fusebox This will also be set if a fuse shadow read reported a multi-bit error. Write '1' to clear.
25 SHDW_UNPROG	Shadow unprogrammed Set if a fuse shadow read was unprogrammed. Write '1' to clear.
24 SHDW_ZERO	Shadow zeroized Set if a fuse shadow read was zeroized. Write '1' to clear.
23-0 —	Reserved

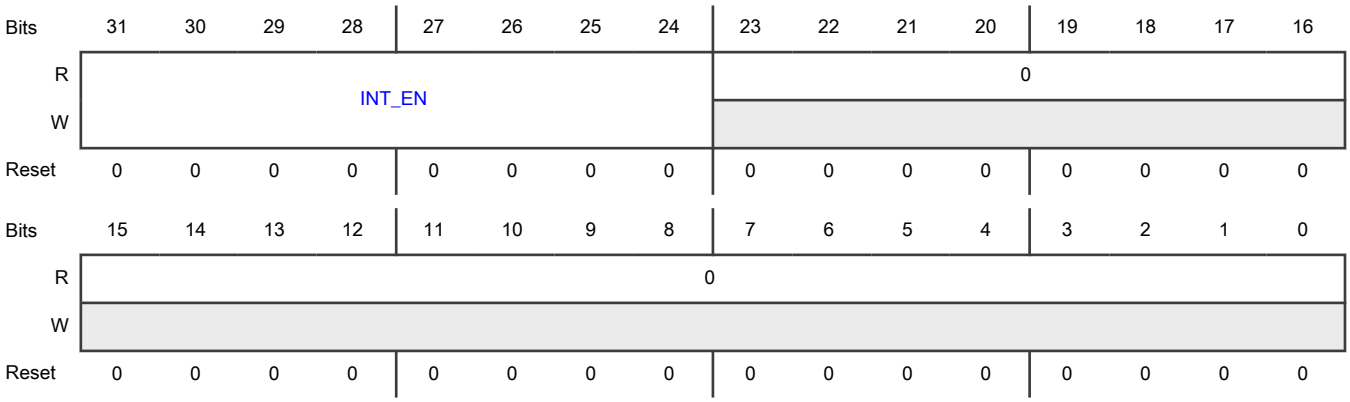
8.4.7 Fuse Interrupt Enable Register (FUSE_INT_EN)

Fuse Interrupt Enable Register

Offset

Register	Offset
FUSE_INT_EN	1008h

Diagram



Fields

Field	Description
31-24 INT_EN	Interrupt Enables AND-ed with the Fuse Event register value to generate the Fuse Interrupt bits. Setting interrupt enable register bits enables the corresponding interrupt bits. See the FUSE_EVNT register for a description of the interrupt signals.
23-0 —	Reserved

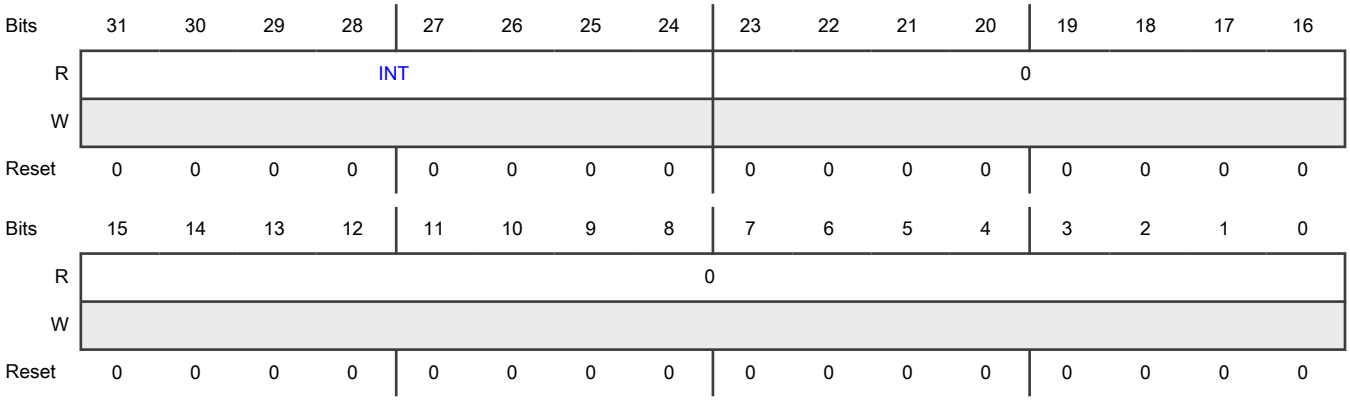
8.4.8 Fuse Interrupt Register (FUSE_INT)

Set when any of the Fuse Interrupt bits are non-zero.

Offset

Register	Offset
FUSE_INT	100Ch

Diagram



Fields

Field	Description
31-24 INT	Interrupts Reports the result of AND-ing the Fuse Event register with the Fuse Interrupt Enable register. See the FUSE_EVNT register for a description of the interrupt signals.
23-0 —	Reserved

8.4.9 Fuse Value Registers (FUSE0 - FUSE511)

The various fuses shadow values can be read from this block of registers. The definition of the fuses is left to the SoC, and not defined here.

NOTE

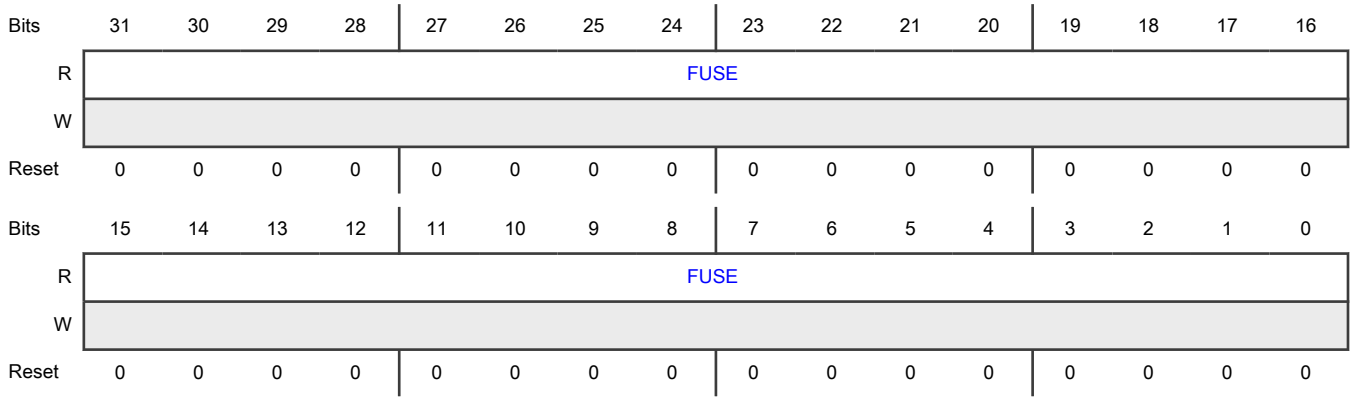
OCOTP will return a bus error if a write access is attempted to a read-only register.

Offset

For a = 0 to 511:

Register	Offset
FUSEa	8000h + (a × 4h)

Diagram



Fields

Field	Description
31-0 FUSE	Fuse Values SoC specific fuse information.

8.5 Functional description

The Fuse Status Block allows the SoC to read ELE fuse and status values without having to use the Messaging Unit.

Fuse values that are public are accessible via the system bus.

FSB also provides access to fuse controller status registers that contain status of FSB's accesses to fuse values in ELE shadow RAM.

The FSB Status register provides state of various fuse controller status flags indicating when different types of fuses are valid and loaded. These flags do not affect behavior of FSB in any way.

FSB implements both read and write transfers to fuse controller status registers and shadow RAM. FSB can return a bus error if a reserved location is accessed or when writes are not supported.

FSB implements support for SoC to stop transfers on the FSB APB when accessing fuses. This can happen if an access to the fuse area is attempted when fuse controller is not ready and the resulting excessive stall creates a timeout situation. A stopped transfer can be followed by a normal transfer without intervention of any kind. The presence of this feature is indicated via VERID.MISC[0]

The meaning of each fuse value is defined by ELE and the SoC. The Fuse Status Block does not imply specific meanings to any fuses.

Specific ELE status signals can also be connected to Fuse Status Block inputs and made available for reading by the SoC. The meaning of any status value is defined by ELE and the SoC. The Fuse Status Block does not imply specific meanings to any status inputs.

8.6 APB errors

FSB asserts the target APB Error depending upon the memory region addressed.

8.6.1 Fuse Registers

When addressing the memory region containing the FUSE_STAT, FUSE_EVNT, FUSE_INT_EN, and FUSE_INT registers APB bus errors will be reported under the following conditions:

- Reading an address that is not 32-bit aligned or does not match a control register

- Writing to an address that is not 32-bit aligned or does not match a writable control register

8.6.2 Fuse Values

When addressing the memory region containing the Fuse Values APB bus errors will be reported under the following conditions:

- Writing to a fuse shadow
- The address is not 32-bit aligned
- There is no fuse shadow RAM at this address
- There is a shadow RAM at this address, but it is not accessible by the FSB APB bus or ELE internal error occurred
- Access to FSB is disabled
- Shadow being accessed is read protected using lock fuse bits. The fuse map table indicates mapping between fuse words and their corresponding locks
- The shadow being accessed is reloading, and fuse access is blocked until the shadow reload is complete

8.7 Acronyms and abbreviations

Table 31. Acronyms and abbreviated terms

Term	Meaning
FSB	Fuse and Status Block
MU	Messaging Unit - provides asynchronous communications between cores in different (and possibly protected) application domains.
MSC	Managed Security Component - an SoC resident security-related component which operates outside of the ELE boundary under SoC application core control, and for which ELE can manage/monitor security state as needed (via TROUT, using a TRIN connection). ELE can privately provision an MSC with a key information via a special-purpose masked bus (see TrustBus).
OCOTP	Secure On-Chip OTP Controller
TRIN	TRust INside - provides a monitoring interface for sensors or ELE for action.
Trust Bus	A private bus between ELE and Managed Security Components
TROUT	TRust OUTside - a logic block associated with a Managed Security Component which is capable of providing alert events to be reported to ELE for action.

Chapter 9
System Boot

9.1 Overview

The boot process begins at the Power-On Reset (POR) where the hardware reset logic forces the boot core to begin the execution starting from the on-chip boot ROM.

The platform boot is performed by the boot ROM and the EdgeLock secure enclave ROM, working in concert to ensure that the intended and authorized set of images are loaded and started on various processing domains contained by the SoC. The EdgeLock secure enclave ROM manages the secure boot flow based on EdgeLock secure enclave (EdgeLock secure enclave) while the boot ROM mainly handles code fetch and other aspects of functional flow.

9.1.1 Features

The main features of the ROM include:

- Cortex-A55 ROM Boot
- Support for booting from various boot devices
- Serial downloader support

The boot ROM supports the following boot devices:

- Serial NOR Flash via FlexSPI
  - Single (1-1-1 opcode-address-data) fast read
  - Quad (1-4-4 opcode-address-data) fast read
  - Octal (8-8-8 opcode-address-data) fast read
  - Auto probe for MxicOctal, MicronOctal and QuadSPINOR
- Serial NAND Flash via FlexSPI
  - 2K Page NAND
  - 4K Page NAND
- SD/eMMC via uSDHC
- Serial Downloader support on USB 2.0 only
- LPSPI (Recovery boot)

9.2 Cortex-A55 ROM Boot

In single boot, the Cortex-A55 ROM loads all containers and images, and then jumps to the A55 Firmware (FW).

The EdgeLock secure enclave authenticates the FW images if Secure Boot is enabled.

The following table provides the boot devices supported.

Table 32. Boot devices supported

Boot Stage	Cortex-A55 ROM
Primary and Secondary image set boot	eMMC on USDHC1 SD on USDHC2 FlexSPI NAND on FlexSPI1

Table continues on the next page...

Table 32. Boot devices supported (continued)

Boot Stage	Cortex-A55 ROM
	FlexSPI NOR on FlexSPI1
Recovery boot	LPSPI 3/4
USB serial download	USB HID on USB1

9.3 Boot Modes

There are 3 different boot modes supported on this chip:

- Normal Boot Mode
- Boot from Internal Fuse Mode
- Serial Download Boot Mode

The boot mode can be selected via the Boot Mode pins or overridden by fuses.

9.3.1 Boot Mode pins

There are four boot mode pins used to select boot mode. The boot mode is selected based on the binary value stored in the internal BOOT_MODE register.

The boot mode is initialized by sampling the BOOT_MODE[3:0] inputs on the rising edge of the POR_B. After these inputs are sampled, their subsequent state does not affect the contents of the BOOT_MODE internal register. The state of the internal BOOT_MODE register may be read from the IPP_BOOT_MODE[3:0] field of the SRC Boot Mode Register (SRC_SBMR2).

The available boot modes are detailed in the table below.

Table 33. Boot mode selection

BOOT CODE	BOOT CORE	BOOT_MODE[3:0]	Function
0x0	Cortex-A55	0000	Boot From Internal Fuses
0x1		0001	Serial Download (USB1)
0x2		0010	USDHC1 8-bit eMMC 5.1
0x3		0011	USDHC2 4-bit SD 3.0
0x4		0100	FlexSPI Serial NOR
0x5		0101	FlexSPI Serial NAND 2K
0x8 - 0xD		1000 - 1101	Reserved

9.3.2 Normal Boot Mode

In this mode, the boot flow is controlled by the boot type selection, boot device selection, and the boot mode settings.

In this mode, the boot code does the following:

- The Cortex-A55 ROM perform hardware initialization, and loads the images from the primary boot device which is selected by the Boot Mode pins or fuses.
- Performs image validation - it requests the EdgeLock secure enclave ROM to do this.

- Then jumps to the Cortex-A55 FW entry point specified in the Image Container.

If any error occurs during normal boot, the Cortex-A55 ROM will try to boot from the Secondary Image Container Set which is in the same boot device (primary boot device). If this fails, the ROM will try to boot from the Recovery Boot device. If Recovery Boot also fails, the Cortex-A55 ROM will jump to the Serial Downloader Mode (see Serial Download Mode).

9.3.3 Boot from Internal Fuses Mode

This mode is similar to the Normal Boot mode but with one difference. In this mode, the Boot Mode pins are ignored. The boot ROM code uses the boot eFUSE settings only. If set to Boot from eFuses, the boot flow is controlled by the BT_FUSE_SEL eFUSE value. If BT_FUSE_SEL = 0, indicating that the boot settings have not been provisioned into the fuse yet, the Cortex-A55 ROM both jump directly to the Serial Downloader. If BT_FUSE_SEL = 1, ROM retrieves the Boot Mode setting from the BT_MODE_FUSES fuse, and then attempts to boot from the selected boot device. The first time a board is used, the default eFUSEs may be configured incorrectly for the hardware on the platform. In such a case, the Boot ROM code may try to boot from a device that does not exist. This may cause an electrical/logic violation on some pads. Using Boot from Fuses mode addresses this problem.

The first time the BT_FUSE_SEL = 0 eFUSE is encountered, it is not blown (thus setting BT_FUSE_SEL). This forces the ROM code to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a Program Image and blow the BT_FUSE_SEL fuse and other boot configuration eFUSEs.

After reset, the Boot ROM code determines that the BT_FUSE_SEL fuse is blown (BT_FUSE_SEL = 1) and the ROM code performs the internal boot according to the new eFUSE settings. This allows a user to set BOOT_MODE[3:0] =4'b0000 on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without pullups/pulldowns on the BOOT_MODE pins.

BT_FUSE_SEL is only an indicator of BOOT_MODE fuse been blown. It has no impact for Internal Boot Mode.

If the fuse, Force_BT_FROM_FUSE, has been blown, the Boot Mode pins will be ignored, and the BootROM will always retrieve the boot mode from the internal fuses.

9.3.4 Serial Download Mode

The Serial Downloader provides a means to download a Program Image to the chip over USB serial connection.

Cortex-A55 ROM supports serial download mode on USB 2.0, and only on USB OTG1. This mode can be disabled by fuse.

9.4 Boot Stages

The Cortex-A55 ROMs support the following four boot stages.

1. Primary Image Container Set Boot (Primary Boot): Boot from the Primary Image Set Primary Boot Device.
2. Secondary Image Set Boot (Secondary Boot): Boot from the Secondary Image Set in Primary Boot Device.
3. Recovery Boot (if enabled via fuse): Boot from the image set in Recovery Boot Device (only one Image Set supported).
4. Serial Download Boot: load the image set via USB.

9.5 Image Container Set

9.5.1 Primary Boot Container Set

The images that will be loaded as part of the boot process are stored in containers. A container can contain one or multiple images, as blocks of data specifying the load address, target address, and so on.

9.5.1.1 Secondary Boot Container Set

The Secondary Boot Container Set is a copy of the Primary Container Set. ROM will always try to load the Primary Container Set first and if the Primary Container Set fails, ROM will then attempt to load the Secondary Container Set.

9.5.1.2 Primary Image Set and Secondary Image Set

The Primary Image Set is used in the Primary boot stage while the Secondary Image Set is used in the Secondary boot stage.

If there are two valid image container sets in the primary boot device:

- Primary Image Container Set: The one that has the newer SW Version. If the SW Versions are the same, or for eMMC fast boot Scenario, Image Container Set0 will be the primary one.
- Secondary Image Container Set: The one that has the older SW Version. If the SW Versions are the same, or for eMMC fast boot Scenario, Image Container Set1 will be the secondary one.

If there is only one valid image container set in the primary boot device:

- Both, Primary Image Container Set and Secondary Image Container Set are this only one valid image container set.

9.5.1.3 Typical Boot Image Sets Layout

The typical image layout is provided in the following table.

Table 34. Typical Cortex-A55 image layout for single boot

Primary Image Container Set	1st Container Header
	1st Signature Block
	Padding for 1KB alignment
	2nd Container Header (Optional)
	2nd Signature Block (Optional)
	EdgeLock secure enclave FW (Optional)
	FCB Copy Image (Optional)
	Cortex-A55 Image
…	
Secondary Image Container Set	

Restrictions to Images:

- The length of all container header(s) in a boot image set is up to 8KB.
- If EdgeLock secure enclave FW exists, it must be in the EdgeLock secure enclave/NXP container, and the EdgeLock secure enclave/NXP container must be the first container in the boot image set.
- The target address of Cortex-A55 FW must be in OCRAM free space or FlexSPI1 NOR space (XIP).
- The images cannot overlap with each other.
- The image offset (EdgeLock secure enclave FW, and Cortex-A55 FW) must be MAX[1KB, PAGE_SIZE_OF_BOOT_DEVICE] aligned.
- Except EdgeLock secure enclave FW, the target loading address must be MAX[1KB, PAGE_SIZE_OF_BOOT_DEVICE] aligned. For the EdgeLock secure enclave FW, the image size must be 4 bytes aligned.
- For eMMC fast boot or USB boot, images (including container headers) need to be continuous to its former.
- Cortex-A55 FW is mandatory for the boot image set.

NOTE

PAGE_SIZE_OF_BOOT_DEVICE value:

- For SPI NAND, it is 2KB/4KB.
- For SD/eMMC, it is 512B.
- For USB, it is 1KB.

9.5.2 Image Container Format

The image container format consists of the following parts.

- Container header
- Image array entry
- Signature block
- User program images and data

The high-level view of the container format is shown in the following figure.

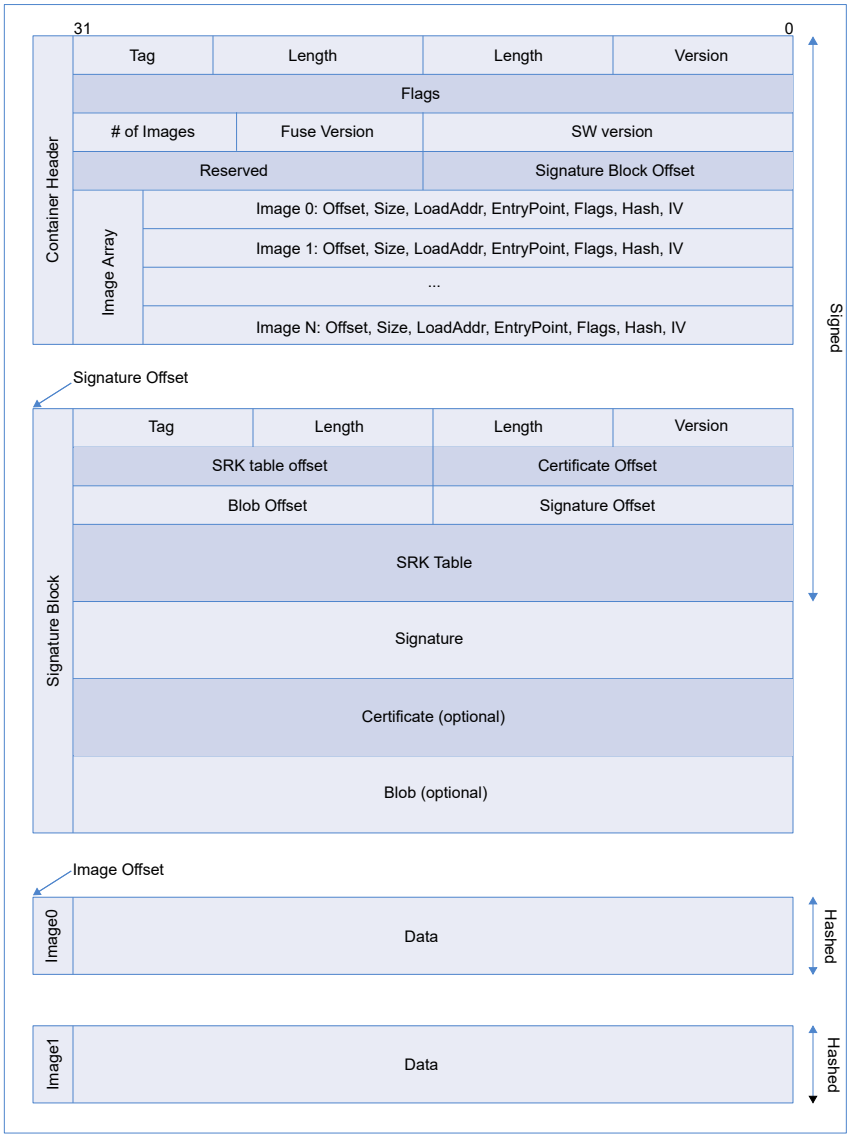


Figure 16. High level view of the container format

ROMs view of the offset/address in the Image container:

- **Blob/Certificate/Signature offset:** Relative to the beginning of Container Header start address, in bytes. 8 bytes alignment.
- **ImageArray.Imagex.Offset:** Relative to the container's start address (beginning of the 1st Container Header start address in the SD card (32KB), for instance), in bytes. Needs to be page aligned.
- **ImgeArray.Imagex.LoadAddr:** The address map is from the Cores view (required to be 4 bytes aligned):
  - For the images booted by Cortex-A55 ROM, the address map is from Cortex-A55 view.
  - 4 bytes aligned
- **ImageArray.Imagex.Entry:** This is from target core's local view. For example,
  - EdgeLock secure enclave FW entry address is from EdgeLock secure enclave view.
  - Cortex-A55 FW entry address is from Cortex-A55 view.

9.5.2.1 Container Header

The container header contains essential information about the entire container image which is used by the ROM.

Table 35. Container header format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Flags			
0x08	# of Images	Fuse Version	SW Version	
0x0c	Reserved		Signature Block Offset	
0x10	Image array (Please see Image Array Entry)			
	Signature Header (Please see Signature Header)			

The container header format fields are defined below.

- **TAG**: Must be 0x87
- **Length**: Size of the container in bytes, from header, up through and including signature block.
- **Version**: Must be 0x00
- **Flags**

Table 36. Flags bitfield description

Bit Field	Description
0-1	SRK Set 0x0 – Container not authenticated 0x1 – NXP SRK 0x2 – OEM SRK 0x3 – Reserved
2-3	Reserved (must be 0)
4-5	SRK Selection 0x0 – SRK1 is used 0x1 – SRK2 is used 0x2 – SRK3 is used 0x3 – SRK4 is used
6-7	Reserved (must be 0)
8-11	SRK Revoke Mask bitmask used to indicate which SRKs to revoke – zero bits set means no SRKs are to be revoked, bit0 – SRK1 is to be revoked,

Table continues on the next page...

Table 36. Flags bitfield description (continued)

Bit Field	Description
	bit1 – SRK2 is to be revoked, bit2 – SRK3 is to be revoked, bit3 – SRK4 is to be revoked,
12-15	Reserved (must be 0)
16-31	Reserved (must be 0)

- **# of images**: Number of images in the image array
- **Fuse Version**: This value must be equal to or greater than the version stored in the fuses to allow loading this container
- **SW Version**: Used to select between multiple images with same Fuse version field.
- **Signature Block Offset**: Offset in bytes from beginning of header to signature block (keys, signature, blob)

9.5.2.2 Container Header Offsets

The following table provides the offset for the 1st image set container header on various boot devices.

Table 37. The offset of the 1st image set

Boot Device	1st Image Container Offset
SD	32KB
eMMC	0 if located in Boot Partition and 32K if in User area
SPI NAND	Right behind FCB/DBBT
FlexSPI NOR	0x1000

The 2nd image set container header and its signature block will be right after the 1st image set container header and it's signature block, with 1KB alignment.

9.5.2.3 Signature Block

Table 38. Signature block format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	SRK Table Offset		Certificate Offset	
0x08	Blob Offset		Signature Offset	
0x0C	Reserved (for 64bit alignment purposes) 32 bit			
0x10	SRK Table (Please see SRK Table)			

Table continues on the next page...

Table 38. Signature block format (continued)

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
…	Signature (Please see Signature Header)			
…	Certificate (Please see Certificate Header)			
…	Blob (Please see Blob (DEK))			

The signature block format fields are defined below.

- **TAG**: 0x90
- **Version**: 0x00
- **SRK Table Offset**: Offset in bytes from beginning of signature block to SRK table. If 0x0000, then SRK table is not present. This should be the case only if the container is not authenticated, and the SRK key set field in the Container header should be 0.
- **Certificate Offset**: Offset in bytes from beginning of signature block to signing key certificate. If 0x0000, then only a SRK is used in signature verification
- **Signature Offset**: Offset in bytes from beginning of signature block to signature
- **Blob Offset**: Offset in bytes from beginning of signature block to DEK Blob. If 0x0000, then no images are encrypted

NOTE

1. SRK Table, Signature, Certificate and Blob must be in the order shown
2. Certificate and Blob are optional
3. SRK Table, Certificate, Blob, and Signature must start on 64 bit boundaries. Any padding needed to make this happen must be zeros.
4. The container signature is calculated of all data from beginning of container header to the last byte before the signature starts. In other words, most of the signature block itself is included in the signature calculations.

9.5.2.3.1 Certificate Header

The table below provides details about the Certificate Header structure:

Table 39. Certificate format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Permissions	Permissions(inverted)	Signature Offset	
0x08	Public Key			
	Signature			

The certificate format fields are defined below.

- **TAG**: 0xaf
- **Version**: 0x00
- **Permissions**: Bitmask used to indicate what a certificate can be used for

- **Permissions (inverted)**: Must be the same as the Permissions field bitwise inverted
- **Signature Offset**: Offset in bytes from beginning of certificate header to signature
- **Public Key**: Public key. Format matches SRK table “SRK record” entry, for both the RSA as well as ECDSA type keys.
- **Signature**: Signature of certificate. The signature is calculated over all data from the beginning of the certificate up to one byte before the signature itself: from the “Tag” byte through and including the public key SRK record.

9.5.2.3.2 Signature Header

The table below provides details about the Signature Header structure:

Table 40. Signature format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Reserved			
0x08	Signature Data			

The signature format fields are defined below.

- **TAG**: 0xD8
- **Version**: 0x00
- **Signature Data**:Signature.
  - RSA-PSS encoding
  - ECDSA: The r and s components are padded with leading zeros to make them each 8 bit aligned, then concatenated – r|s

9.5.2.3.2.1 SRK Table

The SRK table determines the signature type and length, and consists of 1 to 4 SRK records which contains the public keys. The format of the SRK table is inherited from HAB v4.x

Table 41. SRK table format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Version	Length of SRK Table		Tag
0x04	SRK Record 1			
-	SRK Record 2			
-	SRK Record 3			
-	SRK Record 4			

The SRK table fields are defined below.

- **TAG**: 0xD7
- **Length**: The size of the SRK table in bytes
- **Version**: 0x42

9.5.2.3.2.2 SRK Record

Table 42. SRK record format

Offset	Bits 31-24	Bits 23-16		Bits 15-8	Bits 7-0
0x00	Signing Algorithm	Length of SRK			Tag
0x04	SRK Flags	Reserved	Key Size/Curve		Hash Algorithm
0x08	RSA: Exponent Length (bytes)		RSA: Modulus Length (bytes)		
	ECDSA: Y Length (bytes)		ECDSA: X Length (bytes)		
0x0C	RSA: Modulus (Big endian)				
	ECDSA: X (Big endian)				
-	RSA: Exponent (Big endian)				
	ECDSA: Y (Big endian)				

The SRK record fields are defined below.

- **TAG**: 0xE1
- **Length**: The size of the SRK record
- **Signing Algorithm**:
  - RSA-PSS: 0x22
  - ECDSA: 0x27
- **Hash Algorithm**:
  - SHA-256: 0x00
  - SHA-384: 0x01
  - SHA-512: 0x02
- **Key Size/Curve**:
  - PRIME256V1: 0x1
  - SEC384R1: 0x2
  - SEC521R1: 0x3
  - RSA2048: 0x5
  - RSA3072: 0x6
  - RSA4096: 0x7
- **SRK Flags**:
  - None: 0x00
  - CA Flag: 0x80

NOTE

The keys in the SRK table must match the signing key in algorithm and key length

9.5.2.3.2.3 SRK Revoke

The EdgeLock secure enclave sets fuses based on the fields in the container or a message. If an SRK revoke bit or field return flag is set, the EdgeLock secure enclave will set that fuse. Since the containers are issued by the same entity that owns the SRKs, or is authorized by the SRKs owner, it is expected that the SRK revoke bits will correctly reflect the SRK status registered in the fuses, or revoke additional keys. The EdgeLock secure enclave will check that the SRK revoke bits in a parsed container match what is currently set in the fuses, or will revoke the additional keys corresponding to the revoke bits by updating the fuses.

9.5.2.3.2.4 SRK Fuses

The hash for each of the entire SRK table is stored in the SRK fuses. This allows the boot code to validate the keys in the SRK table from each container. For any of the 4 keys in SRK table that are unused, the corresponding key bits will be set to 0.

NOTE

SHA256 is used to hash the SRK tables

9.5.2.3.3 Image Array Entry

The boot ROM loads images in the order that the images appear in the array.

Table 43. Image Array Entry format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Image Offset			
0x04	Image Size			
0x08	Load Address (64 bits)			
0x0c				
0x10	Entry point (64 bits)			
0x14				
0x18	Flags			
0x1c	Image meta data			
0x20	Hash (512 bits)			
…				
0x60	IV (256 bits)			

The image array entry format fields are defined below.

- **Image Offset**: Offset in bytes from start of container header to beginning of the image
- **Image Size**: Size of the image in bytes
- **Load Address**: Address where the image is copied to in memory (absolute address in system memory map) by the ROM
- **Entry Point**: Entry point of the image (absolute address). Only valid for executable image types.
- **Flags**:

Table 44. Flags bitfield description

Bit Field	Description
0-3	Type of image 0x3 Executable 0x4 Data 0x7 Provisioning image 0x9 Provisioning data All other values reserved (These values extend HAB IVT V1)
4-7	Core ID 0x1 Reserved 0x2 Cortext-A55 All other values reserved
8-10	Hash type (all images in the container have the same HASH size) 0x0 – SHA256 0x1 – SHA384 0x2 – SHA512
11	Encrypted Indicate if this image is encrypted or not
12-31	Reserved

- **Image meta data**: For NXP FW private usage.
- **Hash**: SHA hash of image. Fixed size at 512 bits. Left aligned and padded with zero for hash sizes below 512 bits.
- **IV**: Used only for encrypted images (zero otherwise): SHA256 of the plain text image. Fixed size at 256 bits. The lower 128-bit part of the SHA256 value will be retained as IV in the encryption/decryption process.

9.5.2.3.4 Blob (DEK)

The Blob holds the Wrapped Data Encryption Key (DEK). It is optional if no images are encrypted. The format of the Blob is inherited from HAB v4.x.

Table 45. Blob format

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Tag	Length (MSB)	Length (LSB)	Version
0x04	Reserved	Algorithm	Size	Flags
0x08	Wrapped key			

The blob fields are defined below.

- **TAG**: 0x81

- **Length**: Size of the blob in bytes
  - 0x48: 72 bytes, corresponding to a 128 bit AES key blob.
  - 0x50: 80 bytes, corresponding to a 192 bit AES key blob.
  - 0x58: 88 bytes, corresponding to a 256 bit AES key blob.
- **Version**: 0x00
- **Algorithm**: 0x03: AES CBC
- **Size**:
  - 0x10: 128 bit AES key
  - 0x18: 192 bit AES key
  - 0x20: 256 bit AES key
- **Flags**:

  0x80: KEK key flag

  0x01: DEK

9.6 Boot Flow

1. Up to two containers (NXP and OEM containers) are expected to handle by system ROM code while only OEM container is must-have and NXP container is optional.
2. In case NXP container is available in the boot image container set, the NXP container must be the 1st container followed by OEM container. System ROM code always handles the containers one by one based on their container headers order in the header of the boot image container set.
3. If a container has multiple boot images (OEM container may contains multiple images while only EdgeLock secure enclave FW is allowed in NXP container), the images in the container will be handled by ROM code one by one based on the images order in the container header in most cases. The exceptions are the FCB region copy image and the fast boot image, if these two images are available in the OEM container, they will be handled by ROM code prior to other OEM images no matter their orders in OEM container.
4. OEM container contains:
   a. CA55 FW (must-have)
   b. FCB Region Copy Image (optional)
5. For OTFAD case, A55 ROM needs to initializes FlexSPI controller and device with the safe settings, so that EdgeLock secure enclave can access key blob from FlexSPI NOR device. A55 ROM doesn't care whether the OTFAD enabled fuse blown, EdgeLock secure enclave needs to take care of this fuse. A55 will always send the message to EdgeLock secure enclave to enable the OTFAD and check the status from EdgeLock secure enclave. From system ROM perspective, the expected behaviors of EdgeLock secure enclave are:

   IF (OTFAD Enabled fuse set) THEN

   EdgeLock secure enclave enable the OTFAD and send status to A55 ROM.

   ELSE

   EdgeLock secure enclave does not enable OTFAD and always send success to A55 ROM.
6. Before loading EdgeLock secure enclave FW, A55 ROM needs to check the corresponding bits in the GPR register. If the bit set, means the EdgeLock secure enclave FW is in running, A55 ROM skips to load this FW, move to load next image.
7. There is a fuse indicating if EdgeLock secure enclave FW is necessary. System ROM code doesn't check this fuse. In case the NXP container exists in the boot image set, CA55 always loads the NXP container and the EdgeLock secure enclave FW, then request EdgeLock secure enclave to authenticate the NXP container. EdgeLock secure enclave will decide whether to authenticate it or not.

8. In the MUST NOT NEED EDGELOCK SECURE ENCLAVE FW scenario, if CA55 ROM finds a EDGELOCK SECURE ENCLAVE FW container, then send the message to EdgeLock secure enclave. EdgeLock secure enclave should bypass this request and reply success to CA55 ROM.

9.6.1 High Level Boot Flow for A55 ROM

1. System ROM code should initialize all HW/SW resources which system ROM code is needed in ROM boot phase, includes not limits initialize stack/data sections, PLLs, clock root/source and peripherals.
2. System ROM code needs to select the one boot image container set based on both the SW versions of NXP/OEM container in the boot image container set and the boot stage.
3. System ROM code needs to address all containers in the selected boot image container set, includes load them into the target (XIP is also supported on XIP device), and request EdgeLock secure enclave to authenticate/verify the containers and their images.
4. If any failure happens, ROM code will go to the error handling, please refer to the Failure Handling in ROM for the details.
5. In case everything goes well, ROM code eventually jumps to the core image.

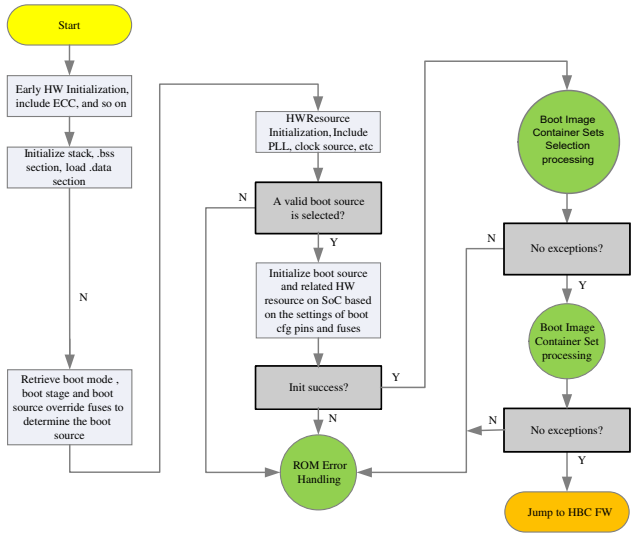

Figure 17. High Level ROM Boot Flow

9.6.2 ROM Early HW Initialization

9.6.2.1 RAM ECC

The ECCs of NICMIX OCRAM are enabled by default, so A55 ROM code needs to take care of NICMIX OCRAM to avoid ECC error which may be caused by accessing to un-initialized RAM space. Please refer ECC support for the details of how ROM code to initialize NICMIX OCRAM.

9.6.3 Boot Image Container Sets Selection

For primary boot stage and secondary boot stage, HBC ROM code boots from the selected primary boot device, and it is allowed up to two boot image container sets on primary boot device.

The offset of the 1st boot image container set is fixed on the primary boot device and hard code in ROM code, please refer to The Offsets of the Container Header section for the details. The offset of the 2nd boot image container set on the primary boot device is specified by the fuses “Secondary_boot_offset”:

Offset = 1MB * (2^n)

If Secondary_boot_offset = 0 → n = 2;

If Secondary_boot_offset = 2 → n = 0;

If Secondary_boot_offset = others and Secondary_boot_offset <= 10 → n = Secondary_boot_offset

If Secondary_boot_offset > 10 → Means there is no the 2nd boot image container set

In case there is only one boot image container set on boot source, ROM code regard it as primary boot image container set and will be used in primary boot stage; In case there is two boot image container sets on boot source, ROM code will pick up the one as primary boot image container set which will be used in primary boot stage and another→ one will be the secondary boot image set which will be used in secondary boot stage. It is determined by the SW version of NXP container and OEM container in two boot image container sets, below diagram shows the flow about how ROM code determine the primary and secondary boot image set.

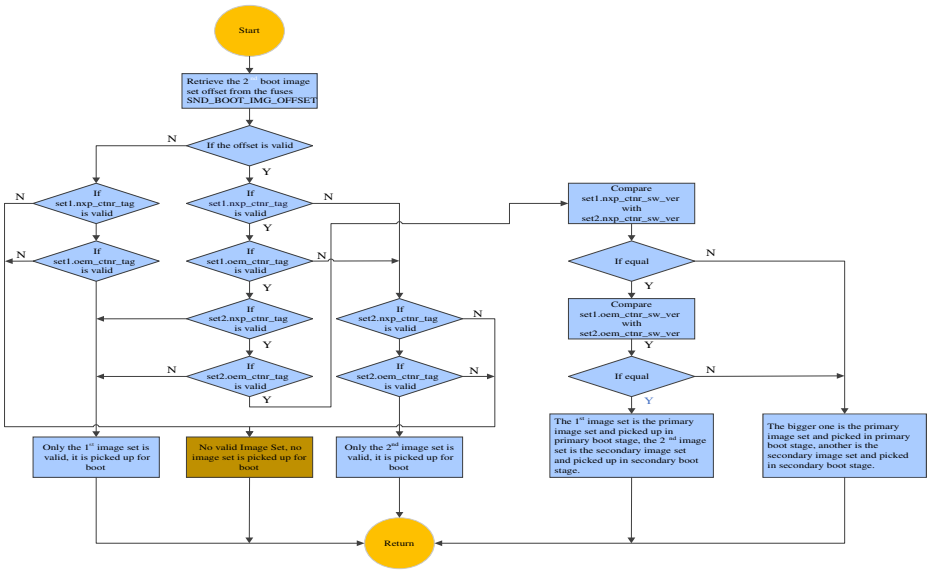

Figure 18. Boot Image Container Sets Selection

9.6.4 Boot Image Container Set Processing

The typical processing of handling boot image container set:

1. System ROM code loads the headers of the containers in boot image set (the headers are placed in the first 8KB space of the boot image set), analyzes the headers.
2. If NXP container exists in boot image container set, system ROM code needs to handle it prior to OEM container. System ROM code loads the NXP container (both header and EDGELOCK SECURE ENCLAVE FW) and request EDGELOCK SECURE ENCLAVE to authenticate NXP container via issuing “AUTH_NXP_CTNR” command to EDGELOCK SECURE ENCLAVE. If EDGELOCK SECURE ENCLAVE reply failure, break ROM boot flow, update boot stage to next stage then reset system.
3. OEM container is must-have, if it doesn’t exist in the boot image container set, system ROM code will break ROM boot flow, update boot stage to next stage then reset system.
4. For OEM container, system ROM code firstly request EDGELOCK SECURE ENCLAVE to authenticate its container header via issuing “AUTH_OEM_CTNR” command to EDGELOCK SECURE ENCLAVE, If EDGELOCK SECURE ENCLAVE reply failure, break ROM boot flow, update boot stage to next stage then reset system.
5. In the regular boot flow, if boot source is FlexSPI NOR device and FCB is available, the FCB check processing will be executed prior to other OEM images; if FCB check fails, break ROM boot flow, update boot stage to next stage then reset system.

6. ROM code will address OEM images one by one based the order in the OEM container (except FCB region copy image since it has been addressed yet), include loading them into target and request EDGELOCK SECURE ENCLAVE to verify via issuing “Image Verify” command to EDGELOCK SECURE ENCLAVE. If any failure, break ROM boot flow, update boot stage to next stage then reset system.

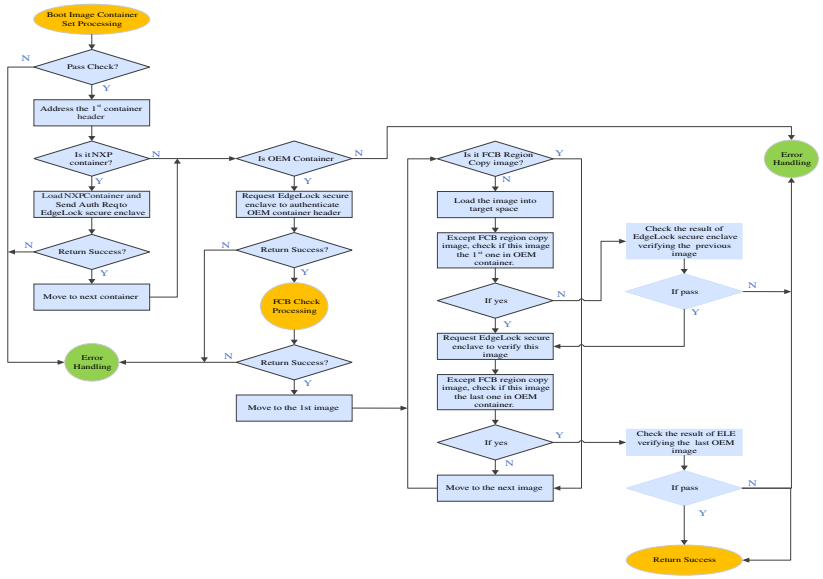

Figure 19. Boot Image Container Sets Selection

9.6.4.1 FCB Check

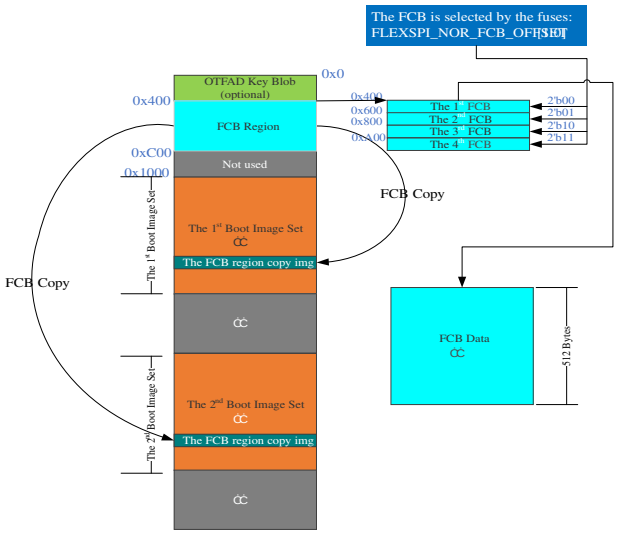
FCB Check processing is to protect FCB content from unexpected modifications because it may introduce the secure issue. For example, if an attacker modifies the FCB on device, then the corrupted FCB data could make the timing marginal, such that the images may pass authentication, but then when we try to execute the code with XIP mode, might not read the correct value from device.

The change request to boot image set:

Needs to build an extra image, names it as FCB region copy image, this image should be placed into OEM container. The content of the FCB region copy image should be exactly same with the content of FCB region at 0x400 on FlexSPI NOR device. Please refer to the “FCB Region” section for the details of FCB region. This FCB region copy image will be packaged into OEM container, and similar with other OEM images, the FCB region copy image should be signed with OEM SRK.

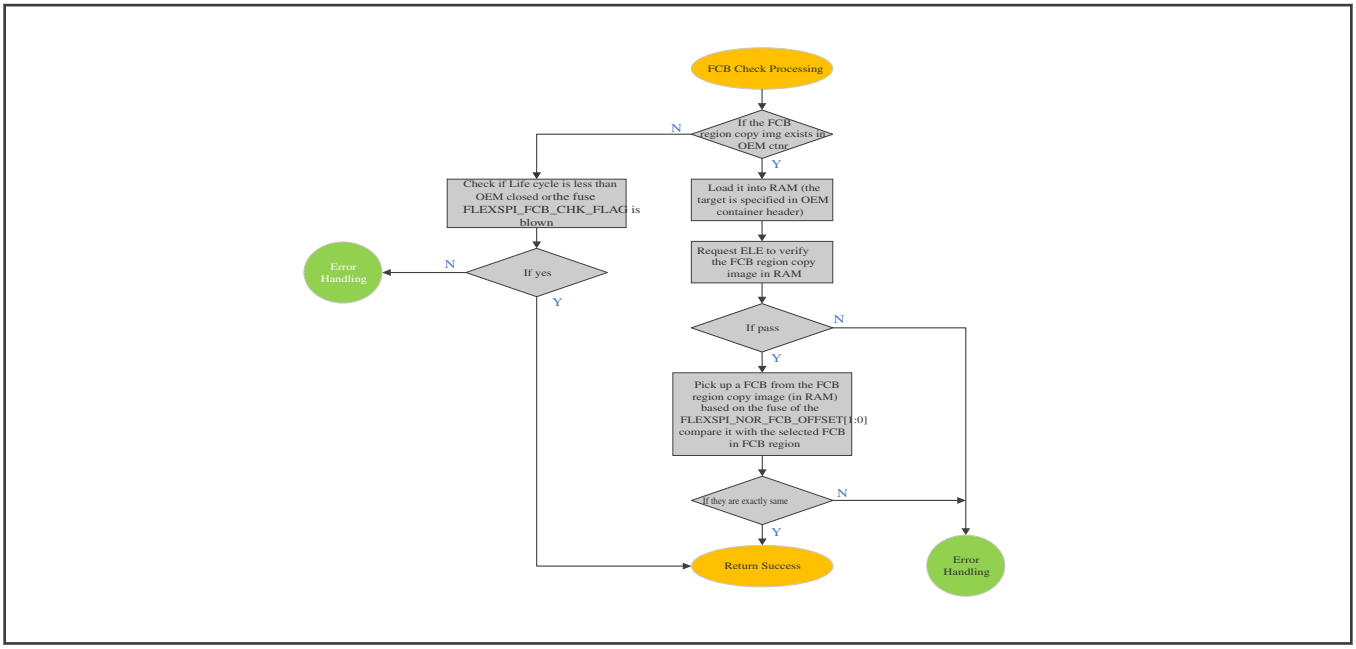
NOTE

The dst of this image must be located in RAM free space (OCRAM).



9.6.4.2 FCB Check Flow

1. Based on the value of the fuses FLEXSPI_NOR_FCB_OFFSET[1:0], ROM code picks up a FCB from FCB region, then retrieve the configuration parameters from this FCB, and use them to initialize FlexSPI NOR device;
2. Address NXP container;
3. Address OEM container:
    a. Request EdgeLock secure enclave to authenticate OEM container header;
    b. Checks if the FCB region copy image exists in OEM container. If yes, load it to RAM (the dst is specified in OEM container header), then request EdgeLock secure enclave to verify it;
    c. If the FCB region copy image pass the image verify, picks up the FCB from the FCB region copy image based on the value of the fuses FLEXSPI_NOR_FCB_OFFSET[1:0], the compare the content of this FCB with the FCB picked up in step #1. If they are exactly same, continue ROM boot flow; if not, break ROM boot flow, move boot stage then reset system.



The table below shows whether the FCB region copy image is must-have or optional.

The fuse FLEXSPI_FCB_CHK_FLAG	The Life Cycle	The FCB region copy image
X	Less than OEM Closed	Optional
0	Equal or bigger than OEM Closed	Must-have
1		Optional

NOTE

Once the FCB region copy image exists in OEM container, the FCB check is mandatory and the result of FCB check impacts the ROM boot, means the ROM boot flow will be broken in case any failure in FCB check.

FCB check is needed or not:

1. If the FCB region copy image exists in OEM container, the FCB check processing must be executed, and the result will impact the ROM boot processing; (FCB check is needed)
2. If the FCB region copy image doesn't exists in OEM container,
    a. If life cycle is less than OEM closed, it doesn't impact ROM boot; (avoid FCB check)
    b. If life cycle is >= OEM closed:
        i. In case FLEXSPI_FCB_CHK_FLAG is blown (=1), it doesn't impact ROM boot; (avoid FCB check)
        ii. In case FLEXSPI_FCB_CHK_FLAG is not blown (=0), ROM boot flow will be broken and move to next boot stage; (FCB check is needed)

9.6.5 AARCH32 A55 ROM

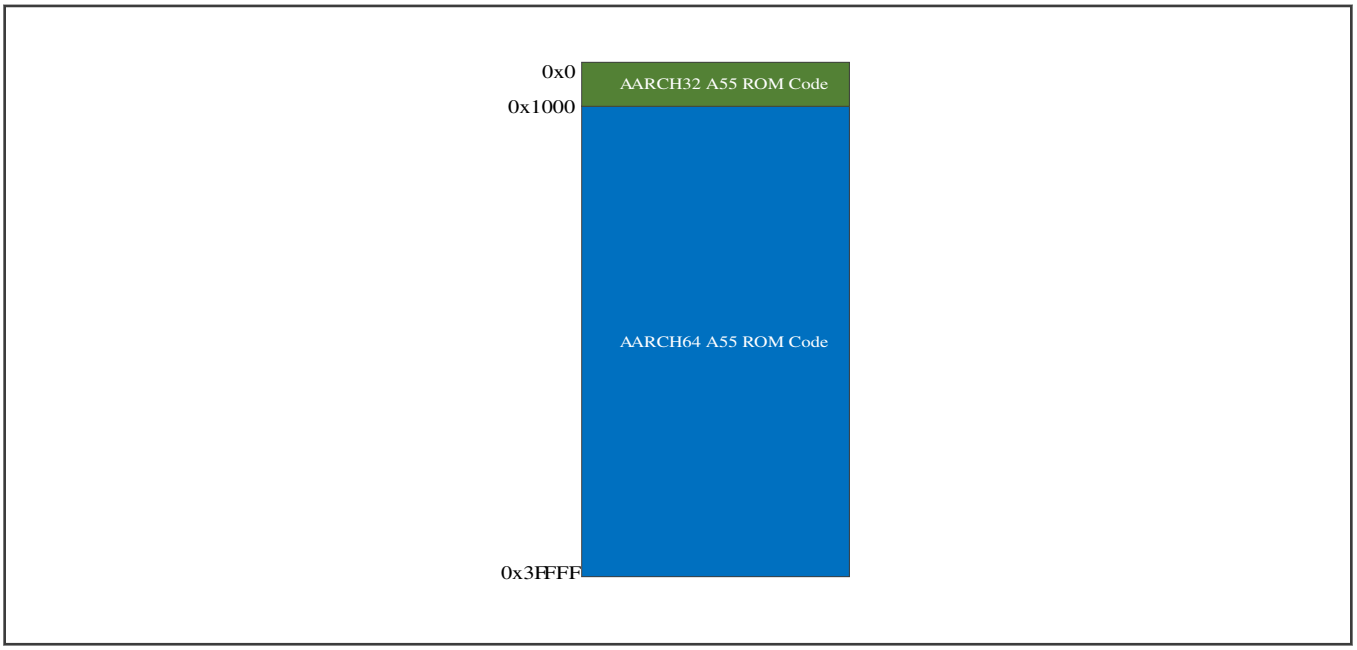
There are two pieces of A55 ROM code:

- AARCH64 A55 ROM code
- AARCH32 A55 ROM code

The purpose to have a AARCH32 CA5 ROM code is to meet the A55 resume usage in AARCH32 mode.

In AARCH64 mode, the start address of CA55 core is decided by RVBAR setting. The reset value of RVBAR is point to 0x1000, means the AARCH64 CA55 ROM code will be executed after reset. And SW is able to update the start address of CA55 core via updating the RVBAR register, for example, place a resume SW in OCRAM space before suspend system, and update the RVBAR register with the entry point of the resume SW in OCRAM, then system is resume, CA55 core starts from OCRAM that the address is specified by RVBAR.

But in AARCH32 mode, CA55 core must starts at 0x0 address, so is not able to update the start address of CA55 core in AARCH32 mode via updating RVBAR. So has to have a AARCH32 CA55 ROM code and place it at 0 address. In AARCH32 mode, after system resume, CA55 core starts from 0 address, it's AARCH32 CA55 ROM code, this AARCH32 CA55 ROM code will retrieve the entry point from RVBAR register, if the entry point is valid, then jumps to it. The entry point reading from RVBAR must be within OCRAM or TCM or DRAM or FlexSPI NOR memory-mapped space, otherwise the entry point will be regarded as invalid, then re-run from 0 address.



9.6.6 Failure Handling in ROM

There are two categories of failures: Fatal and non-Fatal.

Fatal:

- Attack been detected by HW or Cortex-A55 ROM itself (stack cookie, SW secure counter).
- Hard Fault in ROM code.

Non-Fatal:

- Boot device initialization failed.
- Boot device read failure (ECC error, timeout, etc.)
- image failure.

For Fatal failures, ROM trigger a WDOG reset.

