23.5.1.2 Clock Root Control Register (CLOCK_ROOT0_CONTROL - CLOCK_ROOT94_CONTROL)

This register controls clock root generation, including enable, MUX selection and division factor.

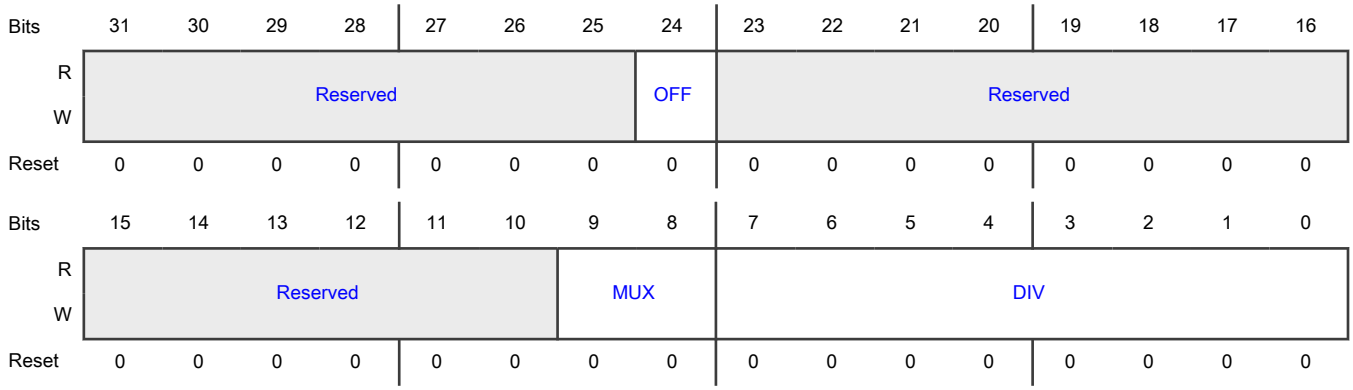
Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 94:

Register	Offset	Description
CLOCK_ROOTa_CONTROL	0h + (a × 80h)	Clock Root Control Register
CLOCK_ROOTa_CONTROL_SET	4h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 1
CLOCK_ROOTa_CONTROL_CLR	8h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_CONTROL is 0
CLOCK_ROOTa_CONTROL_TOG	Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_CONTROL

Diagram



Fields

Field	Description
31-25 —	Reserved
24 OFF	Shutdown clock root. Turn off the generated clock root or not. 0 - Clock is running. 1 - Turn off clock.

Table continues on the next page...

Table continued from the previous page...

Field	Description
23-10 —	Reserved
9-8 MUX	Clock multiplexer. Select clock from 4 clock sources to generate the clock root. 00 - Select clock source 0 01 - Select clock source 1 10 - Select clock source 2 11 - Select clock source 3
7-0 DIV	Clock division fraction. The period of generated clock root is DIV + 1 times longer than selected clock source.

23.5.1.3 Clock root working status (CLOCK_ROOT0_STATUS0 - CLOCK_ROOT94_STATUS0)

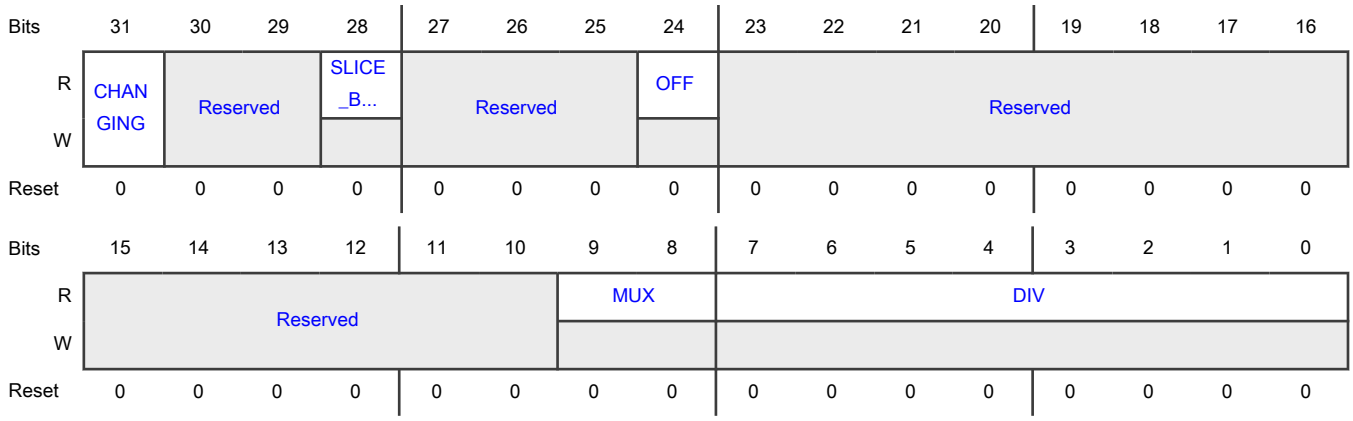
This register shows current clock root running status.

Offset

For a = 0 to 94:

Register	Offset
CLOCK_ROOTa_STATUS0	20h + (a × 80h)

Diagram



Fields

Field	Description
31 CHANGING	Internal updating in clock root This bit indicates the update status of internal clock root logic. 0 - Clock Status is not updating currently 1 - Clock generation logic is updating currently
30-29 —	Reserved
28 SLICE_BUSY	Indication for clock generation logic is applying new setting. 0 - Clock generation logic is not busy. 1 - Clock generation logic is applying new setting.
27-25 —	Reserved
24 OFF	Current clock root OFF setting Current running state of OFF field for clock root. 0 - Clock is running. 1 - Turn off clock.
23-10 —	Reserved
9-8 MUX	Current clock root MUX setting Current running state of MUX field for clock root.
7-0 DIV	Current clock root DIV setting Current running state of DIV field for clock root. The period of generated clock root is DIV + 1 times longer than selected clock source.

23.5.1.4 Clock root access control (CLOCK_ROOT0_AUTHEN - CLOCK_ROOT94_AUTHEN)

This register controls the access to this Clock Root slice. The access control includes 2 parts: TrustZone control and domain based granting.

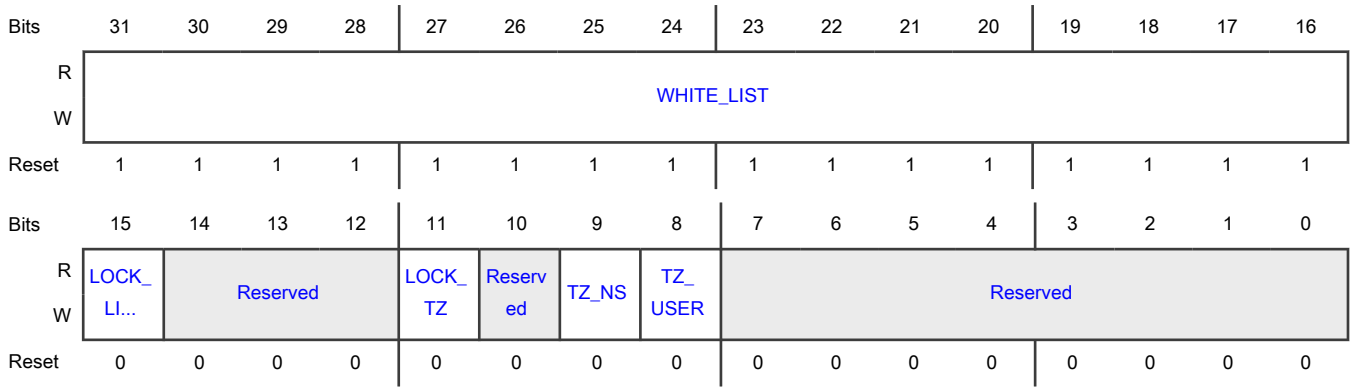
Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 94:

Register	Offset	Description
CLOCK_ROOTa_AUTHEN	30h + (a × 80h)	Clock root access control
CLOCK_ROOTa_AUTHEN_SET	34h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_AUTHEN is 1
CLOCK_ROOTa_AUTHEN_CLR	38h + (a × 80h)	Writing 1 to a bit in this register ensures that the corresponding bit in CLOCK_ROOTa_AUTHEN is 0
CLOCK_ROOTa_AUTHEN_TOG	3Ch + (a × 80h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in CLOCK_ROOTa_AUTHEN

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the given clock root.
15 LOCK_LIST	Lock white list This bit locks whitelist of this Clock Root. When this bit is set, CLOCK_ROOTn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, CLOCK_ROOTn_AUTHEN[TZ_USER] and CLOCK_ROOTn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone setting is not locked. 1 - TrustZone setting is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this Clock Root can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this Clock Root. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this Clock Root can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this Clock Root. 0 - Clock Root settings cannot be changed in user mode. 1 - Clock Root settings can be changed in user mode.
7-0 —	Reserved