For non-fatal failures, ROM sets next boot stage, and then trigger a WDOG reset. After the reset, ROM will try to boot from the secondary image container set. If this fails, it moves to recovery boot. If recovery boot also fails, ROM will move to USB SDP boot. If Booting from the primary boot image set fails, ROM updates the boot stage information stored in the SRC GPR16 register to move to next boot stage, then resets the system. In next boot cycle after system is out of reset, ROM moves to the next boot stage and tries again. The sequence of boot stage moving is Primary image set boot => Secondary Image Set boot => Recovery boot(If enable in fuse) => USB serial download boot;

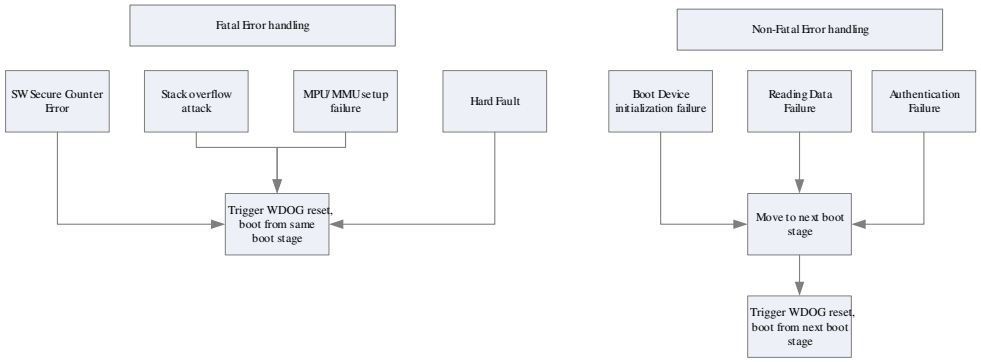


Figure 20. Failure Handling

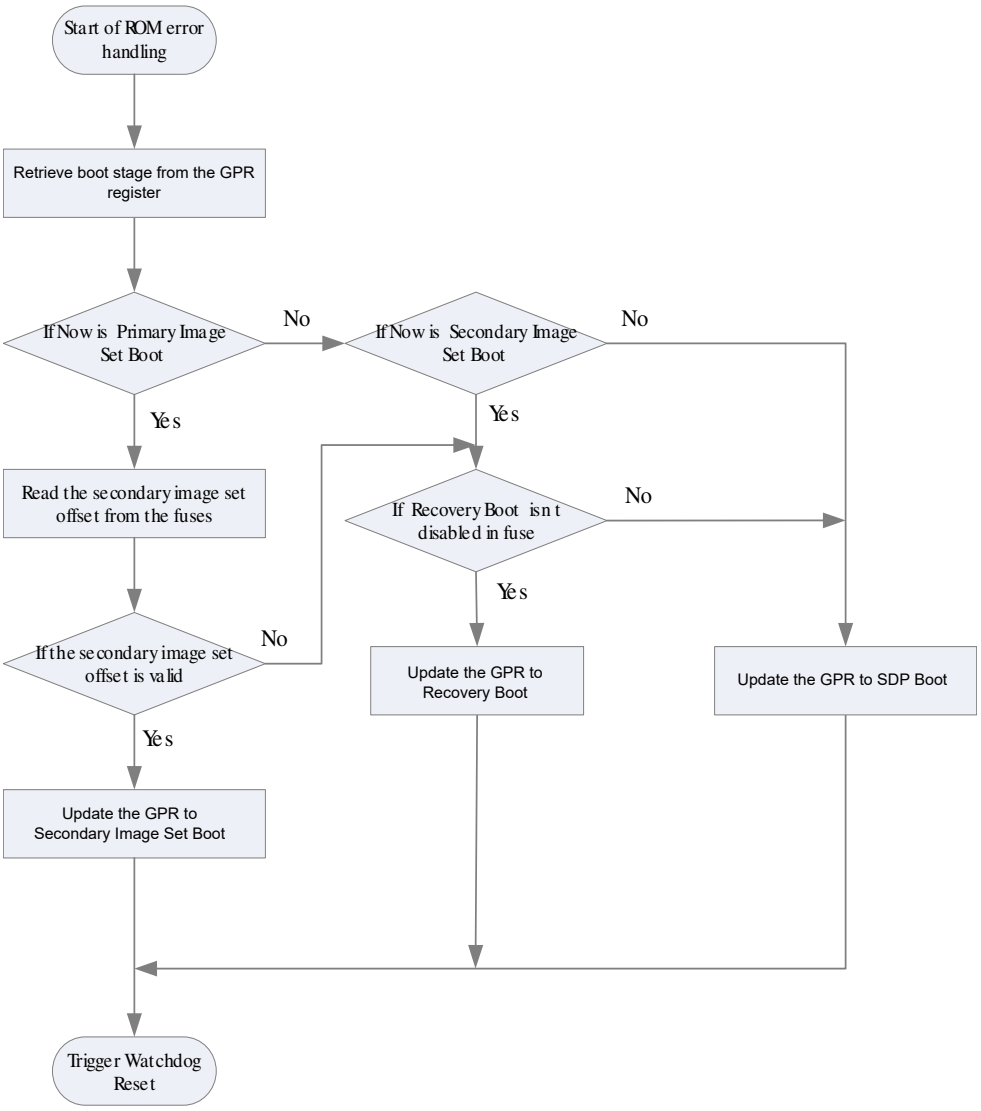

Figure 21. ROM Error Handling

9.7 Platform Initialization In ROM

This section describes the details of the ROM and provides the initialization details. This includes details on:

- ROM memory usage map
- On-chip blocks that the ROM must enable.
- Clock initialization
- Watchdog initialization
- Timer initialization
- Exception handling and interrupt handling
- Failure Handling

9.7.1 Memory Usage

9.7.1.1 Cortex-A55 Memory Usage Map

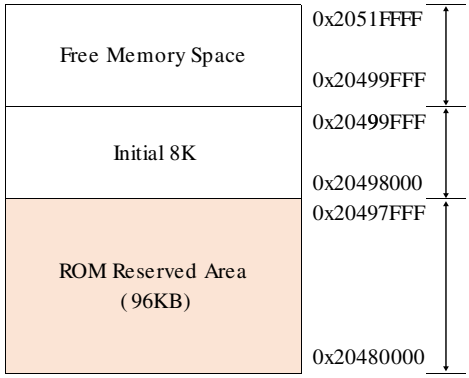

Figure 22. OCRAM Usage in Cortex-A55 ROM Code (Non-secure View)

The initial 8KB is used to store the initial image and can be cleared by post boot firmware.

9.7.2 System HW Settings in ROMs

Table 46. ROM Hardware Usage Overview

Cortex-A55 ROM
EdgeLock secure enclave AHB
CCM/System PLL/ARM PLL
WDOG3
FlexSPI1
IOMUXC
LPSPI3, LPSPI4
Cortex-A55 ICache

Table continues on the next page...

Table 46. ROM Hardware Usage Overview (continued)

Cortex-A55 ROM
USDHC1, USDHC2
USB1
USB1 PHY
OCRAM

9.7.3 Peripheral Clock Enable

The ROM code enables the clocks for the peripherals listed in the following table.

Table 47. Peripheral Clock Enable

Peripheral	Status after ROM exits
WDOG1/3	Enabled
FLEXSPI1	Enabled if FLEXSPI1 NOR/NAND boot
USDHC1/2	Enabled if USDHC1/2 boot
LPSPI1/2/3/4	Enabled if LPSPI1/2/3/4 recovery boot
USB_OTG1	Enabled if SDP boot

9.7.4 Watchdog

By default, the Watchdog (WDOG) hardware is disabled. Unless the fuse WDOGn_ENABLE is blown, ROM will not enable the watchdog. The WDOG timeout can be selected by the fuse 'WDOG Timeout Select'. The fuse setting details are provided below.

'WDOG Timeout Select' configuration options:

- 00 – 1s (Depends on the WDOG reset number)
- 01 – 0.5s
- 10 – 0.25s
- 11 – 0.125s

WWDOG3_ENABLE configuration options:

- 0 – Disabled
- 1 – Enabled”

The Cortex-A55 only uses WDOG3.

9.7.5 Timer

After the necessary internal initialization tasks have been completed, ROM will enable the timer. Once the timer has been enabled, it is in free running mode and ROM will not disable it again.

The Cortex-A55 ROM uses the Generic Timer.

9.7.6 ECC support

There is a HW ECC initialization feature in MECC256. ROM will take advantage of this. This HW engine zeroize all area of OCRAM. ROM polling the register bit until the initialize finishes.

9.7.7 Interrupt and Exception Handling

All interrupts are masked by both the Cortex-A55 ROM.

There are two exception handles in the Cortex-A55 ROM to handle various exceptions:

1. SVC
2. Others
    - Trigger a watchdog reset

9.7.8 Failure Handling in ROM

There are two categories of failures: Fatal and non-Fatal.

Fatal:

- Attack been detected by HW or Cortex-A55 ROM itself (stack cookie, SW secure counter).
- Hard Fault in ROM code.

Non-Fatal:

- Boot device initialization failed.
- Boot device read failure (ECC error, timeout, etc.)
- image failure.

For Fatal failures, ROM trigger a WDOG reset.

For non-fatal failures, ROM sets next boot stage, and then trigger a WDOG reset. After the reset, ROM will try to boot from the secondary image container set. If this fails, it moves to recovery boot. If recovery boot also fails, ROM will move to USB SDP boot. If Booting from the primary boot image set fails, ROM updates the boot stage information stored in the SRC GPR16 register to move to next boot stage, then resets the system. In next boot cycle after system is out of reset, ROM moves to the next boot stage and tries again. The sequence of boot stage moving is Primary image set boot => Secondary Image Set boot => Recovery boot(If enable in fuse) => USB serial download boot;

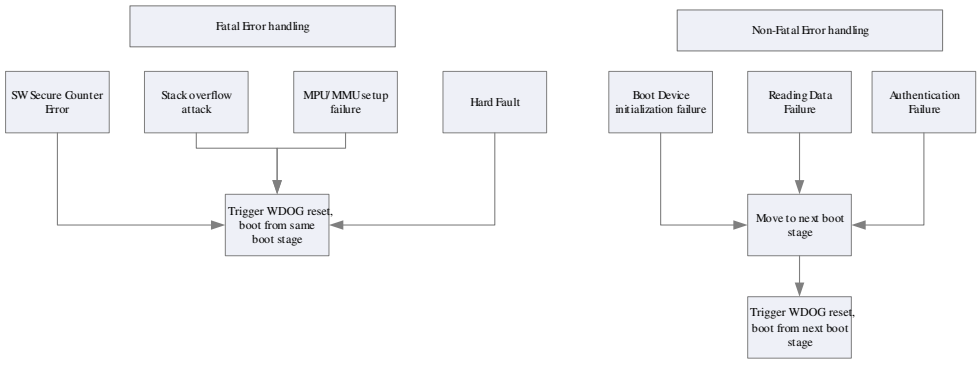

Figure 23. Failure Handling

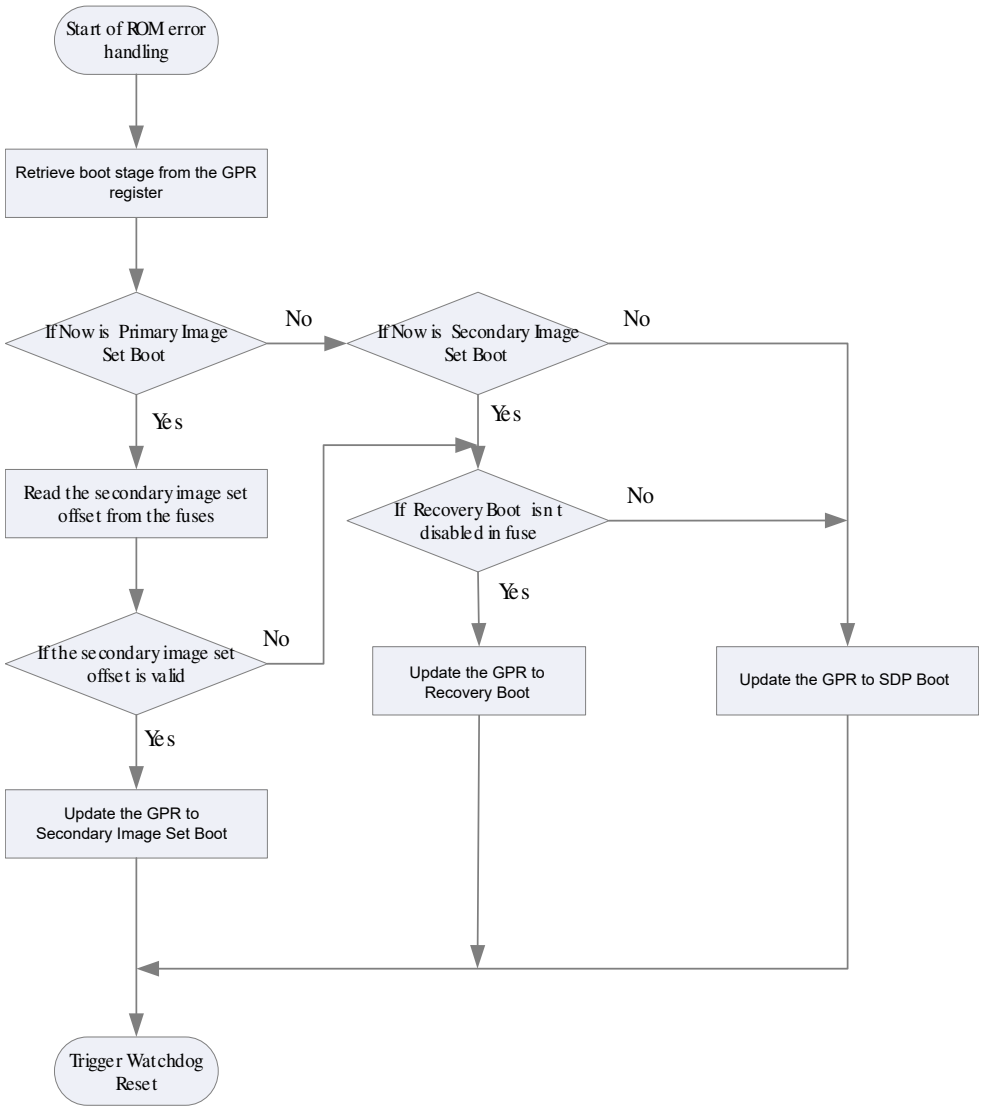

Figure 24. ROM Error Handling

9.7.9 SRC GPR Registers Usage in System ROM Code

Table 48. SRC GPR Registers Usage in System ROM

GPR16	ROM flags	Bit0: EdgeLock secure enclave FW Loaded flag Bit2: CA55 FW Loaded flag Running flag: 0 – The FW is not loaded 1 – The FW is loaded Bit8: SDP on Demand 0 – USB SDP is not on-demand

Table continues on the next page...

Table 48. SRC GPR Registers Usage in System ROM

		1 – USB SDP mode is on-demand Bit[31:28]: CA55 ROM Boot Stage

9.8 Boot Devices

9.8.1 FlexSPI

The ROM supports auto probe (SFDP (JESD-216) discoverable parameters) feature.

9.8.1.1 IOMUX configuration for FlexSPI devices

The following table shows the FlexSPI IOMUX pin configuration.

Table 49. FlexSPI IOMUX Pin Configuration

Signal Name	PAD Name
FlexSPI_A_DATA0	SD3_DATA0 (ALT1)
FlexSPI_A_DATA1	SD3_DATA1 (ALT1)
FlexSPI_A_DATA2	SD3_DATA2 (ALT1)
FlexSPI_A_DATA3	SD3_DATA3 (ALT1)
FlexSPI_A_DQS	SD1_STROBE (ALT1)
FlexSPI_A_SS0_B	SD3_CMD (ALT1)
FlexSPI_A_SS1_B	SD1_DATA3 (ALT1)
FlexSPI_A_SCLK	SD3_CLK (ALT1)
FlexSPI_A_DATA4	SD1_DATA4 (ALT1)
FlexSPI_A_DATA5	SD1_DATA5 (ALT1)
FlexSPI_A_DATA6	SD1_DATA6 (ALT1)
FlexSPI_A_DATA7	SD1_DATA7 (ALT1)

9.8.1.2 FlexSPI eFUSE Configuration

The boot ROM determines the configuration of external Serial NAND/NOR flash by parameters, either provided by eFUSE, or sampled on GPIO pins during boot. See below table for parameters details.

Table 50. FlexSPI Boot eFUSE Configuration

Fuse	Definition	Settings
BOOT_MODE[3:0]	Boot device selection	Cortex-A55 : • 0100 - FlexSPI Serial NOR • 0101 - FlexSPI Serial NAND 2K page
BOOT_CFG0[4]	Override_FlexSPI_NOR_Boot_Selection	0 - Do not override 1 - Override

Table continues on the next page...

Table 50. FlexSPI Boot eFUSE Configuration (continued)

Fuse	Definition	Settings
BOOT_CFG0[6:5]	FlexSPI_NOR_Boot_Override_Selection	00 - Flex SPI (Hyperflash 1.8V) 01 - Flex SPI (Flash with 4B READ(0x13)default supported) 10 - Default Octal mode (Micron) 11 - Default Octal mode (Mxic)
BOOT_CFG0[7]	FlexSPI_NAND_4K_Page_Selection	0 - Not override the default seleciton (2K page) 1 - Override, 4K page is selected
BOOT_CFG2[1:0]	FlexSPI NAND Column Address Width	00 - 12 01 - 13 10 - 14 11 - 15
BOOT_CFG2[3:2]	FlexSPI NAND CS Interval	00 - 100 ns 01 - 200 ns 10 - 400 ns 11 - 50 ns

BOOT_CFG2[23]	FlexSPI NAND Busy Bit Offset Override	0 - Do not override 1 - Override

9.8.1.3 FlexSPI Initialization Flow

A reset pin can be selected via the “FlexSPI NOR Reset Pin Port selection” fuses and “FlexSPI NOR Reset Pin selection” fuses. If a valid number has been programmed in these fuses then ROM code will toggle the selected GPIO pin to execute a cold reset to FlexSPI NOR device. The selected GPIO pin should be able to power down the FlexSPI NOR device on low polarity and power up the device on high polarity.

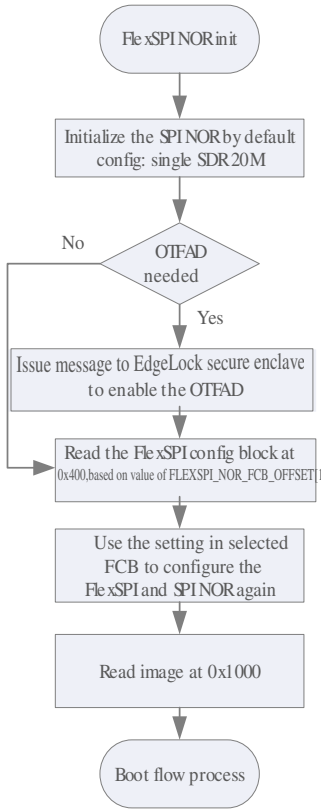

Figure 25. FlexSPI Initialization Flow

9.8.1.4 FlexSPI NOR Memory Map

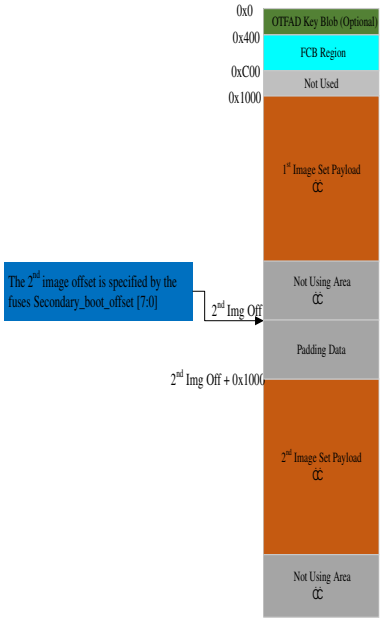

Figure 26. FlexSPI NOR Memory Map

9.8.1.5 FlexSPI NOR FCB region

The FCB region is located at offset 0x400 on FlexSPI NOR device, the size of FCB region is 2KB, so it can have up to 4 FCBs (FlexSPI NOR Configuration Block).

The change request to boot image set:

Two fuses FLEXSPI_NOR_FCB_OFFSET[1:0] are used to select the FCB which will be picked up ROM code to initialize FlexSPI NOR device:

NOTE

the dst of this image must be located in RAM free space (OCRAM).

FLEXSPI_NOR_CONFIG_BLOCK_OFFSET[1:0]	The selected FCB
2'b00	The 1st FCB (offset 0x400)
2'b01	The 2nd FCB (offset 0x600)
2'b10	The 3rd FCB (offset 0x800)
2'b11	The 4th FCB (offset 0xA00)

9.8.1.6 FlexSPI NAND

A typical FlexSPI NAND memory map contains two copies of Firmware Config Blocks (FCBs), two copies of discovered bad-block tables (DBBTs) and two image sets. Two image sets share same FCB and DBBT. The first FCB located at the start of the SPI NAND Flash, which is block0, page0. The second FCB located at (0 + page_index * FCB0->searchStride). Using FCB data structure, the DBBT0 and DBBT1 can be found. Normally, ROM use the first FCB and DBBT. If the blocks for FCB and DBBT are corrupted, ROM will search for the next FCB and DBBT using searchCount.

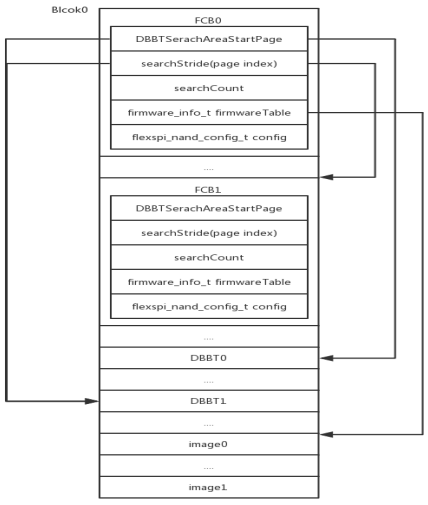

Table 51. FlexSPI NAND Configuration

Name	Offset	Size in bytes	Descriptions
flexspi_mem_config_t memConfig	0x0	448	Generic Memory configuration block over FlexSPI
pageDataSize	0x1c0	4	Data Size in one page, usually it is 2048 or 4096
pageTotalSize	0x1c4	4	Total size in one page, usually, it equals 2 ^ width of column address

5 = 32MB

6 = 64MB

7 = 128MB

8 = 256MB

9.8.1.6.1 SPI NAND flash boot flow and Boot Control Blocks(BCB)

There are two BCB data structures:

- FCB
- DDBT

As a part of the SPI NAND media initialization, the ROM driver uses safe SPI NAND timings to search for the Firmware Configuration Block(FCB) that contains the optimum NAND timings, the page address of the Discovered Bad Block Table (DBBT) Search Area, and the start page address of image table. If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments the page number to the Search Stride number of pages to read for the next BCB until the SearchCount pages have been read. If the search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM enters the serial download mode. The FCB contains the page address of the DBBT Search Area, and the page address for primary and secondary boot images. The DBBT is searched in the DBBT Search Area, just like the FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using the starting page address from the FCB.

9.8.1.6.2 Firmware configuration block (FCB) and Discovered Bad Block Table

The FCB is the first sector in the first good block. The FCB must be present at each search stride of the search area. The search area contains copies of the FCB at each stride distance, so, in case the first NAND block becomes corrupted, ROM finds its copy in the next NAND block. The search area must span over at least two NAND blocks. The location information for the DBBT search area, FW1, and FW2 are all specified in the FCB. This table shows the flash control block structure:

Table 52. FLEXSPI NAND FCB

Name	Offset	Size in bytes	Descriptions
reserved	0x0	4	Not used
fingerprint	0x4	4	32-bit word with a value of 0x20424346, in ascii \"FCB\"
version	0x8	4	32-bit version number; this version of FCB is 0x00000001
DBBTSerachAreaStartPage	0xc	4	page index for the first DBBT
searchStride	0x10	2	FCB and DBBT search stride
searchCount	0x12	2	Search time for both FCB and DBBT
firmwareCopies	0x14	4	not used in ROM
reserved	0x18	40	
firmwareTable	0x40	80	Firmware table, each firmware consist two word. - uint32_t startPage - uint32_t pagesInFirmware ROM only use the first firmware to do primary boot. Put this field here is to be compatible with other projects
reserved1	0x80	128	
flexspi_nand_config_t config	0x100	512	Another config structure for flexspi host driver

Table 53. Discovered Bad Block Table

Name	Offset	Size in bytes	Descriptions
reserved	0x0	4	-
fingerprint	0x4	4	32-bit word with a value of 0x44424254,in ascii \"DBBT\"
version	0x8	4	32-bit version number; this version of DBBT is 0x00000001
reserved	0xc	4	
badBlockNumber	0x10	4	Total number of bad blocks
reserved	0x14	12	
badBlockTable	0x20	1024	block number

Bad Block handling in ROM - During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block. If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

9.8.2 Expansion Device

The ROM supports booting from the eMMC and SD compliant devices.

9.8.2.1 Clock Settings for SD/eMMC

For USDHC1/2, the clock source is SYS_PLL_PFD1, which is 200MHz.

9.8.2.2 IOMUX Configuration for SD/eMMC

Table 54. SD/eMMC IOMUX pin configuration

BOOT_CFG1[31]	uSDHC DLL Select	0 - DLL Slave Mode 1 - DLL Override Mode

9.8.2.4 SD/eMMC Memory Map

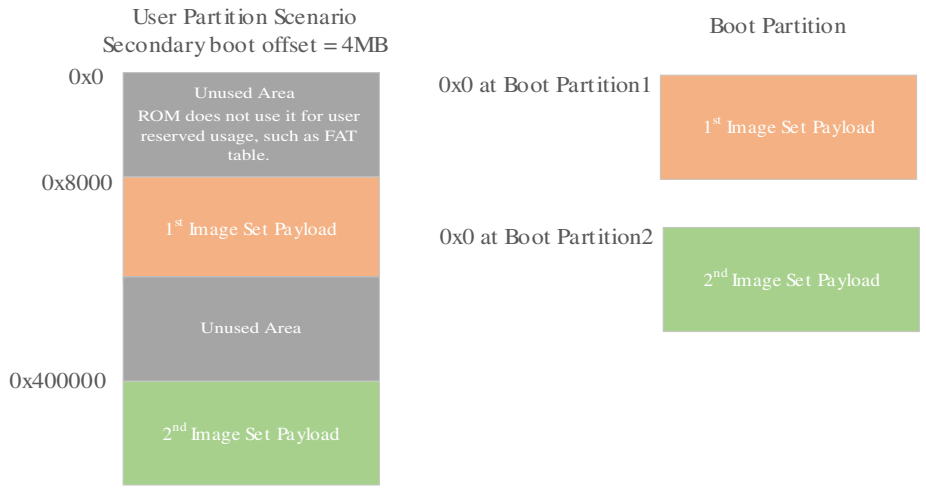

Figure 27. SD/eMMC Memory Map

9.8.3 LPSPI

The chip supports recovery devices, such as serial EEPROM and NOR flash, using the LPSPI. If the primary boot device fails, the boot ROM tries to boot from the recovery device using one of the LPSPI ports.

9.8.3.1 IOMUX Configuration for LPSPI

The following table shows the LPSPI pin configuration.

Table 56. LPSPI pin configuration

Signal Name	LPSPI1	LPSPI2	LPSPI3	LPSPI4
PCS1	PDM_BIT_STREAM0 (ALT2)	PDM_BIT_STREAM1 (ALT2)	GPIO_IO07 (ALT1)	GPIO_IO17 (ALT5)
SIN	SAI1_TXC (ALT2)	UART1_RXD (ALT2)	GPIO_IO09 (ALT1)	GPIO_IO19 (ALT5)
SOUT	SAI1_RXD0 (ALT2)	UART2_RXD (ALT2)	GPIO_IO10 (ALT1)	GPIO_IO20 (ALT5)
SCK	SAI1_TXD0 (ALT2)	UART2_TXD (ALT2)	GPIO_IO11 (ALT1)	GPIO_IO21 (ALT5)
PCS0	SAI1_TXFS (ALT2)	UART1_TXD (ALT2)	GPIO_IO08 (ALT1)	GPIO_IO18 (ALT5)

9.8.3.2 Expansion Device LPSPI fuse Configuration

LPSPI boot can be performed based on setting of the BOOT_CFG.

Table 57. Expansion Device LPSPI FUSE Configuration

Fuse	Definition	Settings
BOOT_CFG8[19]	Disable_A55_SPI_Recovery	0 - Disabled 1 - Enabled
BOOT_CFG8[20]	Reserved	

Table continues on the next page...

Table 57. Expansion Device LPSPI FUSE Configuration (continued)

Fuse	Definition	Settings
BOOT_CFG2[16]	SPI Clock/Data Phase Control	0 - Tx on falling, Rx on rising 1 - Tx on rising, Rx on falling
BOOT_CFG2[17]	SPI SCLK Active	0 - Active high 1 - Active low
BOOT_CFG2[18]	SPI SS Active	0 - Active low 1 - Active high
BOOT_CFG2[19]	Recovery SPI Addressing	0 - 3-bytes (24-bit) 1 - 2-bytes (16-bit)
BOOT_CFG2[24]	Recovery CS Select	0 - CS0 1 - CS1
BOOT_CFG2[27:26]	Recovery Port Select	0 - LPSPI1 1 - LPSPI2 2 - LPSPI3 3 - LPSPI4

9.9 Serial Downloader Boot

9.9.1 USB Serial Download

The Serial Downloader provides a means to download a Program Image to the chip over USB serial connection.

USB serial download boot is supported on USB 2.0 OTG, as HID device. Serial download is only supported via the USB1 instance.

USB boot in ROM code works as a HID device. The ROM will view the USB as a normal boot device, similar to the SD card. The difference from the SD card here is that the USB is a 'stream' device. ROM must 'read' it one byte at a time, and it can not specify the offset for the reading. This means that the image for USB boot must be continuous.

The USB boot flow is as follows:

1. ROM gets into USB boot mode and has been enumerated by Host.
2. The Host sends 8KB (initial image header) through USB. ROM reads 8KB from USB connection.
3. ROM parses the header and reads all SPL into OCRAM, per the information provisioned in the IVT header.
4. ROM authenticates the SPL and then jumps to it, if authentication passes.

USB Serial Download boot can be disabled by fuse.

The USB HID device VID/PID and strings are listed in the following table.

Table 58. VID/PID and strings for USB HID device

Descriptor	Value
VID	0x1FC9

Table continues on the next page...

Table 58. VID/PID and strings for USB HID device (continued)

Descriptor	Value
PID	0x14E
PID for Azure	0x150
bcdDevice	0x0001

9.9.2 USB Serial Download Descriptor on Chip Lifecycle

ROM provides the current lifecycle (LC) status in the USB String Descriptor 2.

Table 59. USB string descriptor 2 lifecycle values

Lifecycle	USB String Descriptor 2 Value
FAB	FA
INVALID/UNKNOWN	IV
BLANK	BA
NXP_PROV	NP
OEM_OPEN	OO
OEM_SWC	OS
OEM_CLOSED	OC
FR_OEM	FO
FR_NXP	FN
OEM_LOCKED	OL

NOTE

For information on life cycle management of this chip, see the chip's Security Reference Manual.

9.9.3 Serial Downloader eFUSE Configuration

The SDP eFUSE settings are provided in the following table.

Table 60. SDP eFUSE Configuration

Fuse	Definition	Settings
BOOT_MODE[3:0]	Boot device selection	Cortex-A55: • 0001 - Serial Downloader
BOOT_CFG10[2]	SDP_Disable	0 - Enabled 1 - Disabled
BOOT_CFG10[3]	SDP_WO	0 - Enabled 1 - Disabled
BOOT_CFG10[4]	SDP_READ_DISABLE	0 - Enabled 1 - Disabled

9.10 Secure Boot

The boot ROM uses the Advanced High Assurance Boot (AHAB) library to provide a secure boot environment for the Cortex-A55 boot procedures.

AHAB is a combination of hardware and software operation, offered by the EdgeLock secure enclave service, using a Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized images. In order for the AHAB to allow an image to run, the image must be signed by a private key holder that matches with the public key embedded in the Fuses.

NOTE

Refer to the chip's Security Reference Manual for additional details on secure boot.

9.11 ROM API

The main purpose is for SPL calling to load/authentication images. The ROM API table is as follows:

Table 61. ROM API Table

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x0	Tag: 0xEA91		Version: 0x0001	
0x4	Reserved as 0x0			
0x8-0xF	Pointer to address of download_image			
0x10 – 0x17	Pointer to address of query_boot_infor			
0x18-0x3F	Reserved as 0x0			

9.11.1 API download_image

The SPL calls this API to load images from the current boot device being active. The definition of this API is as follows.

```
UINT32 load_image(UINT8 *dst, UINT32 offset, UINT32 size, UINT32 xor)
```

The parameters are defined below:

- dst - The physical memory address to be loaded to.
- size - The image size to load. In bytes.
- offset - Where to read from boot device. In bytes. Relative to the beginning of the boot device
- xor - The xor of dst, size, and offset. To address fault injection attack.

The return values are defined below:

- 0xF0 for success others for failure.
- 0x01 – Invalid para. XOR wrong, invalid dest/sizeRead, invalid offset (not page aligned).
- 0x02 – low level device driver read failure (NAND ECC error, SD CRC error, etc.).
- 0x03 – Device not ready (not initialized yet or no valid device at all).
- 0x04 – Out of memory (such as loading data from FlexSPI flash but space is out of FlexSPI NOR device).

NOTE

For USB, the offset will be ignored by ROM.

For eMMC Fast boot, there are two scenarios.

1. Primary boot succeeds, eMMC card in Fast Boot Mode, offset will be ignored by load_image API.
2. Primary boot failed, ROM moves card into normal boot mode, then boots from Secondary Image, offset needs to be provisioned then.

The SPL can call query_boot_infor (BOOT_DEVICE) to check if the card is in Fast Boot Mode. Provisioning "offset" in SPL is recommended since it works for both scenario #1 and #2 above.

NOTE

The API does not need the caller to specify which interface it needs to download.

When booting from SPI NAND and RawNAND, the SPL must pass the good page offset (skip all the bad block) of the NAND device.

9.11.2 API query_boot_infor

```
UINT32 query_boot_infor(UINT32 infor_type, UINT32 *infor, UINT32 xor)
```

The return values are defined below:

- 0xF0 for success and other for failure.
- 1 Invalid para. Invalid Infor type or Invalid Infor type.

The paramaters are defined below:

- infor_type:
  - 01 - BootROM Version
  - 02 - Boot device (see Boot Device Definition).
  - 03 - Device page size (in byte).
  - 04 - The offset (in byte, relative to beginning of the boot image) of the current image's IVT. The intent here is SPL can calculate the physical address (in the boot device) of SW image to be loaded.
  - 05 - Boot Stage (see Boot Stage definition).
  - 06 - The offset (in byte, relative to beginning of the boot device) of the current image. The intent here is SPL can calculate the physical address (in the boot device) of SW image to be loaded.
- Infor - Points to the word to save the infor being queried, valid if returns 0xF0. Must be in TCM/OCRAM free space.
- Xor - The xor of infor_type and Info. To address fault injection attack.

9.11.2.1 Boot Device Definition

Table 62. Boot Device Definition

Bit 31-24	Bit 23-16	Bit 15-8	Bit 7-0
Reserved	Boot Interface	Instance	Device_State

The field definitons are provides below.

- Boot Interface -Indicating the boot interface from which SPL been boot.
  - 0x1 – SD
  - 0x2 – eMMC
  - 0x4 – FlexSPI NOR flash
  - 0x6 – LPSPI EEPROM
  - 0x8 – FlexSPI NAND flash

— 0xE – USB

- Instance - to specify which port the SPL boots from, from 0 (for example, for SD/eMMC boot, 0 means booting from USDHC1 port).
- Device State - to specify the state of the boot device, if needed. Usually Boot Interface dependent.
  — For eMMC: Bit0 – Card in Fast Boot Mode if set.
  — For other Boot Interfaces, this field shall be 0.

9.11.2.2 Boot Stage definition

The Boot Stage values are as defined below:

- 0x6 – Primary Boot
- 0x9 – Secondary Boot
- 0xA – Recovery Boot
- 0x5 – USB boot

9.11.3 Shared ROM Boot Information

i.MX91 ROM supports the ROM handover and Passover data which are supported in i.MX95, shares the ROM boot information to the later running SW, for example SPL (A55 FW). Handover information is some data ROM will put into OCRAM to pass the information to later running SW, for example SPL. Passover information is some data ROM will put into OCRAM to pass boot information (boot device selection for instance) to later running SW, for example SPL.

The base address of the handover and Passover area spaces:

Table 63. Handover and Passover base

	Handover Data Area base address	Passover Data Area base address
CA55 ROM	0x20480000	0x20480200

9.11.3.1 Handover Information

Handover information is some data ROM will put into OCRAM to pass boot information to later running SW, for example SPL.

Table 64. Handover Memory Layout

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Barker (0xC0FFEE16)			
0x04	Size(0x100)		Version (0x2)	
0x08	Reserved			Number of Start List

0xB0 -- 0xFC	Reserved			

Barker – 0xC0FFEE16

Version – 0x2

Size – 0x100, the size of handover data area space in byte

Number of Start List – the valid number of Start List

Boot Data Flag – Defined by System Manager, need to refer to SM doc

Start List[8] : A list to hold images need SM to kick to run.

Table 65. Start List Entry

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x00	Entry Point			
0x04				
0x08	Reserved		CPU RID	
0x0C	Start flags			

Entry Point – The address of the start point of the core image, copies from the “entry” filed in the image array, refer to the Image Array Entry for the detail.

Core ID – copies from the “flags” filed (bit[7:4]) in the image array, refer to the Image Array Entry for the detail definitions of core ID.

Start Flags – The number is copied from the “meta_data” filed in the image array of the container header, defined by SM and transparent to ROM code;

9.11.3.2 Passover Information

Table 66. Passover Memory Layout

Offset	Bits 31-24	Bits 23-16	Bits 15-8	Bits 7-0
0x0	Version(0x2)	Size(0x80)	TAG (0x504F)	
0x4	Boot Mode			
0x8	SD Card Address Mode			
0xC	NAND bad block count been skipped by ROM for 1st Image Container Set

0x34 – 0x7F	Reserved			

TAG – 0x504F

Size – 0x80, the size of passover data area space in byte

Version – 0x2

Boot Mode:

0 – Boot from Fuse

1 – USB Serial download

2 – Normal boot

3 – Infinite Loop Mode (ROM test mode)

4 – Test Mode

SD Card Address Mode:

0 – Byte mode

1 – Section mode

NAND bad block count been skipped by ROM for 1st Image Container Set:

NAND bad block count been skipped by ROM for 2nd Image Container Set:

Indicates how many bad blocks has been jumped over before arriving the picked up image container set.

Boot Stage: Indicating the boot stage from which system boots.

0x06 – Primary Boot

0x09 – Secondary Boot

0x0A – Recovery Boot

0x05 – USB Serial Download Boot

Image Set been Boot from

0 – Boot from 1st Image Container Set.

1 – Boot from 2nd Image Container Set.

Offset of Image End:

Relative to Boot device beginning. To indicate the end of the boot Container Set, so AP IPL know where to read its Container header from. (May kind of duplicated to “Image Set been Boot from”)

ROM Version: The revision number of ROM code

Boot Device State: only used for EMMC boot, indicate whether EMMC fast boot is picked up

0 – Non EMM boot or EMMC regular boot

1 – EMMC fast boot

Boot Device Type:

Indicating the boot device from which system boots.

0x1 – SD

0x2 – MMC

0x3 – SPI NAND

0x4 – xSPI NOR flash

0x6 – SPI NOR (recovery boot)

0xE – USB

Boot Instance:

0 – USDHC1 for EMMC/SD boot or USB OT1 for USB serial download

1 – USDHC2 for EMMC/SD boot or USB OT2 for USB serial download

Boot Device Page Size: the page size of boot source

Container Header Offset: the container offset in the boot image set

Image Offset: the offset of the picked up boot image set on boot source

Chapter 10
IOMUXC GPR

10.1 Overview

The IOMUXC GPR module includes a configuration register.

10.2 Memory map and register definition

This section includes the IOMUXC-GPR memory map and detailed description of Configuration register.

10.2.1 IOMUXC GPR register descriptions

10.2.1.1 IOMUXC GPR memory map

IOMUXC_GPR.IOMUXC_GPR base address: 443D_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	IOMUXC GPR Configuration (CONFIG)	32	RW	0000_8920

10.2.1.2 IOMUXC GPR Configuration (CONFIG)

Lower 16 bits [15:0] are data bits and upper 16 bits [31:16] are lock bits. They are one-to-one mapped and control the access of IOMUXC module. Once a lock bit is set, it and its corresponding data bit cannot be cleared unless a reset. Each field can be assigned to any master ID through configuration.

Table 67. Master IDs

Module	4-bit Master ID
Cortex-A55 cores	000n
Reserved	0010 - 0111
Reserved	1000
Reserved	1001
Edgelock	1010
eDMA3_1(AHB)	1011

Chapter 11
Arm Modules Overview

11.1 Overview

The following Arm modules are supported in this chip:

- Arm Cortex®-A55 MPCore
- GIC-600
- NIC
- TrustZone

11.1.1 Arm Cortex®-A55 MPCore

The Cortex®-A55 MPCore has the following features:

- One Cortex®-A55 processor:
  - 32 kByte L1 Instruction Cache
  - 32 kByte L1 Data Cache
  - 256 kByte L2 cache
  - Media Processing Engine (MPE) with NEONTM technology supporting the Advanced Single Instruction Multiple Data architecture
  - Floating Point Unit (FPU) with support of the VFPv4-D16 architecture
- Support of 64-bit Arm®v8.2-A architecture

In addition, it also includes various components composing the CoreSightTM debug and trace technology, such as ETM, CTM and CTI.

The Cortex®-A55 platform supports following power gating modes:

Table 68. Cortex-A55 Platform Power Modes

-	CPU0	PLATFORM	VDD
ALL_ON	ON	ON	ON
ALL_OFF	OFF	OFF	ON
POWER_DOWN	OFF	OFF	OFF

11.1.2 GIC-600

GIC-600 is used as the interrupt controller for the Cortex®-A55 processor. It supports a distributed microarchitecture containing several individual blocks that are used to provide a flexible GIC implementation.

- Forward compatibility with ARMv8.2 Cores supporting increased 512 CPU threads/chip and multi-chip capabilities
  - Distributed architecture for reduced power, congestion and improved latency
  - End-to-End credited protocols allows bridging communication to any free-flowing transport layer. Transport layer will be native AXI4 stream.
  - Clock and power control for each block for improved power savings
- QoS improvements
  - Increased ITS caching to reduce memory accesses

  - More flexible use of LPI cache and Pending Tables for reduced memory accesses and improved latency bounding
- Improved trace and debug
  - PMU with full snapshot functionality
  - Full ITS command error logging and reporting via ARMv8.2 RAS error records
  - ECC error logging and containment to allow software recovery
- Improved control over 1-of-N interrupt routing
- SPI collators enabling Q-Channel support on main GIC

11.1.3 TrustZone

The TrustZone architecture provides means to help secure systems, using the TrustZone Security Extensions, and Secure peripherals. TrustZone is a security feature on ARM Cortex A series that enables execution separation of trusted (secure) software, and enables access control isolation of trusted resources from non-trusted (non-secure) software and resources, while running on the same CPU. Memory arrays and peripherals are segmented into either Secure (S) or Non-Secure (NS). TrustZone is optimized for energy-efficient, embedded applications that require real-time responsiveness.

More details on TrustZone can be found in “TrustZone® technology can be found at arm.com.

NOTE

"S" = Secure; "NS" = Non-Secure.

Trustzone is always enabled on this chip and is supported through TRDC.

If TrustZone functionality is enabled, then the following restrictions apply to the cores:

- The CPU in a Secure state (CPU-S) can execute instructions from Secure memory (S-memory) only; the CPU cannot execute instructions from Non-Secure memory (NS-memory).
- CPU-S can access data in both S-memory and NS-memory, which means that CPU-S can execute data reads from both S- and NS-memory, and also execute data writes to S or NS-memory.
- CPU-NS can execute instructions only from NS-memory, and cannot execute instructions from S-memory.
- CPU-NS can access data only in NS-memory, which means that CPU-NS can execute data reads from NS-memory only, and can execute data writes to NS-memory only. CPU-NS cannot access data from S-memory.

Chapter 12
ARM Cortex A55

12.1 Overview

The Arm Cortex-A55 implements the Armv8-A architecture. The Cortex-A55 is a high efficiency processor with Media Processing Engine (MPE) with NEON technology supporting Advanced Single Instruction Multiple Data architecture. The Cortex-A55 also includes a floating-point unit (FPU), L1 instruction cache, and L1 data cache, and L2 cache.

There is one A55 core on this chip.

The core also includes various components composing the Arm CoreSight debug and trace technology, such as ETM, CTM and CTI. The debug interface is connected to the DAP and CoreSight debug modules in the SoC to allow debug through JTAG interface.

12.1.1 Block Diagram

The A55 block diagram is shown below.

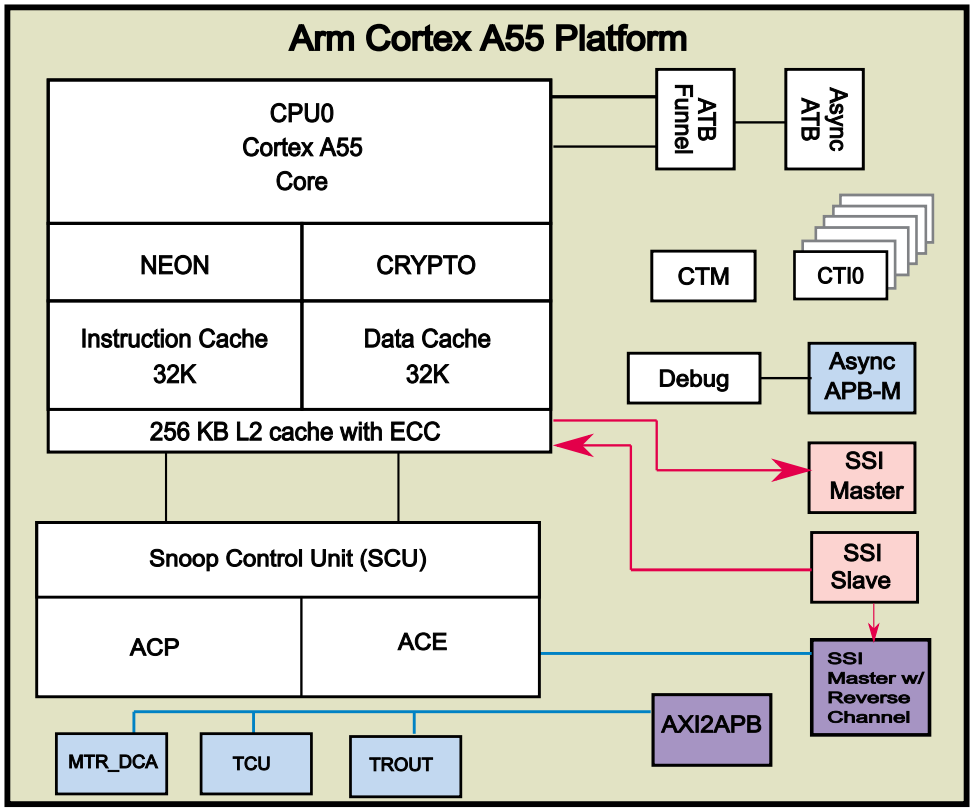

Figure 28. A55 Block Diagram

12.1.2 Features

The Arm Cortex A55 MPCore has the following features:

- One Cortex-A55 processor:
  - 32 kByte L1 Instruction Cache

  - 32 kByte L1 Data Cache
  - 256 kByte per-core L2 cache
  - Media Processing Engine (MPE) with NEON technology supporting the Advanced Single Instruction Multiple Data architecture
  - Floating Point Unit (FPU) with support of the VFPv4-D16 architecture
- Support of 64-bit Arm v8.2-A architecture
- Various components composing the CoreSightTM debug and trace technology, such as ETM, CTM and CTI
- The DynamIQ Shared Unit (DSU) shared between cores, includes Snoop Control Unit (SCU), ACE interface, and so on.

12.2 Functional Description

The sections below discuss the high-level overview of the Arm Cortex-A55 Platform components.

12.2.1 Arm Cortex-A55 MPCore Processor

The Arm Cortex-A55 processor implements the Armv8-A architecture. The A55 complex has one core. Each core has a 32 kByte L1 Instruction Cache, a 32 kByte L1 Data Cache and a 256 kByte per-core L2 cache. Each core also has a Media Processing Engine (MPE) with NEON technology supporting the Advanced Single Instruction Multiple Data architecture and a Floating Point Unit (FPU) with support of the VFPv4-D16 architecture.

12.2.2 DynamIQ Shared Unit (DSU)

The DynamIQ Shared Unit (DSU) is the portion of the A55 complex that is shared between the cores. The DSU includes the Snoop Control Unit (SCU).

12.2.3 Advanced SIMD (NEON)

The Cortex-A55 processor supports the Advanced SIMD and Scalar Floating-point instructions.

See Arm Cortex-A55 documentation for more information.

12.2.4 Atomic Instructions

The Arm Cortex-A55 Core Technical Reference Manual mentions that atomics are supported to cacheable memory but requires a coherent interconnect to support atomics to device or non-cacheable memory. This product does not support such a coherent interconnect. If such an atomic instruction is executed when the interconnect does not support them, it will result in a synchronous Data Abort (for load atomics) or an asynchronous Data Abort (for store atomics)

12.2.5 Debug

The Cortex-A55 platform includes the debug and trace sub-modules. The debug interface is connected to the DAP and CoreSight debug modules in the SoC to allow debug through JTAG interface.

See the System Debug chapter for more information about the A55 Platform debug components, such as ETM, CTI and CTM.

12.2.6 Clocking

The Cortex-A55 platform takes in the following clocks, all of which may be fully asynchronous to each other.

Table 69. A55 Clocks

A55 Platform Clock Name	Source	Frequency (Nominal Voltage)	Description
PERIPHCLK	CCM: Arm_a55_periphclk_root	333MHz	Timers, clock and power management logic in Cortex-A55 platform.
PCLK			Debug Block and DSU Debug APB interfaces.
ATCLK			ATB trace buses output from DSU
GICCLK			GIC AXI-stream interface between DSU and SoC's GIC-600
SCLK	Mux between either Arm_pll_clk or Arm_a55_clk_root	1.4GHz	SCU, ACE interface and A55 core

12.2.7 Interrupts

The Generic Interrupt Controller (GIC) supports and manages interrupts in the cores.

The GIC provides registers for managing:

- Interrupt sources
- Interrupt behavior
- Interrupt routing to one or more cores

GIC-600 is supported

See Arm documentation for more information.

12.3 External Signals

The A55 Platform has no external signals.

Chapter 13
SRAM Controller

13.1 Overview

SRAMCTL acts an interface between an AXI request bus and system RAM. It forwards read and write requests in the AXI protocol to an array of compiled memories.

13.1.1 Block diagram

The following figure shows SRAMCTL's primary components:

- A programming model, which provides controls and status reports.
- A pipeline that manages accesses between the bus master request and memory.

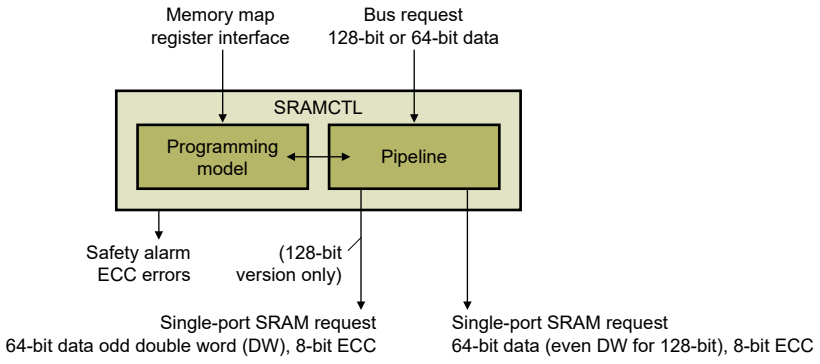

Figure 29. Block diagram

13.1.2 Key features

- For the RAM size and configuration implemented on this chip, see the chip-specific SRAMCTL information.
- Performance:
  - 128-bit bus request data size
- Support for bus master requests in the AXI protocol:
  - Single or burst transactions
  - Access requests are completed in the order they are received
- Access latency:
  - Accesses are pipelined
- Support for 4'd8 exclusive monitors
- A programming model that is provided via memory-mapped registers
- Block initialization of a RAM array to place it in a valid ECC state:
  - Software-initiated initialization
  - Optional wait states between bank writes
- Software-programmable upper bound of the valid accessible address range
- ECC Hsiao scheme for the RAM:
  - 64-bit data and 29-bit address

  - SEC
  - DED
- Safety alarm and monitors for the SRAMCTL pipeline

13.2 Functional description

The primary function of SRAMCTL is to manage bus requests to read and write data in RAM. A successful access receives data from the memory or updates data in the memory.

SRAMCTL also provides these functions:

- RAM initialization
- Detection and reporting of erroneous accesses to RAM
- Safety features

13.2.1 System and local addresses

SRAMCTL uses both system and local addresses. All read and write operations on RAM use system addresses.

Table 70. System and local addresses

Address type	Description	These registers use the address type

System	Byte address of an SRAM location in the chip memory map according to the bus master	• When RAMCR[INIT_SYSA] is 1:
		  — RAM Initialization Address Start (RAMIAS)
		  — RAM Initialization Address End (RAMIAE)
		• RAM System Address (RAMSYSA)
		• RAM Error Injection Base Address (RAMEIA)
		• RAM Maximum-Value Address (RAMMAXA)

Local	In configuration with one bank: 8-byte-aligned address within an SRAM
	In configuration with two banks: 16-byte-aligned address within an SRAM
		• When RAMCR[INIT_SYSA] is 0:
		  — RAMIAS
		  — RAMIAE
		• RAMMEMA[MEMA]

13.2.2 RAM initialization

After reset, data in RAM can have an unknown state. A false ECC error can occur if SRAMCTL reads a memory location before fully writing to it. To prevent this situation, SRAMCTL can initialize the RAM to put the ECC checkbits in the correct state.

For data, the initialized value is 0. Based on this data and the address for initialization provided in RAM Control (RAMCR), RAM Initialization Address Start (RAMIAS), and RAM Initialization Address End (RAMIAE), SRAMCTL calculates the associated checkbits.

Perform these steps to start RAM initialization using software:

1. Program RAMCR[INIT_SYSA] to use system or local memory addresses.
2. Program RAMIAS and RAMIAE to set the lower and upper boundaries, respectively, of the RAM portion to initialize.
3. Write 1 to RAMCR[INIT] to start the initialization.

During initialization, SRAMCTL issues a burst of writes to all memory ports in parallel. It starts by initializing the address that RAM Initialization Address Start (RAMIAS) defines, proceeds sequentially through the memory, and ends after initializing the address that RAM Initialization Address End (RAMIAE) defines.

While the initialization of any address range is in progress, SRAMCTL restricts accesses to *all* addresses in the RAM bank that the SRAMCTL instance controls.

13.2.2.1 Initialization status

To determine the status of an initialization, monitor these fields in RAM Status (RAMSR):

Table 71. Initialization status

To determine whether	Read this RAMSR field
The initialization is in progress	IPEND
The initialization completed successfully or failed	IDONE

13.2.2.2 Initialization addresses: examples

For initialization operations, the byte alignment of system addresses is the same as it is for local addresses: 8-byte-aligned in a one-bank configuration or 16-byte-aligned in a two-bank configuration.

The following table provides examples of system and local addresses for this initialization scenario:

- The RAM to be initialized is based at the system address xxxx_0000h.
- The region of RAM to be initialized is the first 32 bytes.

Table 72. Initialization addresses: examples

Address type	Value of RAMCR[INIT_SYSA]	RAM Initialization Address Start (RAMIAS)	RAM Initialization Address End (RAMIAE)	
			One bank	Two banks
System	1	xxxx_0000h	Any value from xxxx_0018h to xxxx_001Fh	Any value from xxxx_0010h to xxxx_001Fh
Local	0	0h	3h	1h

13.2.3 Erroneous accesses

For a RAM access that SRAMCTL determines is erroneous, the read data is undefined, and SRAMCTL prevents any memory update. The following table identifies:

- Types of erroneous accesses
- The RAM Status (RAMSR) field that registers each type
- Whether, for each error type:
  - SRAMCTL sends an error response to the bus request
  - SRAMCTL sends the error to an external fault receiver

For details about external fault receivers, see the chip-specific SRAMCTL information.

Table 73. Erroneous accesses

Description	RAMSR field	Error response to bus request	Error sent to the external fault receiver
SRAMCTL detects an ECC correctable error.	SGLERR	No	No

Table continues on the next page...

Table 73. Erroneous accesses (continued)

Description	RAMSR field	Error response to bus request	Error sent to the external fault receiver
SRAMCTL detects an ECC uncorrectable error on data from the memory for a read request or for a narrow write.	MLTERR or AERR	Yes	Yes
Any of the following: • A bus master issues an access to any location during an initialization sequence (including a location outside the initialization range). • An attempted access is outside the valid address range. • A read or write transaction fails to complete.	BUSERR	Yes	Yes

13.2.4 Exclusive monitors

SRAMCTL provides exclusive monitors that behave according to the specifications of the AXI bus protocol.

- 8 monitors are available.
- A new request for an exclusive monitor (by the load) is always honored. If all monitors are already taken, the new request displaces the oldest one.
- Each exclusive monitor consumes 64 bytes and is 64-byte aligned.
- The maximum number of bytes that can be transferred in an exclusive burst is 64 bytes, and the burst cannot cross the 64-byte boundary.

13.2.5 Safety features

- The ECC scheme protects the RAM (see ECC algorithm).
- Error injection on memory provides a mechanism to test ECC error detection and reporting (see ECC error injection on memory).
- A safety alarm reports violations of integrity in access address, data, or attributes:
  - When the safety alarm occurs, SRAMCTL notifies an external fault receiver.
  - SRAMCTL provides another error-injection option to enable testing of this safety alarm (see Error injection targeting safety alarm).
  - For more information about the safety alarm, see the chip-specific SRAMCTL information.

13.2.5.1 ECC algorithm

The ECC scheme for RAM implements SECDED using the Hsiao odd-weight column criteria to produce 8-bit ECC checkbits for each RAM bank.

- 64-bit data: ECC_DATA[63:0]
  - Bus WDATA[63:0] if bus_addr[3] = 0 or bus request data size is 64 bits
  - Bus WDATA[127:64] if bus_addr[3] = 0 and bus request data size is 128 bits
- 29-bit address: ECC_ADDR[31:3]
  - mem_ADDR[16:0]
  - {bus_ADDR[31:4],0b}

Table 74. ECC H-matrix

Checkbits [7:0]	ECC_DATA[63:32]

13.2.5.2 ECC error reports

Erroneous accesses identifies the RAM Status (RAMSR) fields that register an ECC address error (via RAMSR[AERR]), a multi-bit error (via RAMSR[MLTERR]), or a single-bit error (via RAMSR[SGLERR]). When any of these ECC errors occurs, SRAMCTL reports additional information about the error:

- RAMSR[SYND] captures the syndrome value.
- RAM System Address (RAMSYSA) captures the system address.
- RAM ECC Address (RAMMEMA) captures the RAM bank address in RAMMEMA[MEMA] and identifies the RAM bank in RAMMEMA[BANK].

  RAMMEMA[MEMA] identifies the RAM bank address as a local address. For example, a value of 0h in RAMMEMA[MEMA] indicates that the error occurred in the first 8 bytes of the bank specified by RAMMEMA[BANK].

These fields provide sufficient information about the error to enable debugging.

For SRAMCTL to report a new ECC error, both RAMSR[AERR] and RAMSR[MLTERR] must be 0. More specifically:

- When both RAMSR[AERR] and RAMSR[MLTERR] are 0, RAMSR[SGLERR] always captures the latest single-bit error. RAMSR[SGLERR] itself does not require clearing.
- When an uncorrectable ECC error occurs, you must modify the affected RAMSR field to prepare for the report of a subsequent ECC error. After RAMSR[AERR] or RAMSR[MLTERR] becomes 1, you must write 1 to the field to clear it.

At any given time, SRAMCTL generates only one report for all memory banks. If multiple banks incur errors, SRAMCTL selects the error to report based on these priorities:

1. In a pipeline with two banks, if both banks incur errors at the same time, SRAMCTL selects the bank with a higher-priority error type. If both banks have the same type of error, SRAMCTL selects bank0.

RAM Correctable Error Count (RAMECCNT) records the cumulative number of RAMSR[SGLERR] events since the last time it was reset.

In case of an overflow of errors that SRAMCTL reporting cannot accommodate, such as a new error occurring while the report of a previous error is still pending, SRAMCTL supports an overflow alarm. In this case, SRAMCTL outputs a notification of the overflow alarm to an external fault receiver.

13.2.5.3 ECC error injection on memory

SRAMCTL's error injection on memory targets the ECC logic by modifying the read data that the memory returns, making it appear to contain errors. The ECC detection logic then reports the error.

The injection does not change the actual content in the memory. It affects the data only at the memory output.

13.2.5.3.1 Error injection addresses

RAMEIDC[EIA_EN] determines which accesses can receive ECC error injection: all accesses or only accesses to a subset of addresses that SRAMCTL registers define.

Table 75. Error injection addresses

Value of RAMEIDC[EIA_EN]	Description	SRAMCTL registers that define addresses
0	Error injection applies to any access that enters the pipeline.	—
1	Two SRAMCTL registers specify the area targeted for error injection.	• RAM Error Injection Base Address (RAMEIA) sets the value for the base address of the targeted area. • RAM Error Injection Address Mask (RAMEIAM) allows further refinement of the targeted area.

13.2.5.3.1.1 Address examples

For the case where RAMEIDC[EIA_EN] is 1, the following table:

- Assumes that the value of RAM Error Injection Base Address (RAMEIA) is 0000_ABCDh.
- Shows how the value of RAM Error Injection Address Mask (RAMEIAM) refines the range of addresses.

Table 76. Address examples

Value of RAMEIAM	Result
FFFF_FFFFh	Only accesses to the exact address, 0000_ABCDh, can receive error injection.
FFFF_FF00h	Accesses from 0000_AB00h to 0000_ABFFh can receive error injection.
0000_0000h	All accesses can receive error injection; the address in RAMEIA is effectively ignored.

13.2.5.3.2 Options for injection data

RAMEIDC[EID_EN] selects between no error injection and local error injection, which uses SRAMCTL registers.

Table 77. Options for injection data

Value of RAMEIDC[EID_EN]	Description	SRAMCTL registers that drive injection data
0	SRAMCTL does not provide error injection.	—
1	Local error injection: Three SRAMCTL registers provide 72 bits of injection data. Each injected bit inverts the value of the corresponding bit from memory read data or ECC checkbits.	• RAM Error Injection Data 0 (RAMEID0) injects errors on read data bits 0–31. • RAM Error Injection Data 1 (RAMEID1) injects errors on read data bits 32–63. • RAMEIDC[EID_CKB] injects errors on ECC checkbits 0–7.

13.2.5.3.2.1 Local error injection examples

For the case where RAMEIDC[EID_EN] is 1b, the following table provides examples of programming values for SRAMCTL registers and describes the effects of those values.

Table 78. Local error injection examples

Programming values	Result	Expected ECC error
• RAM Error Injection Data 0 (RAMEID0) = 0000_0001h • RAM Error Injection Data 1 (RAMEID1) = 8000_0000h • RAMEIDC[EID_CKB] = 00h	Inverts bits 0 and 63 of the memory data.	Double-bit
• RAMEID0 = 0000_0000h • RAMEID1 = 0000_0000h • RAMEIDC[EID_CKB] = 70h	Inverts three bits (70-68) of the memory ECC checkbits.	Multi-bit
• RAMEID0 = 0000_0000h • RAMEID1 = 0000_0000h • RAMEIDC[EID_CKB] = 00h	Does not invert any bits of the memory data; local error injection is effectively disabled.	—

13.2.5.4 Error injection targeting safety alarm

This error-injection option enables testing of the safety logic that monitors the integrity of access address, data, and attributes of a pipeline or in memory.

To inject errors to trigger the safety alarm, write 1 to RAMEIDC[EIP_EN]. As a result of this write, the alarm occurs:

- On the next bus transaction.
- For every subsequent bus transaction that enters the pipeline while RAMEIDC[EIP_EN] remains 1.

To disable this error injection, write 0 to RAMEIDC[EIP_EN].

13.2.6 Clocking

SRAMCTL has two standard clocks: a module clock and a register interface clock.

13.2.7 Interrupts

This module has no interrupts.

13.3 External signals

This module has no external signals.

13.4 Initialization

SRAMCTL itself does not require initialization.

13.5 SRAMCTL register descriptions

SRAMCTL's memory-mapped registers are in a 4 KB space and represent the module's programming model. These registers are accessible in Supervisor mode and with granularity of word size. Attempted accesses of the following types result in a transfer error:

- In User mode
- With non-32-bit width

The registers consist of these functional groups:

Function	Register or registers
Control	RAM Control (RAMCR) RAM Control 2 (RAMCR2)
Initialization	RAM Initialization Address Start (RAMIAS) RAM Initialization Address End (RAMIAE)
Status reporting	RAM Status (RAMSR) RAM ECC Address (RAMMEMA) RAM System Address (RAMSYSA) RAM Correctable Error Count (RAMECCNT)
Error injection	RAM Error Injection Data 0 (RAMEID0)

Table continues on the next page...

Table continued from the previous page...

Function	Register or registers
	RAM Error Injection Data 1 (RAMEID1) RAM Error Injection Data Control (RAMEIDC) RAM Error Injection Base Address (RAMEIA) RAM Error Injection Address Mask (RAMEIAM)
Access validation	RAM Maximum-Value Address (RAMMAXA)

13.5.1 SRAMCTL memory map

OCRAM_CTRL1 base address: 490A_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	RAM Control (RAMCR)	32	RW	0000_0000
4	RAM Initialization Address Start (RAMIAS)	32	RW	0000_0000
8	RAM Initialization Address End (RAMIAE)	32	RW	0000_0000
C	RAM Status (RAMSR)	32	RW	0000_0000
10	RAM ECC Address (RAMMEMA)	32	R	0000_0000
18	RAM System Address (RAMSYSA)	32	R	0000_0000

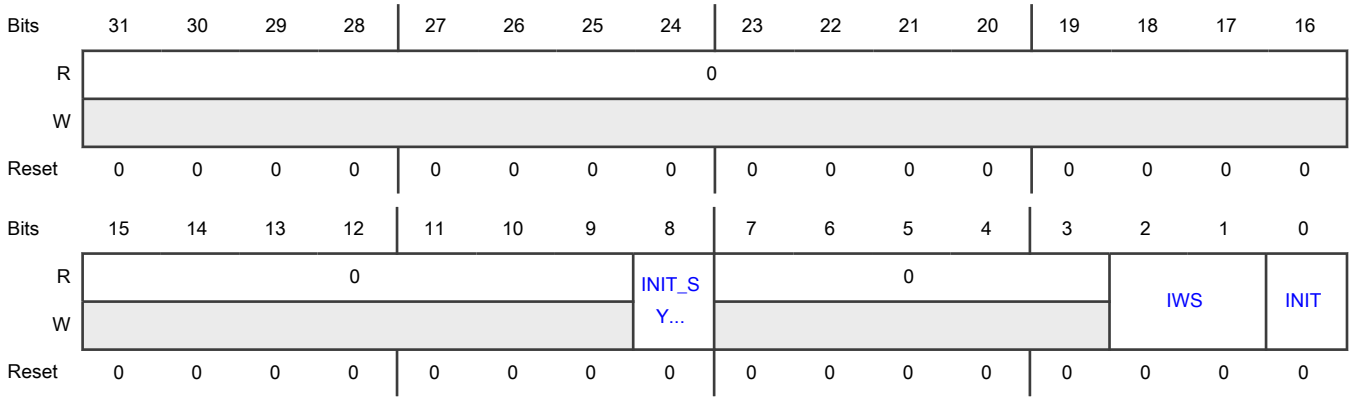
RAMCR	0h

Diagram



Fields

Field	Description
31-9 —	Reserved
8 INIT_SYSA	Initialize With System Address Determines whether the addresses in RAM Initialization Address Start (RAMIAS) and RAM Initialization Address End (RAMIAE) are system or local memory addresses. 0 - Local 1 - System
7-3 —	Reserved
2-1 IWS	Initialization Wait States Specifies the number of wait cycles between memory writes during initialization. A value of 0b enables back-to-back writes with no idle cycles in between. Inserting wait cycles can help manage the power required to write to several RAM banks in the same cycle. 00 - Zero 01 - One 10 - Two 11 - Three
0 INIT	Initialization Request Requests an initialization of RAM for the address range specified in RAM Initialization Address Start (RAMIAS) and RAM Initialization Address End (RAMIAE). The initialization issues a burst of parallel writes to all memory entries within the initialization range. Each time you write 1 to this field, it causes one initialization. To start another initialization, first write 0 to this field and then write 1 to start a new initialization. SRAMCTL changes this field to 0 if you write 0 to RAMSR[IDONE].

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If you write 0 to this field prior to the completion of an initialization, the initialization is aborted. 0 - Not requested 1 - Requested

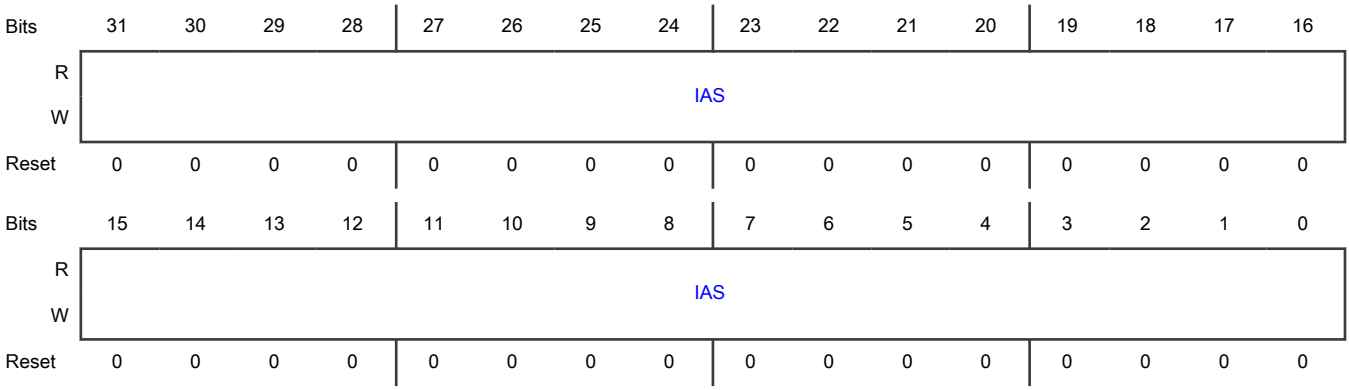
13.5.3 RAM Initialization Address Start (RAMIAS)

Specifies the start address for software-requested initialization.

Offset

Register	Offset
RAMIAS	4h

Diagram



Fields

Field	Description
31-0 IAS	Initialization Address Start Captures the start address for RAM initialization. The value must be within the valid address range; otherwise, nondeterministic behavior results. Write the address in the format that RAMCR[INIT_SYSA] defines.

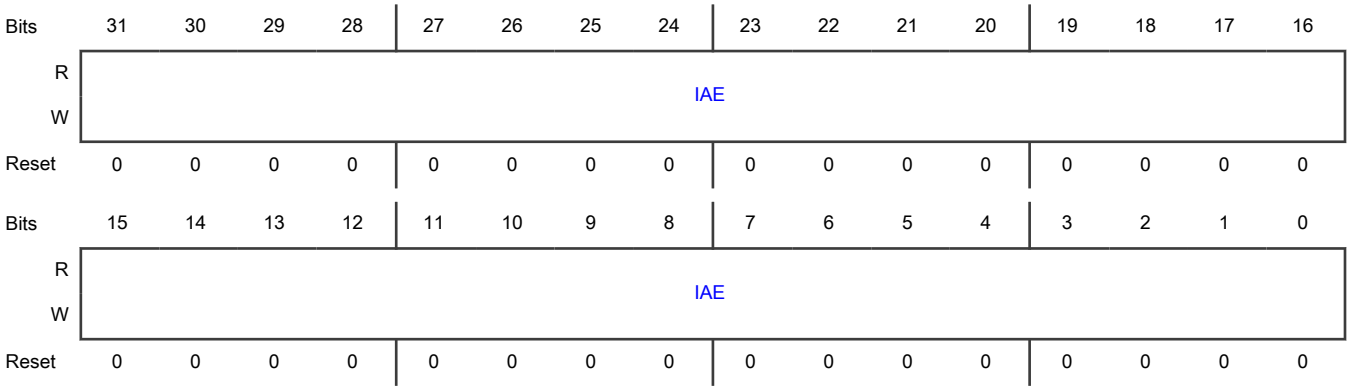
13.5.4 RAM Initialization Address End (RAMIAE)

Specifies the end address for software-requested initialization.

Offset

Register	Offset
RAMIAE	8h

Diagram



Fields

Field	Description
31-0 IAE	Initialization Address End Captures the end address for RAM initialization. The value must be greater than the start address and must be within the valid address range; otherwise, nondeterministic behavior results. Write the address in the format that RAMCR[INIT_SYSA] defines.

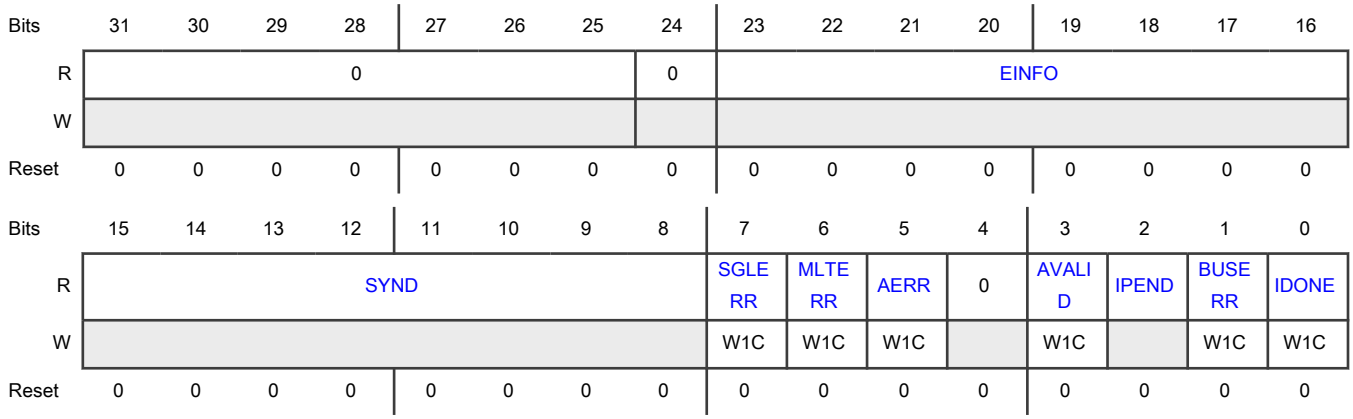
13.5.5 RAM Status (RAMSR)

Reports RAM initialization progress as well as other events and details.

Offset

Register	Offset
RAMSR	Ch

Diagram



Fields

Field	Description
31-25 —	Reserved
24 —	Reserved
23-16 EINFO	Event Information Provides additional information about a reported event. For the meaning of the field's values, see the chip-specific SRAMCTL information.
15-8 SYND	ECC Syndrome Value Records syndrome data associated with the ECC error reported in RAMSR[AERR], RAMSR[MLTERR], or RAMSR[SGLERR]. SRAMCTL updates this field only when RAMSR[AERR], RAMSR[MLTERR], or RAMSR[SGLERR] updates with a new error or when an event causes RAMSR[AVALID] to be 1.
7 SGLERR	ECC Single-Bit Error Indicates whether an ECC single-bit error occurred on a previous access. This field does not require clearing. It always captures the latest single-bit error. SRAMCTL updates this field only when both RAMSR[AERR] and RAMSR[MLTERR] are 0. 0 - No error occurred 1 - An error occurred
6 MLTERR	ECC Multi-Bit Error Indicates whether an uncorrectable ECC multi-bit error occurred on a previous access. After this field or RAMSR[AERR] becomes set to 1, write 1 to clear the set field to enable the report of a subsequent error. SRAMCTL updates MLTERR only when both MLTERR itself and RAMSR[AERR] are 0. 0 - No error occurred

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - An error occurred
5 AERR	ECC Address Error Indicates whether an uncorrectable ECC address error occurred on a previous access. After this field or RAMSR[MLTERR] becomes set to 1, write 1 to clear the set field to enable the report of a subsequent error. SRAMCTL updates AERR only when both AERR itself and RAMSR[MLTERR] are 0. 0 - No error occurred 1 - An error occurred
4 —	Reserved
3 AVALID	Addresses Valid Indicates whether the addresses that are captured in RAM ECC Address (RAMMEMA) and RAM System Address (RAMSYSA) record the location of an event. When another field in this register becomes 1 and thereby reports an error, this field becomes 1 to indicate that the addresses in RAM ECC Address (RAMMEMA) and RAM System Address (RAMSYSA) record the location of that error. This field also becomes 1 when local error injection produces no error. In this case, the field indicates that RAM ECC Address (RAMMEMA) and RAM System Address (RAMSYSA) record the location of the injection target. 0 - Addresses do not correspond to an event 1 - Addresses correspond to an event
2 IPEND	Initialization Pending Indicates whether initialization is in progress. You must not try to clear this field; the attempt results in undefined behavior. To abort an in-progress initialization, you must write 0 to RAMCR[INIT]. 0 - Not in progress 1 - In progress
1 BUSERR	Bus Error Indicates whether a bus error occurred on a previous access because of one of the following events: • A decode error • A collision between the access and a RAM initialization 0 - No error occurred since the last time this field was cleared 1 - An error occurred
0 IDONE	Initialization Done Indicates initialization status.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - An initialization was not requested, is in progress, or did not complete 1 - An initialization completed successfully

13.5.6 RAM ECC Address (RAMMEMA)

Holds the RAM bank address associated with events reported in RAM Status (RAMSR).

An attempted write to this read-only register results in a transfer error.

Offset

Register	Offset
RAMMEMA	10h

Diagram

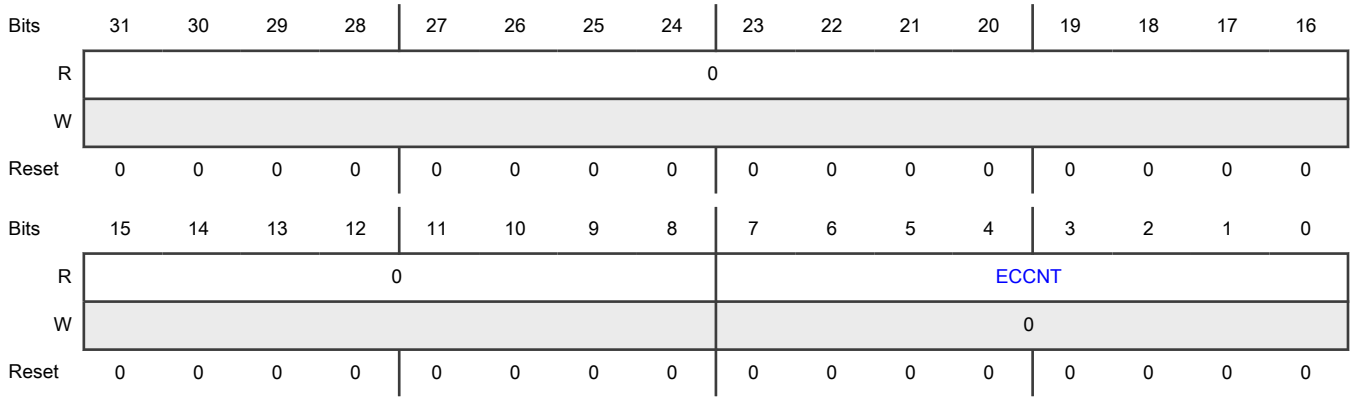
13.5.8 RAM Correctable Error Count (RAMECCNT)

Records the number of ECC single-bit error events.

Offset

Register	Offset
RAMECCNT	1Ch

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 ECCNT	ECC Correctable Error Count Shows the cumulative number of ECC correctable errors since the field was reset. For each error event that RAMSR[SGLERR] captures, the value of this field increments by 1 until it reaches its maximum value of FFh. After reaching that value, the field retains its maximum value even if another correctable error occurs. To reset the counter, write all 0s to this field. Writing nonzero values has no effect.

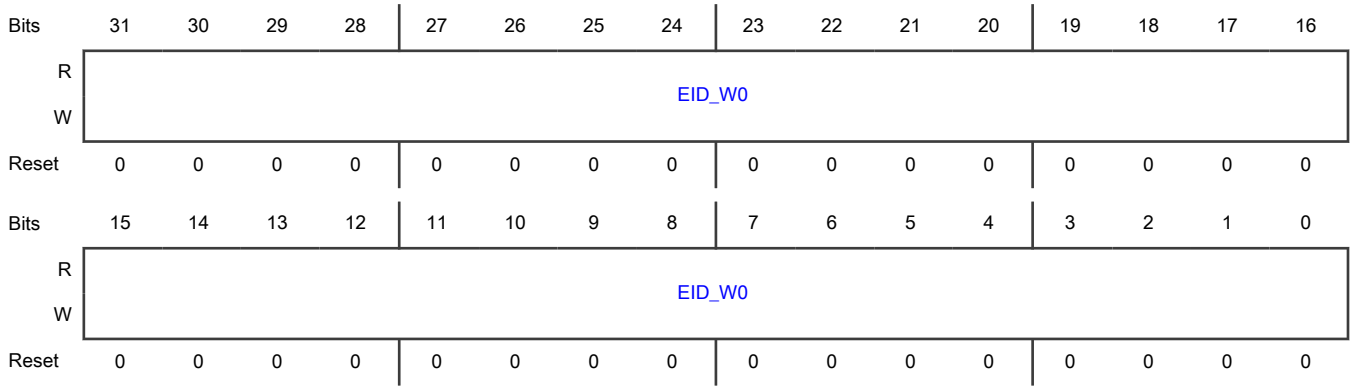
13.5.9 RAM Error Injection Data 0 (RAMEID0)

Specifies the injection bits for the lower word.

Offset

Register	Offset
RAMEID0	20h

Diagram



Fields

Field	Description
31-0 EID_W0	Error Injection Data Word 0 Injects errors targeting the lower word (bits [31:0]) of the RAM read data. This field is ignored if RAMEIDC[EID_EN] is 0.

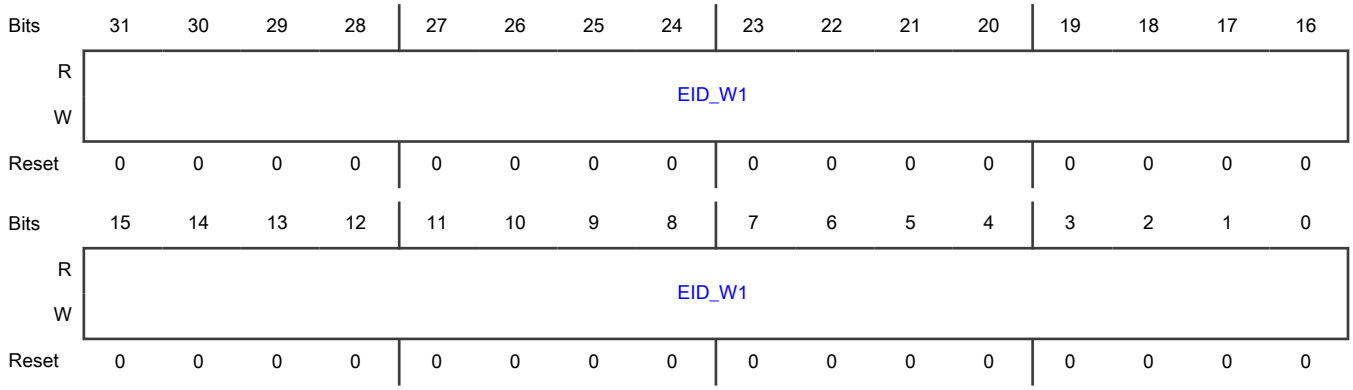
13.5.10 RAM Error Injection Data 1 (RAMEID1)

Specifies the injection bits for the upper word.

Offset

Register	Offset
RAMEID1	24h

Diagram



Fields

Field	Description
31-0 EID_W1	Error Injection Data Word 1 Injects errors targeting the upper word (bits [63:32]) of the RAM read data. This field is ignored if RAMEIDC[EID_EN] is 0.

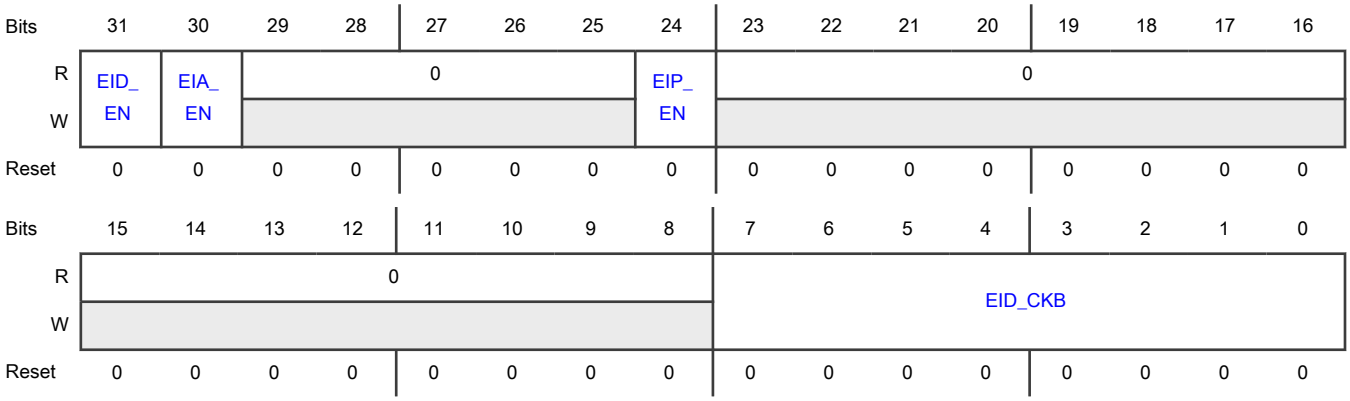
13.5.11 RAM Error Injection Data Control (RAMEIDC)

Controls options for error injection and, for local error injection, specifies injection bits for the ECC checkbits.

Offset

Register	Offset
RAMEIDC	28h

Diagram



Fields

Field	Description
31 EID_EN	Error Injection Data Enable Determines whether local SRAMCTL registers drive error injection on memory. The registers and fields that configure local data error injection are RAMEIDC[EID_CKB], RAM Error Injection Data 0 (RAMEID0), and RAM Error Injection Data 1 (RAMEID1). 0 - No injection 1 - Local injection
30 EIA_EN	Error Injection Address Enable Determines whether RAM Error Injection Base Address (RAMEIA) and RAM Error Injection Address Mask (RAMEIAM) define the range of addresses for local error injection on memory. This field either enables

Table continues on the next page...

Table continued from the previous page...

Field	Description
	RAMEIA and RAMEIAM to qualify the addresses for error injection or disables RAMEIA and RAMEIAM and causes error injection to apply to any access. 0 - Ignore RAMEIA and RAMEIAM 1 - Enable RAMEIA and RAMEIAM
29-25 —	Reserved
24 EIP_EN	Error Injection Into Pipeline Enable Injects errors into the pipeline to cause a safety alarm. 0 - No error injected 1 - Error injected
23-8 —	Reserved
7-0 EID_CKB	Error Injection Data Checkbits Injects errors targeting the ECC checkbits (bits [71:64]) of the RAM read data. This field is ignored if EID_EN is 0b.

13.5.12 RAM Error Injection Base Address (RAMEIA)

Specifies the base of bus addresses into which to inject errors.

Offset

Register	Offset
RAMEIA	30h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-0 EIA	Error Injection Base Address Defines the value for the base address of the area targeted for error injection if RAMEIDC[EIA_EN] is 1. Use RAM Error Injection Address Mask (RAMEIAM) to qualify the base value in this field.

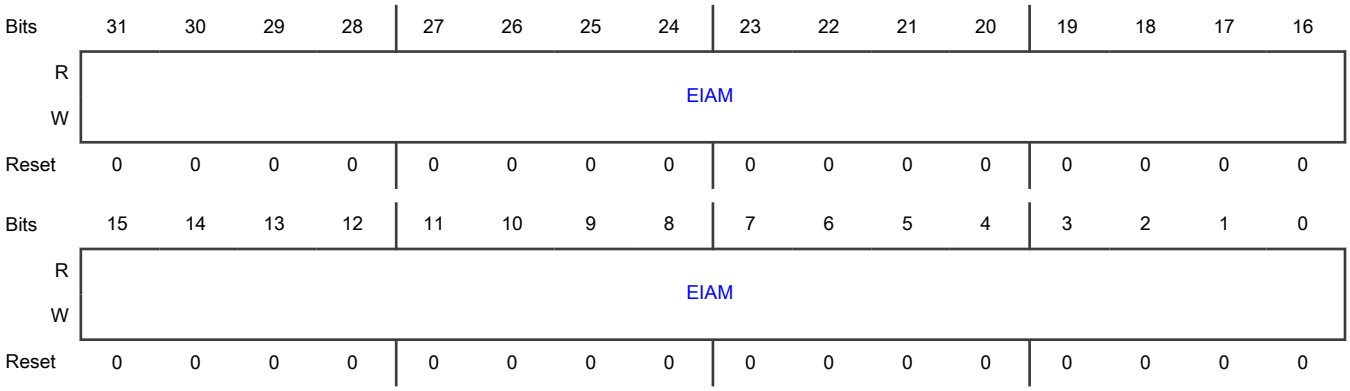
13.5.13 RAM Error Injection Address Mask (RAMEIAM)

Specifies the range of addresses targeted for error injection in the area based at the value of RAM Error Injection Base Address (RAMEIA).

Offset

Register	Offset
RAMEIAM	34h

Diagram



Fields

Field	Description
31-0 EIAM	Error Injection Address Mask Qualifies the addresses targeted for error injection. If RAMEIDC[EIA_EN] is 1: For determining accesses that can receive error injection, the value of RAM Error Injection Base Address (RAMEIA) sets the address unless this field modifies it.

For each bit in EIAM whose value is	The locations of accesses that can receive error injection
1	Must exactly match the corresponding bit in the value of RAMEIA
0	Do not need to match the corresponding bit in the value of RAMEIA

For example:

Field	Description
	When the value of EIAM is / The locations of accesses that can receive error injection / Comments FFFF_FFFFh / Must exactly match the address in the value of RAMEIA / With this setting, EIAM does not modify the addresses targeted for error injection. 0000_0000h / Do not need to match the address in the value of RAMEIA / This setting causes the address in RAMEIA to be ignored. Any accesses can receive error injection. FFFF_0000h / Are in the address range based at the value of RAMEIA[31:16]: *wxyz*_0000h to *wxyz*_FFFFh / —

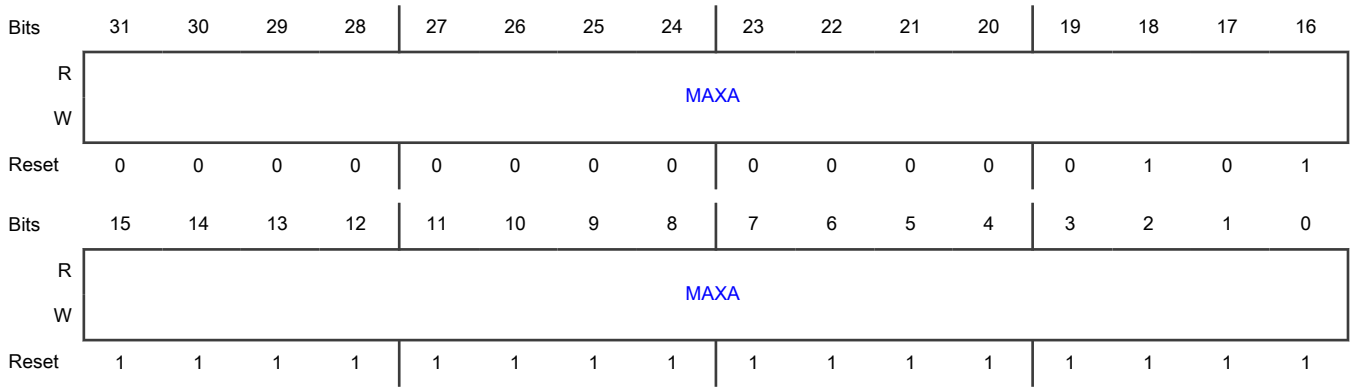
13.5.14 RAM Maximum-Value Address (RAMMAXA)

Specifies the largest value for the bus address within the valid range.

Offset

Register	Offset
RAMMAXA	40h

Diagram



Fields

Field	Description
31-0 MAXA	Maximum Address Sets the value of the largest possible address for a valid request. Attempted accesses to locations above this value cause a decoding error.

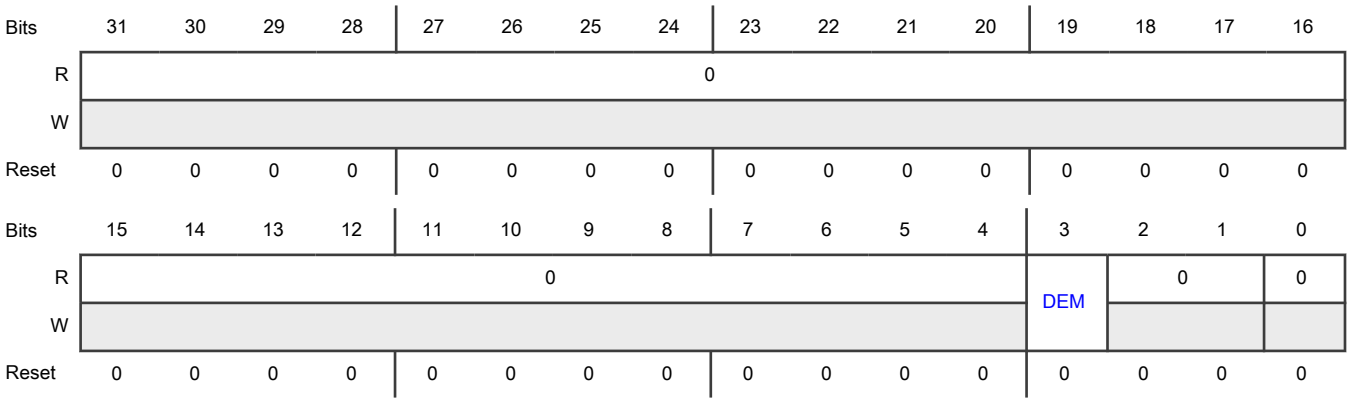
13.5.15 RAM Control 2 (RAMCR2)

Controls features for read and write performance.

Offset

Register	Offset
RAMCR2	80h

Diagram



Fields

Field	Description

Chapter 14
Semaphores2 (SEMA42)

14.1 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

NOTE

Terminology in this chapter has been updated as follows:

Table 79. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave
Stop	Abort

14.1.1 Block diagram

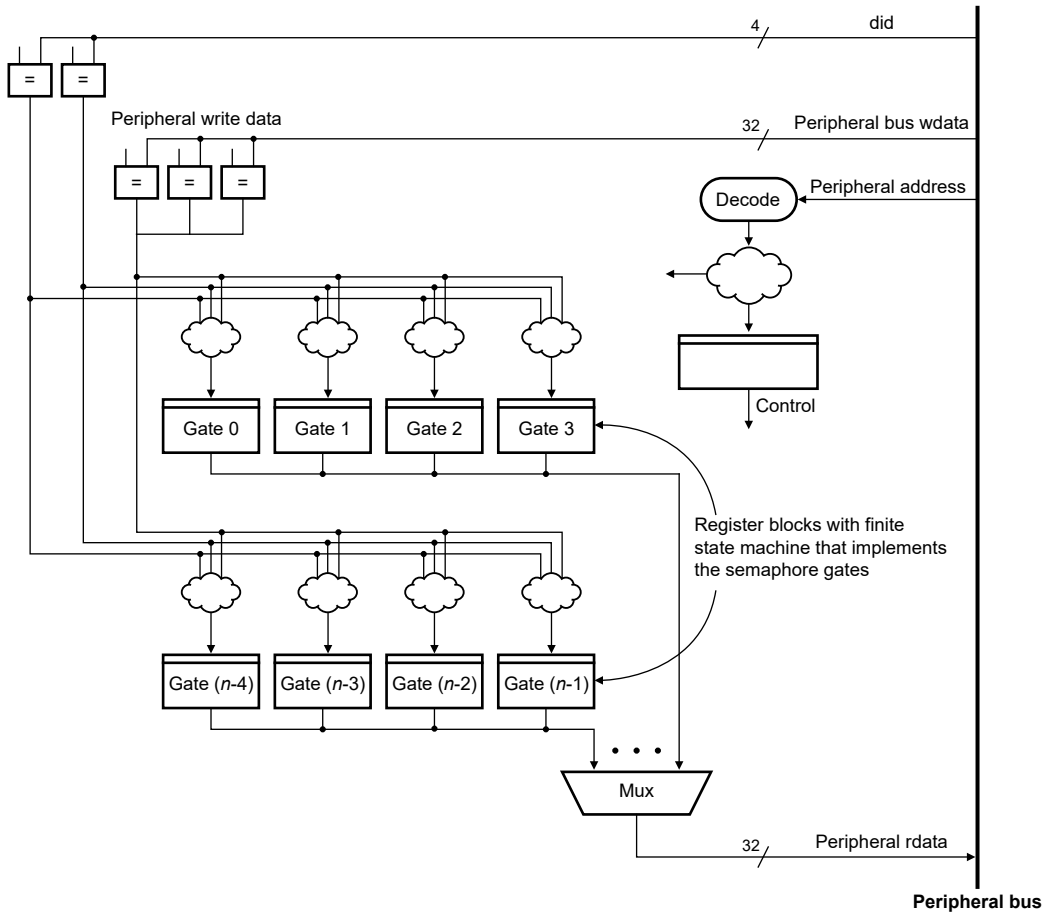

Figure 30. SEMA42 block diagram

14.1.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped target peripheral device. The feature set includes:

- Support for 64 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped target peripheral that offers programming-model accesses.

14.2 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 stops the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

14.2.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: dm*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

14.2.2 64 Hardware-enforced gates

Gates appear as a 64-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (initiator) 0

  if gate = 2h, then state = locked by domain (initiator) 1

  …

  if gate = Fh, then state = locked by domain (initiator) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

14.2.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

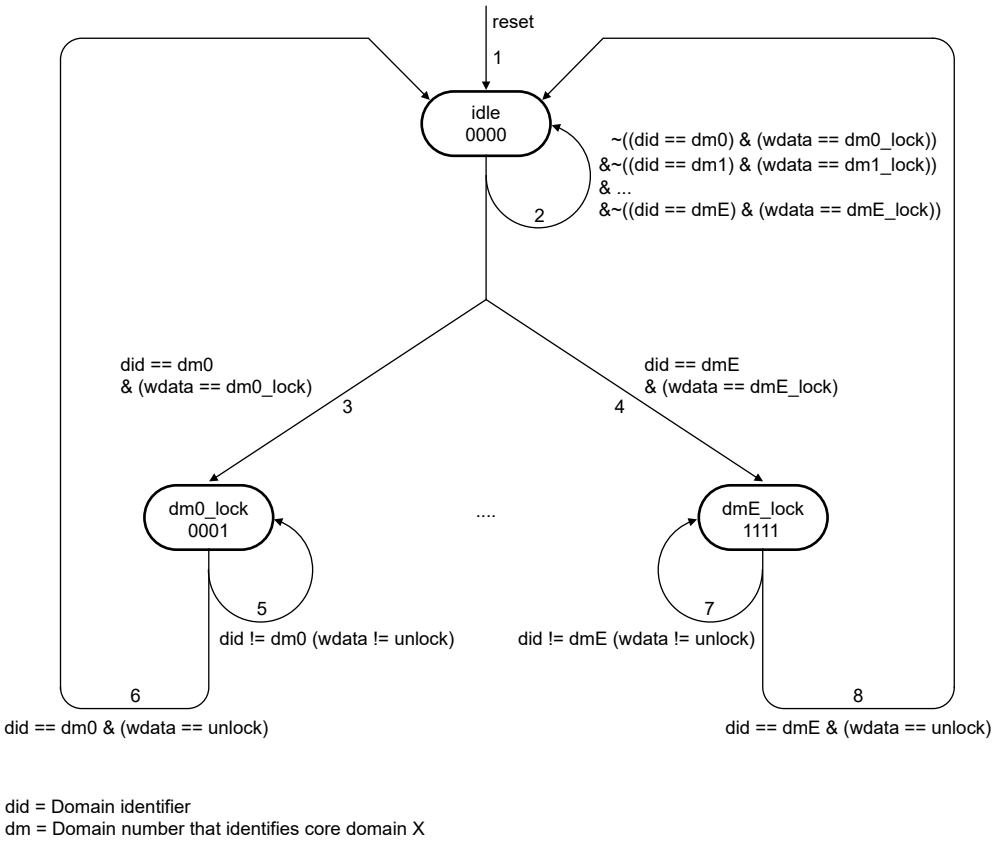

Figure 31. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 80. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.

Table continues on the next page...

Table 80. GATE*n* state transitions (continued)

Current state	Next state	Transition	Description
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

14.2.4 Clocking

Type of clock	Description
Module clock (clk)	Functions the module and controls the access to the registers.

14.2.5 Interrupts

This module has no interrupts.

14.3 External signals

This module has no external signals.

14.4 Initialization

This module does not require initialization.

14.5 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

14.5.1 SEMA42 register descriptions

14.5.1.1 SEMA42 memory map

SEMA42_1 base address: 4426_0000h

SEMA42_2 base address: 4245_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0 - 3F	Gate (GATE0 - GATE63) [1]	8	RW	00
42	Reset Gate Read (RSTGT_R)	16	R	0000
42	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

14.5.1.2 Gate (GATE0 - GATE63)

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain initiators can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

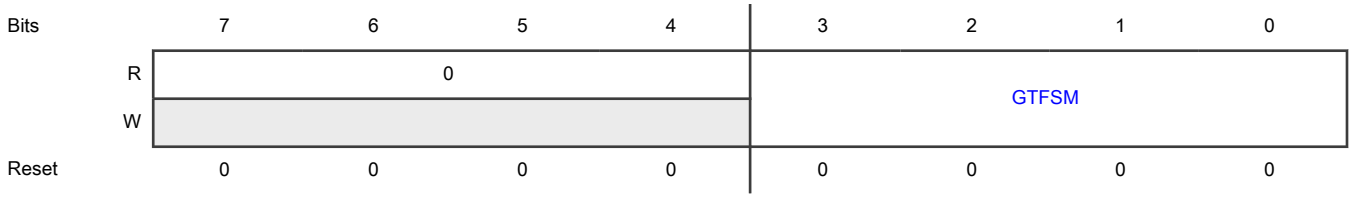
You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Offset

For n = 0 to 63:

Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Diagram



Fields

Field	Description
7-4 —	Reserved
3-0 GTFSM	Gate Finite State Machine Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as:

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0000 - The gate is unlocked (free). 0001 - Domain 0 locked the gate. 0010 - Domain 1 locked the gate. 0011 - Domain 2 locked the gate. 0100 - Domain 3 locked the gate. 0101 - Domain 4 locked the gate. 0110 - Domain 5 locked the gate. 0111 - Domain 6 locked the gate. 1000 - Domain 7 locked the gate. 1001 - Domain 8 locked the gate. 1010 - Domain 9 locked the gate. 1011 - Domain 10 locked the gate. 1100 - Domain 11 locked the gate. 1101 - Domain 12 locked the gate. 1110 - Domain 13 locked the gate. 1111 - Domain 14 locked the gate.

14.5.1.3 Reset Gate Read (RSTGT_R)

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Offset

Register	Offset
RSTGT_R	42h

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
15-14 —	Reserved
13-12 RSTGSM	Reset Gate Finite State Machine Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00 - Idle, waiting for the first data pattern write. 01 - Waiting for the second data pattern write 10 - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11 - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

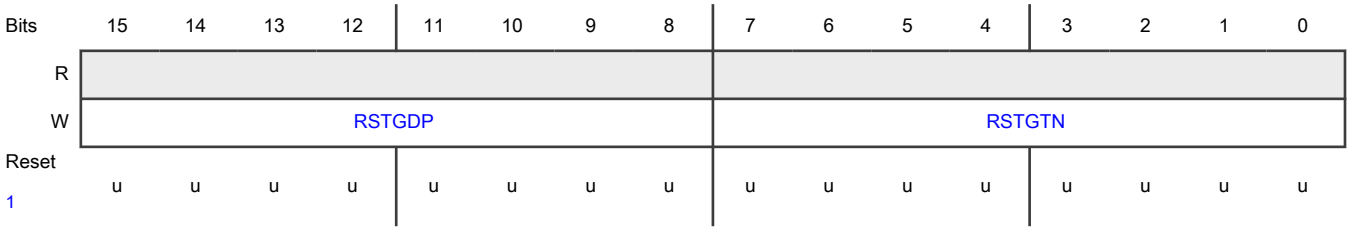
14.5.1.4 Reset Gate Write (RSTGT_W)

Specifies the hardware gate to reset when data patterns are specified.

Offset

Register	Offset
RSTGT_W	42h

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Description
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

Chapter 15
Trusted Resource Domain Controller (TRDC)

15.1 Chip-specific TRDC information

Table 81. Related information in i.MX 91 Applications Processor Reference Manual

Topic	Related module
A55	Arm Cortex CA55 Platform (CA55)
Full description	Trusted Resource Domain Controller (TRDC)
System memory map	Memory Maps
Clocking	Clock Controller Module (CCM)
Signal multiplexing	Port control

NOTE

A core complex should not rely on TRDC and should use the internal MMU for memory management. In addition, initiators like Cortex-A55, that implement the DSU architecture, do support AxPROT internally, but do not drive AxPROT[2] and AxPROT[0] on the system bus. For Cortex-A55, after boot, it is recommended to use the internal MMU for access control.

15.1.1 Module instances

This device has six instances of the TRDC module:

- TRDC AONMIX
- TRDC WAKEUPMIX
- TRDC MEGAMIX
- TRDC NICMIX
- TRDC MEDIAMIX
- TRDC HSIOMIX

NOTE

TRDC settings will be lost if the mix power is off.

NOTE

This chip does not support Flash Logical Window (FLW). The registers for FLW exists but have no effect on device operation.

NOTE

TZ-M is enabled on this chip. TRDC components - MGR, MDAC, MRC and MBC cannot be accessed in a non-secure mode.

15.1.2 Chip-specific TRDC information

Table 82. TRDC MGR Configuration

Location	Parameter Name	Configured Value	AIPS Memory Allocation (KB)	Comments
AONMIX	Number of DIDs	16		Support 16 domains
	Number of MDACs	5		Support 5 MDACs
	Number of MRCs	0	0	Support 1 Region Checkers
	Number of MBCs	1	8	Support 2 Block Checkers
	Total MRC, MBC AIPS memory (KB)		8	
	Number 64K AIPS slots for MRC,MBC		1

Table continues on the next page...

Table 83. DEFAULT DID assignments for all TRDC Components (continued)

7	bit[7] = N/A	eDMA1, eDMA2, eDMA3 Note: Security Requirement: Only assign eDMA instances assigned DEFAULT_DID=7 so we have a single master DID number only for DMA in non-DMA ID replication mode of operation, this will prevent DMA DID from spoofing another master.
8	bit[8] = N/A	CoreSight ETR, TESTPORT
9	bit[9] = N/A	DAP AHB_AP_SYS (JTAG access to System Bus)
10	bit[10] = N/A	For improved security glitch protection assign all other devices - including but not limited to: SoC specific IP (optional), ENET1, ENET2, uSDHC3, USB2, LCDIFs, ISI
11	bit[11] = N/A	USB1
12	bit[12] = N/A	Not Assigned
13	bit[13] = N/A	Not Assigned
14	bit[14] = N/A	Not Assigned
15	bit[15] = N/A	Not Assigned

15.1.3 TRDC MDAC Configuration

DAC_INST_NUM	This value is the instance number of the MDAC for a give TRDC master.
MASTER	Specifies the master to perform region/domain checking.
Location	Specifies which subsystem the TRDC master and MRC component is located in.
BUS Type	Specifies the Slave Memories Bus Type to connect to the MRC.
DAC_REG_NUM	For CPU DACs, this typically depends on the number of processing IDs that the connected CPU will generate, or the number of PID values that software will use for context switches. For non-CPU DACs, this is set to 1. Only one register is needed for non-CPU DAC to source the DID/Secure/Priv attributes for the master.
DAC_CPU	Set to 1 for any "CPU" master that could do context switching.
DEFAULT_DID	This is the DID value that is driven out by the MDAC when MDAC_EN_DDID is set and the MDAC is not yet valid/enabled.
DAC_INST_PID_IN	For DACs connected to CPUs, there's an optional PID input and PID registers. If the processor/CPU connected to DAC sources a process-ID, the integrator would connect that bus to the MDAC and enable this parameter. If the CPU does not source a PID, the user can program the PID registers in the MDAC. Software saves and restores this PID with any context switch.
MAX_DOMAIN_MAPPING	Specifies the number of domains.

Table 84. TRDC MDAC Configuration

				SLV2	-	-	-
				SLV3	-	-	-
	MBC_N2	2	2	SLV0	GIC	7	64
				SLV1	GIC	7	64
				SLV2	Reserved	0	0
				SLV3	Reserved	0	0
	MBC_N3[1]	3	2	SLV0	OCRAM	24	16
				SLV1	OCRAM	24	16
				SLV2	Reserved	0	0
				SLV3	Reserved	0	0

1. For this instance, OCRAM address is remapped from 0x2048_0000 to 0x8000_0000. When the MBC Domain Error Word0 register (MBC-N3_DERR_W0) is read, the actual address is reg value + 0x2048_0000 - 0x8000_0000.

15.1.4.1 TRDC_WAKEUPMIX MBC Global Configuration Register

The reset values of MBC Global Configuration Register (MBC0_MEM0_GLBCFG - MBC1_MEM3_GLBCFG) for TRDC_WAKEUPMIX are as below -

Table 85. Reset Values of MBC0_MEM0_GLBCFG - MBC1_MEM3_GLBCFG

Register	Reset Value
MBC0_MEM0_GLBCFG	0010_0080h
MBC0_MEM1_GLBCFG	0010_0001h
MBC0_MEM2_GLBCFG	0010_0001h
MBC0_MEM3_GLBCFG	0014_0011h
MBC1_MEM0_GLBCFG	0010_0080h
MBC1_MEM1_GLBCFG	0010_0001h
MBC1_MEM2_GLBCFG	0014_0001h
MBC1_MEM3_GLBCFG	0010_0001h

15.1.5 TRDC MRC Configuration

Location	MRC	MRC Instance Number	Number of Slaves	Slave Memory	Number of MRC descriptors
AONMIX	MRC_A0	0	1	Reserved	8
WAKEUPMIX	MRC_W0	0	1	CA55 ROM	8
	MRC_W1	1	1	FlexSPI1	8
NICMIX	MRC_N0	0	2	DRAM	16

MDAC DEFAULT_DID	TRDC_BDB_DID_Bit[x] 1=Deny, 0=Allow, N/A=Not Used	
0	Bit[0] = N/A	Edgelock Enclave
1	Bit[1] = N/A	MTR_MSTR
2	Bit[2] = N/A	Reserved
3	Bit[3] = N/A	CA55, GIC600
4	Bit[4] = N/A	
5	Bit[5] = N/A	uSDHC1
6	Bit[6] = N/A	uSDHC2
7	Bit[7] = N/A	eDMA3_1, eDMA4_2 Note: Security Requirement: Only assign eDMA instances assigned DEFAULT_DID=7 so we have a single master DID number only for DMA in non-DMA ID replication mode of operation, this will prevent DMA DID from spoofing another master.
8	Bit[8] = N/A	CoreSight ETR, TESTPORT
9	Bit[9] = N/A	DAP AHB_AP_SYS (JTAG access to System Bus)
10	Bit[10] = N/A	For improved security glitch protection assign all other devices - ENET, uSDHC3, USB2, LCDIFs, ISI
11	Bit[11] = N/A	USB1
12	Bit[12] = N/A	Not Assigned
13	Bit[13] = N/A	Not Assigned
14	Bit[14] = N/A	Not Assigned
15	Bit[15] = N/A	Not Assigned

NOTE

Access on WAKEUPMIX MRC_W2 will not return transfer error.