23.5.1.5 General Purpose Register (GPR_SHARED0)

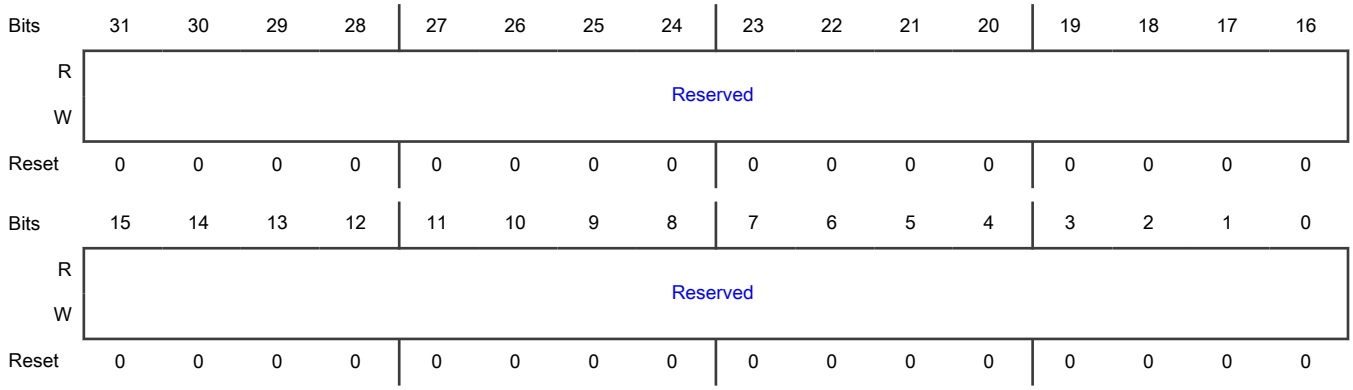
These registers are shared general purpose registers.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED0	4800h	General Purpose Register
GPR_SHARED0_SET	4804h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0 is 1
GPR_SHARED0_CLR	4808h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0 is 0
GPR_SHARED0_TOG	480Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED0

Diagram



Fields

Field	Description
31-0 —	Reserved

23.5.1.6 GPR access control (GPR_SHARED0_AUTHEN)

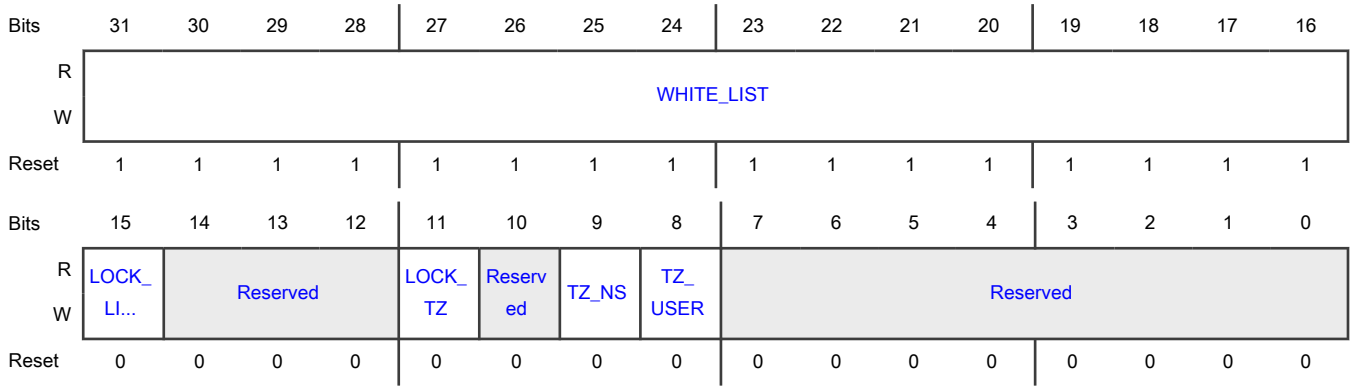
This register manages GPR access control. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED0_AUTHEN	4810h	GPR access control
GPR_SHARED0_AUTHEN_SET	4814h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0_AUTHEN is 1
GPR_SHARED0_AUTHEN_CLR	4818h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED0_AUTHEN is 0
GPR_SHARED0_AUTHEN_TOG	481Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED0_AUTHEN

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the shared GPR.
15 LOCK_LIST	Lock white list This bit lock whitelist. When this bit is set, GPR_SHAREDn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit lock TrustZone settings. When this bit is set, GPR_SHAREDn_AUTHEN[TZ_USER] and GPR_SHAREDn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Whether the registers of this shared GPR can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this shared GPR. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this shared GPR can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this shared GPR. 0 - Registers of shared GPR slice cannot be changed in user mode. 1 - Registers of shared GPR slice can be changed in user mode.
7-0 —	Reserved

23.5.1.7 General Purpose Register (GPR_SHARED1)

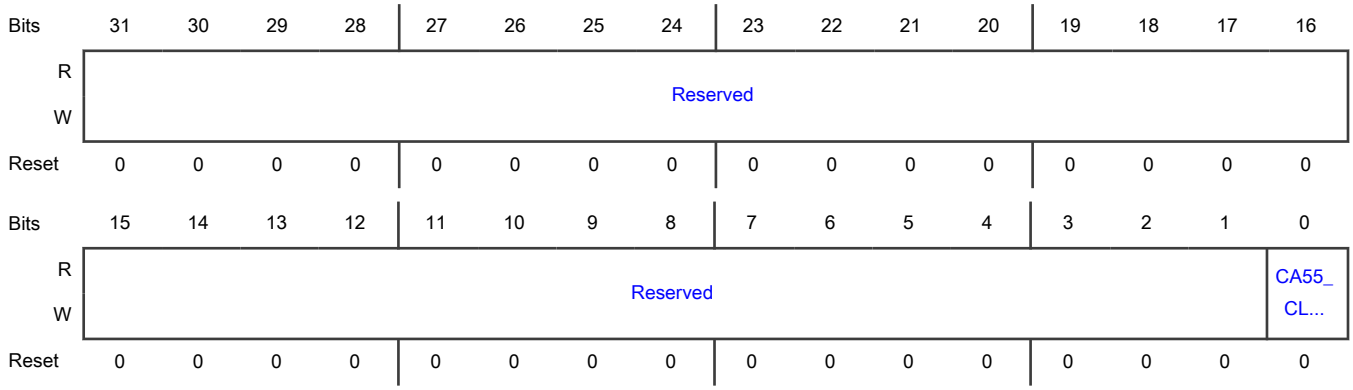
These registers are shared general purpose registers.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED1	4820h	General Purpose Register
GPR_SHARED1_SET	4824h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1 is 1
GPR_SHARED1_CLR	4828h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1 is 0
GPR_SHARED1_TOG	482Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED1

Diagram



Fields

Field	Description
31-1 —	Reserved
0 CA55_CLOCK_SELECT	Clock select signal between ccm clock root and ARM PLL clock This signal goes to ca55mix, used as clock select signal for ca55 0 - Clkroot_arm_a55 is used. 1 - The clock output of ARM PLL is selected.

23.5.1.8 GPR access control (GPR_SHARED1_AUTHEN)

This register manages GPR access control. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
GPR_SHARED1_AUTHEN	4830h	GPR access control
GPR_SHARED1_AUTHEN_SET	4834h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1_AUTHEN is 1
GPR_SHARED1_AUTHEN_CLR	4838h	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_SHARED1_AUTHEN is 0
GPR_SHARED1_AUTHEN_TOG	483Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_SHARED1_AUTHEN

Fields

Field	Description
31-0 GPR	GP register General purpose register. This register has dedicated bits for each domain.

23.5.1.14 GPR access control (GPR_PRIVATE0_AUTHEN - GPR_PRIVATE7_AUTHEN)

This register controls the access to this private GPR slice. The access control includes 2 parts: TrustZone control and domain based granting.

NOTE

The domain based granting only influence the access to GPR_PRIVATEn_AUTHEN.

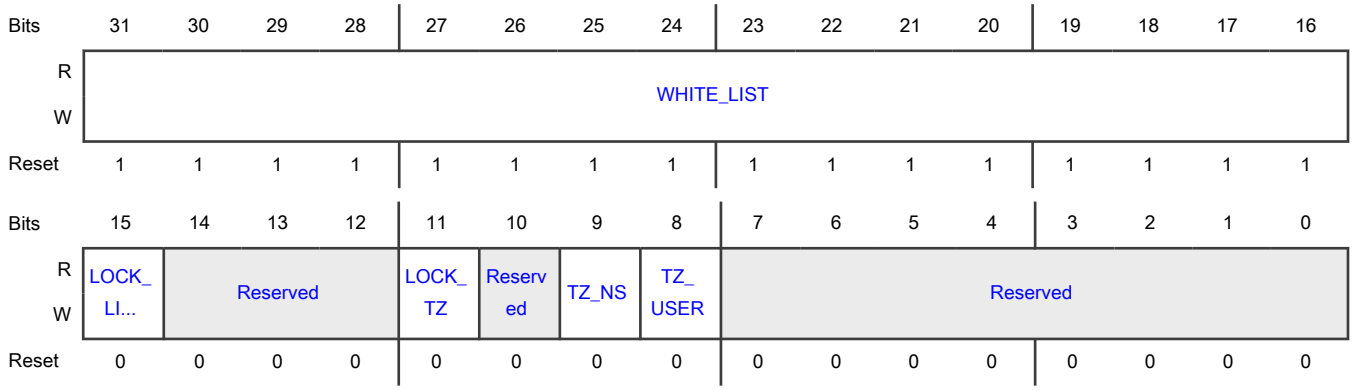
Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

For a = 0 to 7:

Register	Offset	Description
GPR_PRIVATEa_AUTHEN	4C10h + (a × 20h)	GPR access control
GPR_PRIVATEa_AUTHEN_SET	4C14h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 1
GPR_PRIVATEa_AUTHEN_CLR	4C18h + (a × 20h)	Writing 1 to a bit in this register ensures that the corresponding bit in GPR_PRIVATEa_AUTHEN is 0
GPR_PRIVATEa_AUTHEN_TOG	4C1Ch + (a × 20h)	Writing 1 to a bit in this register inverts the value of the corresponding bit in GPR_PRIVATEa_AUTHEN

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Whitelist settings Each bit in this field represent for one domain. Bit16~Bit31 represent for DOMAIN0~DOMAIN15 respectively. Only the corresponding bit of TRDC domain which is set to 1 can change the registers of this private GPR.
15 LOCK_LIST	Lock white list This bit lock whitelist. When this bit is set, GPR_PRIVATEn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit lock TrustZone settings. When this bit is set, GPR_PRIVATEn_AUTHEN[TZ_USER] and GPR_PRIVATEn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this private GPR can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this private GPR. 0 - Cannot be changed in Non-secure mode.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this private GPR can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this private GPR. 0 - Registers of privat GPR cannot be changed in user mode. 1 - Registers of private GPR can be changed in user mode.
7-0 —	Reserved

23.5.1.15 Clock source direct control (OSCPLL0_DIRECT - OSCPLL19_DIRECT)

This register controls the ON/OFF of clock source when clock source is working in Direct Control mode.

Offset

For a = 0 to 19:

Register	Offset
OSCPLLa_DIRECT	5000h + (a × 40h)

23.5.1.20 LPM setting of current CPU domain (OSCPLL0_LPM_CUR - OSCPLL19_LPM_CUR)

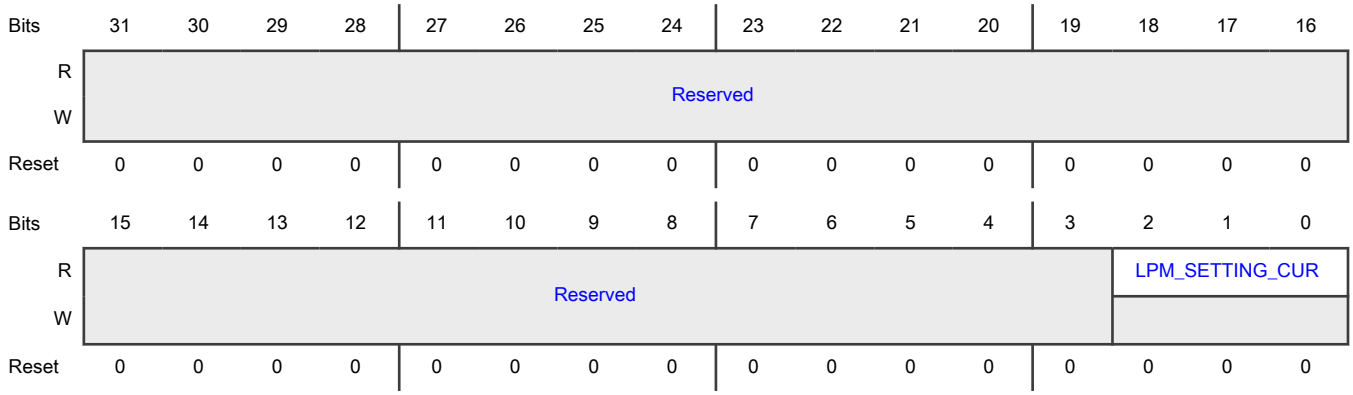
Reading this field will returen OSCPLLn_LPM[LPM_SETTING_Dx], and x represent the CPU domain which launched the read access.

Offset

For a = 0 to 19:

Register	Offset
OSCPLLa_LPM_CUR	501Ch + (a × 40h)

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0 LPM_SETTING_CUR	LPM SETTING of current CPU DOMAIN **NOTE** This field only can be changed by the cpu domain which launched the write access.

23.5.1.21 Clock source working status (OSCPLL0_STATUS0 - OSCPLL19_STATUS0)

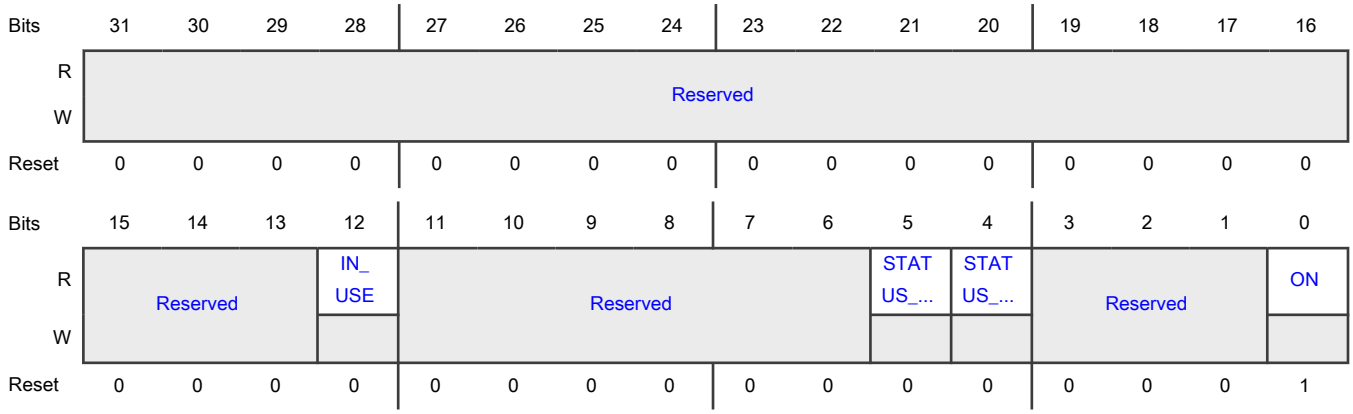
This register shows current clock source running status.

Offset

For a = 0 to 19:

Register	Offset
OSCPLLa_STATUS0	5020h + (a × 40h)

Diagram



Fields

Field	Description
31-13 —	Reserved
12 IN_USE	This Clock Source is being used or not. This field will be 1, if any Clock Root derived from this Clock Source is enabled. 0 - Clock Source is not being used. 1 - Clock Source is being used.
11-6 —	Reserved
5 STATUS_LATE	Late ready signal sent from PLL. This signal means clock source is ready to be used.
4 STATUS_EARLY	Early ready signal sent from PLL control module. This signal means clock source is going to be used.
3-1 —	Reserved
0 ON	Clock source current state Clock source running status. 0 - Clock source is OFF. 1 - Clock source is ON.

23.5.1.22 Clock source domain status (OSCPLL0_STATUS1 - OSCPLL19_STATUS1)

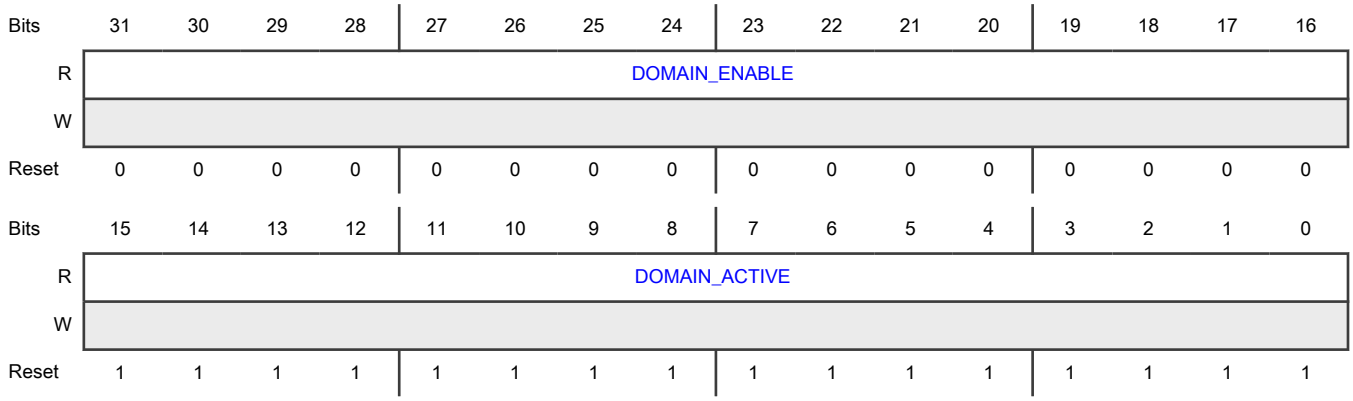
This register shows domain status of clock source.

Offset

For a = 0 to 19:

Register	Offset
OSCPLLa_STATUS1	5024h + (a × 40h)

Diagram



Fields

Field	Description
31-16 DOMAIN_ENABLE	Domain enable Domain x is enabled means that OSCPLLn_LPM_STATUS[CPU_MODE_DOMAINx] is larger than OSCPLLn_LPM[LPM_SETTING_Dx], and this clock source should be ON for DOMAINx. BIT16~BIT31 are corresponding with DOMAIN0~DOMAIN15.
15-0 DOMAIN_ACTIVE	Domain active This field is equal to OSCPLLn_AUTHEN[WHITE_LIST].