NOTE

MRCs should be used to check non-contiguous memory space.

15.2 Overview

TRDC provides an integrated and scalable architectural framework for access control, system memory protection, and peripheral isolation. It allows software to assign chip resources including processor cores, non-core bus initiators, memory regions, and peripherals to processing domains to support enforcement of robust operational environments.

- First, each bus initiating resource is assigned to a domain identifier (domainID, DID). Typically, each processor is assigned to a unique domainID and all remaining non-processor bus initiators assigned to a different domainID.
- Next, the access control policies for the individual domains are programmed into any number of registers implemented in the target memory block and region checkers.
- Finally, all accesses throughout the device are monitored concurrently to determine the validity of each access. If a reference from a given domain has sufficient access rights, it is allowed to continue, else the access is aborted and error information captured.

The access control scheme that TRDC defines supports a 4-level model, combining the traditional privileged (also known as supervisor) and user modes with an additional signal defining the secure, nonsecure attributes of each memory reference. The result is a 4-level hierarchical access control mechanism with different access control policies based on read, write, and execute references, where:

SecurePriv > SecureUser > NonsecurePriv > NonsecureUser

Combined with the secure/nonsecure and privileged/user attributes, a domainID is associated with every system bus transaction and forms the hardware basis for the implementation of TRDC's access control mechanisms.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 86. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave

15.2.1 Block diagram

As previously noted, the TRDC implementation is distributed across multiple submodules instantiated throughout the device. The TRDC submodules include:

- TRDC_MGR
  - The Manager (MGR) submodule coordinates all programming model reads and writes.
- TRDC_DAC
  - The Domain Assignment Controller (DAC) submodule handles resource assignments and generation of the domain identifiers.
- TRDC_MBC
  - The Memory Block Checker (MBC) submodule implements access controls for on-chip internal memories and peripherals based on a fixed-sized block format.

See Figure 32 for a simplified TRDC block diagram focusing on topology and connections.

NOTE

TRDC typically consists of various submodules like DAC, MGR, MBC, and MRC. However, all the submodules as shown in the block diagram below may not be present for this configuration. For chip-specific implementation details of this module's instances, see the chip-specific information.

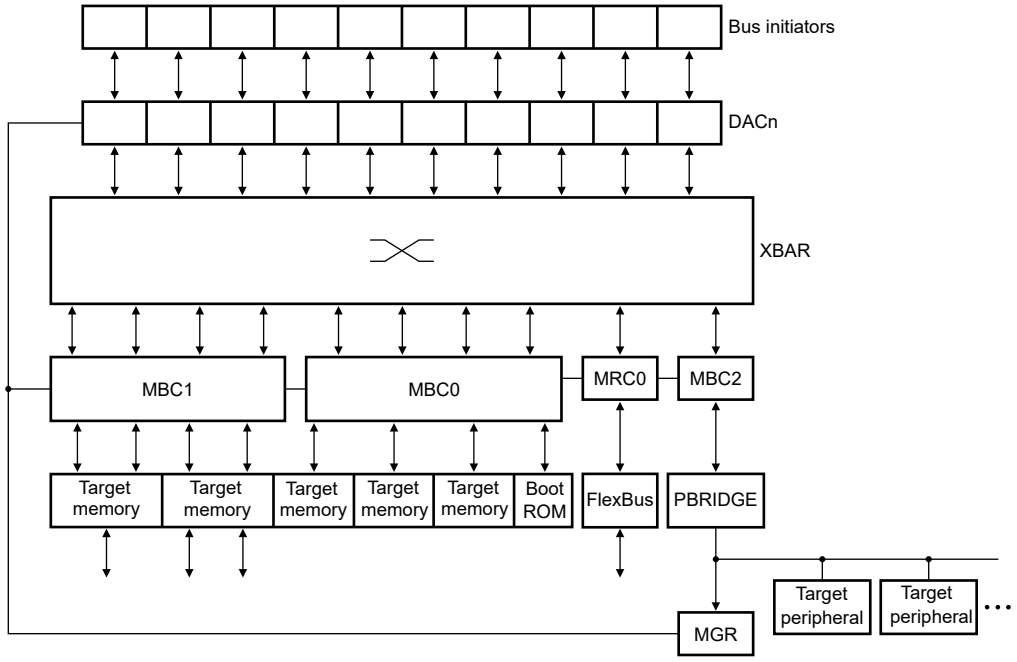

Figure 32. Block diagram

15.2.2 Features

- Ability to assign chip resources to processing "domains":
  - Processor cores, non-core bus initiators, target memories, and target peripherals
  - Each processing domain is assigned a unique domain identifier (domainID, DID)
  - DomainID is an attribute associated with every system bus transaction
  - Used in conjunction with secure/nonsecure, privileged/user attributes
- Defines access rights to targets in MBCs for on-chip memories and peripherals and in MRCs for external memories and peripherals
- Built upon a 4-level hierarchical access control model:
  - SecurePriv > SecureUser > NonsecurePriv > NonsecureUser
  - Defined by multiple sets of user-programmable R/W/X (Read, Write, Execute) flags per access state
- Distributes programming model and hardware implementation across multiple submodules:
  - Supports a broad, highly-configurable architecture definition
  - Supports efficient mechanisms for memory space context switch state changes using nonsecure enables (NSE) for memory blocks and regions

15.3 Functional description

This section provides more details on the operation and implementation of the TRDC submodules.

15.3.1 Modes of operation

TRDC does not support any special modes of operation. As a memory-mapped device located in the core platform's clock domain, it responds strictly on the basis of memory addresses of the connected system buses. TRDC evaluates domain assignment and access control functions on a reference-by-reference basis using the addresses and attributes connected to the system bus port(s).

15.3.2 Manager (TRDC_MGR)

The MGR submodule is responsible for coordinating TRDC's programming model reads and writes.

The complete programming model is large. Additionally, the programming model is distributed across the various submodule instances (DAC, MBC, MRC).

MGR provides:

- The required hardware management for all programming model accesses.
- Generating and distributing the appropriate address decodes and write data to the DAC, MBC, and MRC submodule instances.
- Collecting and combining all the register read data buses and responses.

MGR implements:

- The Control Register
- All the read-only hardware configuration registers (HWCFG[0-1], DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG)
- The program-visible versions of the domain error capture registers.

To support the domain error reporting functionality, MGR collects the individual captured error indicator output signals from all the submodule instances and remaps them so that they are organized into an instance bitmap by domain that the DERRLOCn register array specifies.

15.3.3 Domain Assignment Controller (TRDC_DAC)

The DAC submodule is responsible for the generation of the domainID on every memory transaction for every bus initiator in the device. The resulting domainID, and {nonsecure, privileged} signals are generated and then treated as address attributes and associated with each transaction as it moves through the system.

As a simple example, assume a system with two domainIDs.

- domainID 0 is for critical tasks.
- domainID 1 is for non-critical tasks.
- Two domainIDs require two MDA_Wm_n registers, MDA_W0 and MDA_W1.

During startup, software initializes the MDA_W[0-1] registers.

1. MDA_W0 = 0x8000_0F81
    - VLD = 1
    - DIDS = 0
    - DID = 1
2. MDA_W1 = 0x8000_0FC2
    - VLD = 1
    - DIDS = 0
    - DID = 2

A special mode is provided for driving the DID of non-processor initiators. This is enabled with the DID bypass (DIDB) bit. The DAC has a DID input that can be driven by a initiator and used directly as the DID output. This allows variability in the DID as

dictated by the initiator and is intended to be used by DMA initiators that masquerade as, (that is, drive the DID of) the initiator that programmed it.

15.3.4 Access evaluation

Fundamental to the TRDC's operation is the actual access violation check performed by the memory block checker (MBC) and memory region (MRC).

Previous descriptions have detailed the domain assignment mechanisms and the tracking of the domain identifier as an address attribute through the system bus switching fabric(s). As transactions reach the target memory and peripheral controllers, the address is used to select the appropriate memory region descriptor or block configuration register. Once the appropriate register has been selected, the next function is the actual access evaluation.

For this step, the 3-bit M{B,R}ACSEL field of the selected RGD or BLK_CFG register selects the appropriate GLBAC (global access control policy). The GLBAC register defines the access rights for the domain based on the 4-level model combined with the transaction's access attributes (read = 0/write = 1, secure = 0/nonsecure = 1, execute =1/non-execute=0, user = 0/privileged = 1).

The 4-level model is defined by the concatenation of two address attributes: secure/nonsecure and user/privileged attributes. These two attribute signals (nonsecure, privileged) and the resulting access levels are defined as:

```
if {nonsecure, privileged} == 0b00, then level = SecureUser
if {nonsecure, privileged} == 0b01, then level = SecurePriv(ileged)
if {nonsecure, privileged} == 0b10, then level = NonsecureUser
if {nonsecure, privileged} == 0b11, then level = NonsecurePriv(ileged)
```

The resulting hierarchical access control model specifies:

```
SecurePriv , SecureUser , NonsecurePriv , NonsecureUser
```

After the access evaluation is complete and the access error signal generated, the transaction is allowed to continue if it has sufficient access rights, else the access is aborted with the address and attribute information captured in the appropriate error registers.

15.3.5 Memory Block Checker (TRDC_MBC)

The TRDC's Memory Block Checker provides domain-based access control for all system bus references targeted to on-chip internal memories and peripherals. Using programmed block configuration registers which define the access rights per domain and block, the MBC concurrently monitors system bus transactions and evaluates the appropriateness of each transfer. Memory references that have sufficient access rights are allowed to complete, while references that have insufficient rights are terminated with an access error response.

The TRDC architectural framework supports up to 8 MBC instances where each MBC can support up to 4 sub-regions (MEM[s]). Note monitoring of an AXI memory counts as 2 sub-regions since there are independent read and write channels per AXI memory. Conversely, an AHB connection counts as a single subregion.

Each sub-memory is divided up in equal sized consecutive blocks. Sub-memory 0 (MEM0) can support up to 512 blocks while sub-memory 1-3 (MEM1-MEM3) can each support up to 64 blocks. The number of blocks and size of the block is defined in MBCm_MEMs_GLBCFG[NBLKS,SIZE_LOG2] register fields, where m is the MBC instance number, and s is the sub-memory number. For example, Sub-memory 0 (MEM0) may have 16 consecutive blocks, each of size 64 KB, and corresponding MBCm_DOMd_BLK_CFG_W register to a block will control access to that block.

Each MBCm_DOMd_BLK_CFG_W contains eight access control structures. Each structure is comprised of a 1-bit NSE (NonSecure Enable) plus a 3-bit MBACSEL (Memory Block Access Control Select). The NSE controls secure/nonsecure access to the corresponding block, while the MBACSEL field selects a MBCm_MEMN_GLBACr register which controls the read/write/execute access to the corresponding block. There are 8 programmable MBCm_MEMn_GLBACr registers per block checker, each containing contain read-write-execute control flags for each of the four operating modes:

```
SPR, SPW, SPX - Secure    Privileged {Read, Write, Execute}
SUR, SUW, SUX - Secure    User       {Read, Write, Execute}
NPR, NPW, NPX - Nonsecure Privileged {Read, Write, Execute}
```

```
NUR, NUW, NUX - Nonsecure User       {Read, Write, Execute}
```

GLBAC1-7 also have a lock bit MBCm_MEMn_GLBACr[LK]. When LK=1, the GLBACr register is read-only until the next reset. Furthermore, if MBCm_DOMd_BLK_CFG_W[MBACSEL] selects a GLBAC that is locked, the 3-bit MBCACSEL field is also locked until the next reset. GLBAC0 cannot be locked.

The MBC also has MBCm_DOMd_MEMs_BLK_NSE_W registers. These registers are a bit map of the block NSE bits. Each word supports up to 32 blocks.

```
MBCm_DOMd_MEM0_BLK_NSE_W[0-15] has a maximum of 16 words to support 512 blocks
MBCm_DOMd_MEM[1-3]_BLK_NSE_W[0-1] has a maximum of 2 words to support 64 blocks.
```

The block NSE bits can be programmed by writing these registers or by writing the MBCm_MEMN_BLK_{INDEX, SET, CLR, CLR_ALL} registers.

The MBCm_MEMn_NSE_BLK_{INDEX, SET, CLR, CLR_ALL} registers provide a mechanism to efficiently and quickly manipulate the NSE bitmap with bitmasks to set or clear individual blocks within the bitmap and a single operation to perform a clear all across multiple DIDs. The BLK_INDEX register provides the control definition for the BLK_SET and BLK_CLR operations.

15.3.5.1 Memory block hit determination

MBCm_MEMs_GLBCFG[NBLK, SIZE_LOG2] is used to determine which bits of the address correspond to block number.

```
block_n_hit = (addr[MSB:LSB] == n)
where LSB=SIZE_LOG2
MSB=f{NBLKS,LSB}
```

Note that the block hit determination is based only on the address comparison of the first byte being accessed; that is, the MBC does not check the size of the access to make sure it entirely fits within the region.

15.3.5.2 Memory block access evaluation

For a block n hit, the MBC logic evaluates the access rights defined by the MBCm_DOMd_BLK_CFG_Ww registers. The domainID attribute and block number hit selects the appropriate MBCm_DOMd_BLK_CFG_Ww register to use in the access evaluation. The {R,W,X}, nonsecure and privilege attributes of the access are compared with the MBC global access control policy defined in MBCm_DOMd_BLK_CFG_W[MBACSEL, NSE] fields.

While TRDC_CR[GVLDB] = 1, and for each sub-memory being monitored, the MBC performs a reduction-AND of all the individual error terms from each access evaluation.

Unlike the MRC access evaluation and termination, the MBC access evaluation terminates the access with a bus error and reports an access error for only one condition - when the access doesn't have sufficient access rights. By nature, the block checker can only hit in ONE block, and by implementation, there are no "miss" accesses. Accesses outside of the range covered by the MBC are not sent to the MBC. There also aren't any individual block valid bits. When TRDC_CR[GVLDB] = 1, checking on all blocks is always enabled.

15.3.6 Interrupts

This module outputs an interrupt signal which can be connected to the system's interrupt controller. Please check chip-specific interrupt assignment for details. Interrupt is asserted on detection of access violation by any checker, and it remains asserted until DERRLOCn registers are cleared. This interrupt is in addition to interrupt generated by initiator after receiving bus error due to access violation by memory block checker or memory region checker. So, system may receive interrupt through different channels but from the same access violation at checker.

15.4 External signals

The TRDC module does not directly support any external interfaces.

The *internal* interfaces include a standard 32-bit target bus for all programming model accesses, connections to the address phase signals associated with AHB and/or AXI system buses and connections to the target peripheral buses as shown in TRDC block diagram.

15.5 Initialization

Out of reset, TRDC_CR[GVLDR, GVLDB, GVLDM] bits are cleared, TRDC is disabled and in deny by default mode allowing secure privileged startup code to configure the entire programming model. In deny by default mode, only the DIDs that aren't denied by default are allowed to access memory and peripherals. The allowed DIDs are implementation defined. The initialization process typically is performed in 3 steps:

1. Read the various hardware configuration registers (HWCFG{0,1}, DACFGn, MBCm_MEMs_GLBCFG, MRC_GLBCFG) to obtain the implemented hardware capabilities for the device.
2. Using the information retrieved in Step 1 coupled with the desired domain architecture, program all the register data structures for domain assignment (MDA_Wm_n), memory block configuration (MBCm_DOMd_MEMs_BLK_CFG_Ww) and memory region descriptors (MRCm_DOMd_RGDr_Ww). There are individual valid bits included in these registers which typically would be asserted. Additionally, there are also lock mechanisms available if register settings need to be configured and marked as read-only.
3. Once the TRDC programming model is loaded, the TRDC_CR is written with GVLD {R, B, M} asserted. Upon the assertion of the 3 GVLD bits, deny by default mode is exited and at that point, the TRDC is fully operational. The TRDC remains enabled until the next reset.

15.6 Application information

As described in Overview, the TRDC architecture is intended to provide a broad, highly-capable framework for access control, system memory protection and peripheral isolation. The resulting microarchitecture implementation is distributed throughout the core platform, highly configurable via hardware design parameters and software programmability.

15.6.1 Initiator domain assignments

The typical use case related to initiator domain assignments is to include one (or more) processor core(s) in a single domain, possibly coupled with other bus initiator devices like DMA, etc. The definition of a domain may be static, based simply on the combination of a processor and other optional bus initiators. Alternatively, the processor's operation may be configured to dynamically select between a very small number of domains.

For example, "critical" tasks, whether safety-critical, performance-critical, etc. can be grouped together in one domain and all other tasks into a second domain. Non-processor bus initiators typically have a single MDA_Wm_n configuration register associated with them. The domainID and {nonsecure, privileged} attributes are usually statically assigned, unless the module can "inherit" attributes from a processor programming it (certain modules like DMAs).

The MDA_Wm_n registers, along with the memory region descriptors and the peripheral domain access control registers all have lock features that allow the register resources to be converted into read-only resources to protect the written configuration.

15.6.2 Domain error capture management

Recall when a domain access violation is detected by either a memory region checker or a memory block checker, address and attribute information of the offending access is captured. The DERRLOCn read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_n and DERR_W1_n, the DERRLOCn registers provide the instance number details.

These registers are organized as a word array, *indexed by the faulting domain number*, with the contents of each register providing a bitmap signaling the instance number(s) associated with all submodules containing captured error information for that domain.

It is recommended that the exception handler begin by reading the HWCFG1 register to determine its domainID. Next, it uses the just-retrieved domainID to index into the DERRLOCn array. The resulting DERRLOCn value is then examined to determine the instance number of the reporting MBC and/or MRC submodule.

There may be multiple access violations, across multiple instances, pending for a given domain. It is suggested that exception handler use a "find first one" instruction (alternatively known as "count leading zeroes") to quickly and efficiently find the instance number containing access violation details. Once the instance number has been determined, the captured error address and attribute information can easily be retrieved from the domain error registers. For 32 bits address, the captured error address can be retrieved from DERR_W0_n and the attribute information can be retrieved from DERR_W1_n. For 36 bits address, the captured error address can be retrieved from DERR_W0_n and DERR_W1_n and the attribute information can be retrieved from DERR_W2_n. The 2-bit DERR_W1_n[EST] or DERR_W2_n[EST] field provides information signaling whether one or more errors have been detected by the submodule instance. A special write to DERR_W3_n is required to reset (and rearm) the EST error capture state machine.

This process is repeated until all errors associated with a given domainID have been processed.

A graphical representation of this 2-step retrieval of the domain error address and attributes is shown in Figure 33.

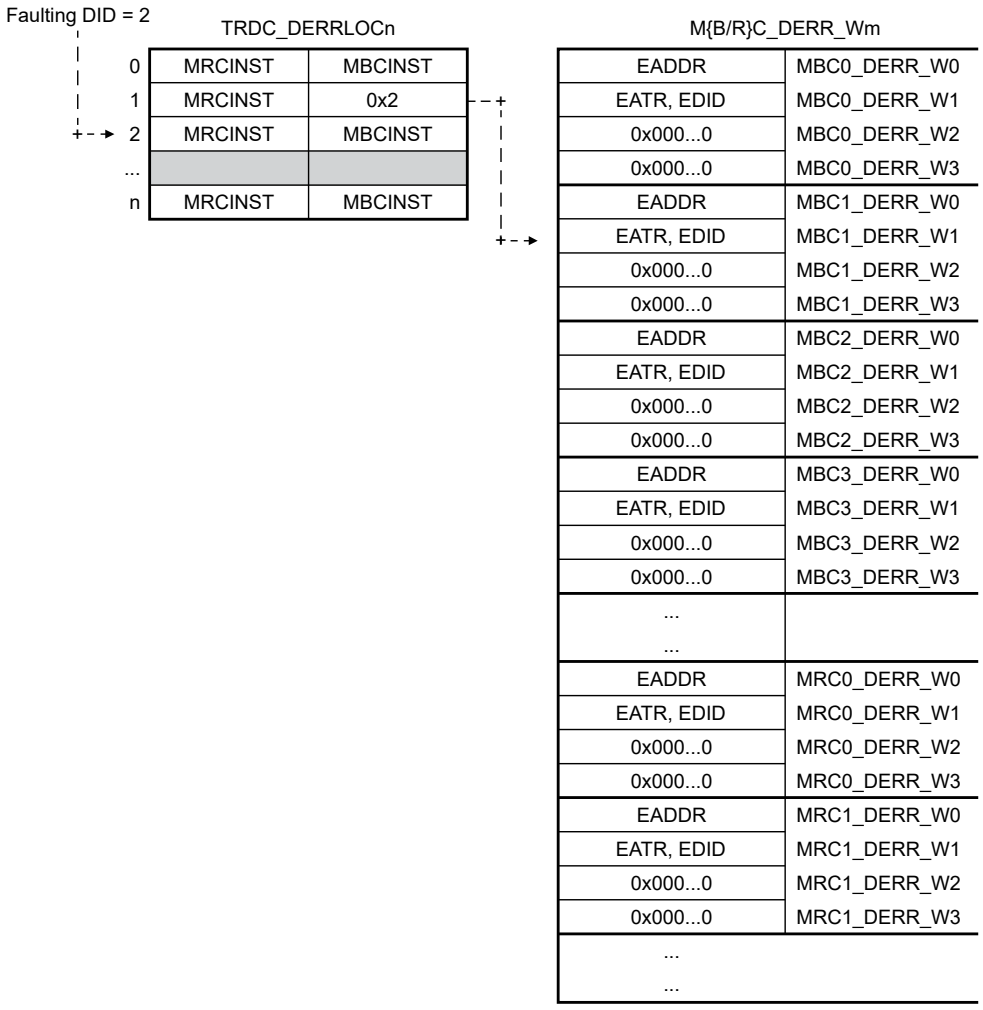

Figure 33. Two-step retrieval of domain error address and attributes

15.7 Register descriptions

The MBCm_NSE_BLK_SET, MBCm_NSE_BLK_CLR and MBCm_NSE_BLK_CLR_ALL registers exist at offset for only domain ID value 0 even when more than 1 domains exist, and address offsets for non-zero domain ID value should be considered reserved space. So, this reserved address space in MBC space does not return transfer error: 0xn14 to 0xn1C where n = (1 to NUM_DID-1) * 2 for each MBC.

If TZ-M is enabled, the TRDC programming model can only be accessed in SecurePrivileged mode. If TZ-M is disabled, it can only be accessed in Privileged mode regardless of Secure or NonSecure; that is it can't be accessed in User mode. Unless noted otherwise, the programming model registers can be accessed via 8-, 16- or 32-bit reads and 32-bit write references. Attempted accesses in a different operating mode, using unsupported write data sizes, writes to read-only resources, or access to reserved spaces are terminated with an error unless noted otherwise. The TRDC programming model is partitioned into these groups of registers:

- Basic hardware control and configuration
- Domain errors: location and details
- Initiator domain assignments
- Memory block and region checkers

It should be noted that many of the programming model registers in TRDC are organized as 2-, 3- or 4- dimensional data structures. For the 2-dimensional structures, the generic arrays contain "m" words representing the "columns" and "n" instances of the structure representing the "rows". These may be described as `structure[n][m]`. They appear in the address space of the programming model memory map in the standard C language row-major layout, that is, the "m" words representing the "column" appear sequentially with the entire row replicated "n" times. The TRDC register structure uses the naming convention of *TRDC_<regname>_Wm_n*, where the column number "m" appears as a numeric suffix on the W (32-bit word) identifier, and the row identifier "n" appears as the final numerical suffix.

For the 4-dimensional structures, the generic arrays contain "m", "d", "s" or "r", and "w" indices corresponding to MBC/MRC instance, domain index, sub-memory or region index and word index. The naming convention for the MBC block configuration and MRC region descriptor word registers are: *MBCm_DOMd_MEMs_BLK_CFG_Ww* and *MRCm_DOMd_RGDr_Ww*

For the reset values in this section, a "*" indicates an initial value determined by the hardware configuration.

15.7.1.2 TRDC Register (TRDC_CR)

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Description
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

15.7.1.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

15.7.1.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

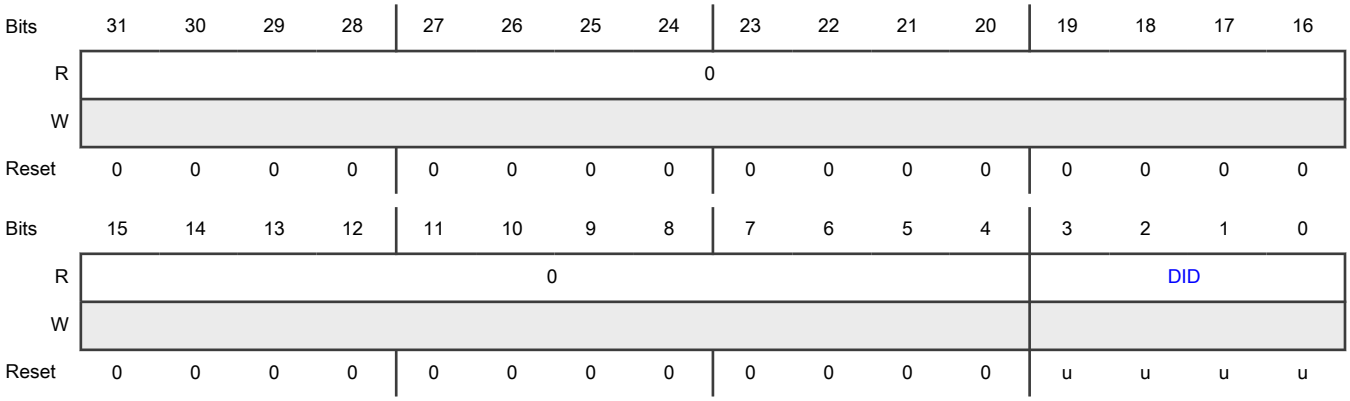
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

15.7.1.5 Domain Assignment Configuration Register (DACFG2 - DACFG4)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG2	102h

Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

15.7.1.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

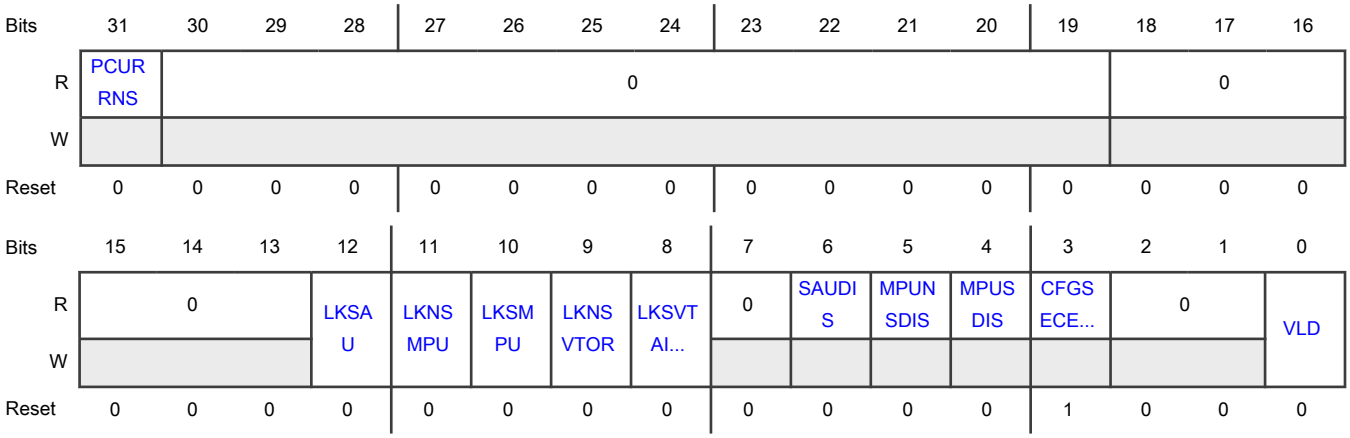
This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

Diagram



Fields

31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

15.7.1.11 TRDC Fault Domain ID (TRDC_FDID)

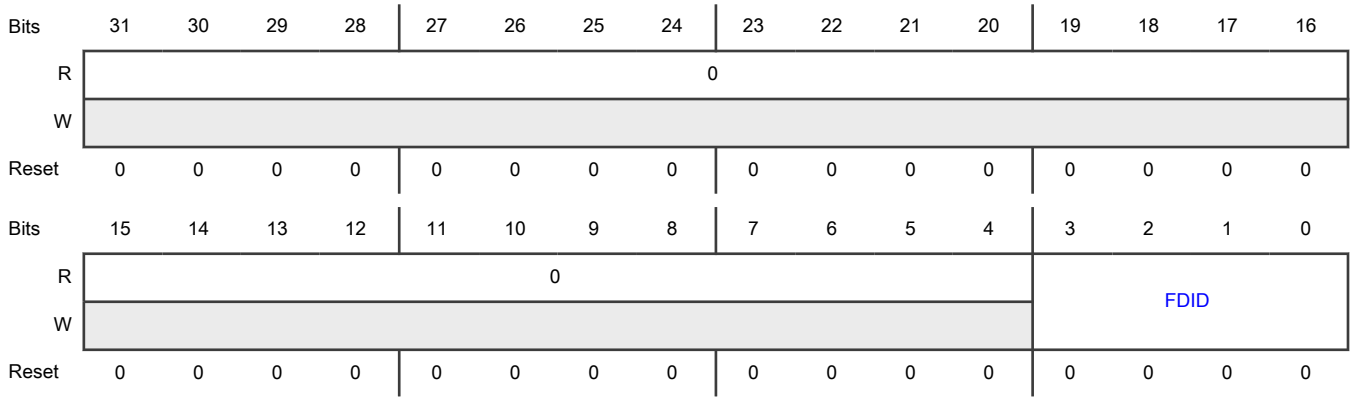
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

15.7.1.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

15.7.1.13 MBC Domain Error Word0 Register (MBC0_DERR_W0)

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
MBC0_DERR_W0	400h

Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000 - mbcxslv0 001 - mbcxslv1 010 - mbcxslv2 011 - mbcxslv3
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

15.7.1.15 MBC Domain Error Word3 Register (MBC0_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

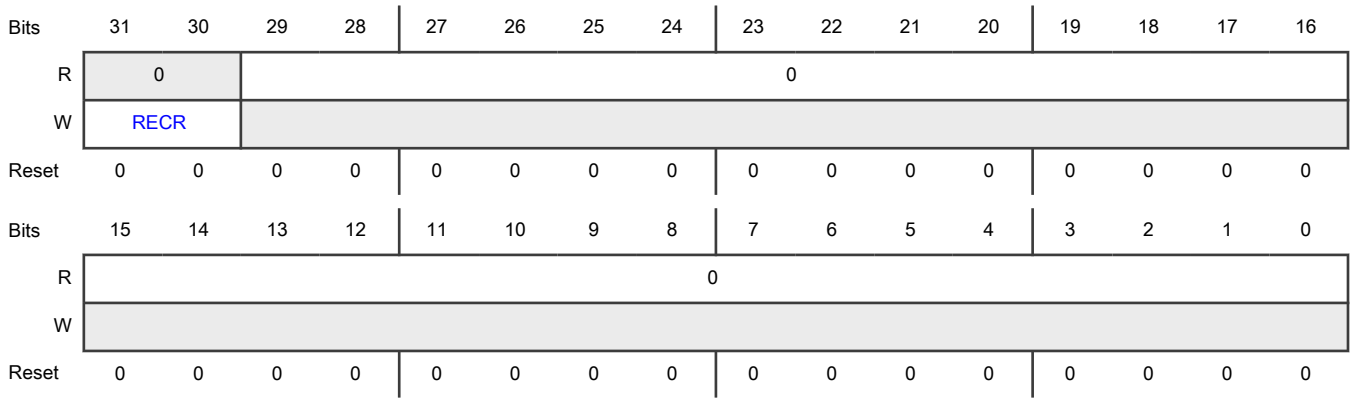
A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Offset

Register	Offset
MBC0_DERR_W3	40Ch

Diagram



Fields

Field	Description
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

15.7.1.16 DAC Initiator Domain Assignment Register (MDA_W0_2_DFMT1 - MDA_W0_4_DFMT1)

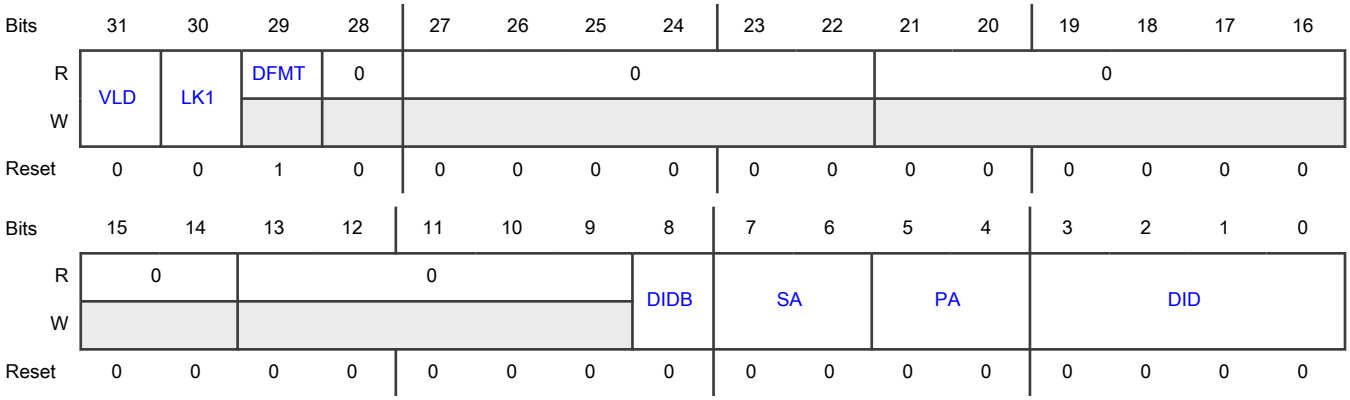
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h

Diagram



Fields

Field	Description
31	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Description
VLD	This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset.

Fields

Field	Description
31-0 W1SET	Write-1 Set If set to 1, sets appropriate NSE bit for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. Write with value 0 has no effect.

15.7.1.20 MBC NonSecure Enable Block Clear (MBC0_NSE_BLK_CLR)

A write to this location clears the appropriate NSE bits as defined by the W1CLR[n]=1 for the selected domains and memories Defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

15.7.1.23 MBC Global Access Control (MBC0_MEMN_GLBAC1 - MBC0_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

15.7.1.24 MBC Memory Block Configuration Word (MBC0_DOM0_MEM0_BLK_CFG_W0 - MBC0_DOM15_MEM2_BLK_CFG_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 87. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0
W1	block 15	block 14	block 13	block 12	block 11	block 10	block 9	block 8

Fields

Field	Description
31 NSE7	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24 MBACSEL6	Memory Block Access Control Select for block B This field selects the global access control associated with block B.

Field	Description
2-0 MBACSEL0	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL0 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B

15.7.1.25 MBC Memory Block NonSecure Enable Word (MBC0_DOM0_MEM0_BLK_NSE_W0 - MBC0_DOM15_MEM2_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 88. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64

Table continues on the next page...

Table 88. Block Config Word to Block Number Relationship (continued)

Block NSE Word	BIT31	BIT30-BIT1	BIT0
		. . .	
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

15.7.2.2 TRDC Register (TRDC_CR)

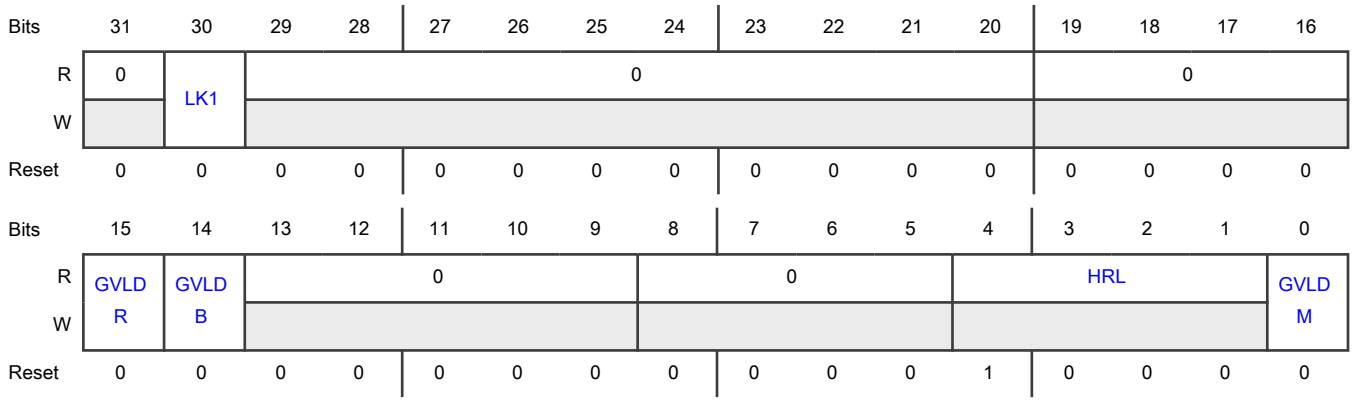
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC’s hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

15.7.2.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

15.7.2.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

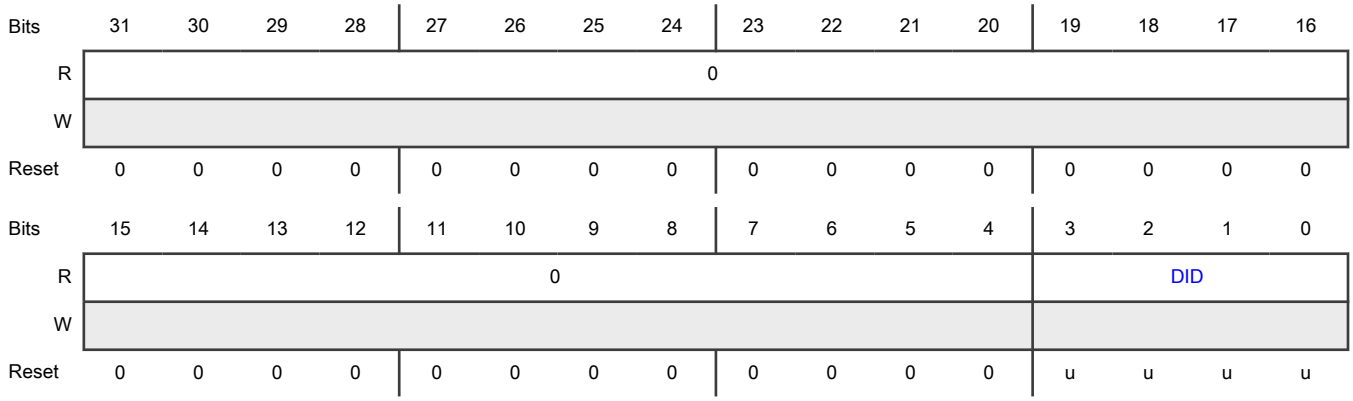
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

15.7.2.5 Domain Assignment Configuration Register (DACFG0 - DACFG1)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG0	100h
DACFG1	101h

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

15.7.2.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

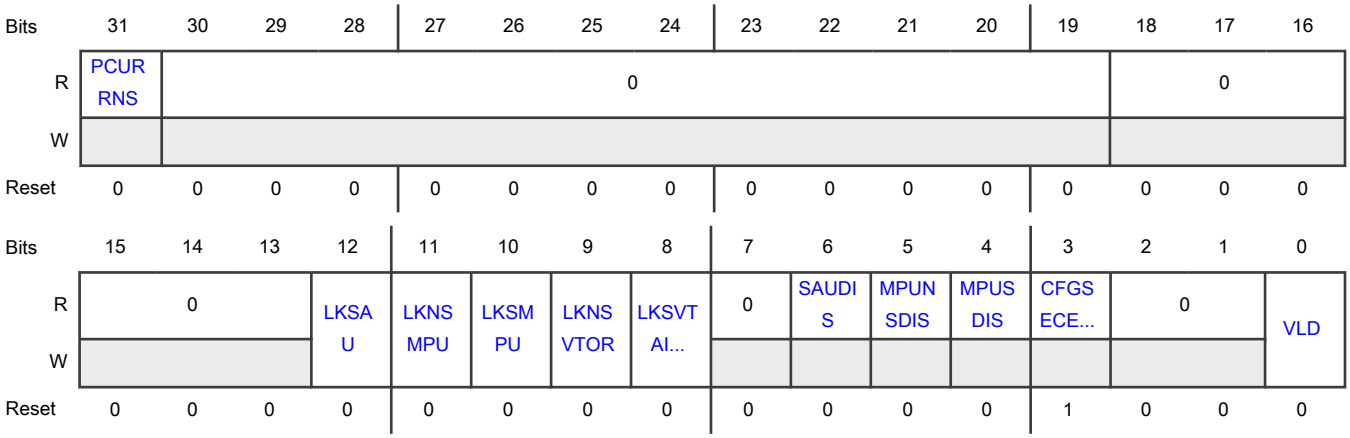
This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

Diagram



Fields

Field	Description
31 PCURRNS	Processor current security Current security state of the processor. 0 - Processor is in Secure state 1 - Processor is in Nonsecure state
30-19 —	Reserved
18-16 —	Reserved
15-13 —	Reserved
12 LKSAU	Lock SAU Asserting this bit prevents changes to the processor's Secure SAU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers from software or from a debug agent connected to the processor

Table continues on the next page...

Table continued from the previous page...

Field	Description
11 LKNSMPU	Lock Nonsecure MPU Asserting this bit prevents changes to the processor's Nonsecure MPU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL_NS, MPU_RNR_NS, MPU_RBAR_NS, MPU_RLAR_NS, MPU_RBAR_A_NSn and MPU_RLAR_A_NSn from software or from a debug agent connected to the processor
10 LKSMPU	Lock Secure MPU Asserting this signal prevents changes to the processor's programmed Secure MPU memory regions and all processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL, MPU_RNR, MPU_RBAR, MPU_RLAR, MPU_RBAR_An and MPU_RLAR_An from software or from a debug agent connected to the processor in Secure state
9 LKNSVTOR	Lock Nonsecure Vector Table Offset Register Asserting this signal prevents changes to the processor's Nonsecure vector table base address. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock this register 1 - Disable writes to the VTOR_NS register
8 LKSVTAIRCR	Lock Secure VTOR, Application interrupt and Reset Control Registers This bit is sticky, once set, it can only be cleared with a reset. Asserting this signal prevents processor changes to: • The Secure vector table base address. • Handling of Secure interrupt priority. • BusFault, HardFault, and NMI security target settings in the processor. 0 - Unlock these registers 1 - Disable writes to the VTOR_S, AIRCR[PRIS], and AIRCR[BFHFNMINS] registers
7 —	Reserved
6 SAUDIS	Security Attribution Unit Disable 0 - SAU is enabled 1 - SAU is disabled
5 MPUNSDIS	NonSecure Memory Protection Unit Disabled 0 - Nonsecure MPU is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Nonsecure MPU is disabled
4 MPUSDIS	Secure Memory Protection Unit Disabled 0 - Secure MPU is enabled 1 - Secure MPU is disabled
3 CFGSECEXT	Configure Security Extension 0 - Armv8M Security Extension is disabled 1 - Armv8-M Security Extension is enabled
2-1 —	Reserved
0 VLD	Valid When VLD =0, all address attribute from IDAU is nonSecure. When VLD=1, values in other fields of this register are valid.

15.7.2.7 TRDC FLW Control (TRDC_FLW_CTL)

This register provides control of the FLW = Flash Logical Window operation.

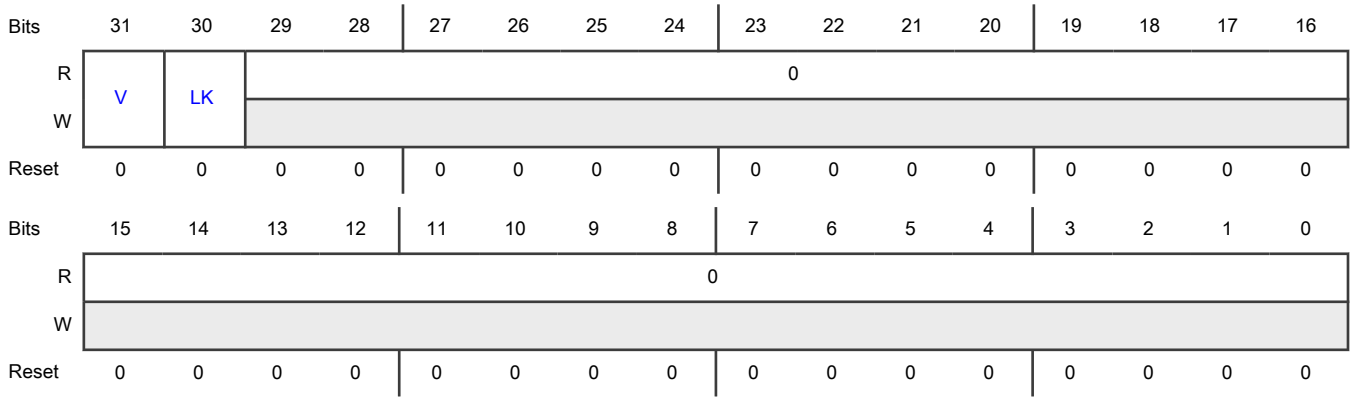
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

Diagram



Fields

Field	Description
31 V	Valid bit 0 - FLW function is disabled. 1 - FLW function is enabled.
30 LK	Lock bit 0 - FLW registers may be modified. 1 - FLW registers are locked until the next reset.
29-0 —	Reserved

15.7.2.8 TRDC FLW Physical Base (TRDC_FLW_PBASE)

This read-only register gives the physical base address of the Flash Logical Window.

This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

Diagram

Fields

Field	Description
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

15.7.2.9 TRDC FLW Array Base (TRDC_FLW_ABASE)

This register gives the flash array base address of the Flash Logical Window.

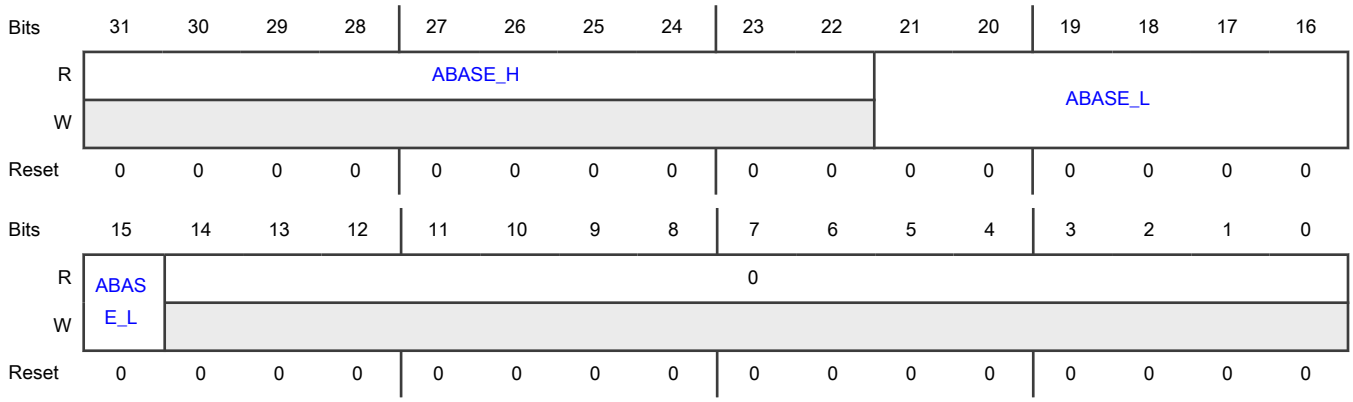
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

Diagram



Fields

Field	Description
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

15.7.2.10 TRDC FLW Block Count (TRDC_FLW_BCNT)

This register gives the size of the Flash Logic Window in 32KByte blocks.

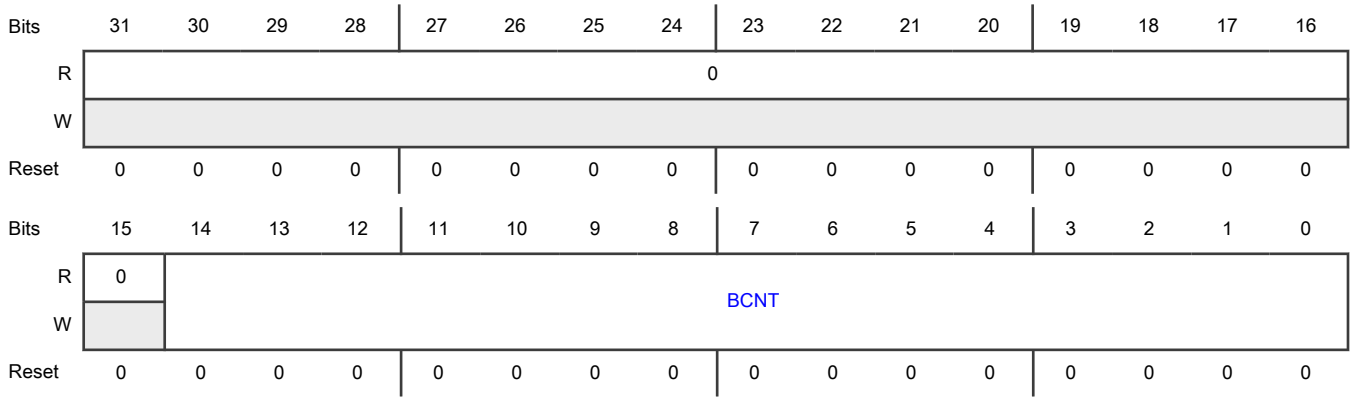
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_BCNT	1ECh

Diagram



Fields

Field	Description
31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

15.7.2.11 TRDC Fault Domain ID (TRDC_FDID)

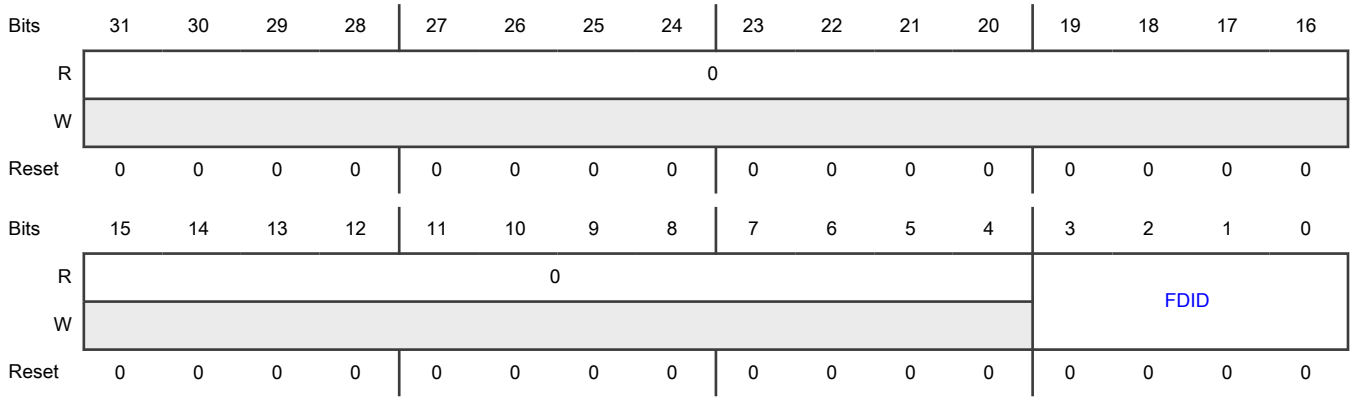
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

15.7.2.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

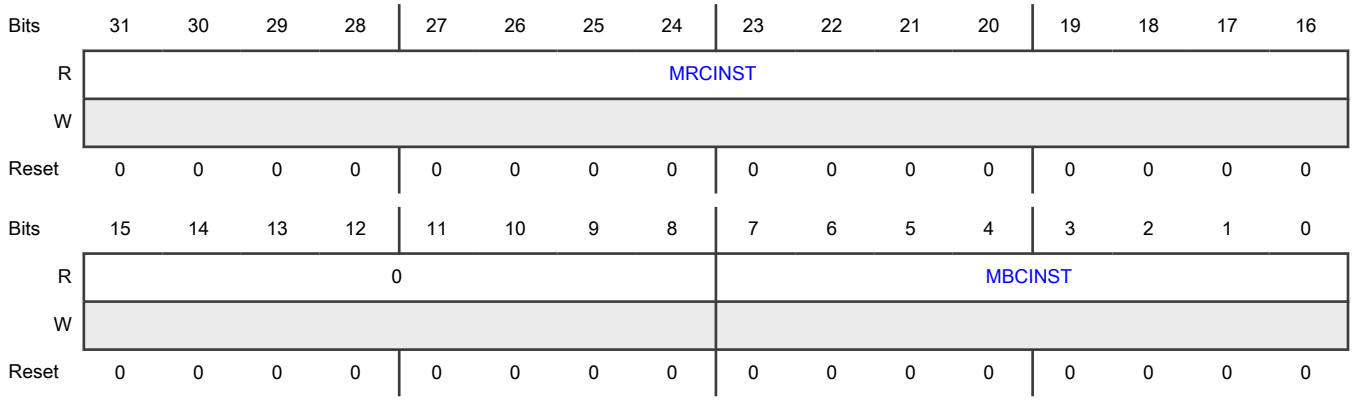
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Diagram



Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

15.7.2.13 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_1_DFMT1)

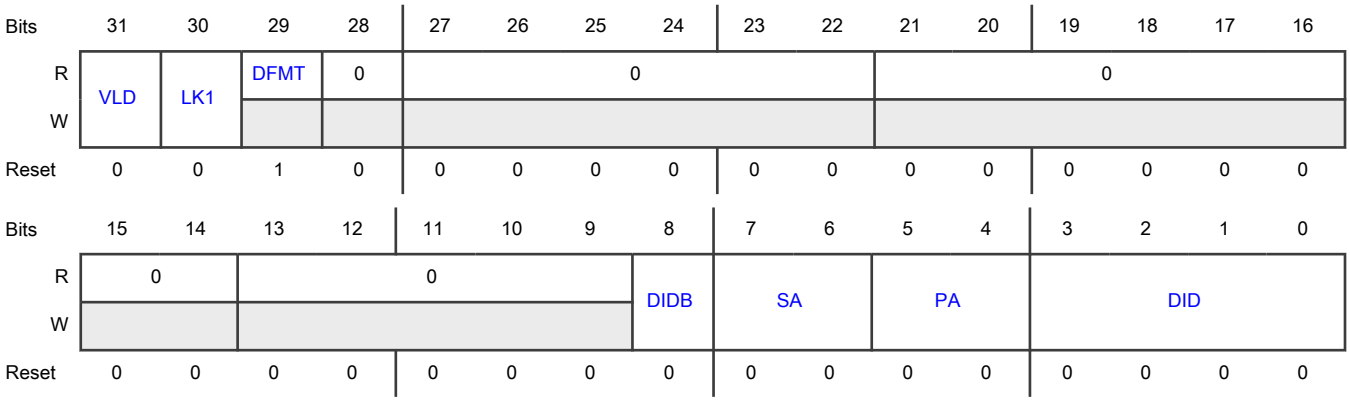
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_0_DFMT1	800h
MDA_W0_1_DFMT1	820h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment

<tr><td>8
DIDB</td><td>DID Bypass
If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor.
Once set, this field is “sticky” and remains set until the next reset.
<table><tr><th>DAC</th><th>DID Input</th></tr><tr><td>0</td><td>0</td></tr><tr><td>1</td><td>DMA Domain ID</td></tr><tr><td>2</td><td>USB Domain ID</td></tr></table>
0 - Use MDAn[3:0] as the domain identifier.
1 - Use the DID input as the domain identifier.</td></tr>
<tr><td>7-6
SA</td><td>Secure attribute
This field defines the secure/nonsecure attribute for non-processor cores.
NOTE
The bus initiator’s input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it.
Reset value of SA:
• if TZM_ENB=0, SA reset value = 2'b01
• if TZM_ENB=1, SA reset value = 2'b00
00 - Force the bus attribute for this initiator to secure.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Description
	01 - Force the bus attribute for this initiator to nonsecure. 10 - Use the bus initiator's secure/nonsecure attribute directly. 11 - Use the bus initiator's secure/nonsecure attribute directly.
5-4 PA	Privileged attribute This field defines the privileged/user attribute for non-processor cores. **NOTE** The bus initiator's input privileged/user attribute is used if PA = 1X, or this VLD = 0. 00 - Force the bus attribute for this initiator to user. 01 - Force the bus attribute for this initiator to privileged. 10 - Use the bus initiator's privileged/user attribute directly. 11 - Use the bus initiator's privileged/user attribute directly.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDB=0.