23.5.1.23 Clock Source access control (OSCPLL0_AUTHEN - OSCPLL19_AUTHEN)

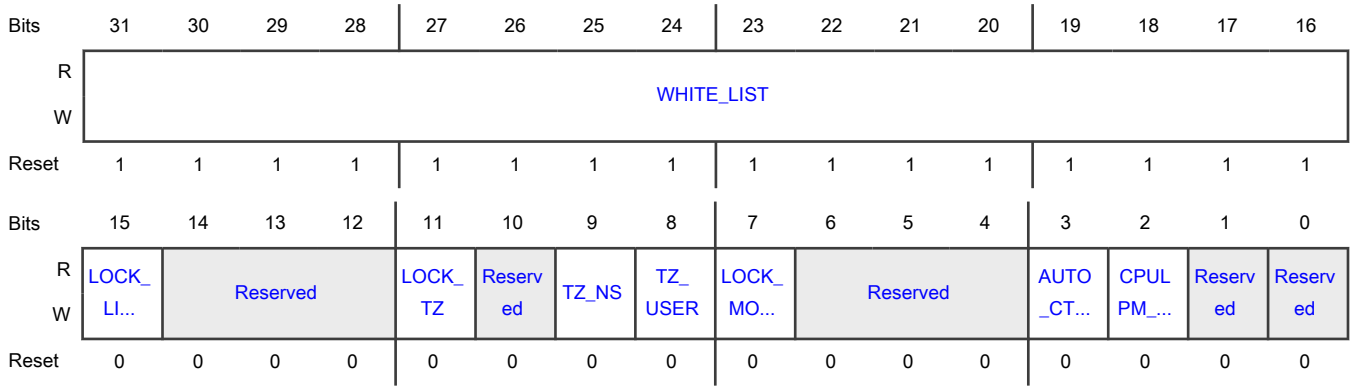
This register controls the access to this Clock Source slice. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

For a = 0 to 19:

Register	Offset
OSCPLLa_AUTHEN	5030h + (a × 40h)

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Whitelist Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the disabling/enabling of the given clock source.
15 LOCK_LIST	Lock white list This bit lock white list. When this bit is set, OSCPLLn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, OSCPLLn_AUTHEN[TZ_USER] and OSCPLLn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Whether the registers of this Clock Source can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this Clock Source. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this Clock Source can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this Clock Source. 0 - Clock Source settings cannot be changed in user mode. 1 - Clock Source settings can be changed in user mode.
7 LOCK_MODE	When this bit is set, CPULPM_MODE and AUTO_CREL cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - CPULPM_MODE and AUTO_CTRL is not locked. 1 - CPULPM_MODE and AUTO_CTRL is locked.
6-4 —	Reserved
3 AUTO_CTRL	Auto mode enable This filed enalbes the Auto mode. **NOTE** The actual working mode of this Clock Source is determined by OSCPLLn_AUTHEN[CPULPM_MODE] and OSCPLLn_AUTHEN[AUTO_CTRL]. 0 - Disable Auto mode 1 - Enable Auto mode
2 CPULPM_MODE	CPULPM mode enable This field enables the CPULPM mode. **NOTE** The actual working mode of this Clock Source is determined by OSCPLLn_AUTHEN[CPULPM_MODE] and OSCPLLn_AUTHEN[AUTO_CTRL]. 0 - Disable CPULPM mode. 1 - Enable CPULPM mode.
1 —	Reserved

0 —	Reserved

23.5.1.24 LPCG direct control (LPCG0_DIRECT - LPCG126_DIRECT)

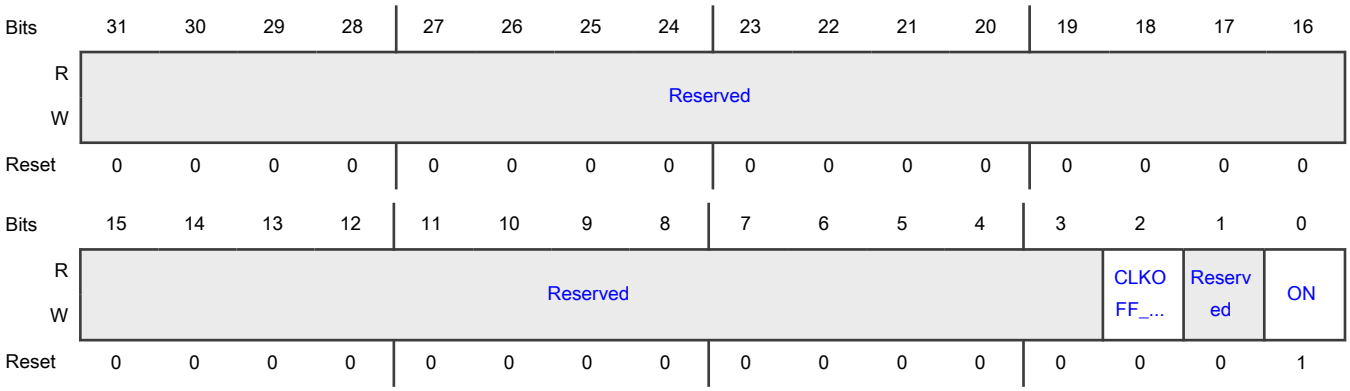
This register controls the ON/OFF of LPCG when LPCG slice is working in Direct Control mode.

Offset

For a = 0 to 126:

Register	Offset
LPCGa_DIRECT	8000h + (a × 40h)

Diagram



Fields

Field	Description
31-3 —	Reserved
2 CLKOFF_ACK_TIMEOUT_EN	Clock off handshake timeout enable This bit enables time out mechanism for clock off handshake, when enabled, clock off acknowlege will be ignored and wait for 16-cycle IPG clock timeout, when disabled, wait for clock off acknowlege. 0 - disable 1 - enable
1 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 ON	Turn on LPCG This bit controls ON/OFF of LPCG. 0 - LPCG gate clock 1 - LPCG ungate clock

23.5.1.25 Low power mode information transfer status (LPCG0_LPM_STATUS0 - LPCG126_LPM_STATUS0)

This register denotes the LPCG low power mode information transfer status for DOMAIN0 ~ DOMAIM7. The information comprises the current low power mode and transfer status.

Offset

For a = 0 to 126:

Register	Offset
LPCGa_LPM_STATUS0	8004h + (a × 40h)

Fields

Field	Description
31-16 DOMAIN_ENABLE	Domain enable Domain x is enabled means that LPCGn_LPM_STATUS[CPU_MODE_DOMAINx] is larger than LPCGn_LPM[LPM_SETTING_Dx], this LPCG should be ON for DOMAINx. BIT16~BIT31 are corresponding with DOMAIN0~DOMAIN15.
15-0 DOMAIN_ACTIVE	Domain active This field is equal to LPCGn_AUTHEN[WHITE_LIST].

23.5.1.32 LPCG access control (LPCG0_AUTHEN - LPCG126_AUTHEN)

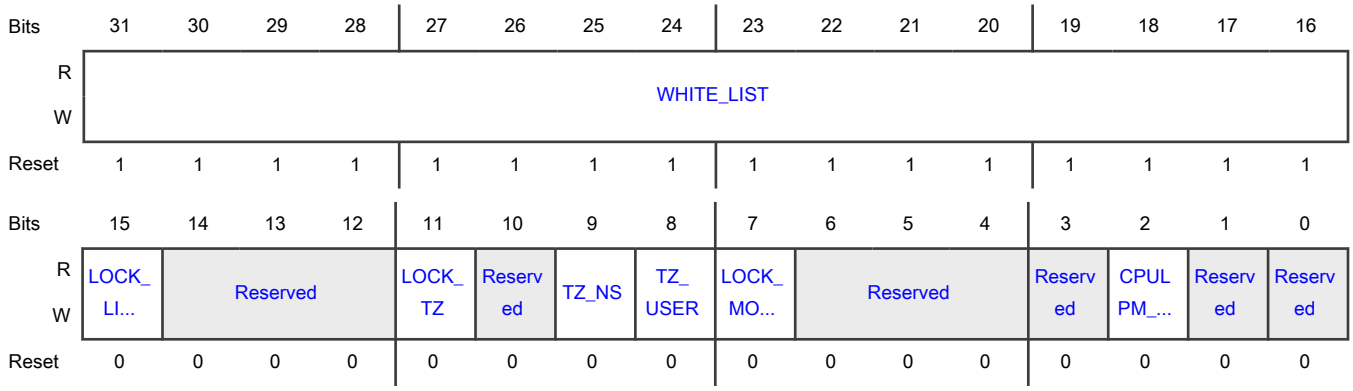
This register controls the access to this LPCG slice. The access control includes 2 parts: TrustZone control and domain based granting.

Offset

For a = 0 to 126:

Register	Offset
LPCGa_AUTHEN	8030h + (a × 40h)

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Whitelist Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read

Table continues on the next page...

Table continued from the previous page...

Field	Description
	data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the disabling/ enabling of the LPCG slice.
15 LOCK_LIST	Lock white list This bit lock white list. When this bit is set, LPCGn_AUTHEN[WHITE_LIST] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - Whitelist is not locked. 1 - Whitelist is locked.
14-12 —	Reserved
11 LOCK_TZ	Lock TrustZone settings This bit locks TrustZone settings. When this bit is set, LPCGn_AUTHEN[TZ_USER] and LPCGn_AUTHEN[TZ_NS] cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - TrustZone settings is not locked. 1 - TrustZone settings is locked.
10 —	Reserved
9 TZ_NS	Non-secure access permission Whether the registers of this LPCG can be changed when CPU is in non-secure mode. The default value is 0, that means only the access from CPU in secure mode can change the registers of this LPCG. 0 - Cannot be changed in Non-secure mode. 1 - Can be changed in Non-secure mode.
8 TZ_USER	User access permission Whether the registers of this LPCG can be changed when CPU is in user mode. The default value is 0, that means only the access from CPU in supervisor mode can change the registers of this LPCG. 0 - LPCG settings cannot be changed in user mode. 1 - LPCG settings can be changed in user mode.
7 LOCK_MODE	When this bit is set, CPULPM_MODE cannot be changed. Once this bit is set, it cannot be cleared, until next system reset. 0 - CPULPM_MODE is not locked. 1 - CPULPM_MODE is locked.
6-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
3 —	Reserved
2 CPULPM_MODE	CPULPM mode enable This field enables the CPULPM mode. 0 - Disable CPULPM mode, this LPCG is in Direct Control mode. 1 - Enable CPULPM mode, this LPCG is in CPULPM mode.
1 —	Reserved
0 —	Reserved

Chapter 24
General Power Controller (GPC)

24.1 Overview

The General Power Controller(GPC) is the centralized power controller, which controls the power mode of the processor(s). The GPC takes the Wait For Interrupt (WFI) signal from CPU platforms, and wakeup events from peripherals, to determine the power mode based on the GPC power management policy. The GPC can also control the power mode transition.

24.1.1 Block diagram

The GPC block consists of the following sub-modules:

- CPU Mode Control (CMC): It contains CPU mode controller for the CPU platform. It controls the CPU mode of the CPU platforms and their private resources.
  - CMC for the Cortex-A55 core0, referred to as the core0 platform.
  - CMC for the Cortex-A55 cluster (SCU), referred to as the CA55 platform.
- UPI CM Mapping (UPI): The connection between CMC and CPU platform is directly hard-wired, but CPU platform can be assigned to any domain in the system. This block is used to map CPU mode control signals into the correct domain.
- GLOBAL CTRL: It is used to control special resources.

The figure below shows the block diagram of the General Power Controller.

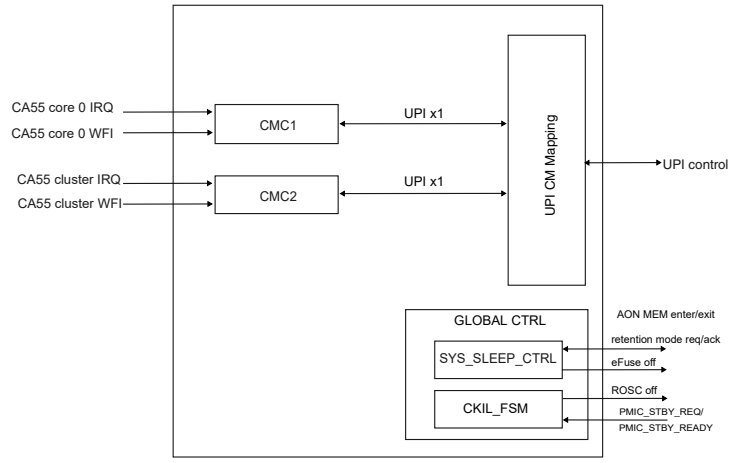


Figure 55. GPC block diagram

24.1.2 Features

The GPC includes the following features:

- Independent CPU modes for each CPU platform
- System sleep management
- Domain access control
- Controllable steps of sleep and wakeup sequence

24.2 Functional description

The following sections describe functional details of the GPC module.

24.2.1 CPU Mode Control (CMC)

The CPU mode is a power mode of the CPU platform. The following are the four CPU modes:

Table 122. CPU Modes

CPU Mode	Description
RUN	The CPU core is active and running under normal operation. All the blocks inside the CPU platform can be accessed when needed. The state of private resources are fully controlled by software configuration.
WAIT	The CPU is in WFI state, but can to get back to RUN mode with very short latency. In typical applications, the CPU will enter WAIT mode whenever there is no active thread running. In WAIT mode, the clock to the CPU core is gated off, the cache is clock gated, and the TCM is still active since there are other modules, such as DMA, that still needs access to it.
STOP	The CPU is in WFI state, and does not require an extremely short exit time. In STOP mode, the clocks to the CPU core, Cache, and TCM are all gated off. The clocks to the bus and peripherals are also gated off. This is the lowest power consumption mode without losing the state of the peripheral. When exiting from STOP mode, there is no need to re-initialize the peripherals.
SUSPEND	Entering SUSPEND mode is for lowest power consumption, and exit time is not critical. In SUSPEND mode, CPU, Cache, and peripherals are all power gated. The biggest difference between SUSPEND and STOP mode is the peripherals will be power gated. Because the peripherals are power gated, entering SUSPEND mode requires the CPU to save the state of the peripherals. When exiting from SUSPEND mode, the CPU needs to restore these states.

CPU Mode transitions happen when the following events occur:

- Sleep Event: CPU enters sleep state with WFI instruction
- Wakeup Event: Any unmasked IRQ wakeup

On a Sleep Event, the CPU has the option to enter WAIT/STOP/SUSPEND mode, or stay in RUN mode. The transition to WAIT/STOP/SUSPEND is called the sleep sequence, and the next state is configured by CM_MODE_CTRL[CPU_MODE_TARGET].

When CPU is in WAIT/STOP/SUSPEND mode, a wakeup request can wake the CPU, and bring it back to RUN mode. This is transition is called the wakeup sequence. The CM_IRQ_WAKEUP_MASK_n register selects which IRQs can wakeup the CPU platform. There are also non-IRQ requests, which can wakeup the CPU. These non-IRQ requests are configured by the CM_NON_IRQ_WAKEUP_MASK register. There is another wakeup event called non-masked interrupt (nmi_in), which can wake the CPU platforms unconditionally.

For the Cortex-A55, there is a special wakeup event called gic_wakeup_req. CM_MISC[IRQ_MUX] can be configured to select if the wakeup is from the IRQs (default selection) or the gic_wakeup_req event.

During a CPU mode transition, the GPC communicates with the system resource controllers by sending the target CPU mode and transition step. Please see the UPI interface for more detials.

If a resource is set as private to a single CPU platform, the resource's power state will change with the CPU platform's mode. If a resource is set as shared by multiple CPU platforms, the resource controller needs to look at all the current modes of the CPU platforms to determine the power state of the resource. For a resource set as shared by multiple CPU platforms, the following rules apply:

- The resource can be power gated, only when all the CPU platforms want to power down the resource.

- The resource can be powered on, when any CPU platform wants to power up the resource.

24.2.2 System Sleep Mode

When a CMC has entered SUSPEND mode, it requests the system to enter system sleep mode.
The mode can be changed by configuring CM_SYS_SLEEP_CTRL[SS_SUSPEND, SS_STOP, SS_WAIT].
The default values are CM_SYS_SLEEP_CTRL[SS_SUSPEND]=1, CM_SYS_SLEEP_CTRL[SS_STOP]=0, and CM_SYS_SLEEP_CTRL[SS_WAIT]=0. If CM_SYS_SLEEP_CTRL[SS_STOP] value is set to 1, when a CMC has entered into STOP mode, the CMC requests the system to enter system sleep mode.

The system is put into system sleep mode only when all the CMCs request the system to enter system sleep mode. If a CPU is disabled by FUSE, the GPC ignores it's CMC system sleep mode requirement. A CPU can also be forced into a system sleep status by configuring GPC_SYS_SLEEP[FORECE_CPU3_DISABLE, FORECE_CPU2_DISABLE, FORECE_CPU1_DISABLE, FORECE_CPU0_DISABLE]. When configured, the GPC will ignore the CMC system sleep mode requirement for the disabled CPU(s).

For details of each system sleep transition step, refer to Table 124.

System sleep mode has the following four functions.

- AON memories (AONMIX memory, HSIO memory, DDR PHY memory) can enter/exit retention mode with configuration of the GPC_AON_MEM_CTRL register.
- eFUSE can be power gated with configuration of the GPC_EFUSE_CTRL register.
- ROSC 24M clock can be turned off with configuration of the GPC_ROSC_CTRL register. Then the GPC works under the 32KHz clock.
- PMIC can be put into standby status with configuration of the PMIC_CTRL, PMIC_PRE_DLY_CTRL, and PMIC_STBY_ACK_CTRL registers.

24.2.3 Unified Power Management Interface (UPI)

GPC does not control the state of the resource directly. During power mode transition, it communicates with the resource controllers through the UPI (Unified Power management Interface) to accomplish the power mode transition.

GPC and resource controllers implement a handshaking mechanism for mode transitions.

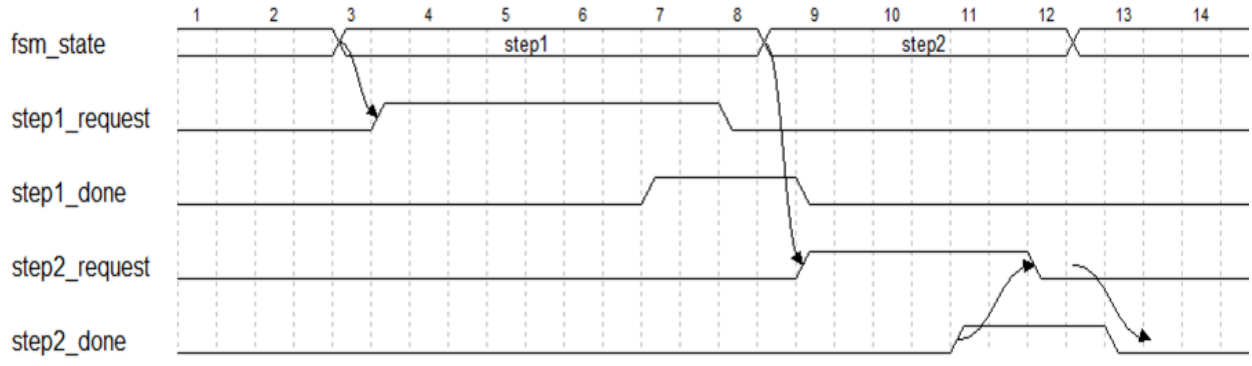

Figure 56. Handshake method

24.2.4 Low Power Sequence

24.2.4.1 CPU mode transition flow

There are two CPU mode control instances:CMC1 for CA55 Core 0,. Each CMC has a state machine to control the sequence of CPU mode transition.