15.7.3.2 TRDC Register (TRDC_CR)

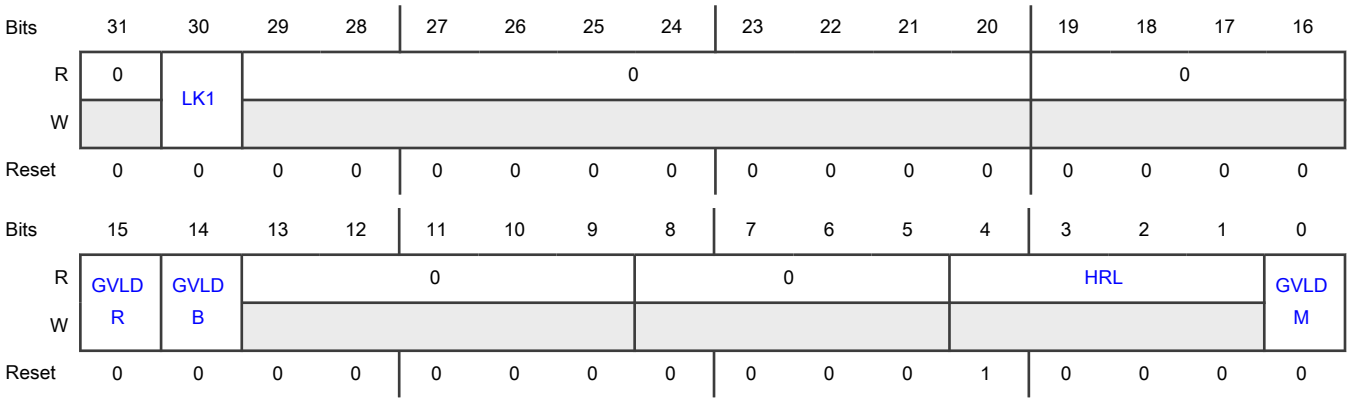
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30	Lock Status

Table continues on the next page...

Table continued from the previous page...

Field	Description
LK1	This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

15.7.3.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

15.7.3.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

15.7.3.5 Domain Assignment Configuration Register (DACFG0 - DACFG3)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG0	100h

W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

15.7.3.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

15.7.3.11 TRDC Fault Domain ID (TRDC_FDID)

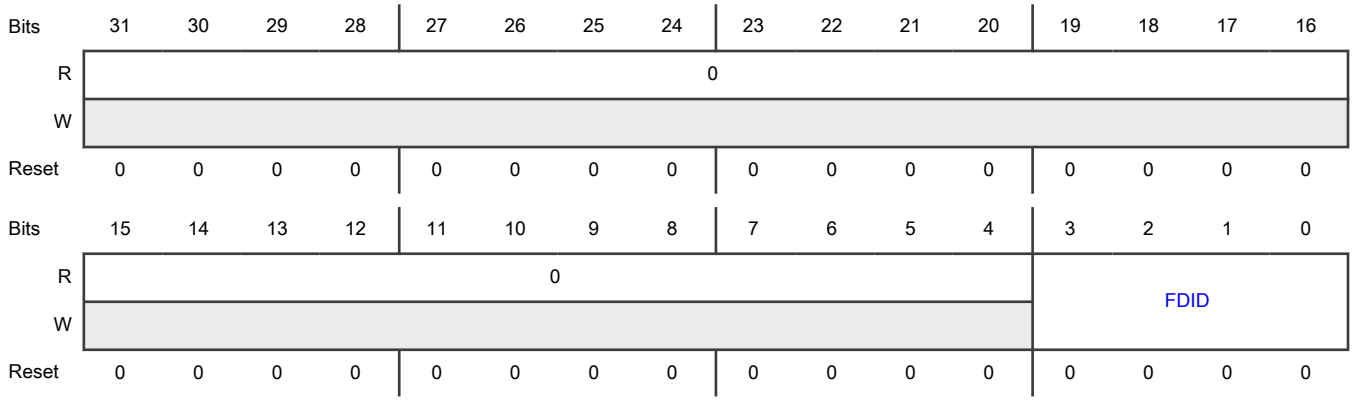
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

15.7.3.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

15.7.3.13 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_3_DFMT1)

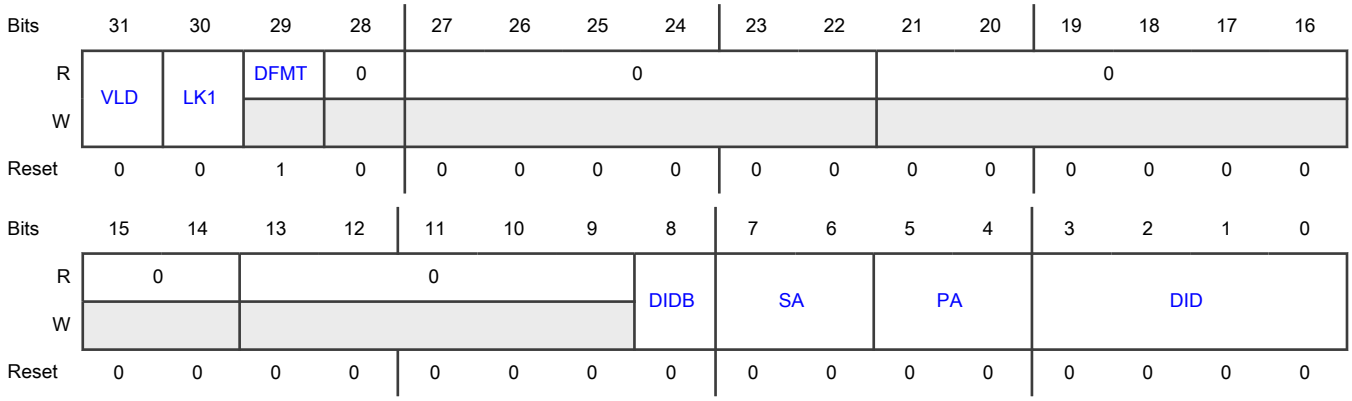
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_0_DFMT1	800h
MDA_W0_1_DFMT1	820h
MDA_W0_3_DFMT1	860h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16	Reserved

15.7.4.2 TRDC Register (TRDC_CR)

This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

15.7.4.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

15.7.4.5 Domain Assignment Configuration Register (DACFG0 - DACFG6)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG0	100h

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

15.7.4.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

Fields

Field	Description
31 PCURRNS	Processor current security Current security state of the processor. 0 - Processor is in Secure state 1 - Processor is in Nonsecure state
30-19 —	Reserved
18-16 —	Reserved
15-13 —	Reserved
12 LKSAU	Lock SAU Asserting this bit prevents changes to the processor's Secure SAU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers from software or from a debug agent connected to the processor

Table continues on the next page...

Table continued from the previous page...

Field	Description
11 LKNSMPU	Lock Nonsecure MPU Asserting this bit prevents changes to the processor's Nonsecure MPU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL_NS, MPU_RNR_NS, MPU_RBAR_NS, MPU_RLAR_NS, MPU_RBAR_A_NSn and MPU_RLAR_A_NSn from software or from a debug agent connected to the processor
10 LKSMPU	Lock Secure MPU Asserting this signal prevents changes to the processor's programmed Secure MPU memory regions and all processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL, MPU_RNR, MPU_RBAR, MPU_RLAR, MPU_RBAR_An and MPU_RLAR_An from software or from a debug agent connected to the processor in Secure state
9 LKNSVTOR	Lock Nonsecure Vector Table Offset Register Asserting this signal prevents changes to the processor's Nonsecure vector table base address. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock this register 1 - Disable writes to the VTOR_NS register
8 LKSVTAIRCR	Lock Secure VTOR, Application interrupt and Reset Control Registers This bit is sticky, once set, it can only be cleared with a reset. Asserting this signal prevents processor changes to: • The Secure vector table base address. • Handling of Secure interrupt priority. • BusFault, HardFault, and NMI security target settings in the processor. 0 - Unlock these registers 1 - Disable writes to the VTOR_S, AIRCR[PRIS], and AIRCR[BFHFNMINS] registers
7 —	Reserved
6 SAUDIS	Security Attribution Unit Disable 0 - SAU is enabled 1 - SAU is disabled
5 MPUNSDIS	NonSecure Memory Protection Unit Disabled 0 - Nonsecure MPU is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Nonsecure MPU is disabled
4 MPUSDIS	Secure Memory Protection Unit Disabled 0 - Secure MPU is enabled 1 - Secure MPU is disabled
3 CFGSECEXT	Configure Security Extension 0 - Armv8M Security Extension is disabled 1 - Armv8-M Security Extension is enabled
2-1 —	Reserved
0 VLD	Valid When VLD =0, all address attribute from IDAU is nonSecure. When VLD=1, values in other fields of this register are valid.

15.7.4.7 TRDC FLW Control (TRDC_FLW_CTL)

This register provides control of the FLW = Flash Logical Window operation.

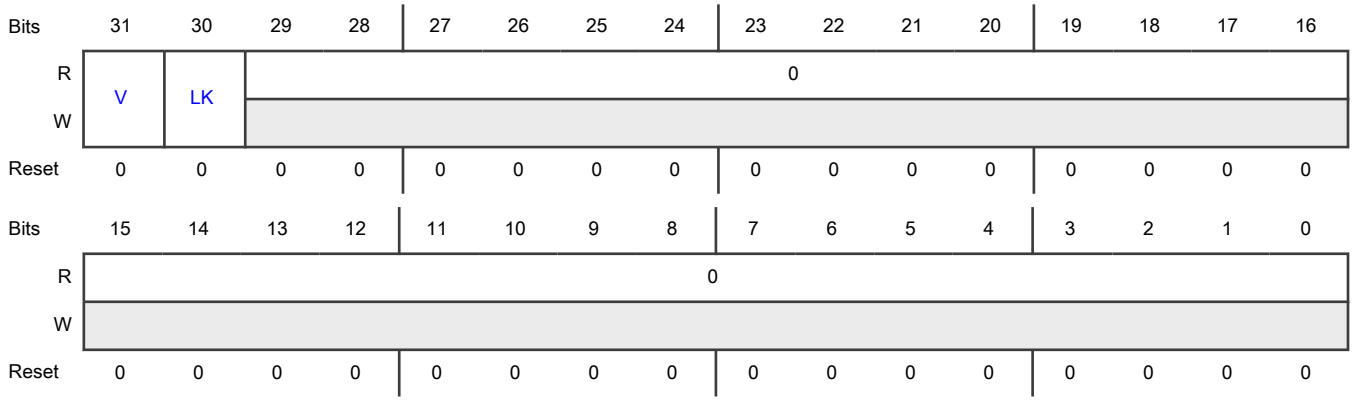
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

Diagram



Fields

Field	Description
31 V	Valid bit 0 - FLW function is disabled. 1 - FLW function is enabled.
30 LK	Lock bit 0 - FLW registers may be modified. 1 - FLW registers are locked until the next reset.
29-0 —	Reserved

15.7.4.8 TRDC FLW Physical Base (TRDC_FLW_PBASE)

This read-only register gives the physical base address of the Flash Logical Window.

This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

Fields

Field	Description
31-0 PBASE	Physical base address Physical address of the base of the FLW (mod 32KBytes).

15.7.4.9 TRDC FLW Array Base (TRDC_FLW_ABASE)

This register gives the flash array base address of the Flash Logical Window.

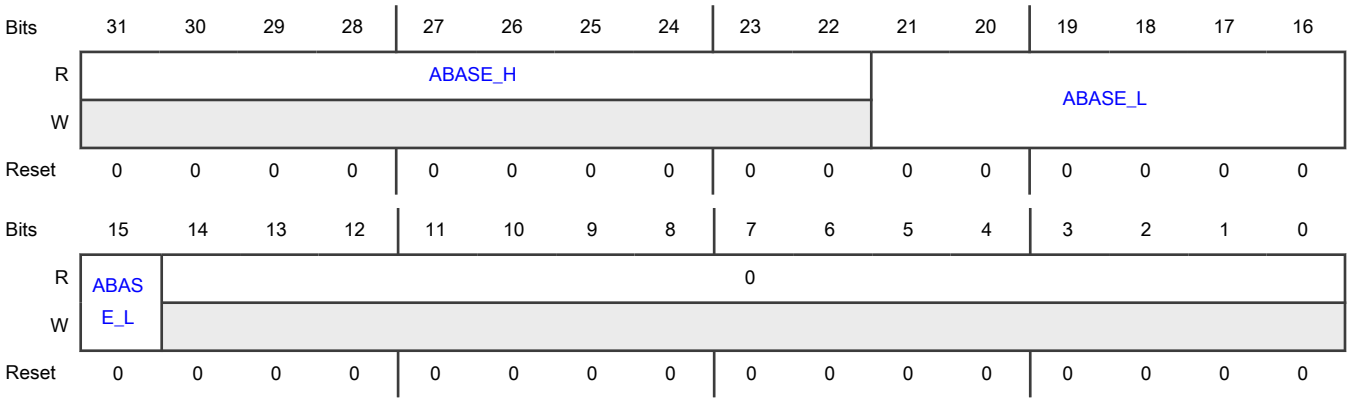
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_ABASE	1E8h

Diagram



Fields

Field	Description
31-22 ABASE_H	Array base address high Flash array address upper bits of the base of the FLW (mod 32KBytes).
21-15 ABASE_L	Array base address low Flash array address lower bits of the base of the FLW (mod 32KBytes).
14-0 —	Reserved

15.7.4.10 TRDC FLW Block Count (TRDC_FLW_BCNT)

This register gives the size of the Flash Logic Window in 32KByte blocks.

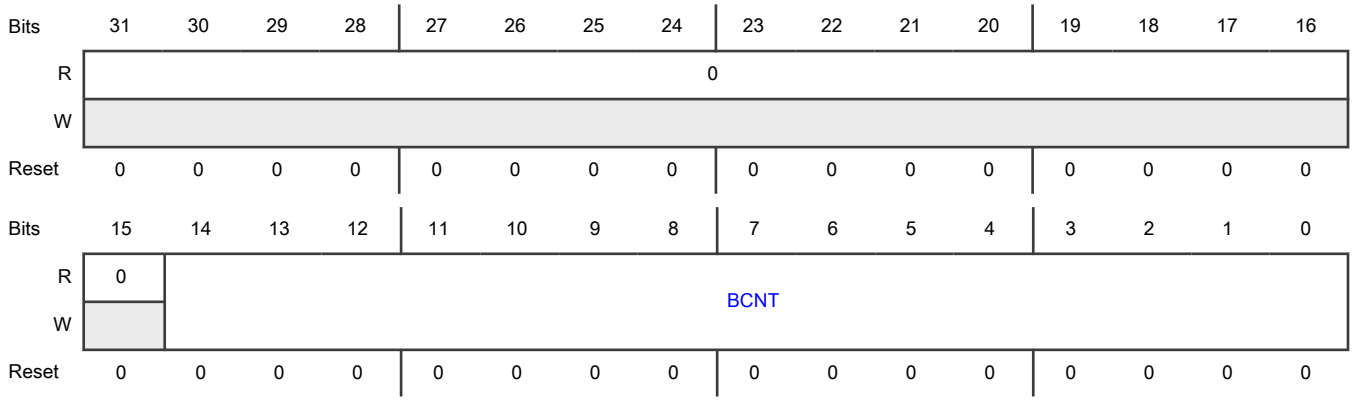
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write. This register is not writable if TRDC_FLW_CTL[LK]=1.

Offset

Register	Offset
TRDC_FLW_BCNT	1ECh

Diagram



Fields

Field	Description
31-15 —	Reserved
14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

15.7.4.11 TRDC Fault Domain ID (TRDC_FDID)

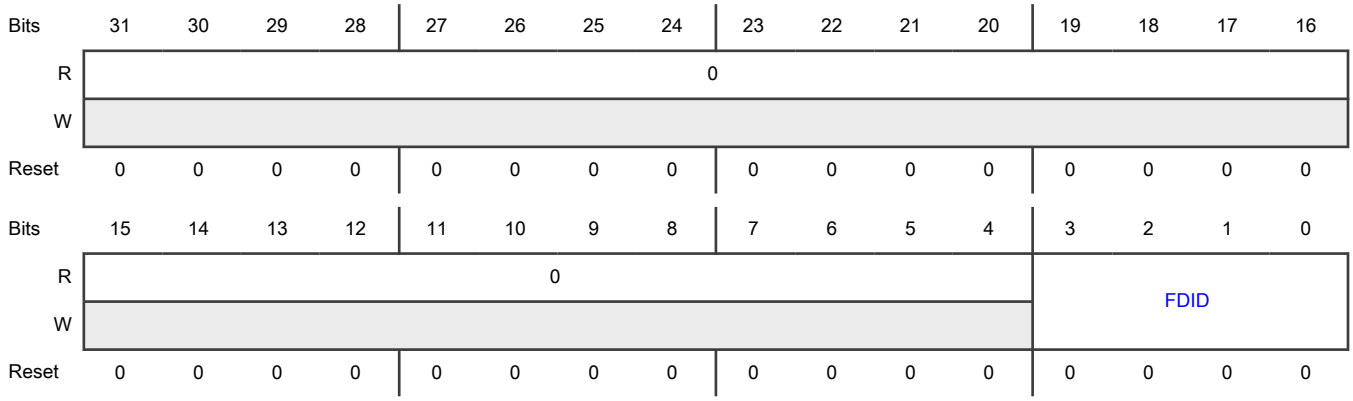
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

15.7.4.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

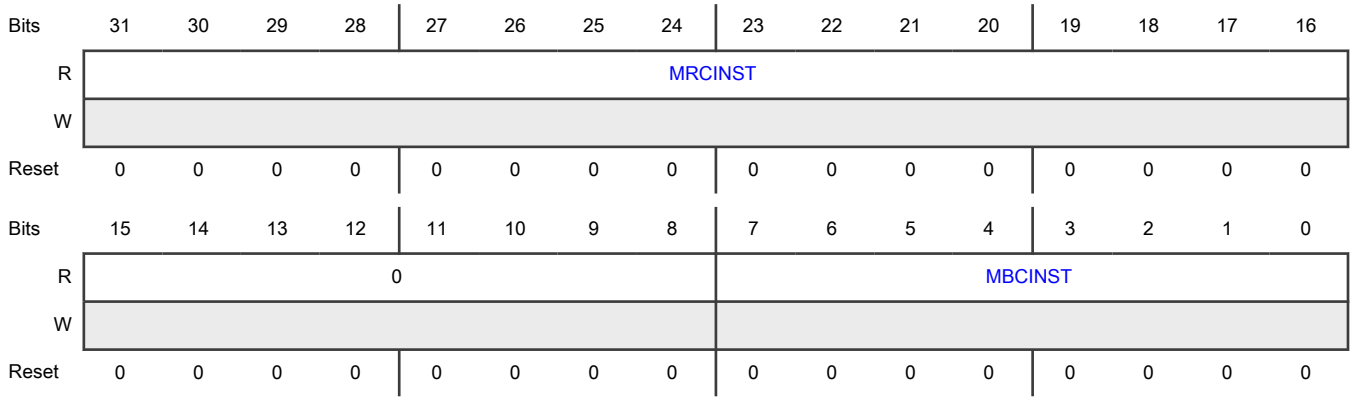
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Diagram



Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

15.7.4.13 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT1 - MDA_W0_6_DFMT1)

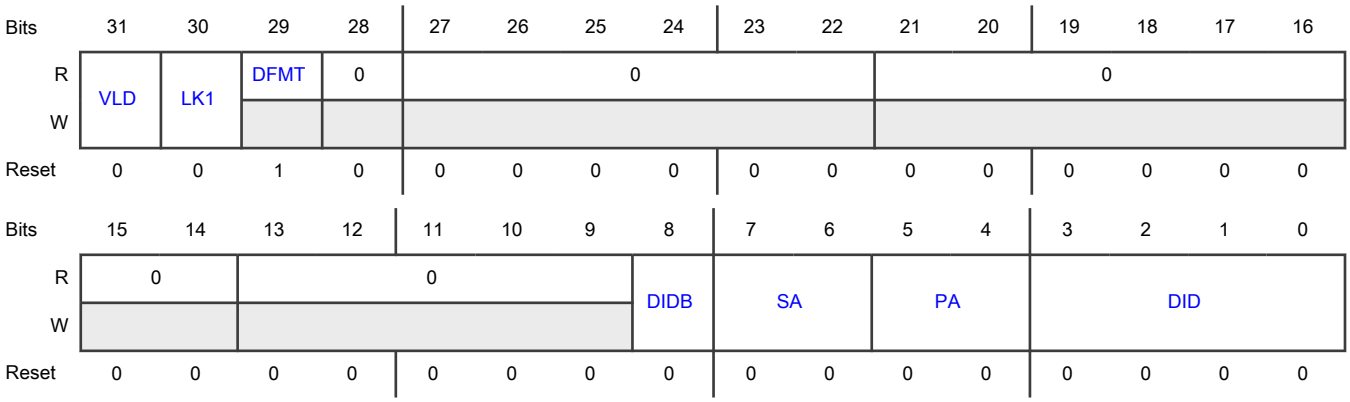
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_0_DFMT1	800h
MDA_W0_1_DFMT1	820h
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h
MDA_W0_5_DFMT1	8A0h
MDA_W0_6_DFMT1	8C0h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29	Domain format

Table continues on the next page...

Table continued from the previous page...

Field	Description
DFMT	Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 —	Reserved
15-14 —	Reserved
13-9 —	Reserved
8 DIDB	DID Bypass If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor. Once set, this field is “sticky” and remains set until the next reset. DAC / DID Input: 0 / 0; 1 / DMA Domain ID; 2 / USB Domain ID 0 - Use MDAn[3:0] as the domain identifier. 1 - Use the DID input as the domain identifier.
7-6 SA	Secure attribute This field defines the secure/nonsecure attribute for non-processor cores.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE The bus initiator's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00 - Force the bus attribute for this initiator to secure. 01 - Force the bus attribute for this initiator to nonsecure. 10 - Use the bus initiator's secure/nonsecure attribute directly. 11 - Use the bus initiator's secure/nonsecure attribute directly.
5-4 PA	Privileged attribute This field defines the privileged/user attribute for non-processor cores. **NOTE** The bus initiator's input privileged/user attribute is used if PA = 1X, or this VLD = 0. 00 - Force the bus attribute for this initiator to user. 01 - Force the bus attribute for this initiator to privileged. 10 - Use the bus initiator's privileged/user attribute directly. 11 - Use the bus initiator's privileged/user attribute directly.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDB=0.

15.7.5.2 TRDC Register (TRDC_CR)

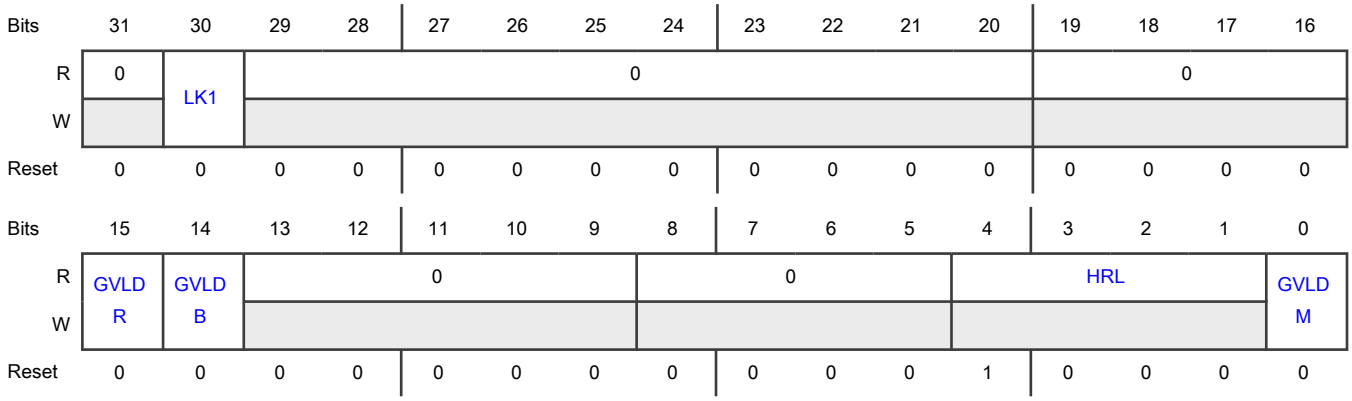
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

15.7.5.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

15.7.5.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

15.7.5.5 TRDC Hardware Configuration Register 2 (TRDC_HWCFG2)

This register contains information on the TRDC's hardware configuration. It provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus initiator. The HWCFG2 register is associated with bus initiators [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG2	F8h

Fields

Field	Description
31-0 PIDPn	Process identifier present Process identifier present from bus initiator n, where n = [31-0]. This field provides a bitmap to signal that bus initiator (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus initiator n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus initiator n sources a process identifier register.

15.7.5.6 TRDC Hardware Configuration Register 3 (TRDC_HWCFG3)

This register contains information on the TRDC's hardware configuration. Specifically, it provides a bitmap signaling the presence of a process identifier (PID) register sourced from the given bus initiator. The HWCFG3 register is associated with bus initiators [63-32], while the HWCFG2 register covers bus initiators [31-0]. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG3	FCh

Fields

Field	Description
31-0 PIDPn	Process identifier present Process identifier present from bus initiator n, where n = [63-32]. This field provides a bitmap to signal that bus initiator n (where n is defined as 32 + bit number) sources a process identifier register to the TRDC_DAC logic.

Table continues on the next page...

Field	Description
	Process identifier present from bus initiator n, where n = [31-0]. This field provides a bitmap to signal that bus initiator (where n is defined as bit number) sources a process identifier register to the TRDC_DAC logic. For each bit in this field: • 0 - Bus initiator n does not source a process identifier register. The TRDC_DAC logic provides the needed PID for processor cores. • 1 - Bus initiator n sources a process identifier register.

15.7.5.7 Domain Assignment Configuration Register (DACFG0 - DACFG1)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG0	100h
DACFG1	101h

Diagram

Bits	7	6	5	4	3	2	1	0
R	NCM	0			NMDAR			
W								
Reset	0	0	0	0	0	1	0	0

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

15.7.5.8 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

15-13 —	Reserved
12 LKSAU	Lock SAU Asserting this bit prevents changes to the processor's Secure SAU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the SAU_CTRL, SAU_RNR, SAU_RBAR and SAU_RLAR registers from software or from a debug agent connected to the processor
11 LKNSMPU	Lock Nonsecure MPU Asserting this bit prevents changes to the processor's Nonsecure MPU memory regions already programmed. All processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL_NS, MPU_RNR_NS, MPU_RBAR_NS, MPU_RLAR_NS, MPU_RBAR_A_NSn and MPU_RLAR_A_NSn from software or from a debug agent connected to the processor
10 LKSMPU	Lock Secure MPU Asserting this signal prevents changes to the processor's programmed Secure MPU memory regions and all processor writes to the registers are ignored. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock these registers 1 - Disable writes to the MPU_CTRL, MPU_RNR, MPU_RBAR, MPU_RLAR, MPU_RBAR_An and MPU_RLAR_An from software or from a debug agent connected to the processor in Secure state
9 LKNSVTOR	Lock Nonsecure Vector Table Offset Register Asserting this signal prevents changes to the processor's Nonsecure vector table base address. This bit is sticky, once set, it can only be cleared with a reset. 0 - Unlock this register 1 - Disable writes to the VTOR_NS register
8	Lock Secure VTOR, Application interrupt and Reset Control Registers

Table continues on the next page...

Table continued from the previous page...

Field	Description
LKSVTAIRCR	This bit is sticky, once set, it can only be cleared with a reset. Asserting this signal prevents processor changes to: • The Secure vector table base address. • Handling of Secure interrupt priority. • BusFault, HardFault, and NMI security target settings in the processor. 0 - Unlock these registers 1 - Disable writes to the VTOR_S, AIRCR[PRIS], and AIRCR[BFHFNMINS] registers
7 —	Reserved
6 SAUDIS	Security Attribution Unit Disable 0 - SAU is enabled 1 - SAU is disabled
5 MPUNSDIS	NonSecure Memory Protection Unit Disabled 0 - Nonsecure MPU is enabled 1 - Nonsecure MPU is disabled
4 MPUSDIS	Secure Memory Protection Unit Disabled 0 - Secure MPU is enabled 1 - Secure MPU is disabled
3 CFGSECEXT	Configure Security Extension 0 - Armv8M Security Extension is disabled 1 - Armv8-M Security Extension is enabled
2-1 —	Reserved
0 VLD	Valid When VLD =0, all address attribute from IDAU is nonSecure. When VLD=1, values in other fields of this register are valid.

15.7.5.9 TRDC FLW Control (TRDC_FLW_CTL)

This register provides control of the FLW = Flash Logical Window operation.

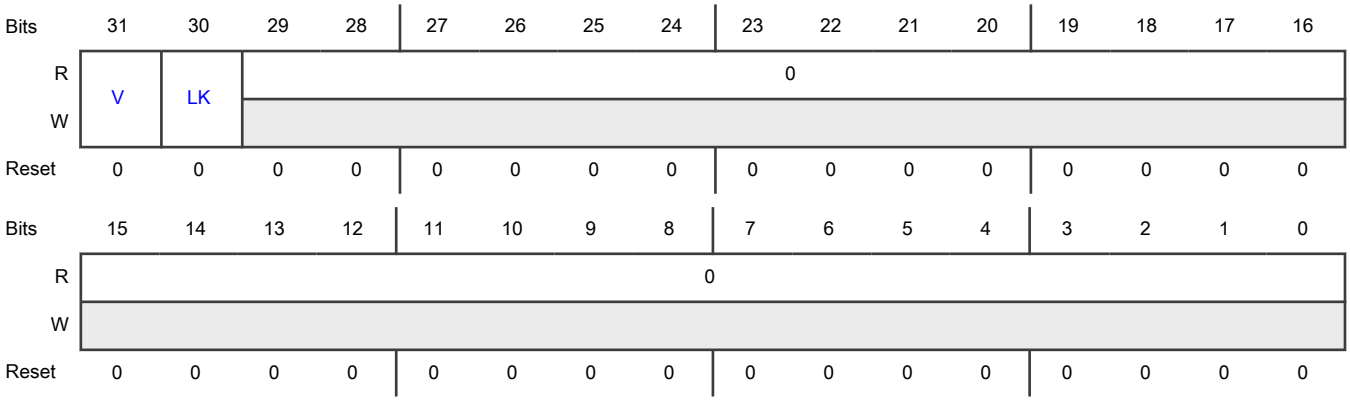
This register exists for this device but has no effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FLW_CTL	1E0h

Diagram



Fields

Field	Description
31 V	Valid bit 0 - FLW function is disabled. 1 - FLW function is enabled.
30 LK	Lock bit 0 - FLW registers may be modified. 1 - FLW registers are locked until the next reset.
29-0 —	Reserved

15.7.5.10 TRDC FLW Physical Base (TRDC_FLW_PBASE)

This read-only register gives the physical base address of the Flash Logical Window.

This register exists for this device but has not effect on device operation.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_FLW_PBASE	1E4h

15.7.5.13 TRDC Fault Domain ID (TRDC_FDID)

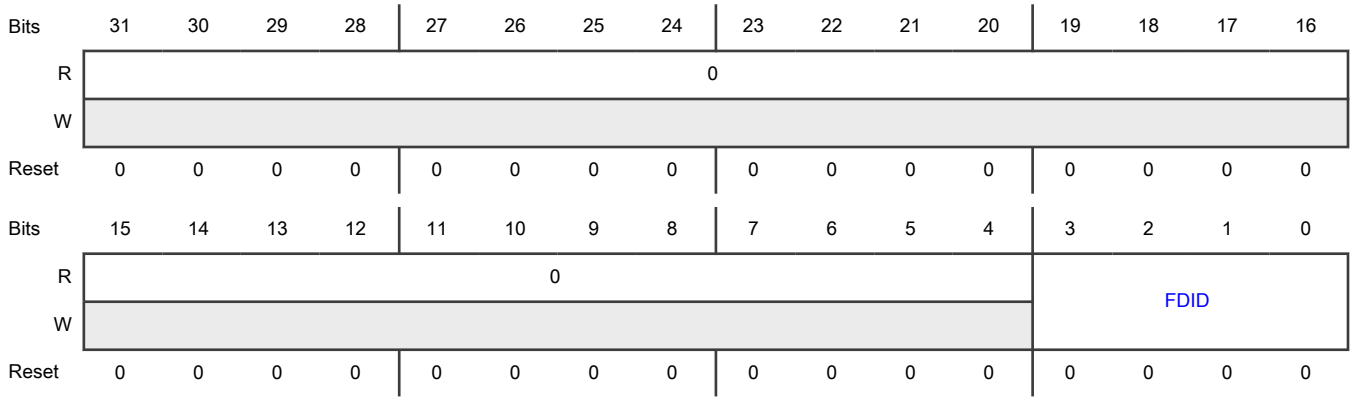
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

15.7.5.14 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap

of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8	Reserved

Field	Description
—	
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

15.7.5.15 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC3_DERR_W0)

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000 - mbcxslv0 001 - mbcxslv1 010 - mbcxslv2 011 - mbcxslv3
23-12 —	Reserved
11	Error read/write

Table continues on the next page...

Table continued from the previous page...

Field	Description
ERW	This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access. 101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

15.7.5.17 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC3_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Offset

Register	Offset
MBC0_DERR_W3	40Ch
MBC1_DERR_W3	41Ch

Fields

Field	Description
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

15.7.5.18 MRC Domain Error Word0 Register (MRC0_DERR_W0)

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

29-0 —	Reserved

15.7.5.21 DAC Initiator Domain Assignment Register (MDA_W0_0_DFMT0 - MDA_W3_1_DFMT0)

The MDA_Wr_m registers provide a 2-dimensional data structure for assigning bus initiators to domains. The number of implemented registers is defined by DACFGm[NMDAR]. This per-initiator domain assignment is then repeated for each bus initiator (MDAm). Thus, m specifies the initiator number and r refers to the specific MDA register for a given bus initiator.

Each Wr within the MDAm structure is a word-sized definition; there are two formats supported, one for processor cores and another for non-processors. Processor initiators typically support one or more Wr domain definitions, while non-processor initiators support a single Wr. Processor initiators Domain Assignment register names use a _DFMT0 suffix. Non-processor initiators Domain Assignment register names use a _DFMT1 suffix.

The DAC submodule is responsible for the generation of domain identifiers for every transaction from every bus initiator. If there is a single Wr for a given initiator, then the specified domain identifier is used directly. If there are multiple Wr values for a given initiator, then the DAC evaluates the conditional terms to determine a “hit”. For all Wr hits, their corresponding domain identifiers are simply logically summed together (boolean OR). Use cases are typically expected to *hit in a single Wr* for a processor initiator. Special care is needed if *none* of the conditional terms hit in any Wr evaluation; for this case, the generated DID = 0 and software needs to be aware of any potential access rights granted for this DID.

Each MDA_Wr_m register has one of two programming models depending on the state of the domain format field, DFMT. The model described in this section is for DFMT = 0. This definition allows three different specifications of the DID for processors. The DFMT = 1 model is described in Initiator Domain Assignment (MDA_Wr_m_DFMT1) register.

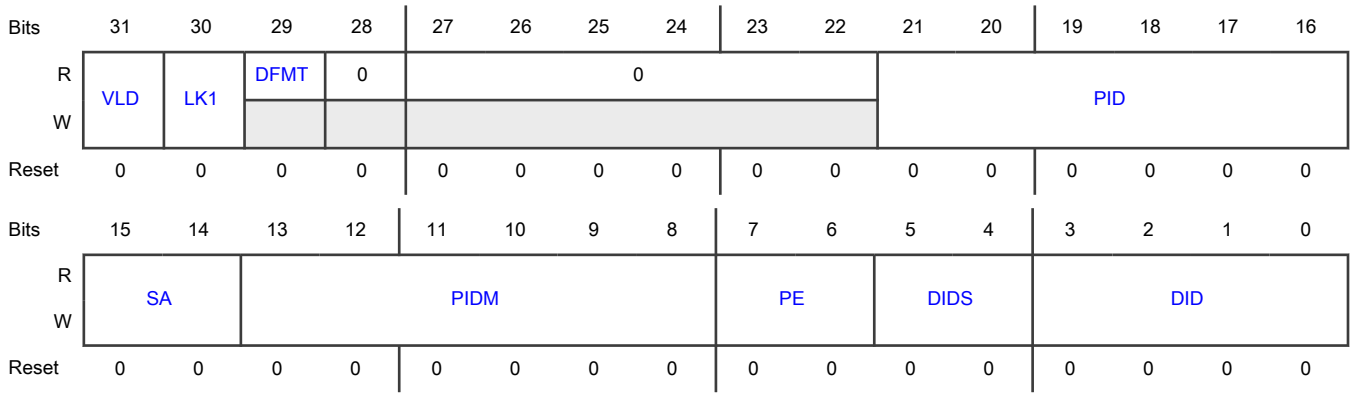
Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

For m = 0 to 1; r = 0 to 3:

Register	Offset
MDA_Wr_m_DFMT0	800h + (m × 20h) + (r × 4h)

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROZ 0 - Processor-core domain assignment 1 - Non-processor domain assignment
28 —	Reserved
27-22 —	Reserved
21-16 PID	Process Identifier This field specifies that the process identifier is to be combined with the PIDM field and included in the domain hit determination. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.
15-14 SA	Secure attribute This field defines the secure/nonsecure attribute for processor cores.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE The bus initiator's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00 - Force the bus attribute for this initiator to secure. 01 - Force the bus attribute for this initiator to nonsecure. 10 - Use the bus initiator's secure/nonsecure attribute directly. 11 - Use the bus initiator's secure/nonsecure attribute directly.
13-8 PIDM	Process Identifier Mask This field provides a masking capability so that multiple process identifiers can be included as part of the domain hit determination. If a bit in the PIDM is set, then the corresponding bit of the PID is ignored in the comparison. The optional inclusion of the PID and PIDM is controlled by the MDA_Wr_m[PE] field.

7-6
PE
	Process identifier enable
	Controls the optional inclusion of the PID, qualified by PIDM, into the domain hit evaluation. It provides the ability to include inclusive or exclusive sets of masked PID values.
	00 - No process identifier is included in the domain hit evaluation.
	01 - No process identifier is included in the domain hit evaluation.
	10 - PE = 2. The process identifier is included in the domain hit evaluation as defined by the expression:
	`partial_domain_hit = (PE == 2) && ((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`
	11 - PE = 3. The process identifier is included in the domain hit evaluation as defined by the expression:
	`partial_domain_hit = (PE == 3) && ~((PID & ~PIDM) == (TRDC_PIDn[PID] & ~PIDM))`

5-4 DIDS	DID Select This field selects the source of the domain identifier. 00 - Use MDAm[3:0] as the domain identifier. 01 - Use the input DID as the domain identifier. 10 - Use MDAm[3:2] concatenated with the low-order 2 bits of the input DID (DID_in[1:0]) as the domain identifier. 11 - Reserved for future use.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDS=00b. DID[3:2] is used when DIDS=10b

15.7.5.22 MBC Global Configuration Register (MBC0_MEM0_GLBCFG - MBC3_MEM3_GLBCFG)

These MBC global configuration read-only registers contain information on the MBC's hardware configuration. Specifically, it defines the number of memory blocks and the size of each block in each MBC mem (r).

NOTE

An all zero value (SIZE_LOG2 = 0, NBLKS = 0) indicates a non-existent memory. For the number of memories implemented in the MBCs, refer to chip-specific information

Offset

For m = 0 to 3; r = 0 to 3:

15.7.5.28 MBC Global Access Control (MBC0_MEMN_GLBAC1 - MBC0_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

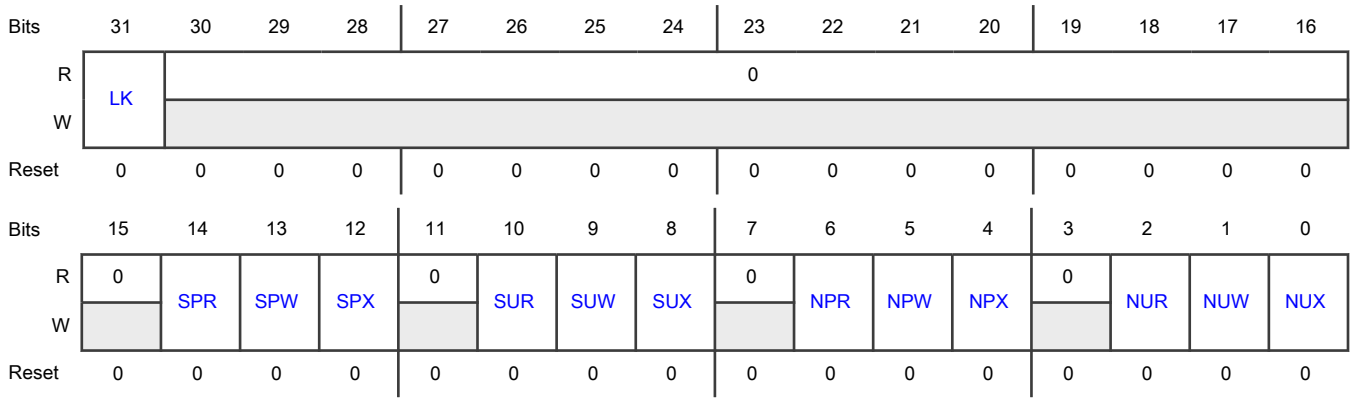
Diagram



Fields

Field	Description
31 LK	LOCK This 1-bit field provides a mechanism to limit writes to the this register to protect its contents. Once set, this bit remains asserted until the next reset. 0 - This register is not locked and can be altered. 1 - This register is locked and cannot be altered.
30-15 —	Reserved
14 SPR	SecurePriv Read SecurePriv read access control flag 0 - Read access is not allowed in Secure Privilege mode. 1 - Read access is allowed in Secure Privilege mode.
13 SPW	SecurePriv Write SecurePriv write access control flag 0 - Write access is not allowed in Secure Privilege mode. 1 - Write access is allowed in Secure Privilege mode.
12 SPX	SecurePriv Execute SecurePriv execute access control flag 0 - Execute access is not allowed in Secure Privilege mode. 1 - Execute access is allowed in Secure Privilege mode.
11 —	Reserved
10 SUR	SecureUser Read SecureUser read access control flag 0 - Read access is not allowed in Secure User mode. 1 - Read access is allowed in Secure User mode.
9 SUW	SecureUser Write SecureUser write access control flag 0 - Write access is not allowed in Secure User mode. 1 - Write access is allowed in Secure User mode.
8 SUX	SecureUser Execute SecureUser execute access control flag

15.7.5.29 MBC Memory Block Configuration Word (MBC0_DOM0_MEM0_BLK_CFG_W0 - MBC3_DOM15_MEM1_BLK_CFG_W1)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 89. Block Config Word to Block Number Relationship

Block Config Word	NSE7/ MBACSEL7	NSE6/ MBACSEL6	NSE5/ MBACSEL5	NSE4/ MBACSEL4	NSE3/ MBACSEL3	NSE2/ MBACSEL2	NSE1/ MBACSEL1	NSE0/ MBACSEL0
W0	block 7	block 6	block 5	block 4	block 3	block 2	block 1	block 0

Fields

Field	Description
31 NSE7	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24 MBACSEL6	Memory Block Access Control Select for block B This field selects the global access control associated with block B.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field is locked (read-only) if MBACSEL6 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
23 NSE5	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
22-20 MBACSEL5	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL5 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
19 NSE4	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
18-16	Memory Block Access Control Select for block B

Table continues on the next page...

Table continued from the previous page...

Field	Description
MBACSEL4	This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL4 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
15 NSE3	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
14-12 MBACSEL3	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL3 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
11 NSE2	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).

Field	Description
2-0 MBACSEL0	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL0 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B

15.7.5.30 MBC Memory Block NonSecure Enable Word (MBC0_DOM0_MEM0_BLK_NSE_W0 - MBC3_DOM15_MEM1_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 90. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64

Table continues on the next page...

Table 90. Block Config Word to Block Number Relationship (continued)

Block NSE Word	BIT31	BIT30-BIT1	BIT0
		. . .	
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

15.7.5.32 MBC Global Access Control (MBC1_MEMN_GLBAC1 - MBC1_MEMN_GLBAC7)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, Nonsecure User. The lock bit provides the ability to lock these control access flags and to lock the MBC_BLK_CFG[MBACSEL] field when a locked MBC_MEMN_GLBAC register is selected.

15.7.5.44 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC0_DOM15_RGD15_W0)

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

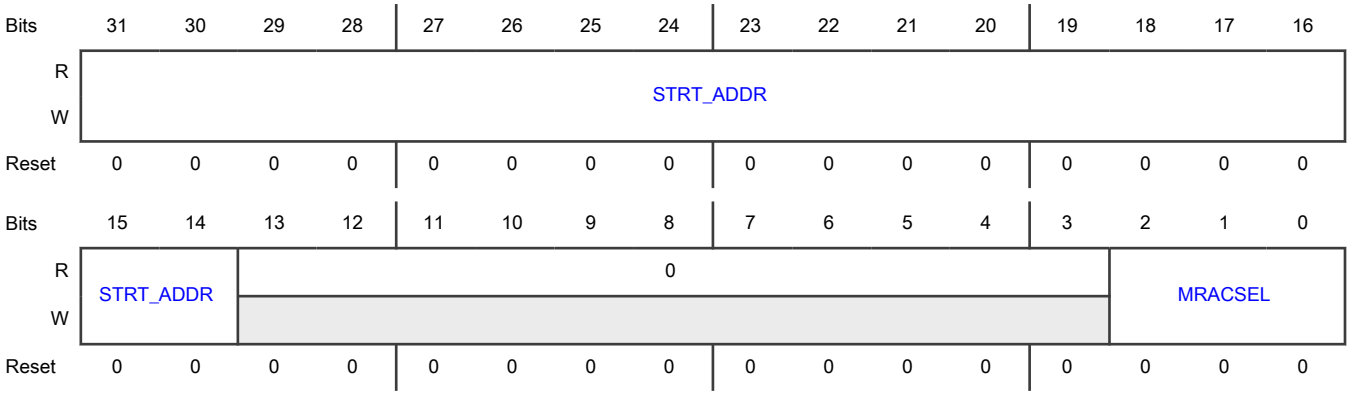
There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Offset

For d = 0 to 15; r = 0 to 15:

Register	Offset
MRC0_DOMd_RGDr_W0	1_8040h + (d × 100h) + (r × 8h)

Diagram



Fields

Field	Description
31-14 STRT_ADDR	Start Address 0-mod-16K physical start address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-3 —	Reserved
2-0 MRACSEL	Memory Region Access Control Select This field selects the global access control associated with region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1. 000 - Select MRC_GLBAC0 access control policy 001 - Select MRC_GLBAC1 access control policy 010 - Select MRC_GLBAC2 access control policy 011 - Select MRC_GLBAC3 access control policy 100 - Select MRC_GLBAC4 access control policy 101 - Select MRC_GLBAC5 access control policy 110 - Select MRC_GLBAC6 access control policy 111 - Select MRC_GLBAC7 access control policy

15.7.5.45 MRC Region Descriptor Word 1 (MRC0_DOM0_RGD0_W1 - MRC0_DOM15_RGD15_W1)

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_[d]_rgd[r]_w[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

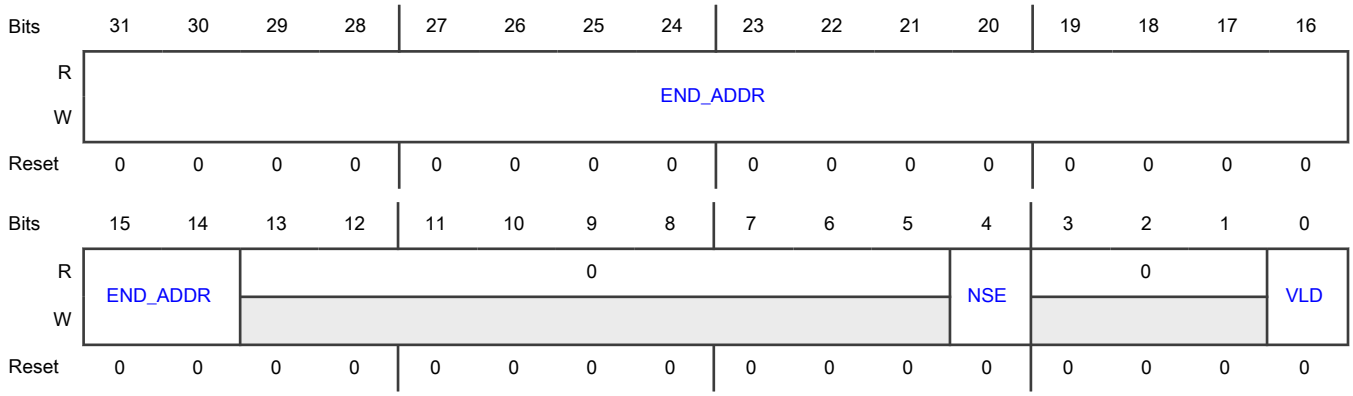
There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Offset

For d = 0 to 15; r = 0 to 15:

Register	Offset
MRC0_DOMd_RGDr_W1	1_8044h + (d × 100h) + (r × 8h)

Diagram



Fields

Field	Description
31-14 END_ADDR	End Address (16K-1)-mod-16K physical end address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
4 NSE	NonSecure Enable Alternate view of NSE flag for Region r. 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1 - Secure and nonsecure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]).
3-1 —	Reserved
0 VLD	Valid If set, this region is valid and accesses are checked for this region. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.

15.7.5.46 MRC Region Descriptor NonSecure Enable (MRC0_DOM0_RGD_NSE - MRC0_DOM15_RGD_NSE)

This register is the bitmap of the individual NSE bits for the region descriptors. Bit n corresponds to region n.

These bits can also be written or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and RGD_W0[NSE] registers.

Offset

For d = 0 to 15:

Register	Offset
MRC0_DOMd_RGD_NSE	1_80C0h + (d × 100h)

15.7.6.2 TRDC Register (TRDC_CR)

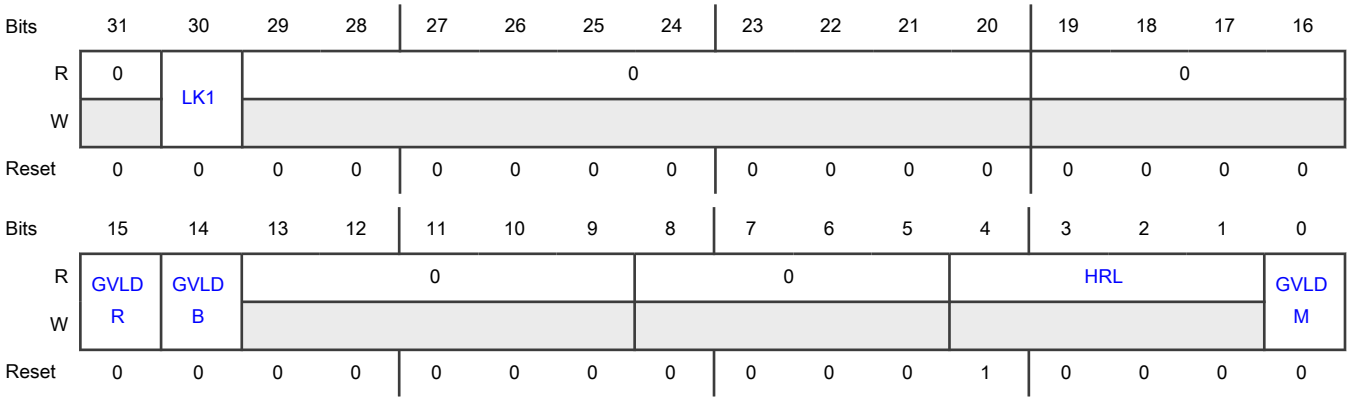
This register provides status about the TRDC and global enable bits for the entire module's operation. A fully operational TRDC requires all global bits GVLD {R,B,M} to be asserted. Undefined behavior results if they are not all asserted. If there are no region checkers (MRCs) present in the configuration, GVLDR need not be asserted for a fully operational TRDC.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_CR	0h

Diagram



Fields

Field	Description
31 —	Reserved
30 LK1	Lock Status This field is the lock status of the TRDC_CR. This field is set when all GVLD bits are set; GVLDR=GVLDB=GVLDM=1b1. Once set, this bit remains asserted until the next reset. 0 - The CR can be written by any secure privileged write. 1 - The CR is locked (read-only) until the next reset.
29-20 —	Reserved
19-16 —	Reserved
15 GVLDR	Global Valid for Memory Region Checkers TRDC global MRC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC MRCs are disabled. 1 - TRDC MRCs are enabled.
14 GVLDB	Global Valid for Memory Block Checkers TRDC global MBC enable/disable. Once set, this bit remains set until the next reset.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - TRDC MBCs are disabled. 1 - TRDC MBCs are enabled.
13-9 —	Reserved
8-5 —	Reserved
4-1 HRL	Hardware Revision Level This read-only field specifies the TRDC's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
0 GVLDM	Global Valid for Domain Assignment Controllers TRDC global DAC enable/disable. Once set, this bit remains set until the next reset. 0 - TRDC DACs are disabled. 1 - TRDC DACs are enabled.

15.7.6.3 TRDC Hardware Configuration Register 0 (TRDC_HWCFG0)

This read-only register contains information on the TRDC's hardware configuration. Specifically, it defines the number of implemented domains and bus initiators along with the number of instances of memory block checkers (MBCs) and memory region checkers (MRCs). The register value at reset is device-specific. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG0	F0h

Fields

Field	Description
31-29 MID	Module ID This field defines major version ID of this module.
28-24 NMRC	Number of MRCs This field defines the number of MRCs on the device [1-16].
23-20 —	Reserved
19-16 NMBC	Number of MBCs This field defines the number of MBCs on the device [1-8].
15-8 NMSTR	Number of bus initiators This read-only field defines the number of bus initiators.
7-5 —	Reserved
4-0 NDID	Number of domains This read-only field defines the number of domains on the device [1-16].