When CMC receives a sleep request from CPU platform, it starts the sleep sequence. The flow cannot be interrupted by a wakeup request until the SLEEP_RSV2 request completes. After the sleep sequence finishes, the CMC stays at IDLE_SLEEP and waits for a wakeup event to start wakeup sequence, which is shown in the left part of the diagram.

Figure 57. CPU mode transition flow

NOTE

SLEEP_RSV2 and WAKEUP_RSV2 are reserved status and don't have a real action.

Table 123. CPU mode transition steps

State	Description
IDLE_RUN	CPU is in RUN mode
SLEEP_A55_HDSK	GPC asserts command to SRC to handshake with CA55
SLEEP_SSAR	GPC asserts command to SRC to send SSAR system save
SLEEP_LPCG	GPC asserts command to CCM to disable LPCGs
SLEEP_PLL	GPC asserts command to CCM to turn PLLs off
SLEEP_ISO	GPC asserts command to SRC to enable isolation signals
SLEEP_RESET	GPC asserts command to SRC to assert reset signals

Table continues on the next page...

Table 123. CPU mode transition steps (continued)

State	Description
SLEEP_POWER	GPC asserts command to SRC to turn off power switch signals
SLEEP_SYS	SSC runs the system sleep transition flow
IDLE_SLEEP	CMC waits for wakeup event to start wakeup sequence
WAKEUP_SYS	SSC runs the wakeup flow
WAKEUP_POWER	GPC asserts command to SRC to de-assert reset signals
WAKEUP_RESET	GPC asserts command to SRC to turn on power switch signals
WAKEUP_ISO	GPC asserts command to SRC to disable isolation signals
WAKEUP_PLL	GPC asserts command to CCM to turn PLLs on
WAKEUP_LPCG	GPC asserts command to CCM to enable LPCGs
WAKEUP_SSAR	GPC asserts command to SRC to send SSAR restore
WAKEUP_A55_HDSK	GPC asserts command to SRC to handshake with CA55

For each step of transition above, there is a control register with the following fields:

- STEP_CNT: This field configures the delay count number.
- CNT_MODE: This field configures the count mode. There are 4 selectable modes available for the delay counter.
- DISABLE: This field disables the step, so that no request is sent out in this transition step.

There is also a read only counter to record the time when the step response is received.

24.2.4.2 System sleep transition flow

There are four transition steps for the system sleep mode. Each step has its own enable register. The system sleep in sequence can be aborted after any step completes because of the wakeup requirement.

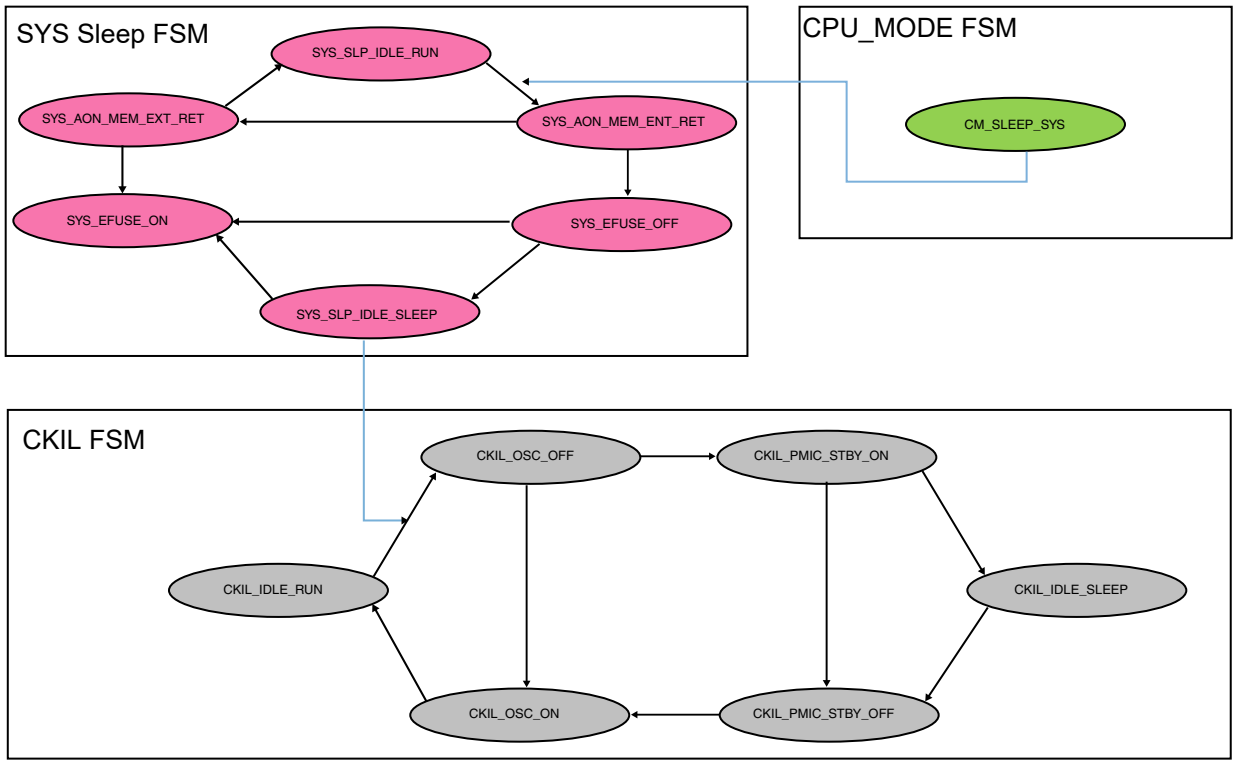

Figure 58. System sleep transition flow

Table 124. System sleep transition steps

State	Description
SYS_SLP_IDLE_RUN	Idle run
SYS_AON_MEM_ENT_RET	AON memories enter retention mode
SYS_EFUSE_OFF	Power off EFUSE
SYS_SLP_IDLE_SLEEP	Idle run
CKIL_OSC_OFF	ROSC 24M clock off
CKIL_PMIC_STBY_ON	Standby on PMIC
CKIL_IDLE_SLEEP	Idle run
CKIL_PMIC_STBY_OFF	Standby off PMIC
CKIL_OSC_ON	ROSC 24M clock on
CKIL_IDLE_RUN	Idle run
SYS_EFUSE_ON	Power on EFUSE
SYS_AON_MEM_EXT_RET	AON memories exit retention mode

24.2.5 Priority of Sleep and Wakeup

IRQs are sent to the GPC, GIC.

IRQs are not sent to CA55 directly, but through the GIC. Before the CA55 enters WFI, the GIC distributor register CORE_PWRDN_EN bit is set. Then executing a WFI instruction automatically masks all interrupts and wake_up events in the core. As a result, applying reset is the only way to wake up the core from this WFI. Therefore, when the CA55 CORE0 WFI and IRQs happen at the same time, the GPC must enter the sleep sequence.

24.2.6 System Domain

24.2.6.1 Domain assignment

Each CPU platform and the CMC connected to it can be assigned to the same domain. CPU_DOMAIN[CPUn_DOMAIN] is used to select the domain assignments for CMCn.

Based on the domain assignment, a mapping mechanism between CPU platform and system domain is implemented inside GPC.

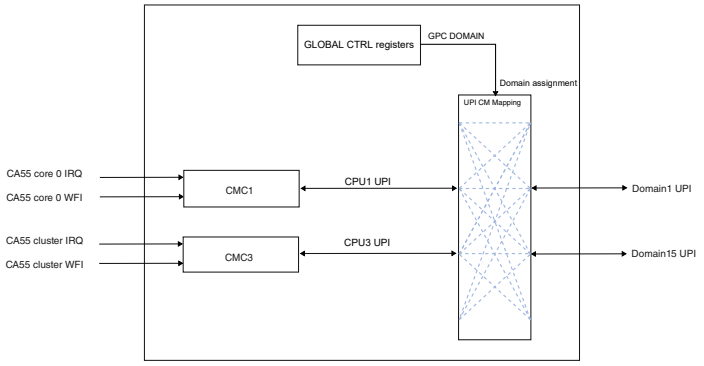

Figure 59. Domain Assignment

When more than one CMCs is assigned to same domain, a two stage priority selects which CMC can control the domain's UPI output. The first stage is CPUn_MASTER flag from GLOBAL which is enabled by register GPC_MASTER[CPUn_MASTER]. Only one CMC with CPUn_MASTER flag owns the domain UPI output. The second stage is for the case when more than one CMC has CPUn_MASTER flag or no CMC has this flag. In this case, the lower indexed CMC has higher priority.

24.2.6.2 Register Access Permissions

The GPC register access is controlled by the following registers and bitfields:

- CM_AUTHEN_CTRL register for CMC access permission
- AUTHEN_CTRL register for GLOBAL registers access permission
- x_AUTHEN_CTRL[WHITE_LIST] field configures which domain IDs can write to the registers
- x_AUTHEN_CTRL[USER] and x_AUTHEN_CTRL[NONSECURE] fields are used to set the privilege and security permission
- x_AUTHEN_CTRL[LOCK_CFG] locks configuration fields and should only be set at initialization
- x_AUTHEN_CTRL[LOCK_LIST] locks WHITE_LIST fields and should only be set at initialization

24.2.7 Resource Low Power Control

24.2.7.1 Hardware Control

The resource behavior under a CPU power mode is configurable. The following is an example of configuring a LPCGn resource under CPU power mode.