15.7.6.4 TRDC Hardware Configuration Register 1 (TRDC_HWCFG1)

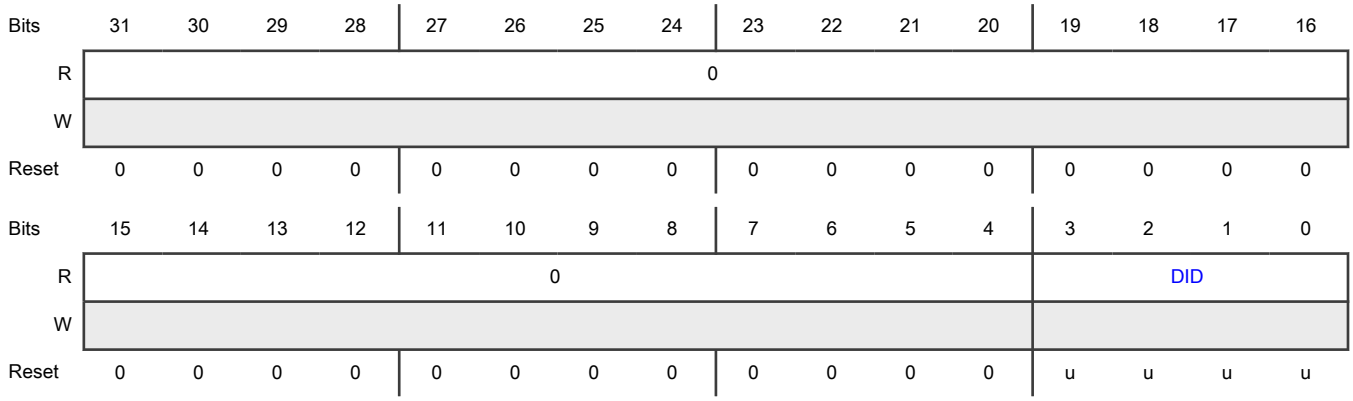
This register contains information on the TRDC's hardware configuration. It provides a mechanism for software to determine its domain number by simply reading the register. See Domain error capture management for more details on typical usage. Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
TRDC_HWCFG1	F4h

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 DID	Domain identifier number This field provides the domain number [0-15] of the requesting bus initiator.

15.7.6.5 Domain Assignment Configuration Register (DACFG2 - DACFG4)

This register defines the number of implemented domain assignment registers for bus initiator m, where m+1 can specify from 1 to 64 bus initiators. These registers are organized as a byte-sized data array and can be read using 8-, 16- or 32-bit accesses. An all-zero value (NCM = 0, NMDAR = 0) indicates a non-existent bus initiator. Attempted writes are error terminated.

Register read will not return transfer error when DACFG for a initiator doesn't exist but it is in the same 32-bit group as DACFG for an existing initiator. For example, when there are only 2 DACFG0-1 registers for 2 initiator, and initiators for DACFG2-3 don't exist, then access to DACFG2-3 won't return transfer error.

Typically, processor bus initiators have one or more domain assignment registers, while non-processor initiators have a single domain assignment register.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
DACFG2	102h
DACFG3	103h
DACFG4	104h

Diagram

Bits	7	6	5	4	3	2	1	0

W								
Reset	1	0	0	0	0	0	0	1

Fields

Field	Description
7 NCM	Non-CPU Initiator This read-only field signals that bus initiator m is a non-CPU initiator. It specifies that the format of the associated MDA_Wr_m register defines a non-processor domain assignment. This field is zero for a non-existent bus initiator. 0 - Bus initiator is a processor. 1 - Bus initiator is a non-processor.
6-4 —	Reserved
3-0 NMDAR	Number of initiator domain assignment registers for bus initiator m This read-only field specifies the number of registers associated with the initiator domain assignment register for a given bus initiator. The value is limited to the range [0-8], where zero indicates a non-existent bus initiator and non-zero values indicate the number of implemented registers associated with this MDAm.

15.7.6.6 TRDC IDAU Control Register (TRDC_IDAU_CR)

This register defines the configuration for the Implementation-Defined Attribution Unit which is tightly-coupled to the TZ-M extensions in the processor core. Many of the fields in this register explicitly control processor TZ-M functions.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_IDAU_CR	1C0h

14-0 BCNT	Block Count Size of FLW in number of 32KByte blocks.

15.7.6.11 TRDC Fault Domain ID (TRDC_FDID)

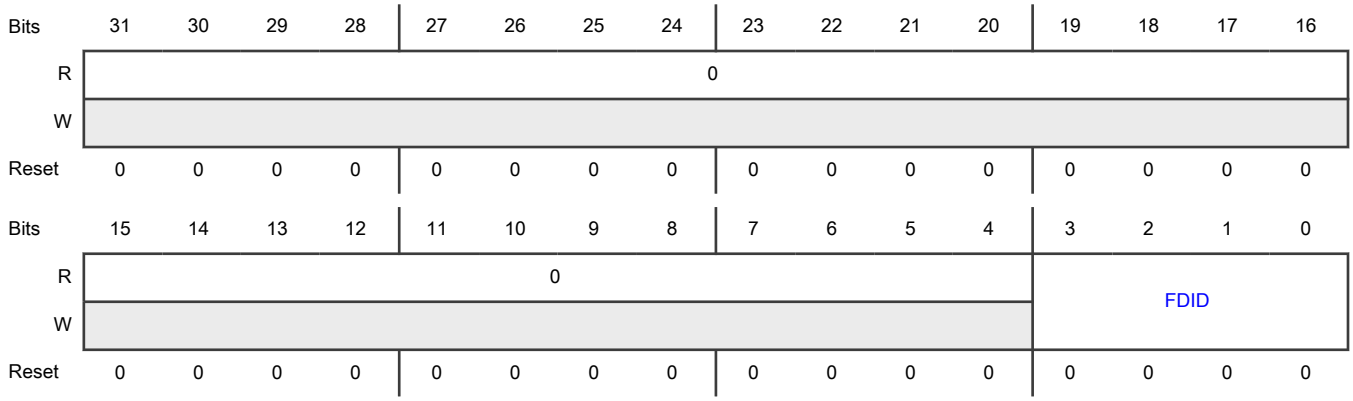
In the event of an access error, this register is used to specify the domainID of the faulting reference before indexing into the Domain Error registers.

If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
TRDC_FDID	1FCh

Diagram



Fields

Field	Description
31-4 —	Reserved
3-0 FDID	Domain ID of Faulted Access This field indicates the domainID of the fault used to index the array of domain error information. The user queries the DERRLOCx registers to find the DomainID of the faulting access and must write this register with the domain ID before reading the Domain Error registers.

15.7.6.12 TRDC Domain Error Location Register (TRDC_DERRLOC0 - TRDC_DERRLOC15)

This array of read-only registers provide the instance number of the submodule where (an) access violation(s) occurred. These registers are organized as a word array, indexed by the faulting domain number, d. The two fields of this register provide a bitmap of instances associated with all submodules containing captured error information for that domain. These instance numbers are then used as indices into the DERR_W0_*i*, DERR_W1_*i*, and DERR_W3_*i*register arrays. See Domain error capture management for more details.

When an access violation is detected by either a Memory Region Checker (MRC) or a Memory Block Checker (MBC), address and attribute information of the offending access is captured. Using the faulting domainID number as the index, d, this array of read-only registers provide additional information signaling the instance number of the submodule where the access violation(s) occurred. Since the resulting exception handler needs the submodule instance to retrieve the captured address and attribute information from DERR_W0_*i* and DERR_W1_*i*, these registers provide the instance number details.

Attempted writes are error terminated.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

For d = 0 to 15:

Register	Offset
TRDC_DERRLOCd	200h + (d × 4h)

R	0								MBCINST							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-16 MRCINST	MRC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MRC. The least-significant bit of this field (bit 16) corresponds to MRC instance 0. The most-significant bit of this field (bit 31) corresponds to MRC instance 15 (MRC instance = i-16 where i is the register bit number), and so on. Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MRCs. For each bit in this field: • 0 - The memory region checker has not detected an access violation or is not physically present. • 1 - The memory region checker has detected one or more access violations for this domain.
15-8 —	Reserved
7-0 MBCINST	MBC instance This field is a bitmap indicating the presence of a detected access violation for domain d in the implemented instances of the MBC. The least-significant bit of this field (bit 0) corresponds to MBC instance 0. The most-significant bit of this field (bit 7) corresponds to MBC instance 7 Multiple bits can be set at any time indicating access violations for this domain have been detected across multiple instances of the MBCs. For each bit in this field: • 0 - The memory block checker has not detected an access violation or is not physically present. • 1 - The memory block checker has detected one or more access violations for this domain.

15.7.6.13 MBC Domain Error Word0 Register (MBC0_DERR_W0 - MBC1_DERR_W0)

This read-only register array provides the address of an access violation detected by memory block checker (MBC). These registers are organized as a word array, which is indexed by the MBC instance number. That is, the index, i, of this array is the instance number of MBC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MBC instance that is not physically present.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected. 01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MBC that detected the access violation. The MBC port number connection is device-specific. See the chip configuration details for more information. This is the MBC target that has the violation. 000 - mbcxslv0 001 - mbcxslv1 010 - mbcxslv2 011 - mbcxslv3
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

15.7.6.15 MBC Domain Error Word3 Register (MBC0_DERR_W3 - MBC1_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a Memory Region Checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

See Domain error capture management for more details.

Fields

Field	Description
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

15.7.6.16 MRC Domain Error Word0 Register (MRC0_DERR_W0 - MRC1_DERR_W0)

This read-only register array provides the address of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the MRC instance number. That is, the index, i, of this array is the instance number of MRC with the access violation. The submodule instance numbers are provided by the DERRLOC registers. The memory mapped error capture detail registers are organized as 24 sequential 16 byte entries.

When an access violation is detected and the offending information captured, subsequent updates to this register are disabled until the required data pattern is written to the DERR_W3_i register. At that time, this register is cleared and re-enabled to capture the next access violation.

Attempted writes are error terminated as are attempted reads of an MRC instance that is not physically present.

Fields

Field	Description
31-0 EADDR	Error address This is the unaliased virtual address of the access that generated the access violation.

15.7.6.17 MRC Domain Error Word1 Register (MRC0_DERR_W1 - MRC1_DERR_W1)

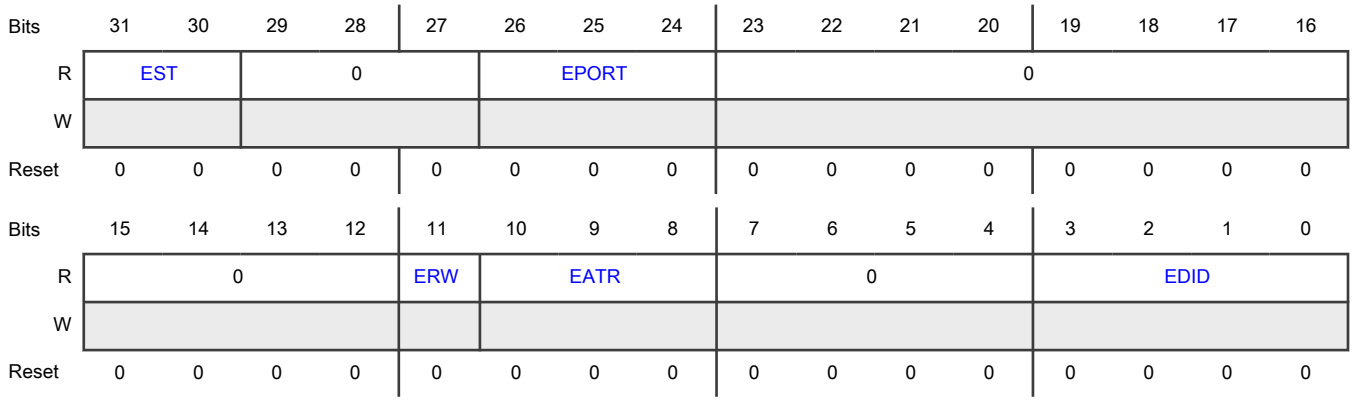
This read-only register array provides the attributes of an access violation detected by memory region checker (MRC). These registers are organized as a word array, which is indexed by the violating submodule instance number. Refer to register Domain Error Location(DERRLOCd), Domain Error Word0 Register(DERR_W0_i), and Domain error capture management for more information.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read

Offset

Register	Offset
MRC0_DERR_W1	484h
MRC1_DERR_W1	494h

Diagram



Fields

Field	Description
31-30 EST	Error state This field signals the state of access violations for this domain in this instance of the block checker or region checker. Once an access violation has been detected and the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. After retrieving the faulting address and attributes, the error capture mechanism must be rearmed by performing a write to DERR_W3_i. 00 - No access violation has been detected.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	01 - No access violation has been detected. 10 - A single access violation has been detected. 11 - Multiple access violations for this domain have been detected by this submodule instance. Only the address and attribute information for the first error have been captured in DERR_W0_i and DERR_W1_i.
29-27 —	Reserved
26-24 EPORT	Error port This field identifies the encoded port number of the MRC that detected the access violation. The MRC port number connection is device-specific. See the chip configuration details for more information.
23-12 —	Reserved
11 ERW	Error read/write This field signals whether the captured access violation occurred on a read or write reference. 0 - Read access 1 - Write access
10-8 EATR	Error attributes This field captures certain attributes of the access violation. 000 - Secure user mode, instruction fetch access. 001 - Secure user mode, data access. 010 - Secure privileged mode, instruction fetch access. 011 - Secure privileged mode, data access. 100 - Nonsecure user mode, instruction fetch access. 101 - Nonsecure user mode, data access. 110 - Nonsecure privileged mode, instruction fetch access. 111 - Nonsecure privileged mode, data access.
7-4 —	Reserved
3-0 EDID	Error domain identifier This field captures the domain identifier of the access violation.

15.7.6.18 MRC Domain Error Word3 Register (MRC0_DERR_W3 - MRC1_DERR_W3)

This register is used to rearm the error capture logic and clear the DERR_W0_i and DERR_W1_i registers. After the domain access violation error details have been read, typically in an exception service routine, a 32-bit word write to this register is required to rearm the error capture logic.

A read of this location returns zeroes. Attempted reads of a memory region checker (MRC) or Memory Block Checker (MBC) instance that is not physically present are error terminated.

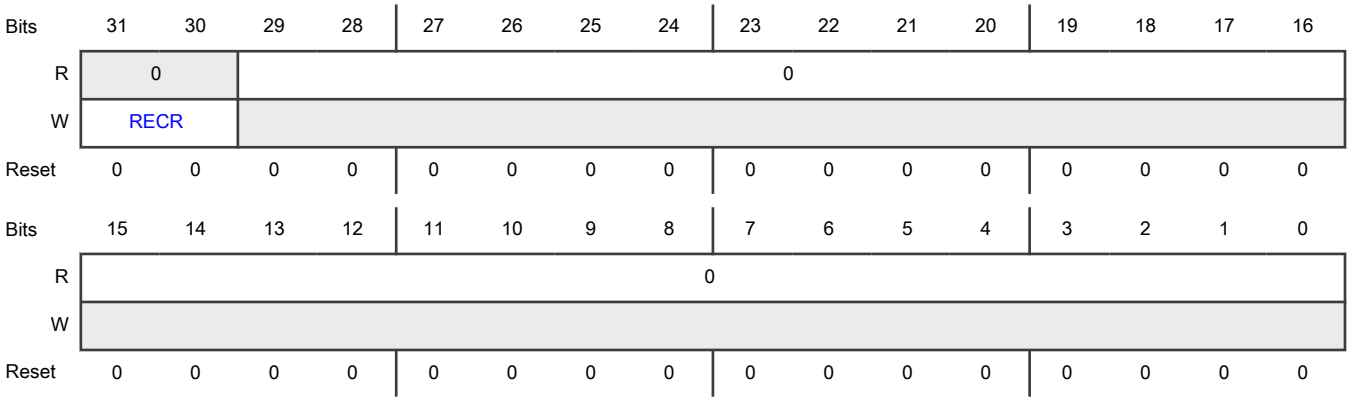
See Domain error capture management for more details.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/Write

Offset

Register	Offset
MRC0_DERR_W3	48Ch
MRC1_DERR_W3	49Ch

Diagram



Fields

Field	Description
31-30 RECR	Rearm Error Capture Registers This 2-bit, write-only field controls the rearming of the domain error capture registers. Once an access violation has been detected with the faulting address and attribute information stored, subsequent errors are simply recorded as an overrun condition without any data captured. Writing 01b to this field rearms the error capture mechanism and clears the DERR_W0_i and DERR_W1_i registers. A write of any value other than 01b has no effect.
29-0 —	Reserved

15.7.6.19 DAC Initiator Domain Assignment Register (MDA_W0_2_DFMT1 - MDA_W0_4_DFMT1)

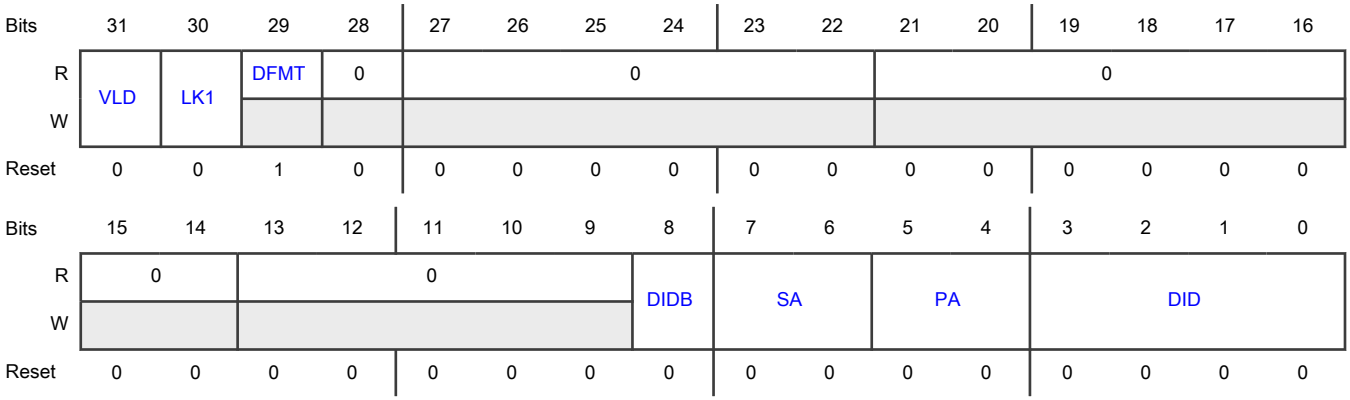
This register is identical to Initiator Domain Assignment (MDA_Wr_m_DFMT0) register except that the domain format field, DFMT, is 1 and the PID field is not used. This format supports two different specifications of the DID for non-core bus initiators.

Access: If TZ-M is enabled, then SecurePrivileged, else NonsecurePriv Read/write.

Offset

Register	Offset
MDA_W0_2_DFMT1	840h
MDA_W0_3_DFMT1	860h
MDA_W0_4_DFMT1	880h

Diagram



Fields

Field	Description
31 VLD	Valid This field indicates the domain assignment is valid. It is further qualified by TRDC_CR[GVLDM] = 1. If TRDC_CR[GVLDM] is cleared, the DID output is defined by the SoC-specific *default DID* value. See the TRDC chip configuration section for more details. If both MDA_Wr_m[VLD] and TRDC_CR[GVLDM] are asserted, the DID output is defined by the remaining contents of this register. 0 - The Wr domain assignment is invalid. 1 - The Wr domain assignment is valid.
30 LK1	1-bit Lock This field provides a locking mechanism that can be used to limit the ability to write the register. Once set, this bit remains asserted until the next reset. 0 - Register can be written by any secure privileged write. 1 - Register is locked (read-only) until the next reset.
29 DFMT	Domain format Identifies this register's domain assignment format. **NOTE** This bitfield access is ROO 0 - Processor-core domain assignment

Table continues on the next page...

Table continued from the previous page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td></td><td>1 - Non-processor domain assignment</td></tr>
<tr><td>28
—</td><td>Reserved</td></tr>
<tr><td>27-22

<tr><td>21-16
—</td><td>Reserved</td></tr>
<tr><td>15-14
—</td><td>Reserved</td></tr>
<tr><td>13-9
—</td><td>Reserved</td></tr>
<tr><td>8
DIDB</td><td>DID Bypass
If asserted, this bit enables the bypassing of an input DID value as the domain identifier for this non-processor bus initiator. This capability allows non-processor bus initiators, for example, a DMA to masquerade as a processor.
Once set, this field is “sticky” and remains set until the next reset.
<table><tr><th>DAC</th><th>DID Input</th></tr><tr><td>0</td><td>0</td></tr><tr><td>1</td><td>DMA Domain ID</td></tr><tr><td>2</td><td>USB Domain ID</td></tr></table>
0 - Use MDAn[3:0] as the domain identifier.
1 - Use the DID input as the domain identifier.</td></tr>
<tr><td>7-6
SA</td><td>Secure attribute
This field defines the secure/nonsecure attribute for non-processor cores.</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE The bus initiator's input secure/nonsecure attribute is used if SA = 1X, or this VLD = 0. If TZM_ENB = 0, the initiator attribute is forced to nonsecure. A nonsecure write cannot program this field to 2'b00, which is a security level higher than the mode of the process that is writing it. Reset value of SA: • if TZM_ENB=0, SA reset value = 2'b01 • if TZM_ENB=1, SA reset value = 2'b00 00 - Force the bus attribute for this initiator to secure. 01 - Force the bus attribute for this initiator to nonsecure. 10 - Use the bus initiator's secure/nonsecure attribute directly. 11 - Use the bus initiator's secure/nonsecure attribute directly.
5-4 PA	Privileged attribute This field defines the privileged/user attribute for non-processor cores. **NOTE** The bus initiator's input privileged/user attribute is used if PA = 1X, or this VLD = 0. 00 - Force the bus attribute for this initiator to user. 01 - Force the bus attribute for this initiator to privileged. 10 - Use the bus initiator's privileged/user attribute directly. 11 - Use the bus initiator's privileged/user attribute directly.
3-0 DID	Domain identifier This 4-bit field is the domain ID attribute that is sent on the accesses from the bus initiator connected to the DAC when DIDB=0.

15.7.6.20 MBC Global Configuration Register (MBC0_MEM0_GLBCFG - MBC1_MEM3_GLBCFG)

These MBC global configuration read-only registers contain information on the MBC's hardware configuration. Specifically, it defines the number of memory blocks and the size of each block in each MBC mem (r).

NOTE

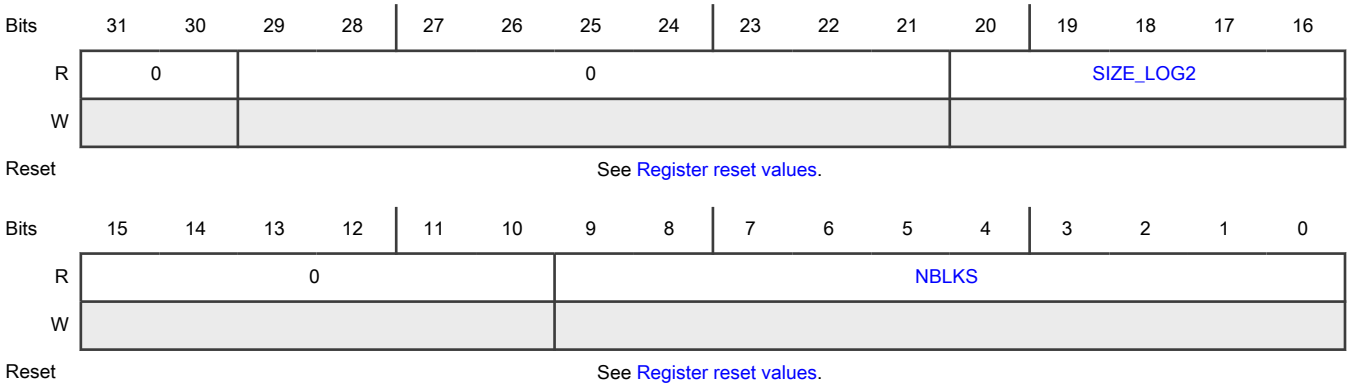
An all zero value (SIZE_LOG2 = 0, NBLKS = 0) indicates a non-existent memory. For the number of memories implemented in the MBCs, refer to chip-specific information

Offset

For m = 0 to 1; r = 0 to 3:

Register	Offset
MBCm_MEMr_GLBCFG	1_0000h + (m × 2000h) + (r × 4h)

Diagram



Register reset values

Register	Reset value

MBC0_MEM1_GLBCFG–MBC0_MEM2_GLBCFG	000C_0001h
MBC0_MEM3_GLBCFG	000C_0011h
MBC1_MEM0_GLBCFG	000C_0080h
MBC1_MEM1_GLBCFG–MBC1_MEM3_GLBCFG	000C_0001h

Fields

Field	Description
31-30 —	Reserved
29-21 —	Reserved
20-16 SIZE_LOG2	Log2 size per block For example SIZE_LOG2=0x0C is 2^12=4 KB blocks.
15-10 —	Reserved
9-0 NBLKS	Number of blocks in this memory

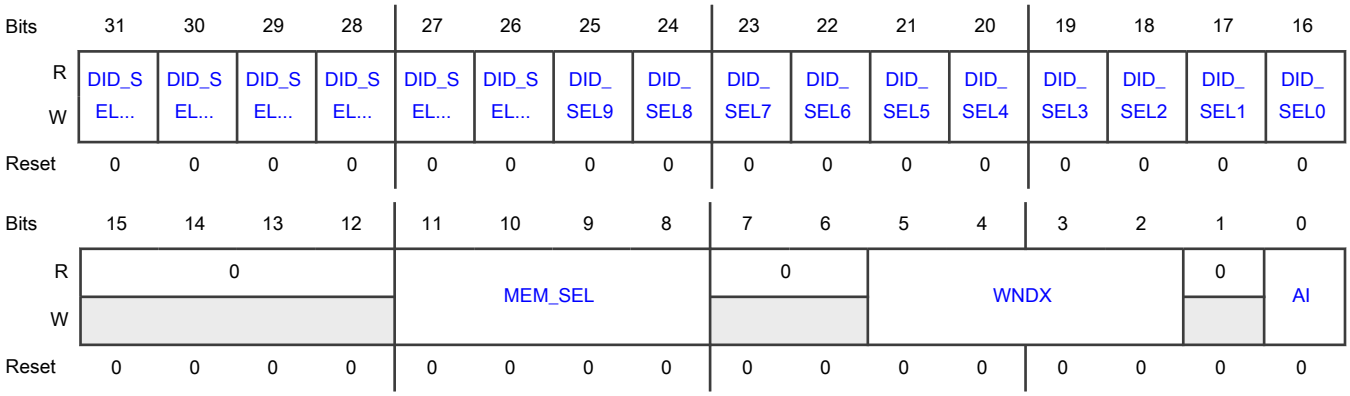
15.7.6.21 MBC NonSecure Enable Block Index (MBC0_NSE_BLK_INDEX - MBC1_NSE_BLK_INDEX)

This R/W register defines the selected memories that are affected by the writes to the NSE_BLK_SET and NSE_BLK_CLR registers.

Offset

Register	Offset
MBC0_NSE_BLK_INDEX	1_0010h
MBC1_NSE_BLK_INDEX	1_2010h

Diagram



Fields

Field	Description
31-16 DID_SELn	DID Select Destination domain bitmap select. 0 - No effect. 1 - Selects NSE bits for this domain.
15-12 —	Reserved
11-8 MEM_SEL	Memory Select Destination memory bitmap select. • Bit [11] - MBC MEM 3 • Bit [10] - MBC MEM 2 • Bit [9] - MBC MEM 1 • Bit [8] - MBC MEM 0
7-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
5-2 WNDX	Word index into the block NSE bitmap. It selects the BLK_NSE_Wn register, where WNDX determines the value of n.
1 —	Reserved
0 AI	Auto Increment 0 - No effect. 1 - Add 1 to the WNDX field after the register write.

15.7.6.22 MBC NonSecure Enable Block Set (MBC0_NSE_BLK_SET - MBC1_NSE_BLK_SET)

A write to this register sets the appropriate NSE Bits for the selected domains and memories defined at the word location NSE_BLK_INDEX[WDNX]. If NSE_BLK_INDEX[AI] = 1, then the NSE_BLK_INDEX[WDNX] field is incremented by 1 (modulo-16) after the write is completed. This register reads as zero.

15.7.6.27 MBC Memory Block Configuration Word (MBC0_DOM0_MEM0_BLK_CFG_W0 - MBC1_DOM15_MEM3_BLK_CFG_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_CFG_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

These registers are read/write for both the alternate view of the NSE bit and the 3-bit MBACSEL field. This is an array of 4 bit fields defining the block configuration for the given submemory. Each 4-bit field includes an alternative view of the associated NSE bit plus a 3-bit access control select that selects the global access control value that applies to the referenced memory block.

For a given memory block, B, if the value programmed in the MBACSELn field selects a locked MBC_MEMN_GLBACr register, the MBACSEL field is locked until the next reset. Depending on BLK_CFG_W, the NSEn/MBASELn fields correspond to different blocks. The following table describes the relationship between W (word index) and B (block number).

MEM0 supports up to 512 blocks ; W0 - W63

MEM1-3 supports up to 64 block ; W0 - W7

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

Table 91. Block Config Word to Block Number Relationship

Fields

Field	Description
31 NSE7	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
30-28 MBACSEL7	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL7 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B
27 NSE6	NonSecure Enable for block B 0 - Secure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]), nonsecure accesses to block B are not allowed. 1 - Secure and nonsecure accesses to block B are based on corresponding MBACSEL field in this register (MBCm_DOMd_MEMs_BLK_CFG_Ww[MBACSEL]).
26-24 MBACSEL6	Memory Block Access Control Select for block B This field selects the global access control associated with block B.

Field	Description
2-0 MBACSEL0	Memory Block Access Control Select for block B This field selects the global access control associated with block B. **NOTE** This field is locked (read-only) if MBACSEL0 = r and MBC_MEMN_GLBACr[LK] = 1. 000 - select MBC_MEMN_GLBAC0 access control policy for block B 001 - select MBC_MEMN_GLBAC1 access control policy for block B 010 - select MBC_MEMN_GLBAC2 access control policy for block B 011 - select MBC_MEMN_GLBAC3 access control policy for block B 100 - select MBC_MEMN_GLBAC4 access control policy for block B 101 - select MBC_MEMN_GLBAC5 access control policy for block B 110 - select MBC_MEMN_GLBAC6 access control policy for block B 111 - select MBC_MEMN_GLBAC7 access control policy for block B

15.7.6.28 MBC Memory Block NonSecure Enable Word (MBC0_DOM0_MEM0_BLK_NSE_W0 - MBC1_DOM15_MEM3_BLK_NSE_W0)

MBC[m]_DOM[d]_MEM[s]_BLK_NSE_W[w], where,

- m - mbc index
- d - domain index
- s - memory target index
- w - word index

This is the bitmap of the individual NSE bits for the memory block.

NOTE

This register is shown with fields such that it covers entire 32 bit register. However, actual fields may be less if number of blocks are such that fields don't align to 32 bits. These absent fields may be shown but user can refer to table below to deduce actual fields and treat absent fields as reserved.

The following table describes the relationship between W (word index) and B (block number).

Table 92. Block Config Word to Block Number Relationship

Block NSE Word	BIT31	BIT30-BIT1	BIT0
W0	block 31	block 30 - block 1	block 0
W1	block 63	block 62 - block 33	block 32
For MEM0, block 64 - block 511			
W2	block 95	block 94 - block 65	block 64

Table continues on the next page...

Table 92. Block Config Word to Block Number Relationship (continued)

Block NSE Word	BIT31	BIT30-BIT1	BIT0
		. . .	
W15	block 511	block 510 - block 481	block 480

The NSE bitmap can be accessed directly by register reads and writes to these locations, or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and BLK_CFG[NSEn] registers.

15.7.6.38 MRC Region Descriptor Word 0 (MRC0_DOM0_RGD0_W0 - MRC1_DOM15_RGD7_W0)

MRC[m]_DOM[d]_RGD[r]_W[w], where,

- m - mrc index
- d - domain index
- r - region descriptor index
- w - word index

The MRC[m]_DOM[d]_RGD[r]_W[w] registers provide a 3-dimensional data structure for defining access control policies per domain for each supported memory region.

Memory map/register definition:

There two word-size registers (W[w]) defined in each memory region. There are up to 16 memory region checkers (MRCs), m, each supporting up to 16 memory region descriptors (RGD), r. The number of MRCs is defined by HWCFG0[NMRC].

Offset

For m = 0 to 1; d = 0 to 15; r = 0 to 7:

Register	Offset
MRCm_DOMd_RGDr_W0	1_4040h + (m × 1000h) + (d × 100h) + (r × 8h)

31-14 END_ADDR	End Address (16K-1)-mod-16K physical end address [31:14] of region r. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.
13-5 —	Reserved
4 NSE	NonSecure Enable Alternate view of NSE flag for Region r. 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1 - Secure and nonsecure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]).
3-1 —	Reserved
0 VLD	Valid If set, this region is valid and accesses are checked for this region. **NOTE** This field is locked (read-only) if MRACSEL = r and MRC_GLBACr[LK] = 1.

15.7.6.40 MRC Region Descriptor NonSecure Enable (MRC0_DOM0_RGD_NSE - MRC1_DOM15_RGD_NSE)

This register is the bitmap of the individual NSE bits for the region descriptors. Bit n corresponds to region n.

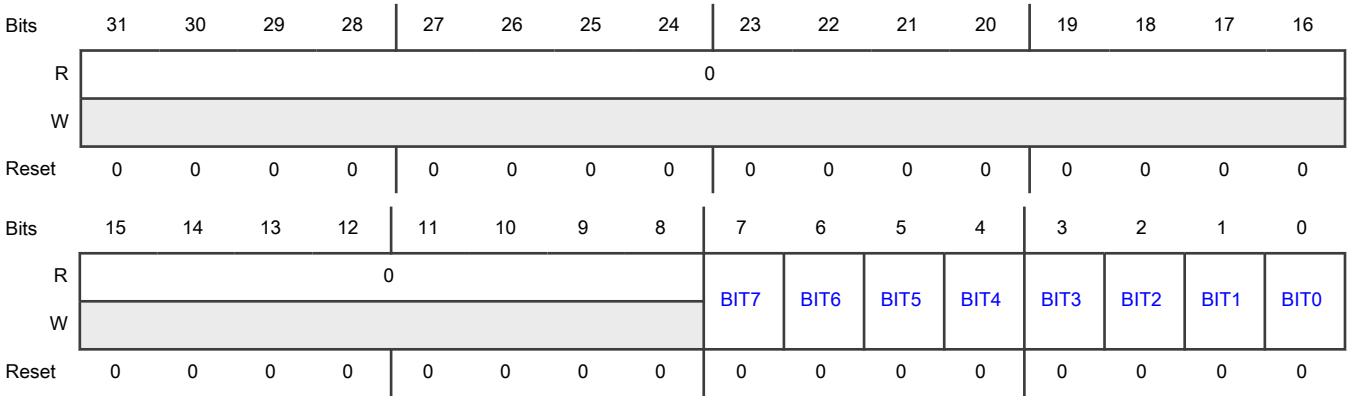
These bits can also be written or "indirectly" through writes to NSE_SET, NSE_CLR, NSE_CLR_ALL, and RGD_W0[NSE] registers.

Offset

For m = 0 to 1; d = 0 to 15:

Register	Offset
MRCm_DOMd_RGD_NSE	1_40C0h + (m × 1000h) + (d × 100h)

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 BITn	Bit n NonSecure Enable [n = 0 - 15] 0 - Secure accesses to region r are based on corresponding MRACSEL field in this register (MRCm_DOMd_RGDr_Ww[MRACSEL]), nonsecure accesses to region r are not allowed. 1 - Secure and nonsecure accesses to region r are based on corresponding MRACSEL field in register (MRCm_DOMd_RGDr_Ww[MRACSEL]).

15.7.6.41 MRC Global Access Control (MRC1_GLBAC0)

These fully programmable R/W fields define the R/W/X (read/write/execute) access control flags with each of the 4 supported operating modes: SecurePriv, SecureUser, NonsecurePriv, NonsecureUser. The lock bit provides the ability to lock these control access flags, to lock the MRC_BLK_CFG[MRACSEL] field, and to lock the MRC_RGD[STRT_ADDR, END_ADDR, VLD] fields when a locked MRC_GLBAC register is selected.

Chapter 16
System Counter (SYS_CTR)

16.1 Chip-specific SYS_CTR information

Table 93. Reference links to related information

Topic	Related module	Reference
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

NOTE

Software can read A55 core's generic timer counter value via A55 CP15 to get the SYS_CTR value.

16.1.1 Module instances

This chip has one instance of the SYS_CTR module.

16.2 Overview

SYS_CTR is a programmable system counter that provides you with a shared time base to multiple processors. It is intended for applications in which the counter is always powered on and supports multiple unrelated clocks.

16.2.1 Block diagram

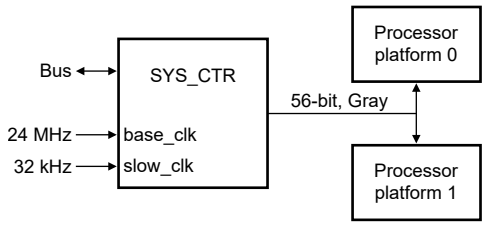

Figure 34. Block diagram

16.2.2 Features

- Two counter clock frequencies:
  - Base clock for normal operation
  - Alternate slow clock for low-power operation
- 56-bit counter width
- Gray-coded counter output for distribution to the processor timers
- Two compare frames, with each frame:
  - Containing a 64-bit compare value
  - Supporting a programmable interrupt generation

16.3 Functional description

SYS_CTR inputs two counter clock sources and outputs a gray-coded counter value and interrupt signals (one per compare frame) to the platform's interrupt controller.

16.3.1 Modes of operation

Table 94. Modes of operation

Mode	Function
Normal	The counter increments on the rising edge of the selected clock when enabled in Normal mode.
Debug	You can configure the SYS_CTR debug operation via Counter Control (CNTCR): • If CNTCR[HDBG] = 0, SYS_CTR continues to operate. • If CNTCR[HDBG] = 1, SYS_CTR halts when its debug input signal is asserted.

16.3.2 Operation

After reset, SYS_CTR is disabled with the count value reset to 0 and base frequency selected. After the counter is enabled, it increments the appropriate value on each rising edge of the selected clock. Because SYS_CTR handles a 56-bit count value across multiple clock domains, synchronization is necessary. SYS_CTR provides synchronization mechanisms between the various clock domains.

After the system switches the counter's clock source, there is a short pause while the clock multiplexer is handling the clock transition. To maintain an accurate count value, the clock control logic employs two offset counters: one for base-to-slow transition and the other one for slow-to-base transition. These offset counters only operate during the clock transition time to compensate for the idled source clock. Both counters run off the base clock. The transition offset values are added to the system count value at an appropriate time after the counter's clock is restored.

NOTE

Both the base clock and alternate clock must be running when changing frequencies.

16.3.3 Clocks

Table 95. Clocks

Clock	Description
base_clk	Base clock This clock is used during normal operation.
slow_clk	Slow clock This clock is used during low-power mode. It is internally divided by 64 before use.

16.3.4 Interrupts

Each SYS_CTR compare frame (SYS_CTR_COMPARE) is capable of generating one maskable interrupt.

16.4 External signals

This module has no external signals.

16.5 Initialization

To initialize SYS_CTR:

1. Write an initial value to Counter Count Value Low (CNTCV0) and Counter Count Value High (CNTCV1), if a different value is desired.
2. Write 1 to CNTCR[EN] to enable the counter.

16.6 Application information

To use a compare frame:

1. Write the desired count value into Compare Count Value Low (CMPCVL0 - CMPCVL1) and Compare Count Value High (CMPCVH0 - CMPCVH1).
2. Enable interrupts using CMPCR0[IMASK], if required.
3. Write 1 to CMPCR0[EN] to enable the compare function.
4. Read CMPCR0[ISTAT] to check whether the count value is reached.

16.7 Programming model

SYS_CTR contains three programming model sections. Each section has an independent module enable to allow individual secure access control. See the following table for details.

Table 96. Programming model

Programming model	Description
Control	Controls the counter frequency, enable, debug, and count value. This model also contains the frequency-modes table that supplies control and status for the frequency of SYS_CTR.
Read	Allows you to read the count value.
Compare	Controls the compare value frequency, enable, interrupt mask, and interrupt status for each compare frame.

16.8 Memory map and register definition

16.8.1 SYS_CTR_CONTROL register descriptions

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

16.8.1.1 SYS_CTR_CONTROL memory map

SYS_CTR_CTLBASE1.SYS_CTR_CONTROL base address: 4429_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	Counter Control (CNTCR)	32	RW	0000_0000
4	Counter Status (CNTSR)	32	R	0000_0100

Table continues on the next page...

Table continued from the previous page...

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
8	Counter Count Value Low (CNTCV0)	32	RW	0000_0000
C	Counter Count Value High (CNTCV1)	32	RW	0000_0000
20	Frequency-Modes Table 0 (CNTFID0)	32	R	016E_3600
24	Frequency-Modes Table 1 (CNTFID1)	32	R	0000_0200
28	Frequency-Modes Table 2 (CNTFID2)	32	R	0000_0000
C0	Counter Control 2 (CNTCR2)	32	RW	0000_0000
FD0	Counter ID (CNTID0)	32	R	0000_0000

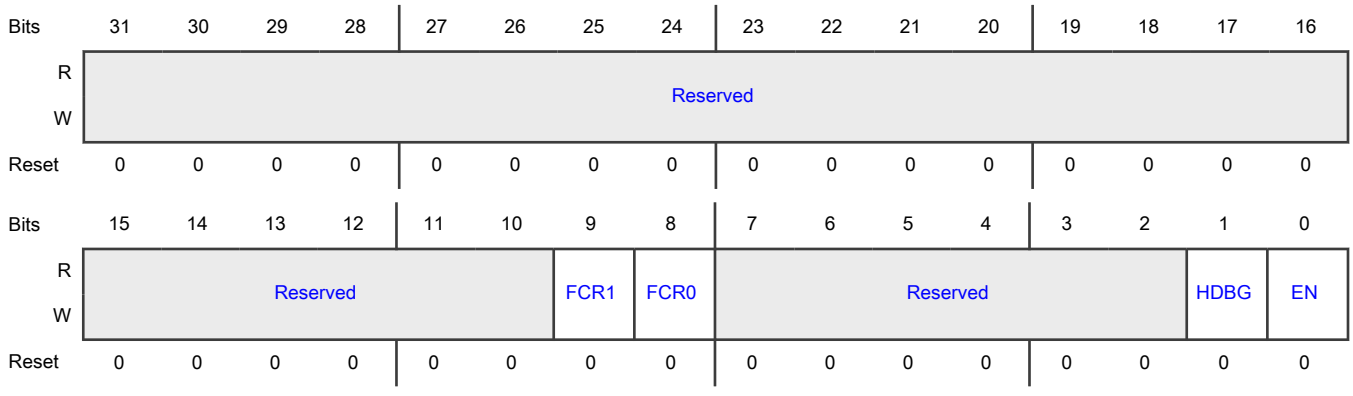
16.8.1.2 Counter Control (CNTCR)

Defines the basic operating configuration of SYS_CTR, which operates using a fixed base frequency. However, the counter can increment at a lower alternate frequency than the base frequency, using a correspondingly larger increment. For example, the counter can increment by 46,875 and run at a frequency of 1/46875 of the base frequency, which is the normal operating frequency. The alternate frequency is a significantly lower operating frequency used to reduce power consumption. The frequency-modes table identifies the two available frequencies. These two frequencies are the base frequency (table entry 0) and the lower, alternate frequency (table entry 1). Writing 1 to CNTCR[FCR1] selects the alternate frequency, and writing 1 to CNTCR[FCR0] selects the base frequency. Writing 1 or writing 0 to both FCR0 and FCR1 has no effect and the frequency does not change.

Offset

Register	Offset
CNTCR	0h

Diagram



Fields

Field	Description
31-10 —	Reserved
9 FCR1	Frequency Change Request, ID 1 Selects frequency-modes table entry 1. 0 - No change 1 - Alternate frequency
8 FCR0	Frequency Change Request, ID 0 Selects frequency-modes table entry 0. 0 - No change 1 - Base frequency
7-2 —	Reserved
1 HDBG	Enable Debug Halt Specifies whether the assertion of the debug input is ignored. 0 - Ignored 1 - Causes SYS_CTR to halt
0 EN	Enable Counting Enables counting. 0 - Disable 1 - Enable

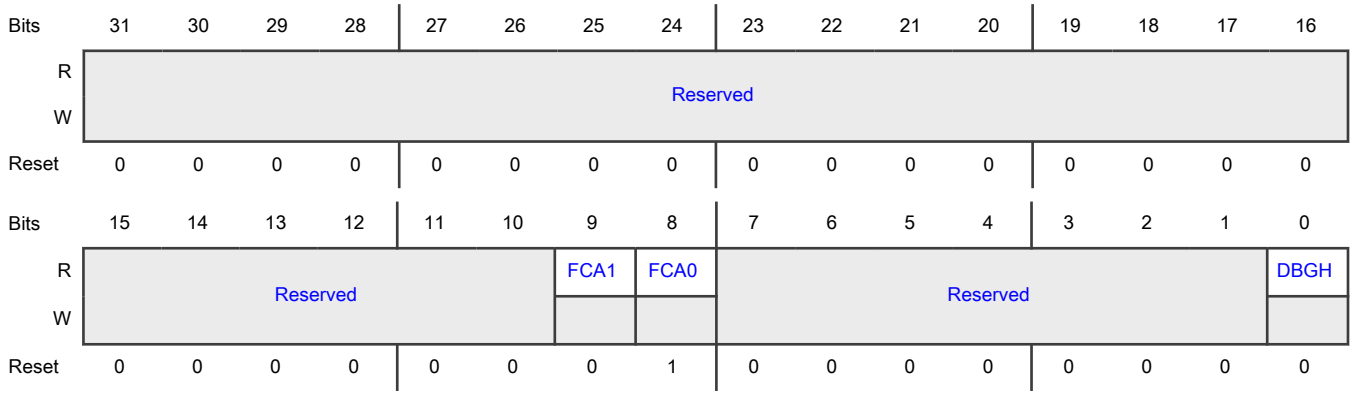
16.8.1.3 Counter Status (CNTSR)

Provides information concerning the clock frequency and debug state of SYS_CTR.

Offset

Register	Offset
CNTSR	4h

Diagram



Fields

Field	Description
31-10 —	Reserved
9 FCA1	Frequency Change Acknowledge, ID 1 Indicates whether the alternate frequency, entry 1, is selected. 0 - Not selected 1 - Selected
8 FCA0	Frequency Change Acknowledge, ID 0 Indicates whether the base frequency, entry 0, is selected. 0 - Not selected 1 - Selected
7-1 —	Reserved
0 DBGH	Debug Halt Indicates whether debug halted the counter. 0 - Did not halt 1 - Halted

16.8.1.4 Counter Count Value Low (CNTCV0)

Specifies the current count value bits (31–0).

NOTE

You must write to the CNTCV registers when operating on the base frequency only. Writes to these registers when running on the alternate frequency may have unpredictable results.

Offset

Register	Offset
CNTCV0	8h

23-0 CNTCV1	Counter Count Value Bits [55:32] Specifies the upper 24 bits of the 56-bit system count value.

16.8.1.6 Frequency-Modes Table 0 (CNTFID0)

Indicates the frequency-modes table starting at offset 20h.

Table entries contain 32 bits, and each entry specifies the SYS_CTR update frequency in Hz. The first entry in the table specifies the base frequency of SYS_CTR. To ensure that the overall counter accuracy is maintained, any subsequent entries in the table are exact divisors of the base frequency.

When SYS_CTR is operating at a lower frequency than the base frequency, the increment applied at each counter update is base_frequency ÷ selected_frequency; a 32-bit word of 0 value marks the end of the table. That is, the word of memory immediately after the last entry in the table is 0.

Offset

Register	Offset
CNTFID0	20h

Fields

Field	Description
31-0 CNTFID1	Counter Frequency ID 1 Indicates the alternate frequency, 512 Hz.

16.8.1.8 Frequency-Modes Table 2 (CNTFID2)

Indicates the frequency-modes table starting at offset 20h.

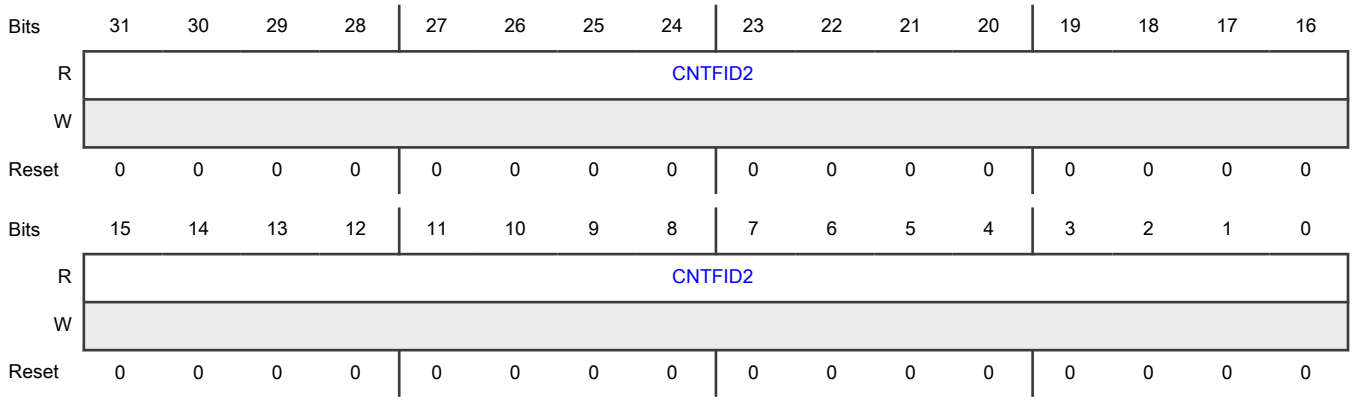
Table entries are 32 bits, and each entry specifies the SYS_CTR update frequency in Hz. The first entry in the table specifies the base frequency of SYS_CTR. To ensure that the overall counter accuracy is maintained, any subsequent entries in the table are exact divisors of the base frequency.

When SYS_CTR is operating at a lower frequency than the base frequency, the increment applied at each counter update is base frequency ÷ selected frequency; a 32-bit word of 0 value marks the end of the table. That is, the word of memory immediately after the last entry in the table is 0.

Offset

Register	Offset
CNTFID2	28h

Diagram



Fields

Field	Description
31-0 CNTFID2	Counter Frequency ID 2 Indicates the end of the frequency-modes table.

16.8.1.9 Counter Control 2 (CNTCR2)

Enables automatic configuration of SYS_CTR via hardware.

SYS_CTR operates using a fixed base frequency. However, the counter can increment at a lower alternate frequency than the base frequency, using a correspondingly larger increment. For example, the counter can increment by 46,875 and run

at a frequency of 1/46875 of the base frequency, which is the normal operating frequency. The alternate frequency is a significantly lower operating frequency used to reduce power consumption. The frequency-modes table identifies the two available frequencies. These two frequencies are the base frequency (table entry 0), and the lower and alternate frequency (table entry 1). Writing 1 to CNTCR2[HWFC_EN] enables hardware to automatically switch to the lower, alternate frequency clock after the chip enters low-power mode. When exiting this mode, hardware automatically switches back to the base frequency. If CNTCR2[HWFC_EN] = 0, frequency changes are fully under software control via Counter Control (CNTCR).

Offset

Register	Offset
CNTCR2	C0h

Fields

Field	Description
31-0 CNTID	Counter Identification Specifies counter ID 0, the architectural version of this system counter.

16.8.2 SYS_CTR_READ register descriptions

These read frame registers read the same values as the control frame registers for the count value and counter ID. They are processed via a separate mechanism from the control frame to allow Nonsecure and User mode accesses.

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

16.8.2.1 SYS_CTR_READ memory map

SYS_CTR_CTLBASE1.SYS_CTR_READ base address: 442B_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
8	Counter Count Value Low (CNTCV0)	32	R	0000_0000

16.8.3 SYS_CTR_COMPARE register descriptions

Each compare frame:

- Consists of a 256-byte region.
- Has its own compare value and control register.
- Is capable of generating a maskable interrupt.

NOTE

Write or read access to reserved locations does not generate a transfer error.

NOTE

All 32-bit registers allow only 32-bit wide write operations, and are aligned to 32 bits.

16.8.3.1 SYS_CTR_COMPARE memory map

SYS_CTR_CTLBASE1.SYS_CTR_COMPARE base address: 442A_0000h

16.8.3.4 Compare Control (CMPCR0 - CMPCR1)

Provides control and status of the compare function. When enabled, CMPCR0[ISTAT] indicates whether the counter value is greater than or equal to the value in CMPCV*n*. The ISTAT equation is:

Value of CMPCR0[ISTAT] = CNTCV*n* ≥ CMPCV*n*

CMPCR0[ISTAT] takes no account of the value of CMPCR0[IMASK]. If CMPCR0[ISTAT] = 1 and CMPCR0[IMASK] = 0, the interrupt request is asserted. Writing 0 to CMPCR0[EN] makes CMPCR0[ISTAT] = 0 and negates the interrupt output signal.

Chapter 17
System Debug

17.1 Overview

The chip debug architecture is based on Arm CoreSight technology, with support for the Cortex-A55 and EdgeLock Secure enclave cores.

17.1.1 Block Diagram

The block diagram for the system level debug architecture is provided below.

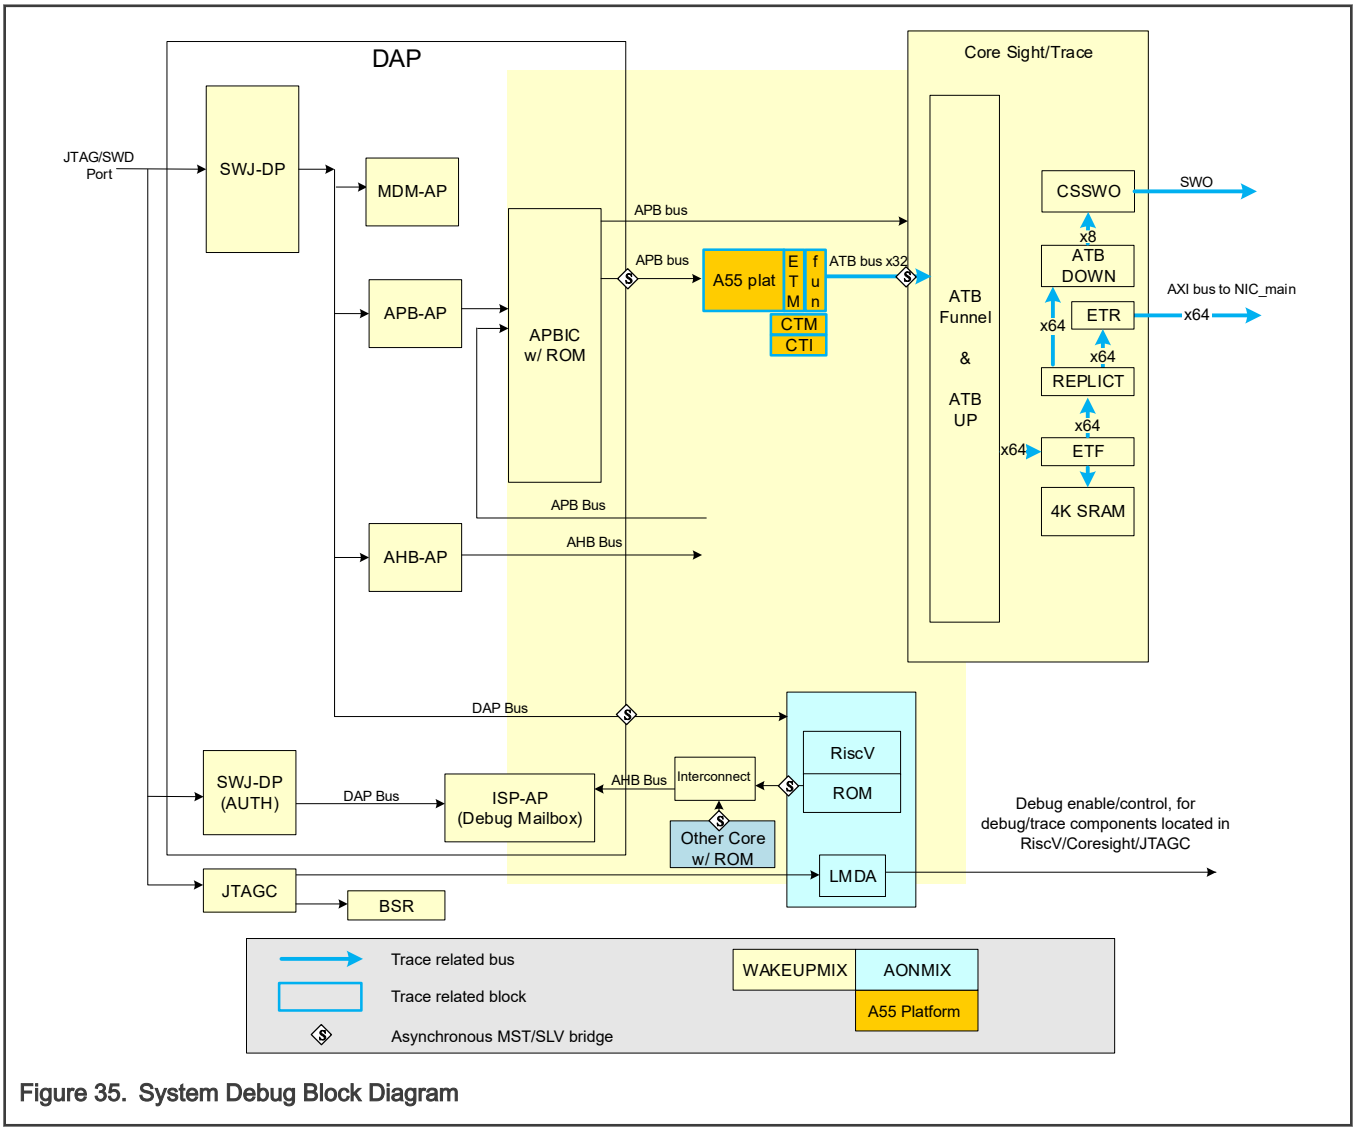

Figure 35. System Debug Block Diagram

The debug/trace components are listed below:

- Debug Access Port (DAP) - Has Serial Wire port (SWJ-DP) which interprets the data coming in and routes to appropriate Access Port (AP).
- Serial Wire port (SWJ-DP) - Consists of a wrapper around the JTAG-DP and SW-DP. It selects JTAG or SWD as the connection mechanism and enables either JTAG-DP or SW-DP as the interface to the various on chip debug/trace components. It is enabled only after debug is authenticated.

- SWJ-DP (AUTH) is another SWJ-DP instance dedicated for ISP-AP. It is enabled only when debug authentication is required, means it will be disabled if debug is authenticated.
- JTAGC
  - JTAGC and DAP/SWJ-DP share the same JTAG interface from PAD.
  - Achieve boundary scan testing, with an external BSR connected.
  - Supports Challenge-response authentication, with LMDA in EdgeLock secure enclave.
  - Supports IEEE 1149.6/AC JTAG.
- Debug Access port for Cortex-A55 platform.
- Debug Access port for Coresight.
- RISC-V DAP-AP - Debug Access port for RISC-V core in EdgeLock secure enclave.
- ISP-AP - Debug Access port for Debug Mailbox, to allow the debugger to communicate with onboard ROM code.
- MDM-AP registers for debugger to control multi-core halt/resume cores.
- Coresight components.
- Cross-Trigger Interface (CTI) and Cross-Trigger Matrix (CTM).

17.1.2 Features

The key features of the debug system include:

- Supports 1149.1/ARM SWD interface. Supports both 5-pins (JTAG) and 2-pins (SWD) interfaces, to make efficient use of package pins, serial wire shares the JTAG pins use an auto-detect mechanism.

NOTE

1149.7 Compact JTAG is NOT supported.

- Supports both non-intrusive and halt-mode trace/debug options
- Supports trace for various cores, including a trace Memory Controller (TMC) to enable capturing trace
  - 4KB ETF in SOC trace block
  - ETR (4G memory range, 64-bit wide) to allow routing trace data to system memory
  - CoreSight Serial Wire Output
- Supports cross trigger between the Cortex-A55
- MDM-AP registers for debugger to control multi-core halt/resume cores
- Supports narrow timestamp for trace components
- Supports ISP-AP (Debug Mailbox), allowing the debugger to communicate with onboard ROM code, providing debug authentication based on messages
- Supports challenge-response authentication

NOTE

Arm ELA-500 and Coresight SoC-600 are not supported.

17.2 Functional description

17.2.1 Debug Access Port (DAP) TAP

DAP is a standard Arm component, comprising of several components. These components are used to access the DAP from an external debugger and Access Ports to access on-chip debug system resources. The DAP supports 1149.1/Arm SW-DP interface,

which means that the JTAG interface can be operate in standard 5-pin JTAG-DP interface or in 2-pin SW-DP interface. The following figure shows the connectivity between the DAP and the pads.

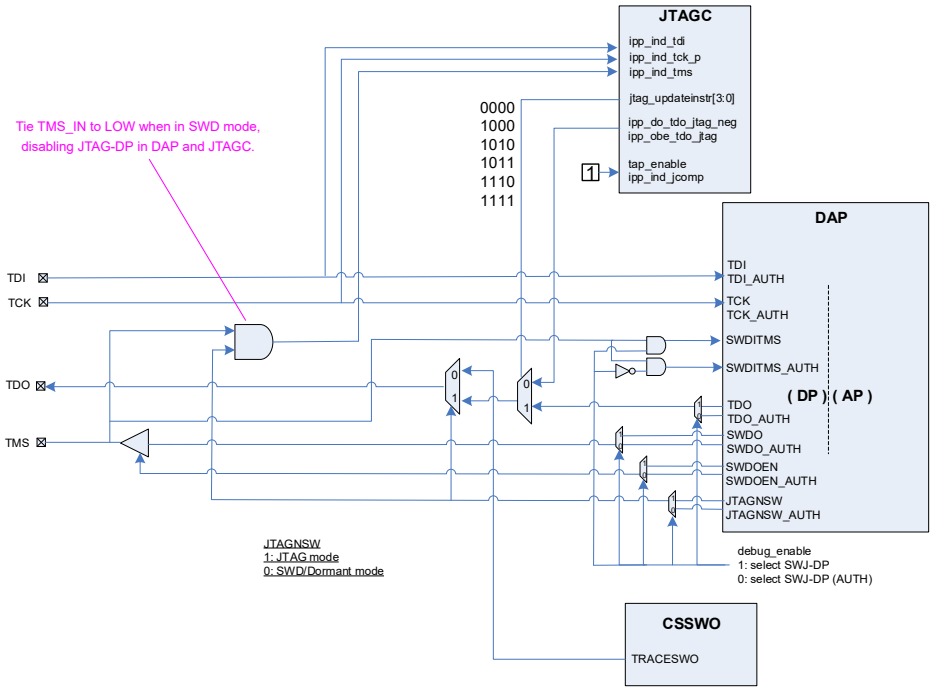

Figure 36. JTAG Pad Connectivity

For PAD descriptions, see External Signals.

17.2.2 JTAGC and JTAG mux

The JTAGC and SWJ-DP/SWJ-DP (AUTH) share the same 5-pin JTAG interface from PAD. SWJ-DP and SWJ-DP (AUTH) will not be enabled at the same time, controlled by the authentication status from LMDA.If debug is authenticated, select SWJ-DP, otherwise select SWJ-DP (AUTH).

SW-DP pins (TCK,TMS) are connected directly from and to SoC pins.

- When SW-DP is enabled, both JTAGC and JTAG-DP will be disabled.
- When SW-DP is disabled, the output to TDO from JTAGC and JTAG-DP will be selected by a mux and that mux is controlled by decode of the IR inside the JTAGC (JTAGC output port jtag_updateinstr[4:0]), and then connected to SoC pins for debug and/or test purposes.

Selection is based on the following table of decodes.

Table 97. Instruction Register

Instruction	Value	Module
EXTEST (Arm)	4'b0000	Arm JTAG-DP
IDCODE (JTAGC)	4'b0001	JTAGC
SAMPLE/PRELOAD	4'b0010	JTAGC
SAMPLE	4'b0011	JTAGC
EXTEST (JTAGC)	4'b0100	JTAGC

Table continues on the next page...

Table 97. Instruction Register (continued)

Instruction	Value	Module
TEST_LEAKAGE	4'b0101	JTAGC
ENABLE_TEST_CTRL	4'b0110	JTAGC

IDCODE (Arm)	4'b1110	Arm JTAG-DP
BYPASS (Arm)	4'b1111	Arm JTAG-DP

Partial of TARGETID[31:0] input for SWJ-DP should also be connected to JTAGC, for coherence, as below:

Table 98. JTAG TARGETID

JTAGC	SWJ-DP	description
jtagc_pin_plug[9:0]	TARGETID[21:12]	Part Identification Number
jtagc_prn_plug[3:0]	TARGETID[31:28]	Part Revision Number
jtagc_jcomp_plug[0:J-1]	1'b1 (J=1)	JTAG JCOMP value

17.2.3 AP Select Decoding

The recommendation for AP selects decoding is provided in the following table.

NOTE

SWJ-DP (AUTH) has only one DAP slot (the first DAP slot) targeting ISP-AP, so it has no DAPBUSIC decoding logic.

The DAPBUSIC in the table below is only for SWJ-DP rather than SWJ-DP (AUTH).

Table 99. Address Decoding for DAPBUSIC

Destination	DAPBUSIC_AP_SEL[31:24]

17.2.4 Trace

The debug and trace implementation for the Cortex-A55 is shown in the following figure.

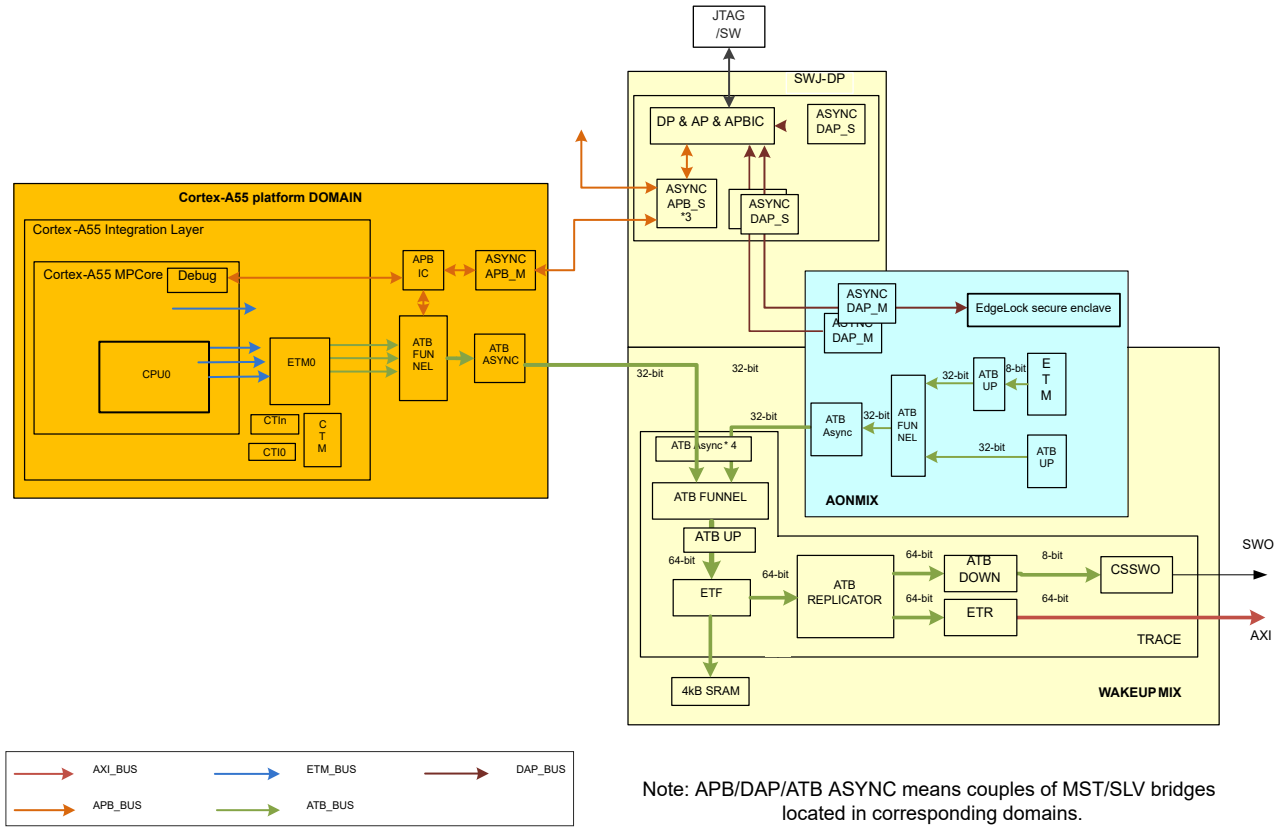

Figure 37. Trace Diagram

- Trace sources include ETM in Cortex-A55.

- One Embedded Trace FIFO (ETF, can operate as ETB, programmable), 4KB size as 128x256 (width x depth) with single port of SRAM.
- ATB funnel can capture trace data from Cortex-A55.
- ETR - Routing trace to system enabling to reuse SoC resources. (4G memory range, 64-bit wide).

17.2.5 Embedded Cross Trigger (ECT)

The ECT for coreSight consists of a few CTIs and CTM. The diagram below shows the structure of the ECT. The ECT enables subsystems to interact, that is cross trigger with each other. It is used for multiple core run control and trace cross trigger.

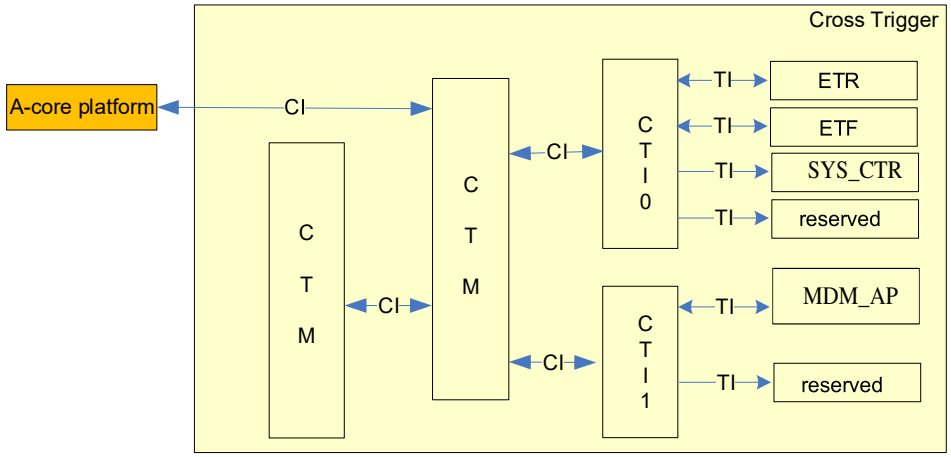

Figure 38. Embedded Cross Trigger Diagram

17.2.6 Timestamp Generation

There is no Arm Coresight Timestamp Generator in the system, and instead the System Counter is the source of the time used by all of the following components:

- System Counter internal counters and comparators.
- Cortex-A55 timestamp value (for trace).
- TSTMR1 and TSTMR2 read-only timestamp snapshot registers.
- Cortex-A55 Arm Generic Timer input.

The Cortex-A55 Arm Generic Timer is provided the full width uncompressed timestamp directly from the System Counter, without going through any Coresight Narrow timestamp encoder or decoder blocks. The Coresight Narrow timestamp IP are not used for the Cortex-A Generic Timer inputs in order to provide the maximum accuracy for the Cortex-A functional usage, as recommended by Arm. See the diagram below for details.

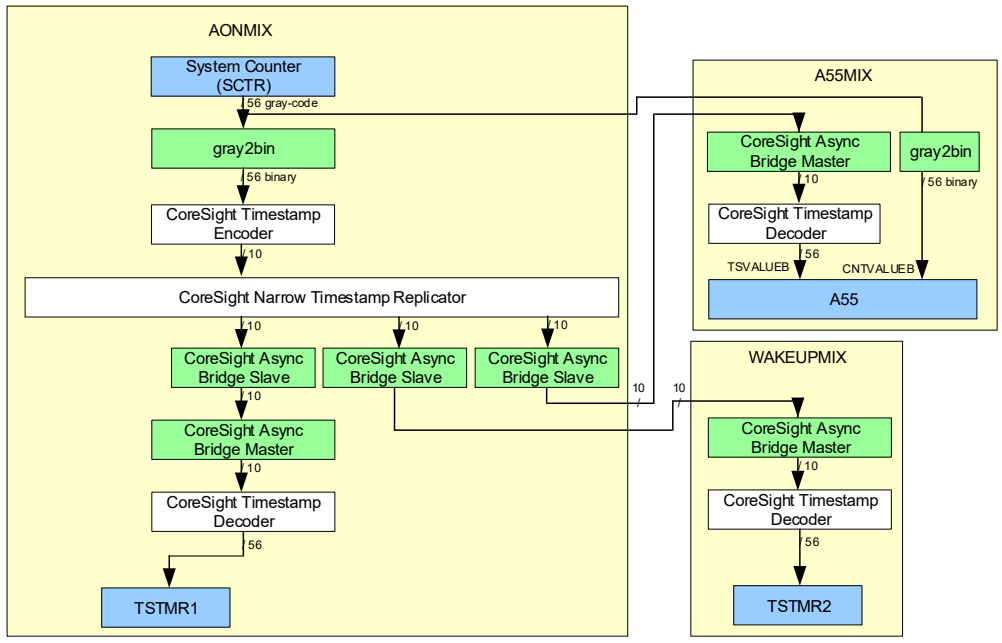

Figure 39. Timestamp Distribution

17.2.7 Debug Access Control from ROM Code

Once debug is authenticated, an external debugger tool may break code execution at any moment. This can potentially be during the boot process, when the ROM code is executing. If this occurs, the normal ROM execution is interrupted. The chip environment is uncertain (for example, the CLOCK initialization status, the interrupt status, the MPU settings).

When the debug tool loads the Flashloader, it will reset the core and halt the core first and then load the Flashloader. Tasks such as the analog trim and clock initialization may be interrupted.

To address this, the chip allows the ROM code to receive a request whenever a debug request is received, gate the debug request until the ROM code enters a safe state to allow the debugger to continue. This is for reasons purely related to debug ease-of-use, not for reasons related to security.

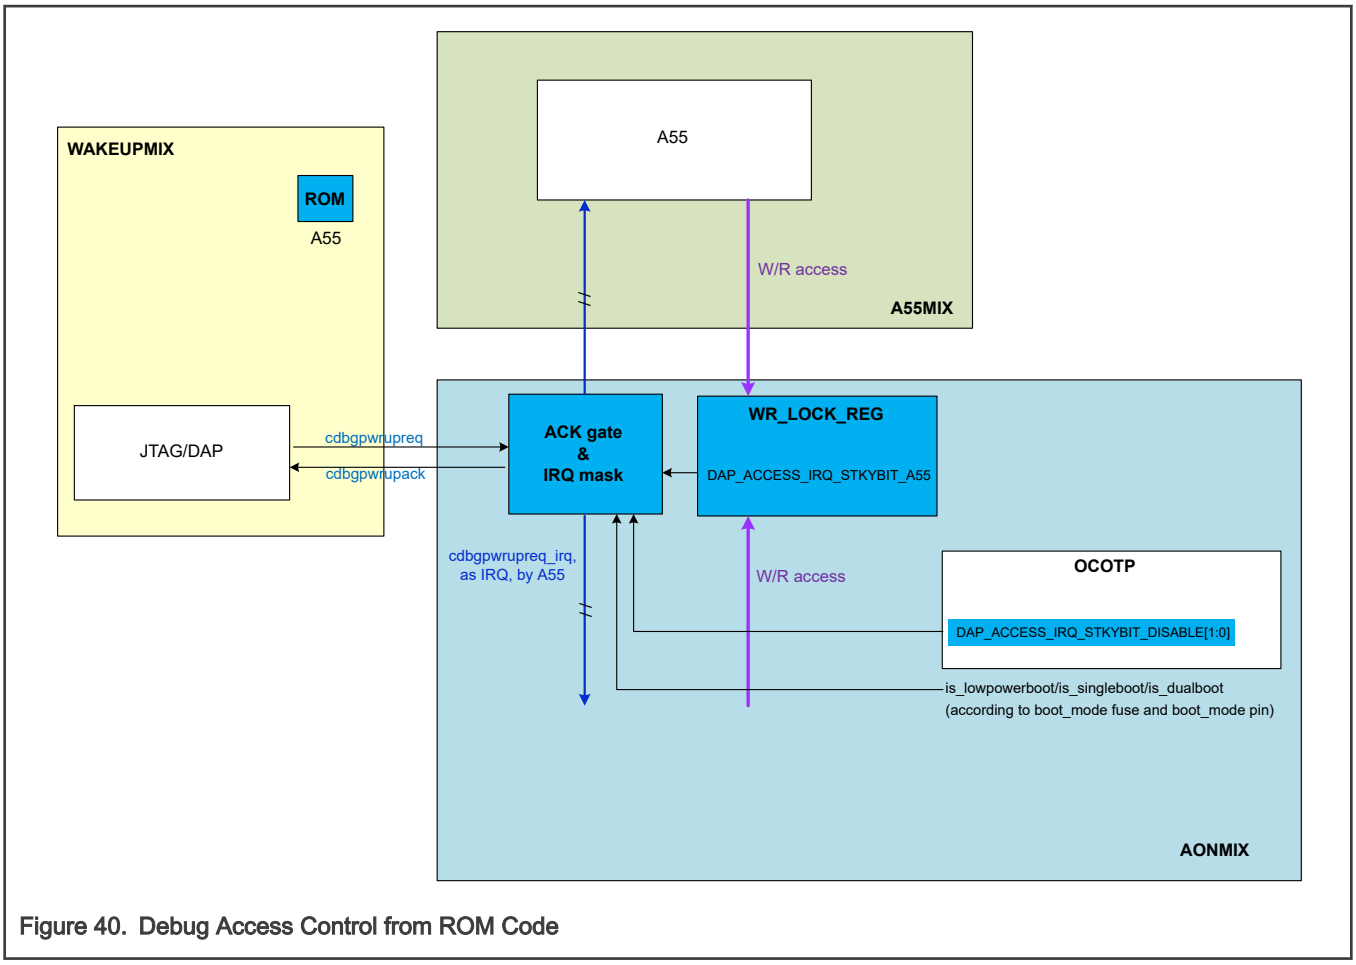

Figure 40. Debug Access Control from ROM Code

Details for the fuse controlling the debug access control from ROM code is provided in the following table.

Table 101. Fuse definition controlling debug access control from ROM code

DAP_ACCESS_IRQ_ STKYBIT_DISABLE[1]	DAP_ACCESS_IRQ_ STKYBIT_DISABLE[0]	Debug Control Logic
0	X	Disable DAP Access qualified by IRQ and sticky-bit logic. Direct DAP Access.
1	0	Enable DAP Access qualified by IRQ and sticky-bit logic.
1	1	Disable DAP Access qualified by IRQ and sticky-bit logic. Direct DAP Access.

DAP_ACCESS_IRQ_STKYBIT_DISABLE supports BootROM control of debug enable, and both fuse bits are in a section of BootROM that may be controlled by either NXP or OEM. By default, this feature is disabled when no fuses are blown.

This feature for the Cortex-A55 will be enabled or disabled at the same time. Therefore, there is no case where one is enabled but another is disabled.

- For single boot mode (Cortex-A boot), will select A55's sticky bit.

Pseudo code for the solution is pasted below:

```
      assign dap_access_irq_fuse_disabled =  (DAP_ACCESS_IRQ_STKYBIT_DISABLE[1] == 0) ||
((DAP_ACCESS_IRQ_STKYBIT_DISABLE[1] == 1) && (DAP_ACCESS_IRQ_STKYBIT_DISABLE[0] == 1));

      assign dap_accessible = dap_access_irq_fuse_disabled?  1'b1 :

      (is_singleboot) ?   (DAP_ACCESS_IRQ_STKYBIT_A55) :

      assign cdbgpwrupack = cdbgpwrupreq && fuse_latched && dap_accessible;
      assign cdbgpwrupreq_irq = cdbgpwrupreq && (~cdbgpwrupack);
```

NOTE

- DAP_ACCESS_IRQ_STKYBIT_A55 is a W/R register controlled by the Cortex-A55 ROM. Once set to "1", it will be "1" unless there is a reset.
- cdbgpwrupreq_irq will be the final IRQ, by the Cortex-A55.

17.3 External Signals

The JTAG signals are outlined in the following table.

Table 102. External signals

Name	I/O	JTAG	SWD	Pullup (PU) / Pulldown (PD)
TMS/SWDIO	I/IO	Mode selection	Data In/Out	PU
TCLK/SWCLK	I	Clock	Clock	PD
TDI	I	Data input	-	PU
TDO	O	Data output	-	NC

18.1.1 Module instances

This device has one instance of the JTAGC module.

18.2 Overview

JTAGC allows you to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from JTAGC is communicated in serial format.

18.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. See the chip-specific configuration information within this chapter as well as Register description for more information about the JTAGC registers.

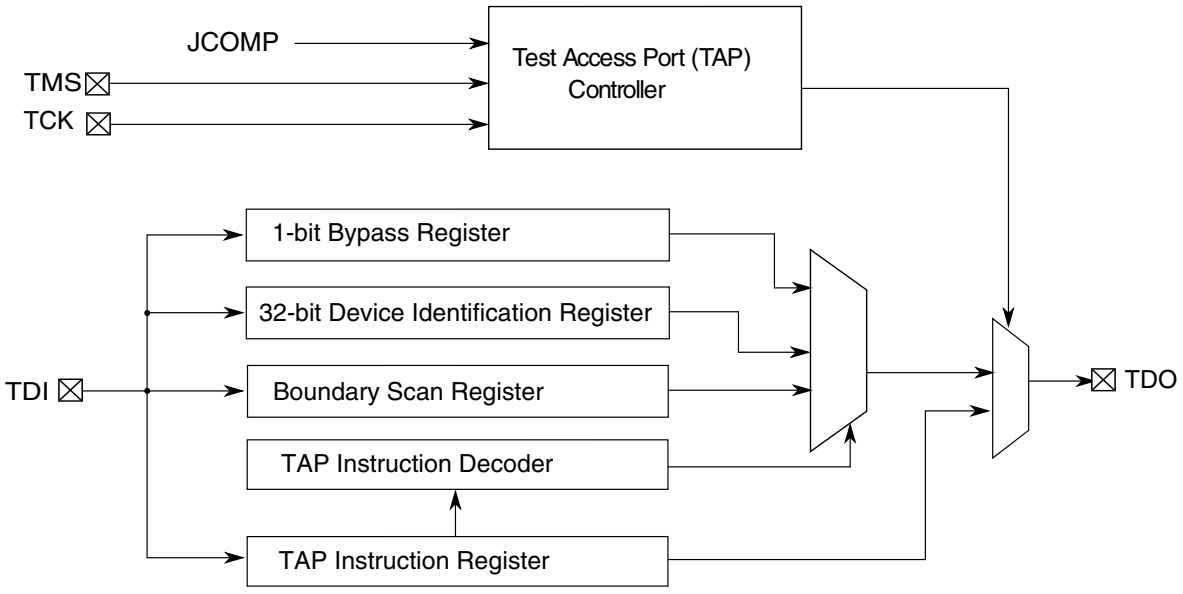

Figure 41. JTAG (IEEE 1149.1) block diagram

18.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 TAP interface
  - Four pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1–2001 defined instructions as well as several public and private device-specific instructions (see JTAGC block instructions for a list of supported instructions).
- Bypass register, boundary scan register, and device identification register
- TAP controller state machine that controls the operation of the data registers, instruction register, and associated circuitry

18.3 Functional description

18.3.1 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1–2001 defined test modes are supported, as well as a bypass mode.

18.3.1.1 IEEE 1149.1–2001 defined test modes

The JTAGC block supports several IEEE 1149.1–2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register when the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, PRELOAD.

Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic when the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the following instructions are active:

- BYPASS

- HIGHZ
- CLAMP

The functionality of each test mode is explained in more detail in JTAGC block instructions.

18.3.1.2 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. When in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

18.3.2 IEEE 1149.1-2001 (JTAG) TAP

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction.

Data is shifted between TDI and TDO through the selected register (instruction, test data, or the bypass register) starting with the least significant bit, as illustrated in the following figure.

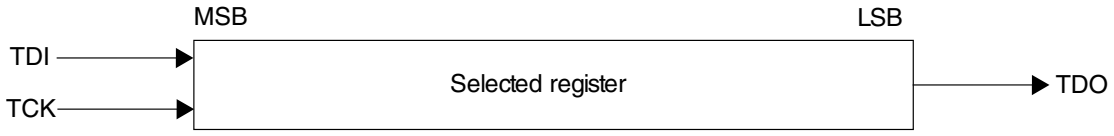

Figure 42. Shifting data through a register

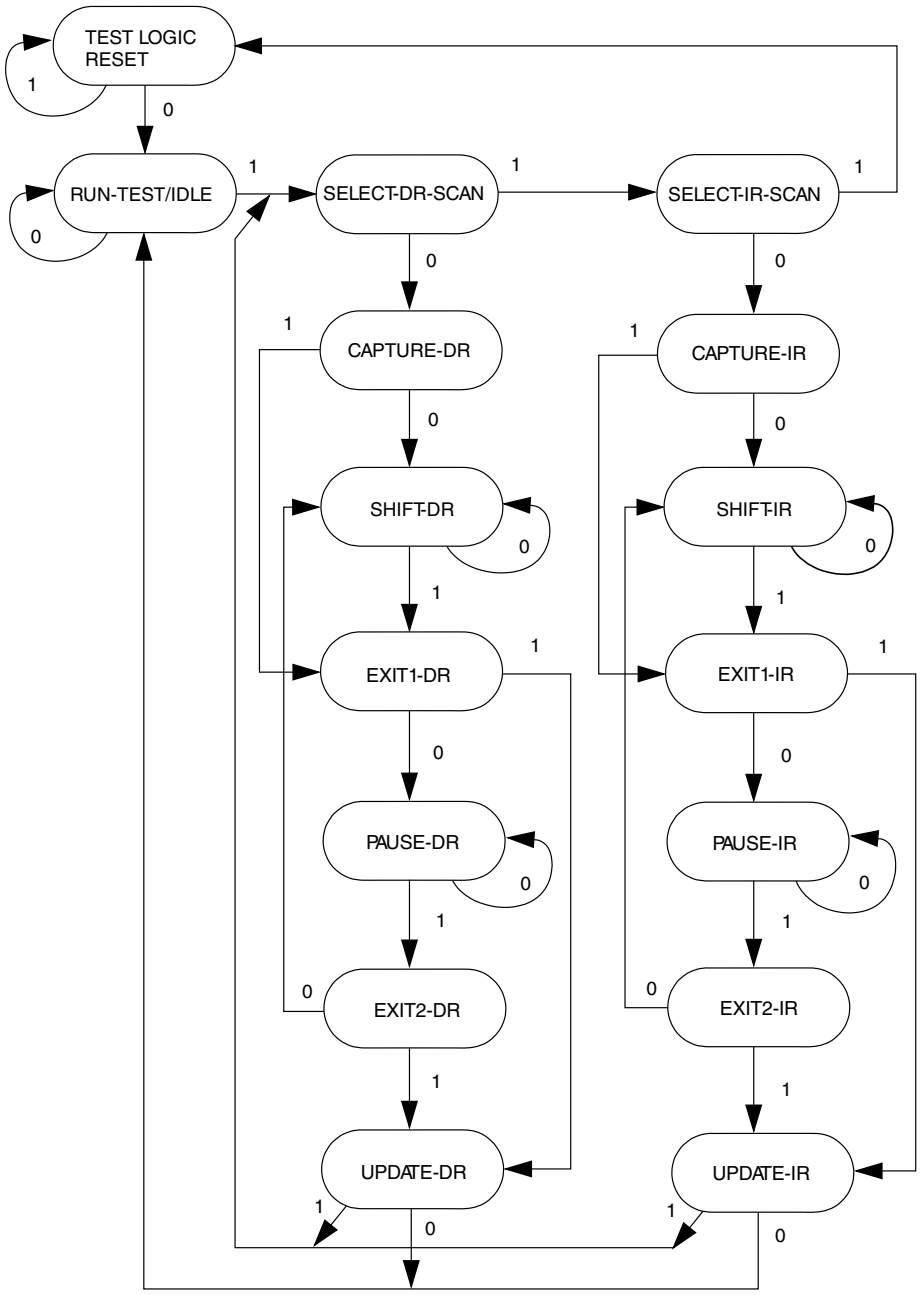
18.3.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin.

The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the figure shows, holding TMS at logic 1 when clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.



The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

Figure 43. IEEE 1149.1-2001 TAP controller finite state machine

18.3.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

18.3.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions when the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated after the required number of bits have been acquired.

18.3.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions. See the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

NOTE

See the chip specific information JTAGC block instructions for applicable to your device.

18.3.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

18.3.4.2 PRELOAD instruction

The PRELOAD instruction has two functions:

- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

18.3.4.3 EXTEST external test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the data is loaded into the boundary scan register using the PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state when performing external boundary scan operations.

18.3.4.4 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. When HIGHZ is active all output drivers are placed in an inactive drive state (for example, high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

18.3.4.5 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register when the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) when conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

18.3.4.6 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. When the BYPASS instruction is active the MCU operates normally.

18.3.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

18.3.6 Clocking

There is one clock for this module. For more information See External signals.

18.3.7 Interrupts

This module has no interrupts.

18.3.8 Reset

The JTAGC block is placed in reset when:

- Power-on reset is asserted
- JCOMP is negated
- TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state

Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state.

When in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the MCU.
- The instruction register is loaded with the IDCODE instruction.

18.4 External signals

JTAGC includes a set of signals that connect to off-chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 105. JTAG signal properties

Name	I/O	Function	Reset state
TCK	Input	Test clock	Weak pulldown
TDI	Input	Test data in	Weak pullup
TDO	Output	Test data out	High Z[1]
TMS	Input	Test mode select	Weak pullup
JCOMP	Input	JTAG compliance	Weak pulldown

1. TDO output buffer is disabled when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

18.4.1 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

18.4.2 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

18.4.3 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is tristateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in TAP controller state machine.

18.4.4 Test mode select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

18.4.5 JCOMP JTAG compliance

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding—otherwise the JTAGC TAP controller remains in reset.

18.5 Initialization

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller.
2. Load the appropriate instruction for the test or action to be performed.

18.6 Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

18.7 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

18.7.1 Instruction register

The JTAGC block uses a 4-bit instruction register as shown in the following figure.

The instruction register allows instructions to be loaded into the block to select the test to be performed, or the test data register to be accessed, or both. Instructions are shifted in through TDI when the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states.

Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 0b1, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

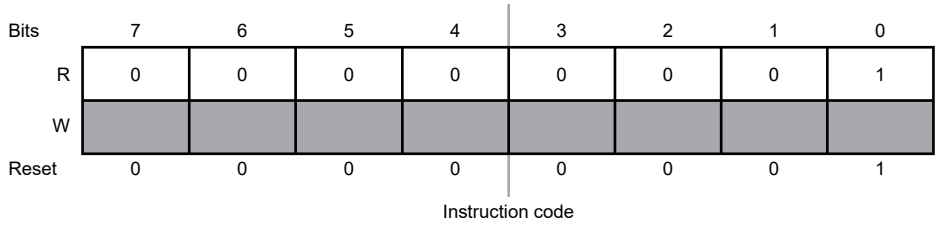


Figure 44. Instruction register

18.7.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the following instructions are active:

- BYPASS
- HIGHZ
- CLAMP

After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

18.7.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP.

The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state when the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

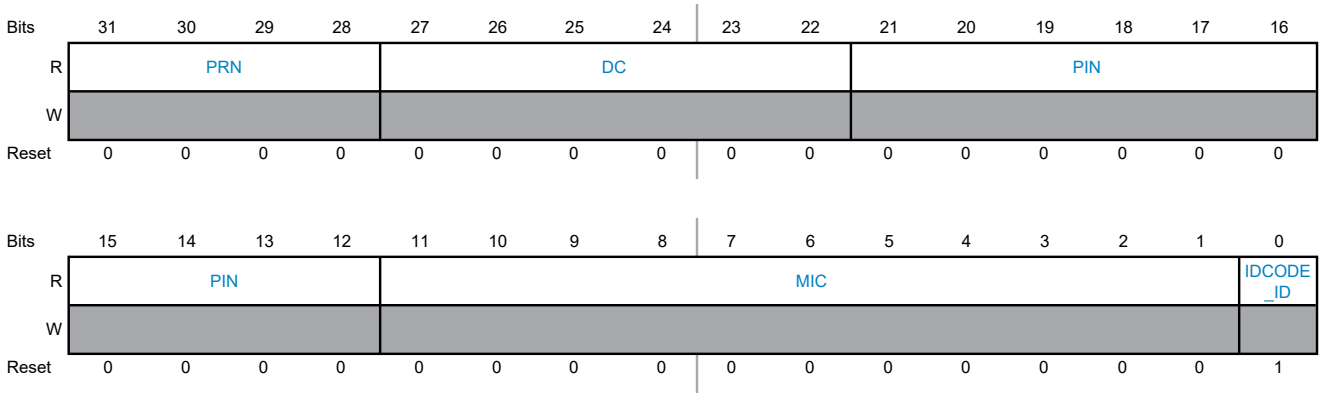

Figure 45. Device identification register

The following table describes the device identification register functions. The device identification register values are described in the chip-specific JTAGC information.

Table 106. Device identification register field descriptions

Field	Function
PRN	Part revision number Contains the revision number of the part.
DC	Design center Indicates the design center.
PIN	Part identification number Contains the part number of the device.
MIC	Manufacturer identity code Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID .
IDCODE ID	IDCODE register ID Identifies this register as the device identification register and not the bypass register. Always set to 1.

18.7.4 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, PRELOAD instructions are active. It is used to:

- Capture input pin data
- Force fixed values on output pins
- Select a logic value and direction for bidirectional pins

Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in Boundary scan. The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

18.8 Glossary

TAP	Test access port
TCK	Test clock
TDI	Test data in
TDO	Test data out
TMS	Test mode select
JCOMP	JTAG compliance

Chapter 19
External Signals and Pin Multiplexing

19.1 Overview

The chip contains a limited number of pins, most of which have multiple signal options. These signal-to-pin and pin-to-signal options are selected by the input-output multiplexer called IOMUX. The IOMUX is also used to configure other pin characteristics, such as voltage level, drive strength, and hysteresis.

The muxing options table lists the external signals grouped by the module instance, the muxing options for each signal, and the registers used to route the signal to the chosen pad.

19.1.1 Muxing Options

Please refer the Pinlist spreadsheet attached with this RM for more details.

NOTE

ENET1 is Ethernet QoS with TSN and ENET2 is Ethernet MAC.

NOTE

LPUART DCB_B is the same as LPUART DCD_B.

Chapter 20
IOMUX Controller (IOMUXC)

20.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one pad to several functional blocks. This sharing is done by multiplexing the pad's input and output signals.

Every module requires a specific pad setting (such as pull up or keeper), and for each pad, there are up to 8 muxing options (called ALT modes). The pad settings parameters are controlled by the IOMUXC.

The IOMUX consists only of combinatorial logic combined from several basic IOMUX cells. Each basic IOMUX cell handles only one pad signal's muxing.

20.1.1 Block diagram

The figure below illustrates the IOMUX/IOMUXC connectivity in the system.

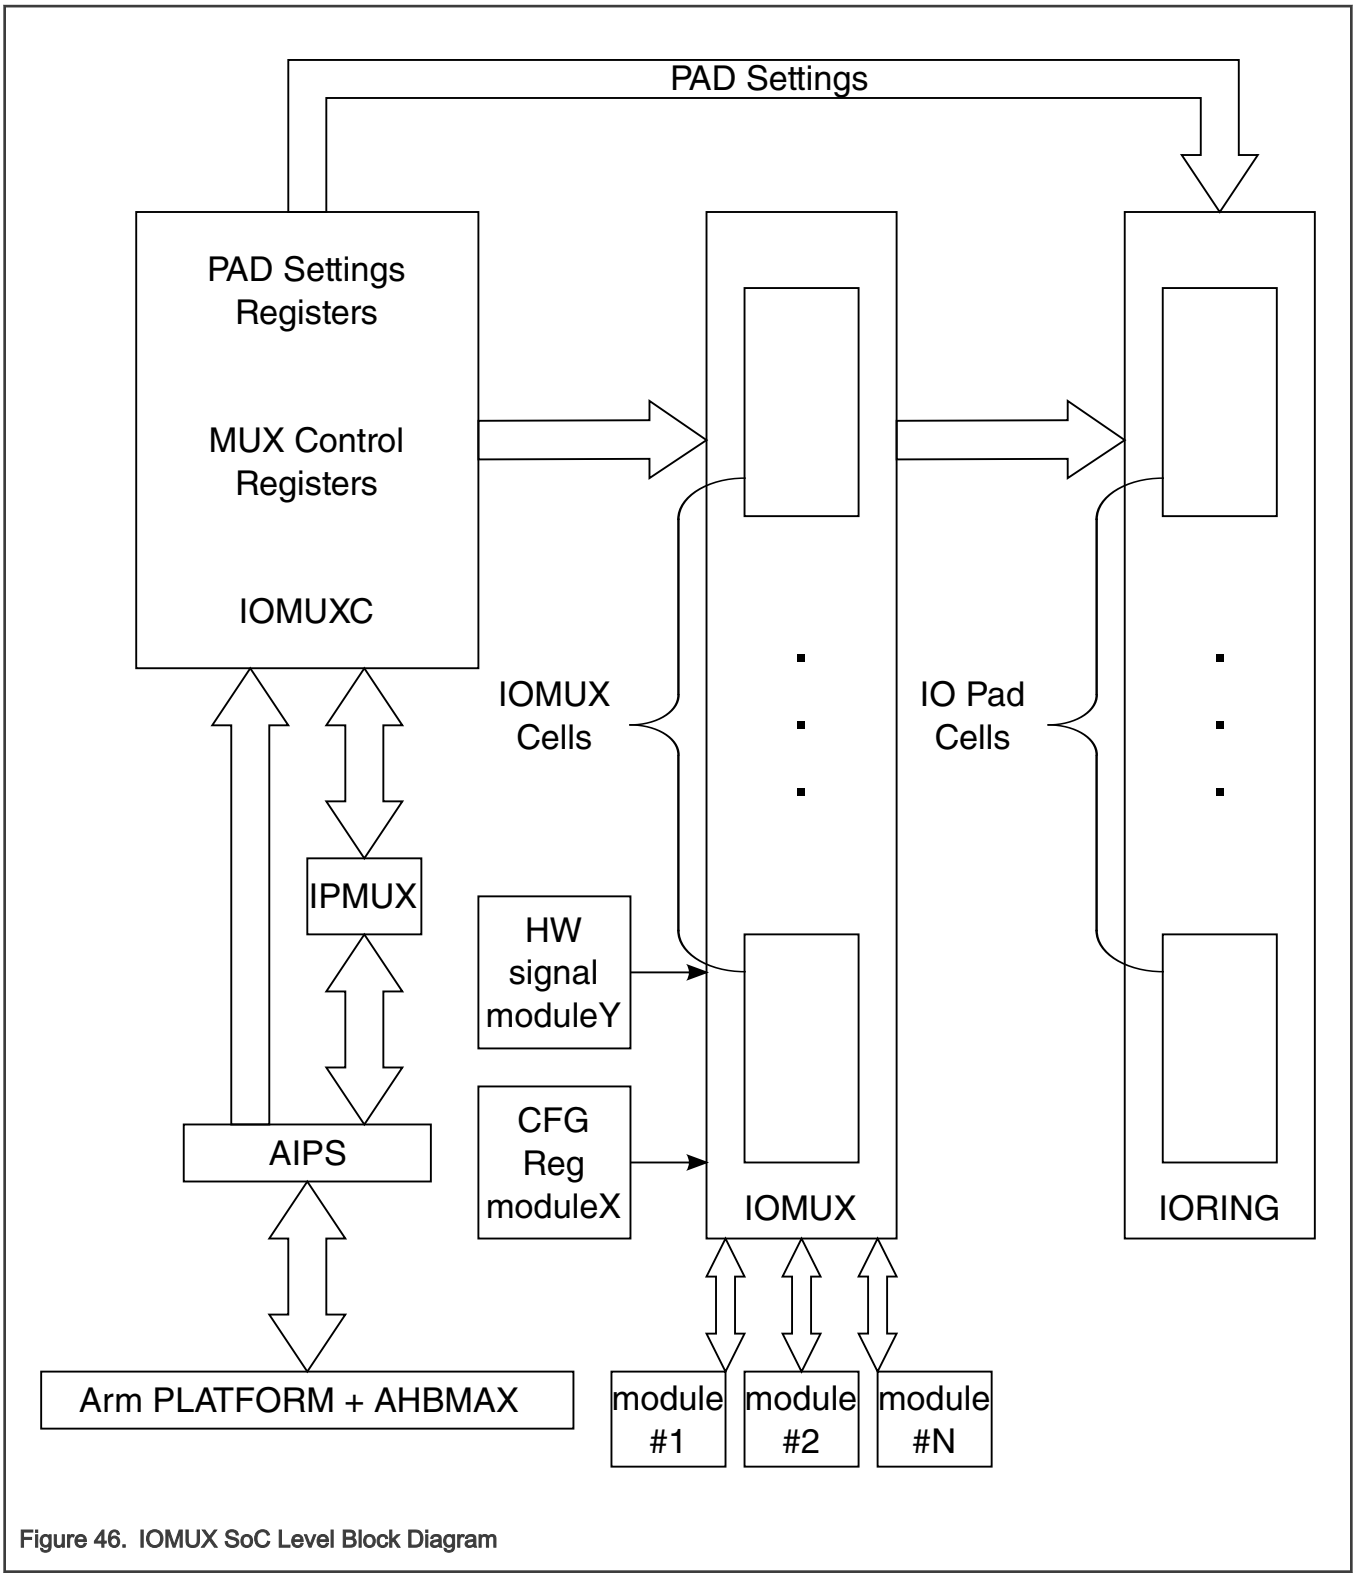

Figure 46. IOMUX SoC Level Block Diagram

20.1.2 Features

The IOMUXC features include:

- 32-bit software mux control registers (SW_MUX_CTL_PAD_<PAD NAME>) to configure 1 of 12 alternate (ALT) MUX_MODE fields of each pad and to enable the forcing of an input path of the pad(s) (SION bit).
- 32-bit software pad control registers (SW_PAD_CTL_PAD_<PAD_NAME>) to configure specific pad settings of each pad.
- 32-bit input select control registers to control the input path to a module when more than one pad drives this module input.

Each SW MUX/PAD CTL IOMUXC register handles only one pad.

Only the minimum number of registers required by software are implemented by hardware. For example, if only ALT0 and ALT1 modes are used on Pad x then only one bit register will be generated as the MUX_MODE control field in the software mux control register of Pad x.

The software mux control registers may allow the forcing of pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

20.2 Functional description

This section provides a complete functional description of the block.

The IOMUX consists of a number of basic iomux cell units. If only one functional mode is required for a specific pad, it would have been no need for IOMUX and the signals can be connected directly from the module to the I/O. The IOMUX cell is required whenever two or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

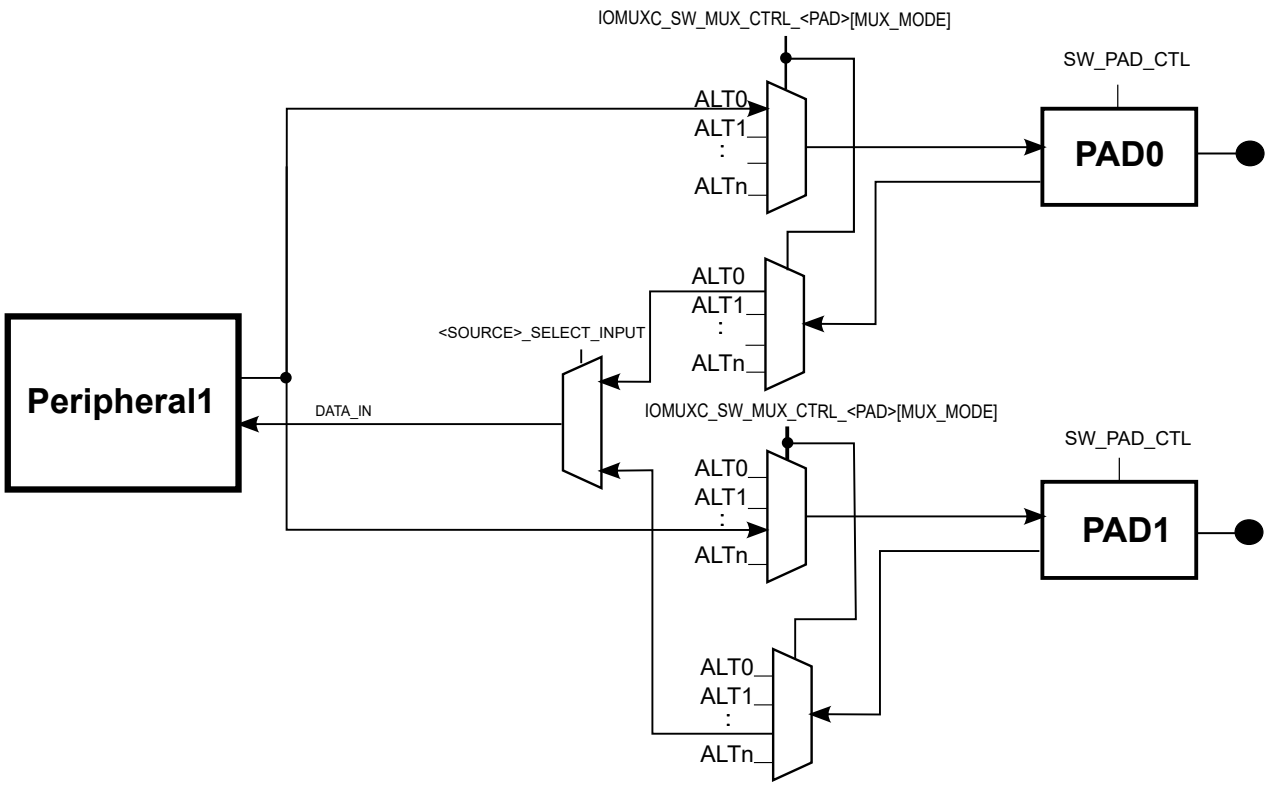

Figure 47. IOMUX Cell Block Diagram

20.2.1 SW Loopback through SION bit

A limited option exists to override the default pad functionality and force the input path to be active regardless of the value driven by the corresponding module. This can be done by setting the SION (Software Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1".

Uses include:

- LoopBack - Module x drives the pad and also receives pad value as an input.

20.2.2 Daisy chain - multi pads driving same module input pin

In some cases, more than one pad may drive a single module input pin. Such cases require the addition of one more level of IOMUXing; all of these input signals are muxed, and a dedicated software controlled register controls the mux in order to select the required input path.

A module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

This means that a module port involved in "daisy chain" requires two software configuration commands, one for selecting the mode for this pad (programable via the SW_MUX_CTL_<PAD> registers) and one for defining it as the input path (via the daisy chain registers).

The daisy chain is illustrated in the figure below.

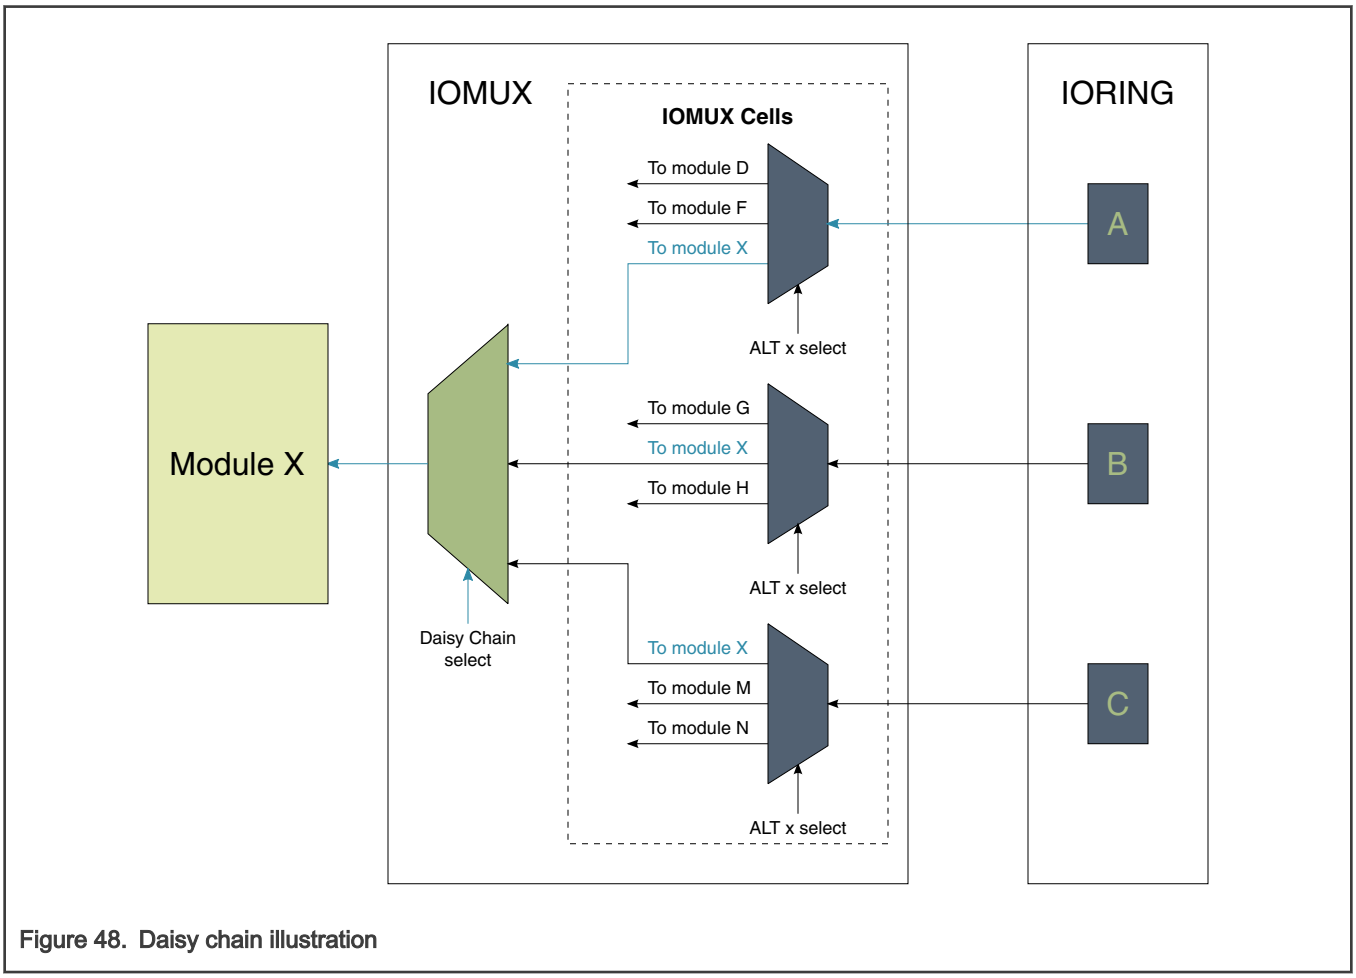

Figure 48. Daisy chain illustration

20.2.3 Clocks

The table found here describes the clock sources for IOMUXC. Please see Clock Controller Module (CCM) chapter for clock setting, configuration and gating information.