1. Configure the CCM register LPCGn_AUTHEN[CPULPM_MODE] to 1.
2. Configure the CCM register LPCGn_LPMn.

3. Configure the CCM register LPCGn_AUTHEN[WHITE_LIST].
4. Configure the GPC CMC register CM_MODE_CTRL[CPU_MODE_TRAGET]. Configure the GPC global register GPC_DOMAIN to assign the CPU control domain, and then execute the "WFI" instruction.
5. The GPC runs the Low Power Sequence up to the WAKEUP_LPCG/SLEEP_LPCG step, then sends the lpcg_request together with cpu_power_mode_n via the UPI.
6. The CCM will turn on or turn off the LPCGn clock based on the LPCGn_LPMn setting in step 2.

24.2.7.2 Resource Domain Assignment

Each resource can be assigned to any (one or multiple) of the 16 domains. This domain assignment is configured in the resource controller's register AUTHEN[WHITE_LIST]. When the resource is controlled by hardware, the WHITE_LIST field indicates which domain UPI request needs to be cared. Take LPCG-n clock gating as an example, which is illustrated below.

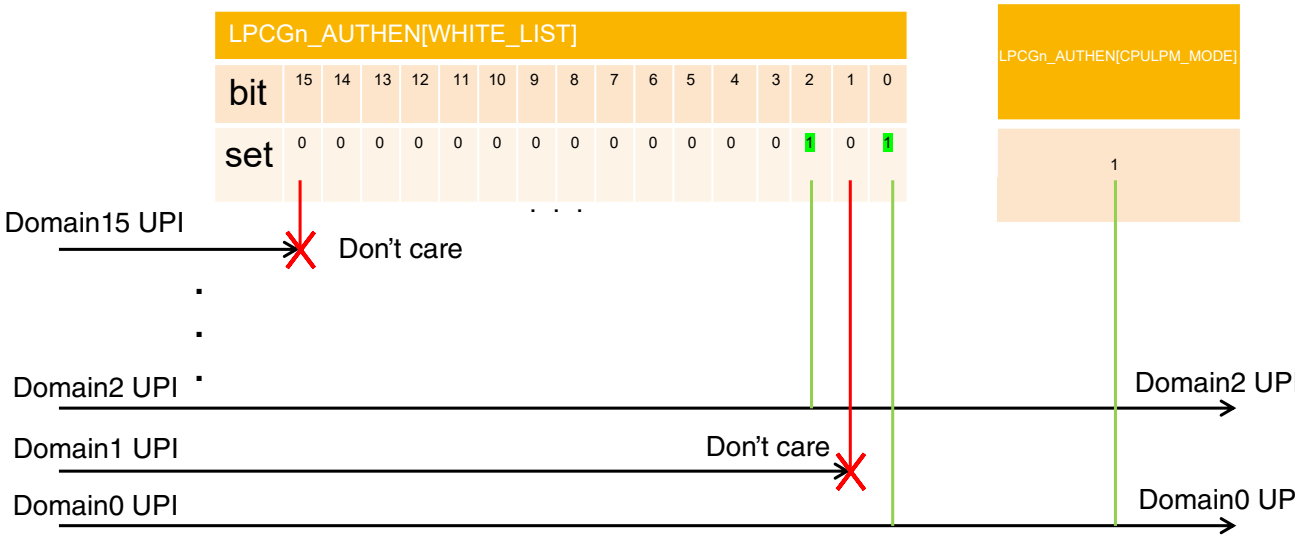

Figure 60. Resource Domain Assignment

The LPCGn_LPMn register provides 16 domain settings (LPM_SETTING_D0 - LPM_SETTING_D15), one for each of the 16 domains. The final resource shut off request is logic AND of all the shared domain requests.

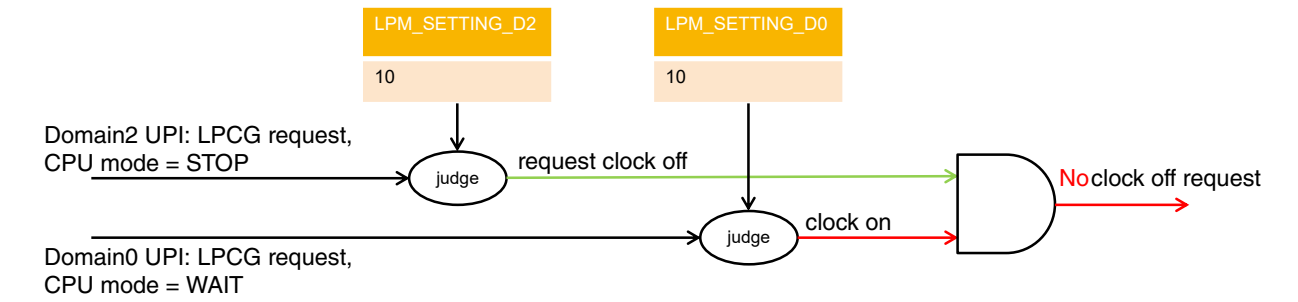

Figure 61. Shared Resource Hardware Control

24.2.7.3 Software Control

The resource behavior can be directly controlled by software. In this mode, the CCM register LPCGn_AUTHEN[CPULPM_MODE] must be set to 0.

24.2.7.4 Switch Between Hardware Control and Software Control

When switching from software control to hardware control, software needs to ensure that the resource is ON. LPCGn_LPMn should be configured to a common value, not always on or always off.

24.2.8 Clocks

This section describes clocks and special clocking requirements of the GPC module.

Table 125. Clocks

Clock	Description
ipg_clk	Main GPC clock. This clock originates from RCOSC 24 MHz and and can be turned off by setting GPC_ROSC_CTRL[ROSC_OFF_EN].
32k_clk	32 kHz clock used to wakeup GPC and RCOSC.

24.2.9 Interrupts

The interrupt inputs of each CMC are independent and the same as the CPU platforms they are connected to. Each CMC has up to 256 IRQ inputs to wake up the core or system.

24.3 External Signals

There are no external signals pinned out for the GPC.

24.4 Initialization

See Low Power Sequence for low power entry and exit flow and considerations.

24.5 Memory Map and register definition

This section includes the GPC module memory map and detailed descriptions of all registers.

NOTE

Write/Read to the Reserved locations will not generate a transfer error.

Chapter 25
System Reset Controller (SRC)

25.1 Overview

The System Reset Controller (SRC) is responsible for the generation of all the system reset signals and boot argument latching. Its main functions are as follows:

- Deals with all global system reset sources from other modules, and generates global system reset.
- Responsible for power gating of MIXs (Slices) and their memory low power control.

The SRC takes the POR_B from the PAD and fuse bits to complete the boot sequence, and the GPC low power request to complete the power down/up sequence.

25.1.1 Block diagram

The SRC module consists of the following submodules:

- Cold reset control: This submodule is used to process the cold reset source, such as the watchdog, the tempsensor. These cold reset sources can assert system reset or single mix reset.
- src_signals_driver_ckil: This sub module uses POR_B from the pad and the jtag_rst_b signal to generate the system reset signal (src_system_early_rst_b) and the MIX SLICE reset signal (slice_early_rst_b).
- MIX SLICES: There are 10 MIX SLICES. Each slice corresponds to one resource on the chip. Each slice consists a set of controllers, such as the reset controller and the PG (power gating) controller. See Figure 62 for additional information.
- MEM SLICES: There are 10 MEM SLICES. Each slice corresponds to one memory on the chip.

The figure below shows a high-level block diagram of the SRC.

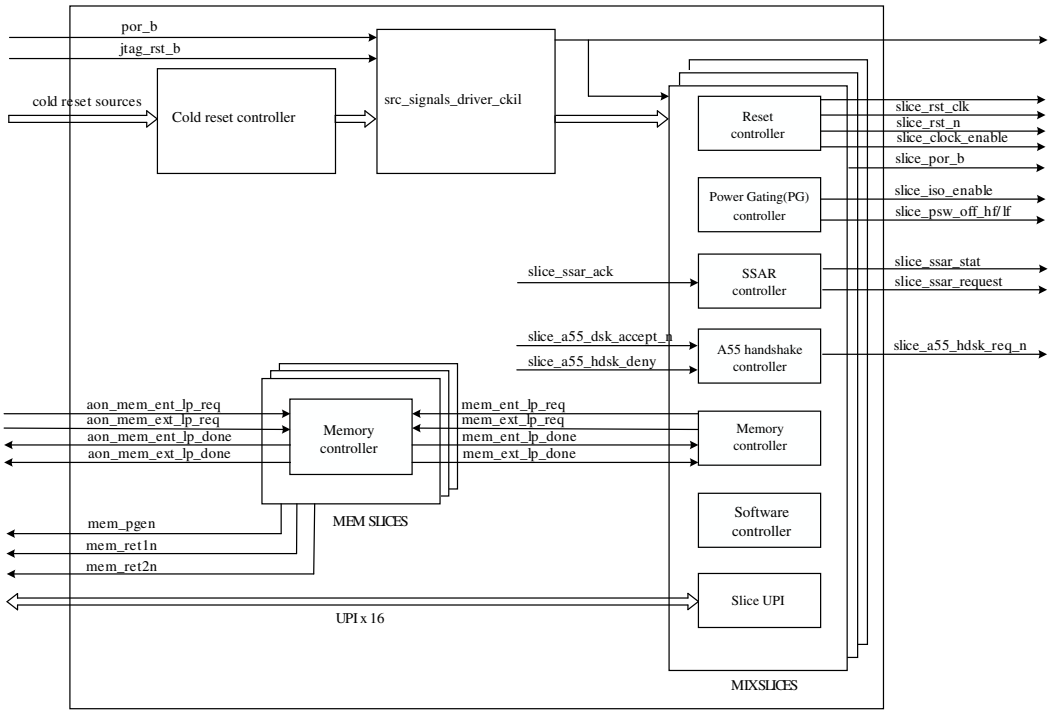

Figure 62. SRC block diagram

25.1.2 Features

The SRC includes the following features:

- Supports two boot modes
- Latches the SRC_BOOT_MODE pins and boot configuration signals from the on-chip Fuse
- Supports system cold reset
- Supports reset control, power control, and memory power control for all MIXs
- Supports handshake with EdgeLock Enclave before a sensitive MIXs reset/power status is changed
- Supports A55 MIX core0/1 and cluster dependency
- Supports A55 MIX power handshake
- Domain access control

25.2 Functional description

The reset control determines the source and type of reset, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire chip.