Table 107. IOMUXC Clocks

Clock Name	Description
ipg_clk_s	Peripheral access clock

20.3 Memory Map and register definition

This section includes the IOMUXC module memory map and detailed descriptions of all registers.

NOTE

Write/Read to the Reserved locations will not generate a transfer error.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Fields

Field	Description
31-24 APC	Domain Access Field For APC, the upper 4 bits are lock bits and the lower 4 bits are domain control bits. The higher 4 bits control whether the lower 4 bits can be changed, respectively. If the lock bit is set to 1, the corresponding domain control bit cannot be changed. The higher 4 bits are sticky registers, which means that once they are set to 1, they cannot be set to 0 unless reset. The domain control bits control whether the corresponding domain can access the IOMUX registers. When set to 1, the corresponding domain cannot access the IOMUX register. When set to 0, the corresponding domain can access the IOMUX register. Domain control bit 3 controls access for domain 3, bit 2 controls access for domain 2, and bit 1 controls access for domain 1. Domain control bit 0 controls whether other domains can access the IOMUX register.

Chapter 21
General-Purpose Input/Output (GPIO)

21.1 Chip-specific GPIO information

Table 108. Reference links to related information

Topic	Related module	Reference
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip supports four instances of GPIO. GPIO1 is in AONMIX and GPIO2, GPIO3, GPIO4 in WAKEUPMIX. For more details, please refer the Pin Assignments spreadsheet attached with this document.

GPIO1_IO[5], GPIO1_IO[7], GPIO1_IO[11] and GPIO1_IO[13] are output only or tristated.

For the GPIO1,GPIO2 and GPIO4, the following bits are Reserved in the PCNS, PCNP, PCNP, PDOR, PCOR, PTOR, PDIR, PDDR, PIDR, ISFRn registers.

- Bit[31:17] should be Reserved for GPIO1
- Bit[31:30] should be Reserved for GPIO2
- Bit[31:30] should be Reserved for GPIO4

21.2 Overview

GPIO communicates to the processor core via a zero wait-state interface for maximum pin performance.

21.2.1 Block diagram

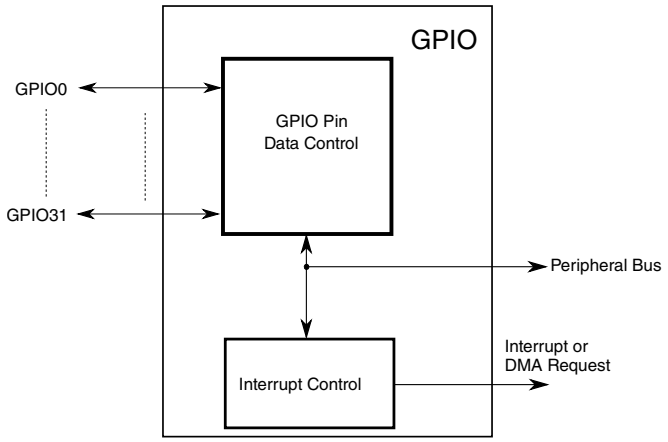

Figure 49. Block diagram

21.2.2 Features

- Port Data Input (PDIR) displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt modules for that pin are enabled.
- Port Data Output (PDOR), with corresponding set, clear, and toggle registers, controls the output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) controls the direction of each pin when the pin is configured for the GPIO function.
- Port Input Disable (PIDR) controls disabling of the input for each general-purpose pin.
- Pin interrupts:
  - Interrupt flags and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt or DMA request is configured for each pin.
  - Support for edge-sensitive (rising, falling, or both) or level-sensitive (low, high) interrupts is configured for each pin.
  - Asynchronous wake-up in Low-Power mode.
  - GPIO generates a total of 2 interrupts, and 2 DMA requests.
  - Each pin can be used to generate a single interrupt, or DMA request.
- Protection registers:
  - Each pin is configured for secure or nonsecure and privileged or nonprivileged access.
  - Each interrupt, and DMA request domain is configured for secure or nonsecure and privileged or nonprivileged access.

21.3 Functional description

21.3.1 Low-Power mode

You can configure GPIO to exit Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

21.3.2 Debug mode

GPIO remains functional in Debug mode.

21.3.3 General-purpose input

The logic state of each pin is available via Port Data Input (PDIR) if:

- The corresponding field in Port Input Disable (PIDR) is 0.
- The pin is configured for a digital function.

21.3.4 General-purpose output

The logic state of each pin is controlled via Port Data Output (PDOR) and Port Data Direction (PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input or output.

Table 109. General-purpose output

If	Then
A pin is configured for the GPIO function and the corresponding PDDR field is 0	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding PDDR field is 1	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR field.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allow one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

21.3.5 Clocking

GPIO receives a single clock, which is used for register access and synchronization with external pin inputs. There are no special considerations.

21.3.6 Reset

GPIO receives a single reset, which resets the peripheral. There are no special considerations.

21.3.7 External interrupts

The external interrupt capability of GPIO is available in all digital pin muxing modes.

GPIO generates a total of 2 interrupts, and 2 DMA requests. You can configure each pin individually for interrupt, or DMA requests:

- Each output implements a separate interrupt status flag (ISF) register for that domain.
- Each output generates a single interrupt.
- Each output generates a single DMA request.

You can configure each pin individually for any of the external interrupt modes shown in the following table.

Table 110. Available pin configurations for external interrupts

Signal conditions	Software polling using flags	Interrupts	DMA requests
Rising-edge	Yes	Yes	Yes
Falling-edge	Yes	Yes	Yes
Rising- and falling-edge	Yes	Yes	Yes
High-level	—	Yes	—
Low-level	—	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless GPIO is in Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

GPIO generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to either ISFR0[ISF*n*] or ICR0[ISF].

GPIO generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit Low-Power mode.

21.3.8 Global interrupt control

The two global interrupt control registers (Global Interrupt Control Low (GICLR) and Global Interrupt Control High (GICHR)) allow a single register write to update the upper 16 bits of Interrupt Control a (ICR0 - ICR31) for up to 16 pins, all with the same value.

These global interrupt control registers allow you to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read 0.

21.3.9 DMA

GPIO generates 2 requests. For each pin, you can configure DMA requests to assert for either rising, falling, or both edge detection. See External interrupts for more information.

21.3.10 Access protection

GPIO implements access protection registers (PCNS and PCNP) for each pin, as shown in Table 111.

Table 111. PCNS and PCNP register access protection implementation

Access	Description
Secure	You can write to or read the pins configured for secure access only in the Secure state.
Nonsecure	You can write to or read the pins configured for nonsecure access only in the Nonsecure state.
Privilege	You can write to the pins configured for privilege access only in the Privilege state.
Nonprivilege	You can write to the pins configured for nonprivilege access in both the Privilege and Nonprivilege states.

GPIO implements access protection registers (ICNS and ICNP) for each interrupt, and DMA request as shown in Table 112.

Table 112. ICNS and ICNP register access protection implementation

Access	Description
Secure	You can configure the outputs programmed for secure access only in the Secure state.
Nonsecure	You can configure the outputs programmed for nonsecure access only in the Nonsecure state.
Privilege	You can configure the outputs programmed for privilege access only in the Privilege state.
Nonprivilege	You can configure the outputs programmed for nonprivilege access in both the Privilege and Nonprivilege states.

You can write to the access protection registers (PCNS, PCNP, ICNS, and ICNP) only in the Secure-Privilege state; you can optionally lock these registers until the next reset.

Configuring a pin interrupt, or DMA request requires the following access permissions:

- Access permission to configure the pin.
- Access permission to either configure to the desired interrupt, or DMA request, or writing 0 to ICR*n*[IRQC].
- Access permission to either configure with the existing interrupt,, or DMA request, or if the current value of ICR*n*[IRQC] is 0.
- The interrupt configuration is not locked.

21.4 External signals

Table 113. External signals

Signal	Description		Direction
GPIO31–GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	

Table continues on the next page...

Table 113. External signals (continued)

Signal	Description		Direction
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each chip. See the "Signal Multiplexing" chapter for the number of GPIO pins within each port available on this chip.

21.5 Initialization

To initialize GPIO:

1. Initialize the GPIO pins for the output function:
   a. Configure the output logic value for each pin by using Port Data Output (PDOR).
   b. Configure the direction for each pin by using Port Data Direction (PDDR).
2. Initialize the interrupt function by writing to Interrupt Control a (ICR0 - ICR31) for the corresponding pins and desired configuration. If the pin is previously used for a different function, first write 0100_0000h to Interrupt Control a (ICR0 - ICR31) to disable the previous function and clear the flag.

21.6 Application information

GPIO includes the following applications:

- Reading the state of a single pin by performing a byte read of Pin Data (P0DR - P31DR).
- Updating the state of a single pin by performing a byte write to Pin Data (P0DR - P31DR).
- Reading the state of multiple pins by reading Port Data Input (PDIR).
- Updating the state of multiple pins by using the following ways:
  - Writing to Port Data Output (PDOR).
  - Writing to Port Set Output (PSOR) to write 1 to Port Data Output (PDOR).
  - Writing to Port Clear Output (PCOR) to write 0 to Port Data Output (PDOR).
  - Writing to Port Toggle Output (PTOR) to toggle Port Data Output (PDOR).

21.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the "Signal Multiplexing" chapter for the exact control bits of each port.

21.7.1 GPIO register descriptions

Fields

Field	Description
31-25 —	Reserved
24 ISF	Interrupt Status Flag Indicates whether the configured interrupt is detected. The pin interrupt configuration is valid in all digital pin muxing modes. The fields in Interrupt Status Flag (ISFR0 - ISFR1) have the same function. ISF can be cleared with either register field. If the pin is configured to generate a DMA request, then the corresponding flag is cleared automatically at the completion of the requested DMA transfer. Otherwise, the flag remains set until a logic 1 is written to the flag. If the pin is configured for a level-sensitive interrupt and the pin remains asserted, then the flag is set again immediately after it is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Not detected 1 - Detected

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When writing 0 - No effect 1 - Clear the flag
23 LK	Lock Locks ICR[23:0], and you cannot update the locked field until the next system reset. If this field is 0, interrupt configuration by ICR[23:0] is not locked and can be updated. If this field is 1, interrupt configuration by ICR[23:0] is locked and cannot be updated until the next system reset. 0 - Not locked 1 - Locked
22-21 —	Reserved
20 IRQS	Interrupt Select Configures the selected interrupt, or DMA request. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0 - Interrupt, or DMA request 0 1 - Interrupt, or DMA request 1
19-16 IRQC	Interrupt Configuration Specifies the ISF and DMA request configuration. The pin interrupt configuration is valid in all digital pin muxing modes. When changing the interrupt configuration, it is recommended to first disable ISF and then write the new configuration. The corresponding pin is configured to generate interrupt, or DMA request. **NOTE** See the GPIO chip-specific information to determine the GPIO instances that support interrupt, DMA request, or trigger capabilities. 0000 - ISF is disabled 0001 - ISF and DMA request on rising edge 0010 - ISF and DMA request on falling edge 0011 - ISF and DMA request on either edge 0100 - Reserved 0101 - ISF sets on rising edge 0110 - ISF sets on falling edge 0111 - ISF sets on either edge 1000 - ISF and interrupt when logic 0

When reading 0 - Not detected 1 - Detected When writing 0 - No effect 1 - Clear the flag

Chapter 22
Clock and Power Overview

22.1 Overview

This chip targets many applications with power requirements that include low power consumption, long battery life, always-on capability, instant-on capability, and doesn't require active cooling. To meet these requirements, the chip design focuses on reducing current consumption, while simultaneously enabling the maximum level of peak performance, and also a balanced level of sustained performance. The chip architecture uses a wide range of power-management techniques, used in combination, for system design flexibility.

This chapter describes these architecture details as a high-level clock and power management overview of the chip.

22.2 Components of Clock and Power Management

The centralized clock generation, power generation and distribution are implemented by the following blocks:

Table 114. Clock and Power Components

Name	Description
PLL	The chip supports Arm PLL, SYSTEM PLL, AUDIO PLL, DRAM PLL and VIDEO PLL.
Crystal OSC (XTALOSC)	The XTALOSC includes a 24 MHz oscillator. The 24MHz crystal oscillator is the primary clock source for all the PLLs, and clock generation for the CPU and high-speed interfaces as well as the low-speed clock source for CCM/SRC/GPC.
PLLs and PFDs	The PLLs and their associated PFDs generate the clocks with various frequencies required to feed the CCM clock generator that supplies the different functional blocks. See the PLL and PFD section in Clock Controller Module (CCM) for information on the PLL and PFD architecture, functional description and programming model.
Clock Control Module (CCM)	The CCM module provides control for clock generation, division, distribution, synchronization, and coarse-level gating. See Clock Controller Module (CCM) for information on the CCM architecture, functional description and programming model.
Low Power Clock Gating (LPCG)	The LPCG distributes the clocks to all blocks in the SoC and handles automated clock gating and block level software-controllable clock gating. See Clock Controller Module (CCM) for information on the LPCG architecture and functional description.
General Power Controller (GPC)	This module controls the power state of the SoC. The GPC handles the power gating under low power modes and also manages the power up / power down sequences. See the General Power Controller (GPC) chapter for information on the GPC architecture, functional description and programming model.
System Reset Controller (SRC)	This module generates the reset signals to all the modules in the SoC. The SRC will appropriately assert reset signals for power transitions, entry, and exit. See the System Reset Controller (SRC) chapter for information on the SRC architecture, functional description and programming model.

Together, the modules listed above provide enhanced power-management features with the centralized control for the clock, reset, and power-management signals on the SoC.

22.3 Power Management

The power management design on the chip satisfies many use cases that depend on a key balance of performance and low-power consumption. In order to meet these criteria, the system power management needs to be dynamic and flexible. This is accomplished on a multi-core system by utilizing a power scheme that considers each CPU domain, and arbitrates the appropriate power mode configuration to satisfy the needs of both CPUs, and the system as a whole. The following are additional features supported by the power management architecture:

- Programmable power mode transition rules
- Independent operation mode for individual CPU cores
- Intelligent clock and power management for multi-core architecture
- Unified power management interface (UPI) for all on-chip resources, including clock, power, reset, and peripherals

NOTE

- When switchable MIXes, such as MEDIAMIX/DDRMIX/WKUPMIX, are powered off, corresponding opposite SSI sides in NICMIX can generate SLVERR.
- Always-on MIXes, such as HSIOMIX/AONMIX, cannot be powered off, so cannot generate SLVERR by SSI.
- When clock gating is enabled, SSI cannot generate SLVERR for both switchable/always-on MIX.

22.3.1 Resources and Chip Domains

The chip is divided into resources and domains. Resources are controlled by resource controllers. Domains are grouped by central bus controllers and crossbars. Some domains reside within larger domains, which may have power dependencies. The Resource types and Chip Domains are listed in the tables below:

Table 115. Resources

Resource	Description
CPU Platforms	The processor and associated on-platform peripherals that support the complex. The CPU Platform supported on this chip is the A55 platform.
System Controllers	The System Controllers are the associated peripherals that control or define the power management resources for the chip. These modules include GPC, PMU, CCM, SRC.
Functional blocks	The functional blocks are comprised of all the other peripherals, other than System Controllers. These modules include external memory controllers, timers, high-speed and low-speed peripherals, audio and video peripherals, connectivity, and others.

22.3.2 Power Modes

The chip supports the following power modes: -

- RUN: In this mode, the Cortex®-A55 CPU is active and running, some portion can be shut off for power saving.
- Low Power RUN: This mode is defined as a very low power run mode with all external power rails are on. In this mode, all the unnecessary power domain (MIX) can be off, except AONMIX and the internal modules required, such as OSC24M/PLL. Cortex-A55 is power down and DRAM can be in self-refresh/retention mode. All the modules in the AONMIX, such as SAI/CAN/LPUART, can be used directly.
- IDLE: The CPU can automatically enter this mode when there is no thread running and all high-speed devices are not active. CPU can be put into power gated state but with L3 data retained, DRAM and bus clock are reduced, most of the internal logic is clock gated but still remain powered. Compared to RUN mode, all the external power from PMIC remains the same, and most of the modules remain their state, so the interrupt response in this mode is very small.
- SUSPEND: It is the most power saving mode where all the clocks are off and all the unnecessary power supplies are off. Cortex®-A55 CPU is fully power gated, all internal digital logic and analog circuit that can be power down will be off, all PHYs

are power gated. VDD_SOC (and related digital supply) Voltage is reduced to the “Suspend Mode” voltage. The exit time from this mode will be much longer than IDLE but the power consumption will also be much lower.

- BBSM: This mode is also called RTC mode. In this mode, only the power for the BBSM domain remain on to keep RTC and BBSM logic alive.
- OFF: This mode has all power rails OFF. BBSM, IDLE and SUSPEND are referred as Low Power Mode for the chip, SUSPEND and IDLE are the two typical low power modes defined based on the use case of Linux kernel.

22.3.2.1 Low Power Modes

The state of each module in the IDLE mode, SUSPEND mode and BBSM mode are defined in the table below.

	IDLE	SUSPEND
CCM LPM Mode	WAIT	STOP
ARM A55 CPU0	OFF	OFF
MEDIA	OFF	OFF
DRAM Controller & PHY	ON	OFF
ARM_PLL	OFF	OFF
DRAM_PLL	OFF	OFF
SYSTEM_PLL1	ON	OFF
XTAL	ON	OFF
RTC	ON	ON
External DRAM Device	Self-Refresh [1]	Self-Refresh [2]
DDR clock	266MHz	OFF
AXI clock	133MHz	OFF
Module clocks	ON as needed	OFF
GPIO wakeup	Yes	No
RTC wakeup	Yes	Yes
USB remote wakeup	Yes	No [3]
Other wakeup source	Yes	No
WAKEUPMIX	ON	OFF
NICMIX	ON as needed	OFF

1. Automatic enter self-refresh when there is no DRAM access
2. Put into self-refresh mode by SW before entering low power mode
3. Remote wakeup can be supported if the USB PHY power is on in this mode

22.3.2.2 CPU Power Modes

The Cortex®-A55 CPU platform supports the power states that are defined as CPU modes. The CPU Modes are detailed below.

Table 116. CPU Modes

CPU Mode	Description
RUN	The Cortex®-A55 CPU is active and running.
WAIT	The Cortex®-A55 CPU is in the WFI state. The CPU core and L1 cache are clock gated, TCM and peripheral can still be alive. The chip can wakeup from this mode from IRQ with a very short latency.
STOP	The Cortex®-A55 CPU is in the WFI state. The CPU core, L1 cache, TCM, and it's private peripherals are all clock gated. The chip requires a longer time to wakeup from this mode.
SUSPEND	The Cortex®-A55 CPU core and L1 cache are power gated (except the cache). The TCM is in retention mode. SUSPEND mode consumes the least amount of power, while keeping parts of the system alive. But the chip requires a much longer time to wakeup from this mode.
OFF	The Cortex-A55 core supports a full shutdown mode where power can be removed completely and no state is retained.

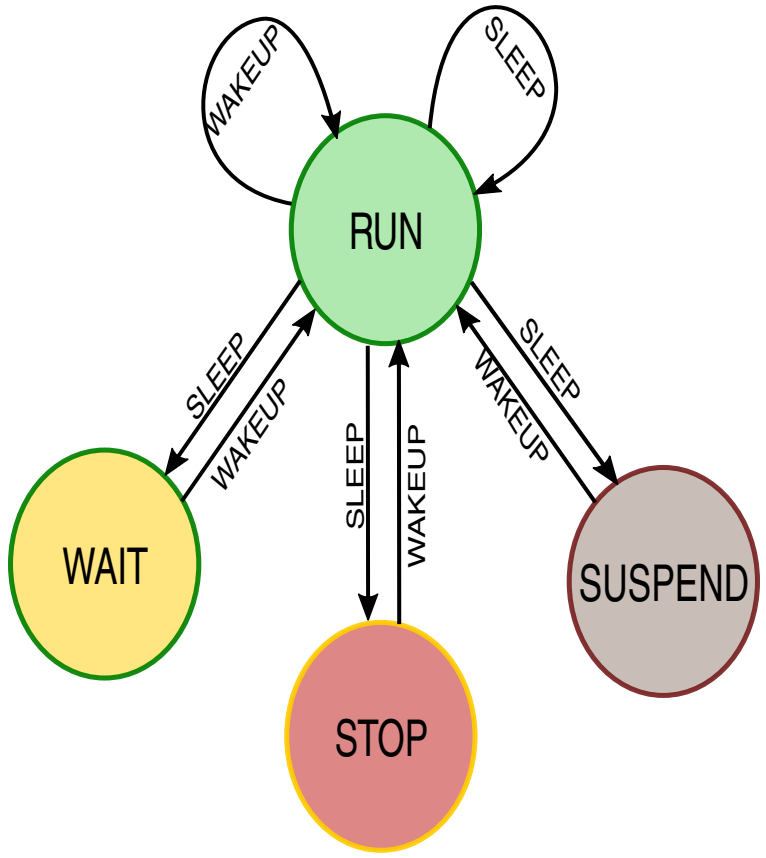

Figure 50. CPU Modes

22.3.3 Power Sequence

The power up and power down sequence is optimized for use with an external PMIC.

Power Up:

1. NVCC_BBSM_1P8 supply must be turned on. The chip will assert PMIC_ON_REQ at this point in time.

2. VDD_SOC digital voltage supplies should be turned on.
3. VDD analog, PHY and PLL supplies should be turned on.
4. All remaining 1.8V supplies should be turned on including VDD_1P8 analog, PHY and PLL supplies and 1.8V NVCC IO supplies.
5. DDR IO supplies should be turned on.
6. All 3.3V supplies must be turned on, including 3.3V NVCC IO supplies and VDD_USB_3P3.

NOTE

3.3V supply step may be simultaneous with either the 1.8V or the DDR supplies if desired.

7. POR_B should be released. It should be asserted during the entire power up sequence.

Power Down:

- NVCC_BBSM_1P8 supply must be turned off after any other power supply.
- VDD_SOC must be turned off after the other (non-BBSM) power rails or at the same time as other (non-BBSM) rails. No sequence for other power rails during power down.

22.4 Clocks

22.4.1 Clock System Diagram

The overall clock system for the chip is shown in the diagram below.

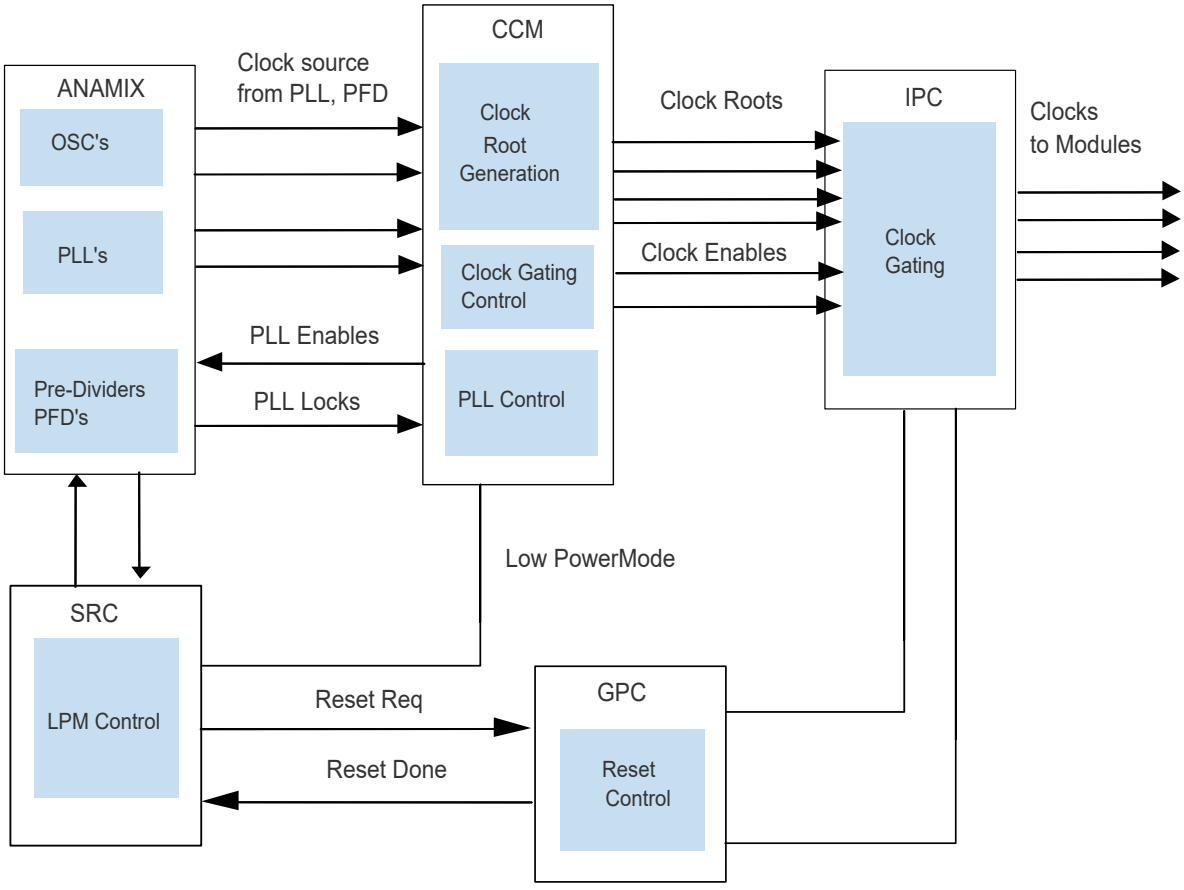

Figure 51. Clock System

The OSCs, PLLs, PFDs and Pre-Dividers generate the clock sources with fixed or variable frequency. The clock sources feed the clock root generation logic inside CCM, which generates numerous clock roots required for core, bus, and peripheral blocks. These clock roots are branched to each module through the LPCG logic, which contains the clock gating cells for each clock. Control signals for the LPCGs are in CCM (clock enable signal). Some of the clocks need to be gated off during reset, because of this, the SRC module will also send clock gate signals to the LPCG.

In low power mode, GPC will drive the low power mode state signal to CCM, then CCM will enable clock gating based on the configuration. At the same time, CCM may also deassert enable signals for PLLs and PFDs, so these modules can power off during low power modes. When the chip enters STOP mode, CCM may deassert the OSC enable signal to shut off the OSC, it may also assert the STOP mode signal to set OSC to low power mode.

The detailed functional description for each block will be described in the following sections.

22.4.2 Oscillators

This chip has two XTAL modules:

- 24MHz XTAL module for system clock
- 32KHz XTAL module for RTC

22.4.3 PLL and PFD

The PLLs are used in the chip to generate the high speed clocks required by the modules in SoC. A few PLLs are equipped with Phase Fractional Dividers (PFDs) in order to generate additional frequencies. The following PLLs are used in this chip:

Table 117. PLLs

PLL	Description	Spread Spectrum	Configurable
ARM_PLL	The ARM_PLL/INTEGER PLL is used to generate the clock for the Arm Cortex-A55 platform. It is a programmable integer-frequency multiplier PLL, capable of an output frequency over 1 GHz. This PLL is physically located near the high-speed Cortex-A55 processor.	-	Yes
SYS_PLL1	This is a fractional PLL fixed at a fixed VCO frequency of 4.0GHz. Attached to this integer PLL are 3 PFD (phase frequency detector) circuits, also referred to as DFS (digital frequency synthesis) circuits, which generate Fclkout = FVCO/(MFI+MFN/5)). The PLL PFDs also have a fixed /2 divisor output, so that /2 of each of the 3 clocks are also available for use by the CCM. These clock sources will be used for the majority of AXI/AHB buses in the chip.	Yes[1]	Yes
AUDIO_PLL	An AVPLL used to generate reference clocks, mainly for serial audio interfaces, and external audio codecs. This fractional multiplier PLL provides a low-jitter and high precision audio clock with standardized audio frequencies.	Yes	Yes
VIDEO_PLL	An AVPLL used to generate reference clocks, mainly for display and video interfaces. This fractional multiplier PLL provides a low-jitter and high-precision video clock at standardized video frequencies.	Yes	Yes

1. SYSTEM_PLL1 is also used to generate the 125MHz clocking for Ethernet RGMII. So spread spectrum on SYSTEM_PLL1 can only be enabled when Ethernet is not used.

NOTE

Please see the datasheet for all supported maximum PLL frequencies.

Each PLL can use one of the following clock sources as it's reference clock:

- Primary Option: 24 MHz clock from 24 MHz oscillator (XTAL).

The SYS_PLL, DRAM_PLL, AUDIO_PLL and VIDEO_PLL have the capability to spread spectrum the generated signal. They do not require exact/constant frequency, and can be changed as a part of dynamic frequency scaling procedure and/or can be spread-spectrum modulated.

Only the AUDIO_PLL has the capability to spread spectrum the generated signal. It does not require exact/constant frequency, and can be changed as a part of dynamic frequency scaling procedure and/or can be spread-spectrum modulated.

The main output clocks for the PLLs (PLLx_CLK) are not configurable, but their PFDs are. Each PFD works independently by interpolating the VCO of the PLL to which it is connected. It effectively takes the PLL VCO frequency and produces 18/N x Fvco at it's output where N ranges from 12 to 35. PFD is a completely digital design with no analog components or feedback loops. The frequency switch time is much faster than a PLL because keeping the base PLL locked and changing the integer N only changes the logical combination of the interpolated outputs of the VCO. Note that the PFD not only enables faster frequency

changes than a PLL, but also allows the configuration to be safely changed "on-the-fly" without going through the output clock disabling/enabling process.

The basic logical connections for the PLLs, PFDs and Dividers is shown in the diagram below:

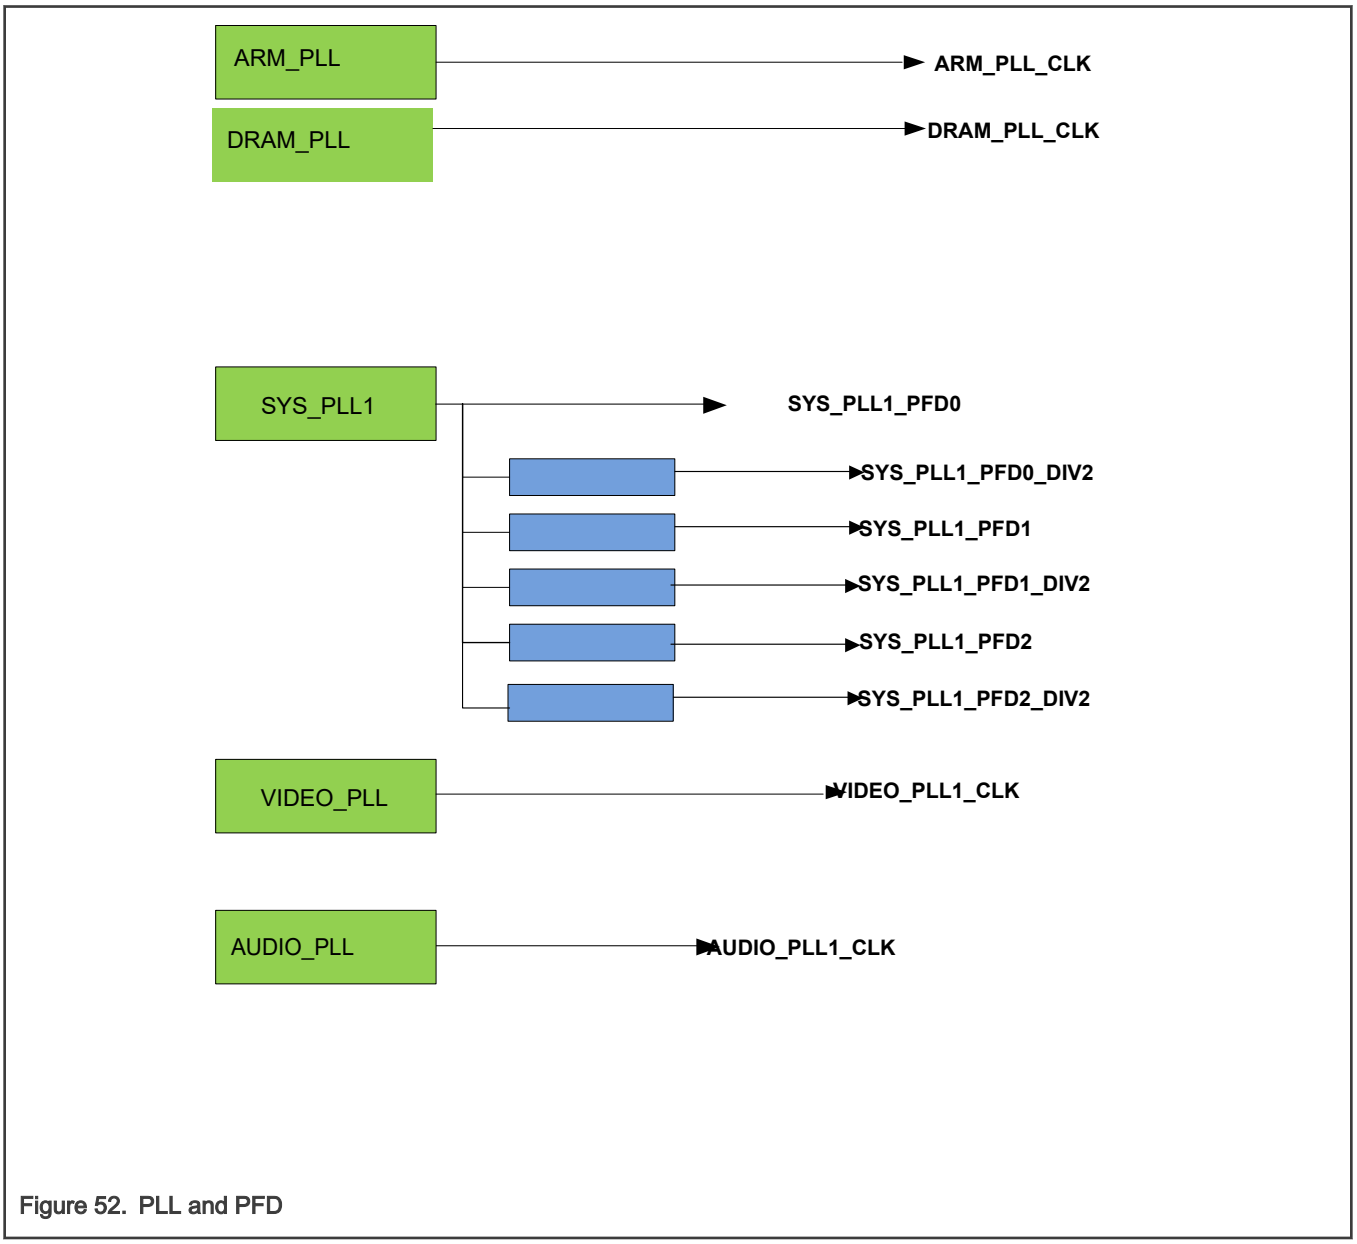

Figure 52. PLL and PFD

PLL configuration and control functions are accessible via configuration and status registers. The CCM block contains the detailed descriptions of the memory mapped registers, and control functions of the clock generation sub-module. Please see CCM for more information.

22.4.4 Clock Root Generation

Clock generation in the CCM creates clock roots for on-chip peripherals. Each clock root will have a dedicated clock slice. It takes the clock source from Oscillators, PLL/PFD or Pre-Dividers, and generate the clock root with required frequency.

The CCM can manage on-chip peripheral clocks by controlling the low power clock gating cells (LPCGs) before the clock roots enter the peripherals.

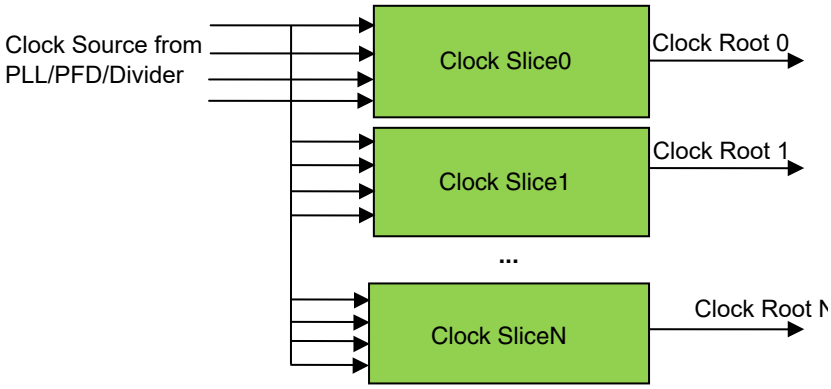

Figure 53. Clock Root Generation from Clock Slice

The LPCGs are implemented to control peripheral functions, and there could be several LPCGs for each functions in a peripheral.

For details on the programming model, please refer to CCM Memory Map/Register Definition.

22.4.5 Low Power Clock Gating (LPCG)

The clock roots generated inside CCM are distributed to the entire SoC through LPCG. The LPCG block receives the root clocks from CCM and splits them to clock branches for each functional block. The clock branches are individually gated clocks.

See the CCM chapter for more information about clock gating.

Chapter 23
Clock Controller Module (CCM)

23.1 Overview

The Clock Control Module (CCM) manages the on-chip module clocks. The oscillators, PLLs, and Phase Fractional Dividers (PFD) will generate clock sources with fixed or variable frequencies.

23.1.1 Block diagram

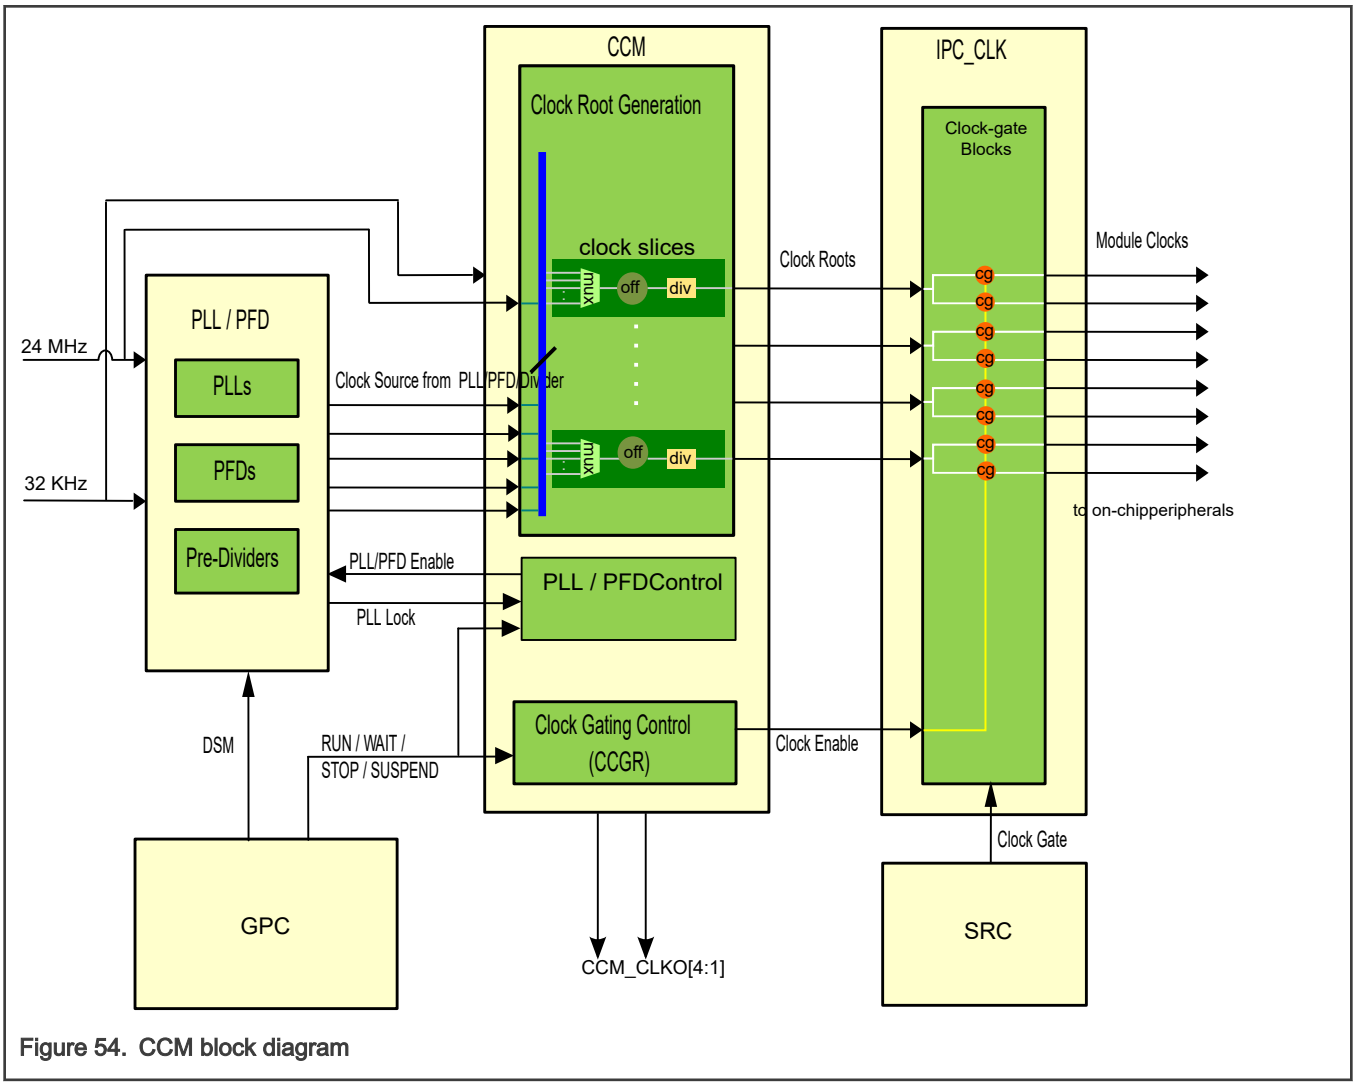

Figure 54. CCM block diagram

The clock root generation logic inside CCM will generate various clock roots required for core, bus, and peripheral blocks. These clock roots will be delivered to each module through IPC_CLK, which contains the clock gating logic for each clock.

The control signal for CCGRs in CCM will be the source for clock enable signals. Since some of the clocks need to be gated off during the reset, the System Reset Controller (SRC) will also send clock gate signals to the IPC_CLK.

In low power mode, the General Power Controller(GPC) will drive the low power mode state signal to CCM, and CCM will enable clock gating based on the configuration. At the same time, CCM may also de-assert enable signals for PLLs/PDFs, so these modules can be powered off during the low power mode.

23.1.2 Features

The CCM includes the following features:

- Clock Root
  - Up to 4 clock sources for each clock root
  - 8-bit divider support up to divide by 256 in each clock root
  - Each clock root can be shutdown by software
- Peripheral clock can be auto gated according to CPU work mode, software configurations, or system work mode
- PLLs and PFDs can be auto shutdown according to CPU work mode, software configurations, or system work mode
- Access Control
  - Two access control schemes: Trustzone, and Domain
  - Write access to each component can be protected independently
  - Independent setting for user, privileged, secure, non-secure
  - Domain mode access can be controlled by whitelist
  - Access control setting can be locked independently

23.2 System Clocks

The table found here shows the CCM output clocks' system-level connectivity.

Table 118. System Clocks Table

23.3 Functional description

CCM is comprised of several functional blocks:

- Clock Root
- Clock Gate
- Clock Source
- General Purpose Registers (GPR)

These functions can be configured under various CCM modes. The first section will describe the ways to configure these functions under different CCM modes. And the other sections will describe these functions independently.

23.3.1 Configuration of Functions

CCM functional blocks support the following modes:

- Direct Configuration mode
- CPU Low Power mode
- Auto mode (only for clock sources)

The default CCM mode is Direct Configuration mode.

23.3.2 Clock Sources

Clock roots are generated from various clock sources, which can be either oscillators or PLLs. Clock source is implemented to control PLLs and oscillators, to be automatically turned OFF or ON on system low power actions.

The following table shows the clock sources for the CCM:

Table 119. Clock Sources

Control Channel	Clock Source	Description
OSCPLL0	OSC_24M_CLK	OSC 24MHz CLK
OSCPLL1	ARM PLL	ARM PLL VCO (Not connected to the clock tree)
OSCPLL2	ARM PLL CLK	ARM PLL output clock
OSCPLL3	SYSTEM PLL	SYSTEM PLL VCO (Not connected to the clock tree)
OSCPLL4	SYSTEM PLL PFD0	SYSTEM PLL PFD0 (OSCPLL channel can reset SYSTEM PLL PFD. It handles DFS[ENABLE].)
OSCPLL5	SYSTEM PLL PFD0 CLK	SYSTEM PLL PFD0 clock (OSCPLL channel can gate off SYSTEM PLL PFD0 CLK. It handles DFS[CLKOUT_EN].)
OSCPLL6	SYSTEM PLL PFD0 DIV2 CLK	SYSTEM PLL PFD0 divided by 2 clock
OSCPLL7	SYSTEM PLL PFD1	SYSTEM PLL PFD1 (OSCPLL channel can reset SYSTEM PLL PFD. It handles DFS[ENABLE].)
OSCPLL8	SYSTEM PLL PFD1 CLK	SYSTEM PLL PFD1 clock (OSCPLL channel can gate off SYSTEM PLL PFD0 CLK. It handles DFS[CLKOUT_EN].)
OSCPLL9	SYSTEM PLL PFD1 DIV2 CLK	SYSTEM PLL PFD1 divided by 2 clock
OSCPLL10	SYSTEM PLL PFD2	SYSTEM PLL PFD2 (OSCPLL channel can reset SYSTEM PLL PFD. It handles DFS[ENABLE].)
OSCPLL11	SYSTEM PLL PFD2 CLK	SYSTEM PLL PFD2 clock (OSCPLL channel can gate off SYSTEM PLL PFD0 CLK. It handles DFS[CLKOUT_EN].)
OSCPLL12	SYSTEM PLL PFD2 DIV2 CLK	SYSTEM PLL PFD2 divided by 2 clock

Table continues on the next page...

Table 119. Clock Sources (continued)

Control Channel	Clock Source	Description
OSCPLL13	AUDIO PLL	AUDIO PLL VCO (Not connected to the clock tree)
OSCPLL14	AUDIO PLL CLK	AUDIO PLL output clock
OSCPLL15	DRAM PLL	DRAM PLL VCO (Not connected to the clock tree)
OSCPLL16	DRAM PLL CLK	DRAM PLL output clock
OSCPLL17	VIDEO PLL	VIDEO PLL VCO (Not connected to the clock tree)
OSCPLL18	VIDEO PLL CLK	VIDEO PLL output clock
OSC_PLL19	OSC_32K_CLK	OSC_32KHz_CLK

NOTE

The clock source calculates whether the clock is required for each CPU domain. If clock source is not needed for any domain, clock will be shutdown.

Clock Source blocks have 3 work mode: Direct Control mode, CPULPM mode and Auto mode. Direct Control mode is the default mode. After reset, all Clock Source blocks work in Direct Control mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. Trustzone unauthenticated access will be ignored.

The OSCPLLn_AUTHEN and OSCPLLn_DIRECT registers can be changed in any mode, while the write access should be from the domain granted by OSCPLLn_AUTHEN[WHITE_LIST] and Trustzone authenticated. The default value of OSCPLLn_AUTHEN[WHITE_LIST] is 0xFFFF, which means all 16 domains are granted.

The OSCPLLn_LPM_CUR registers can only be written in CPULPM mode, otherwise the write access will be ignored. And the write access in CPULPM mode should also comply with the Trustzone access control.

In Direct Control mode, the ON/OFF of clock source is determined by OSCPLLn_DIRECT[ON] directly. The default state of OSCPLL is ON.

In CPULPM mode, the ON/OFF of clock source is dependent on the settings in OSCPLLn_LPMs and the current mode every domain is in. There are 3-bit clock dependent level settings for each domain respectively. The bigger the 3-bit value is, the stronger the clock is dependent. Valid values are as follows:

- 0: this clock is not needed in any mode
- 1: this clock is needed in RUN mode, but not needed in WAIT, STOP, SESPEND mode
- 2: this clock is needed in RUN and WAIT mode, but not needed in STOP, SUSPEND mode
- 3: this clock is needed in RUN, WAIT and STOP mode, but not needed in SUSPEND mode
- 4: this clock is needed in RUN, WAIT, STOP and SUSPEND mode

NOTE

The mode above means the mode of domain (CPU platform) instead of CCM mode. There are 4 CPU mode: RUN, WAIT, STOP and SUSPEND. If the CPU is in SUSPEND mode, all clocks are treated as NOT needed.

For PLLs which are used as input to CCM for use as clock roots by the SoC (this in general includes all PLLs in ANAMIX but not SoC-specific PLLs elsewhere in the SoC which are only used by one MIX or PHY), an AUTO_CTRL feature is supported in the CCM. When AUTO_CTRL is enabled, if a PLL is not selected by any CCM clock root, then that PLL will be disabled automatically. Similarly, if a PLL has multiple PFD outputs and a given PFD output is not selected by any CCM clock root, then that PFD output will be disabled automatically.

23.3.3 Clock Root

CCM clock root generation contains multiple clock root channels. All clock roots are asynchronous each other, even all the clock root setting are the same.

Each clock channel contains an 4-to-1 MUX, and a 8-bit divider. The clock MUX selects 1 clock out of 4 clock inputs. The 8-bit divider can divide selected clock by up to 256. The clock output of the clock channel can be gated off.

The clock root channel setting can be changed from any value to any value, and at any time. It is also possible to change the clock setting when the clock root channel is gating off. If more than one setting is changed at the same time, internal logic will use a procedure to change the setting. The procedure will make sure the clock output is not faster than the current clock root setting or target clock root setting. If the application does care about the clock during transition, software will need to change the setting one field at a time. This typically happens when a clock must be faster than the given frequency. In this case, the application needs to change each field one at a time and wait for the field to take effect before changing the next field.

Although a clock root channel is designed to be able to switch clocks regardless of clock input status. When the current selected clock input is off, the application needs to avoid changing the clock MUX after the clock input is turned on. This will lead to unstable behavior for the clock root and loading peripherals. To avoid this scenario, the application can either switch the clock MUX before turning on the clock input, or wait until the clock input is stable before changing the MUX option.

The division fractor of the divider is equal to CLOCK_ROOTn_CONTROL[DIV]+1.

All registers are readable for any domain in any mode, but write access are restricted. Unauthenticated write access will be ignored. Only the access from the domains on the whitelist can change the value of CLOCK_ROOTn_CONTROL register, after passing trustzone authentication.

NOTE

LPIT1, TPM1 is clocked by AON bus and LPIT2, TPM3 is clocked by WAKEUP bus. LPIT1, TPM1 and LPIT2, TPM3 have their trigger output 0 used as input by CAN1 and CAN2 respectively. Because of this, these instances are clocked by the bus clock - the same clock used to clock the respective CAN module (bus_aon_clk_root and bus_wakeup_clk_root respectively) in order to ensure that these signals are timed synchronously between these modules.

NOTE

The tstmr1_clk_root, tstmr2_clk_root, mqs1_clk_root, mqs2_clk_root are not used.

23.3.4 Clock Gate

Before a clock root goes to on-chip peripherals, the clock roots go through the IPC_CLK. These IPC_CLK are implemented to perform automatic clock gating when a domain enters and leaves low-power states. The IPC_CLKs are mapped to peripherals so software can be simplified. IPC_CLKs are also implemented to control peripheral functions, and different IPC_CLKs could interface different clocks of the peripheral.

Clock gates have 2 work modes: Direct Control mode and CPULPM mode. Direct Control mode is the implicit mode. After reset, all clock gates work in Direct Control mode.

All registers are readable for any domain in any mode, but write access is restricted for protection. Trustzone unauthenticated access will be ignored.

The LPCGn_AUTHEN and LPCGn_DIRECT registers can be changed in any mode, while the write access should be from the domain granted by LPCGn_AUTHEN[WHITE_LIST] and Trustzone authenticated. The default value of LPCGn_AUTHEN[WHITE_LIST] is 0xFFFF, which means all 16 domains are granted.

The LPCGn_LPM_CUR registers can only be written in CPULPM mode, otherwise the write access will be ignored. And the write access in CPULPM mode should also comply with the Trustzone access control.

In Direct Control mode, the ON/OFF of LPCG is determined by LPCGn_DIRECT[ON] directly. The default state of LPCG is ON.

In CPULPM mode, the ON/OFF of LPCG is dependent on the settings in LPCGn_LPMs and the current mode every domain is in. There are 3-bit clock dependent level settings for each domain respectively. The bigger the 3-bit value is, the stronger the clock is dependent. Valid values are as follows:

- 0: this clock is not needed in any mode
- 1: this clock is needed in RUN mode, but not needed in WAIT, STOP, SUSPEND mode
- 2: this clock is needed in RUN and WAIT mode, but not needed in STOP, SUSPEND mode
- 3: this clock is needed in RUN, WAIT, STOP, SUSPEND mode

NOTE

The mode above means the mode of domain (CPU platform) instead of CCM mode. There are 4 CPU mode: RUN, WAIT, STOP and SUSPEND. If the CPU is in SUSPEND mode, all clocks are treated as NOT needed.

In CPULPM mode, LPCG will calculate whether the clock is required by any CPU domain. If clock is not needed for any domain, the clock will be shutdown.

NOTE

The mode above means the mode of domain (CPU platform) instead of CCM mode. There are 4 CPU mode: RUN, WAIT, STOP and SUSPEND. If the CPU is in SUSPEND mode, all clocks are treated as NOT needed.

In CPULPM mode, LPCG will calculate whether the clock is required by any CPU domain. If clock is not needed for any domain, the clock will be shutdown.

23.3.5 General Purpose Registers (GPR)

The general purpose registers provide miscellaneous controls and data saving functions. The GPRs are divided in two regions - shared and private region.

In shared region, all CPU domains access the same registers. If any CPU updates the value in the shared region, all the other CPU domains can read out the new value. The registers have an access control bit field to protect it from being changed unexpectedly.

In private region, each CPU domain has its own register. A CPU domain can only access registers belonging to itself. Since all the registers share the same address, a CPU domain will not have access to registers belonging to another CPU domain.

Shared registers can be read by any domain at any time, while write access to shared registers must be from domains granted by GPR_SHAREDn_AUTHEN[WHITE_LIST] and Trustzone authenticated. Every shared register has independent whitelist.

Private registers can be and only can be read or written by corresponding domain with Trustzone authentication.

GPR_SHAREDn_AUTHEN and GPR_PRIVATEn_AUTHEN registers can be read by any domain at any time, but the write access must be from domains granted by respective whitelist and Trustzone authenticated.

Type	GPR	Position	Width	Description
Shared	0	0	2	EXT_CLK_SEL. Selecting ext_clk from 4 external clocks: • 00b - Select ext1_clk. • 01b - Select ext2_clk. • 10b - Select ext3_clk. • 11b - Select ext4_clk. Changing the value of this field when ext_clk is used is not allowed, otherwise ext_clk will be gated off. Note: Only EXT_CLK1 exists in Imx91.
Shared	1	32	1	arm_pll_sel.
Shared	2	64	1	dram_pll_sel.

23.4 Reset

The reset of CCM will be released along with system early reset and clocks are provided during system reset. For each power domain, early reset of the power domain in which that clock gate resides, will be fed for correct power up and reset flow.

23.5 CCM Memory Map and Register definition

23.5.1 CCM register descriptions

23.5.1.1 D_IP_MX91_CCM memory map