The boot argument latching includes the BOOT_MODE pin, when the system comes out of reset.

25.2.1 MIX and MEM SLICES

There are 10 MIX Slices and 10 MEM Slices. Each slice corresponds to one resource or memory on the chip. The slice and resource assignment is provided below.

Table 126. MIX Slice Assignment

MIX SLICE index	Resource Name
0	EdgeLock Enclave
1	AONMIX
2	WAKEUPMIX

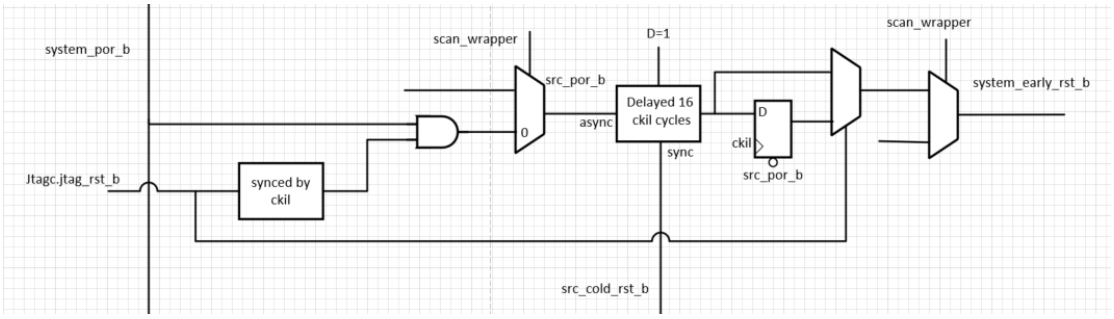
25.2.2 src_signals_driver_ckil

This submodule uses POR_B from the pad (system_por_b) and the jtag_rst_b signal to generate the system reset signal (system_early_rst_b).



25.2.3 Reset controller

The reset controller is used to generate reset signals for resources in the chip. It has four reset signals. The signals and the sequence is provided in the following figure.

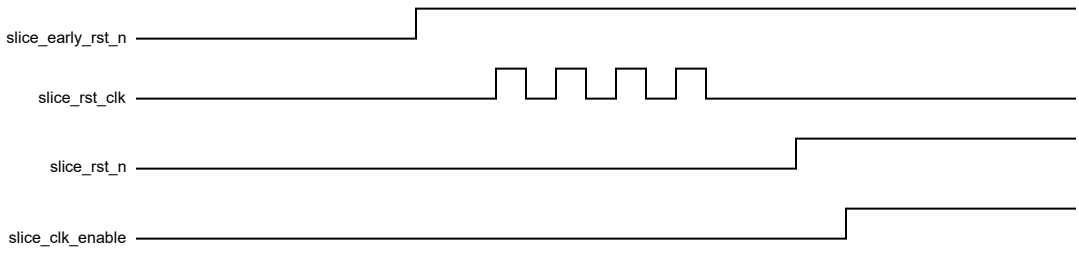


Figure 63. Reset Controller Sequence

Table 128. Reset Controller Signals

Signal	Description
slice_early_rst_n	This signal's release time is earlier than fuse load finished. Active low.
slice_rst_clk	Used for sync-reset logic.
slice_rst_n	Functional reset. Active low.
slice_clk_enable	Used for clock gating. It's release time is later than slice_rst_b, this means that there is no clock when slice_rst_b is releasing.

25.2.4 Power Gating (PG) controller

The power gating controller is used to generate power gating signals and isolation signals. The signals are described in the following table.

Table 129. PG Controller Signals

Signal	Description
slice_iso_enable	When it is high, the mix output signals are clamped to be default value.
slice_psw_off_hf/lf	Power switch gating signal. Active high.
slice_psw_ack_hf/lf	Power switch ack signal. Active high.

25.2.5 SSAR controller

The SRC supports the handshake mechanism with EdgeLock Enclave before executing power off, and after completing power up.

There are 3 signals for each slice. These signals are described in the following table.

Table 130. SSAR Controller Signals

Signal	Direction	Description
ssar_req	Output	Assert to send a notification or request to EdgeLock Enclave.
ssar_stat	Output	Indicates low power status: 0 - indicates power off, 1 - indicates power on
ssar_ack	Input	Assert to indicate that EdgeLock Enclave has gotten the notification or accepted the request.

The Waveform for one slice interface is provided below.

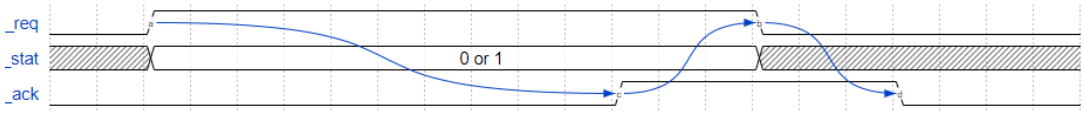

Figure 64. Waveform

25.2.6 A55 handshake controller

The SRC supports the handshake mechanism with A55 before executing A55 power off, and after completing A55 power up.

There are 3 signals for each slice and are described in the following table. These signals can only be sent out by the A55 core0, A55 core1, and A55 cluster slices.

Table 131. SSAR Controller Signals

Signal	Direction	Description
a55_hdsk_qreq_n	Output	Assert to send a notification or request to A55.
a55_hdsk_qaccept_n	Input	Assert to indicate that A55 has accepted the request.
a55_hdsk_qdeny	Input	Assert to indicate that A55 has rejected the request.

25.2.7 Memory controller

Each memory slice can control one memory block on the chip. There are two memory types.

- AON memories (AONMIX memory/ROM, HSIO memory, DDR PHY Memory): these are controlled by the GPC dsm.
- PSW memories: these are controlled by the GPC low power memory step.

25.2.8 Software controller

Software can control each SRC slice controller by configuring the SLICE_SW_CTRL[10:0] bits. SLICE_SW_CTRL[PDN_SOFT] is used for one-key power down/power up.

NOTE

Software access can be active only when AUTHEN_CTRL[LPM_MODE] = 0.

There are two methods to power up and power down a SRC slice.

1. One-key power down/ power up method
2. Step by step power down/ power up method

The one-key power down/power up method is provided below:

- To power off the SRC slice:
    1. Set MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
    2. SET SLICE_SW_CTRL[PDN_SOFT] = 1, for software power down.
- To power on the SRC slice:
    1. Set MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
    2. Set SLICE_SW_CTRL[PDN_SOFT] = 0, for software power up.

NOTE

1. For initial power up, the register should be configured to an unsensitive value.
2. For initial power up of the CA55, SCR[BT_RELEASE_A55_PLAT] should set to 1.

The step by step power down/power up method is provided below:

- To power off the SRC slice:
    1. Set SLICE_SW_CTRL[ISO_CTRL_SOFT] = 1, for Software isolation on.

2. Set MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
3. Set MEM_CTRL[SW_MEM_CTRL] = 1, for software control MEM to enter low power.
4. Set SLICE_SW_CTRL[RST_CTRL_SOFT] = 1, reset and clock gate enable.
5. Set SLICE_SW_CTRL[PSW_CTRL_S OFT] = 1, for software power switch off.

- To power on the SRC slice:
  1. SLICE_SW_CTRL[PSW_CTRL_S OFT] = 0, for software power switch on.
  2. MEM_CTRL[MEM_LP_EN] = 1, to enable MEM low power control.
  3. MEM_CTRL[SW_MEM_CTRL] = 0, for software control MEM to exit low power.
  4. SLICE_SW_CTRL[RST_CTRL_SO FT] = 0, reset release and clock gate disable.
  5. SLICE_SW_CTRL[ISO_CTRL_SO FT] = 0, for software isolation off.

The MIX slice status can be monitored via the Function Status (FUNC_STAT) register. The MEM slice status can be monitored via the MEM Status (MEM_STAT) register. The status must be monitored at each step when using the "step by step power down/power up method" listed above.

Software can control the memories power by configuring the MEM Low Power Control (MEM_CTRL) register.

25.2.9 Switching between hardware control and software control

When switching from software control to hardware control, software needs to ensure that the resource is ON. LPM_SETTING should be configured to common value, not always on or always off.

25.2.10 Cold reset controller

The table below shows the cold reset sources. Each cold reset source can assert system reset or single MIX reset via the SRMRn registers, and can be masked via the SRMASK register. The are two trigger modes available and can be selected through the SRTMR register.

Table 132. Cold Reset Sources

Reset sources	Description
csu_reset_b	Asserts when security violation happens
ipp_user_reset_b	Asserts when the ONOFF pad is pressed down in test mode
wdog1_cm33_rst_b	Asserts when the peripheral WDOG1 timeouts
wdog2_cm33_rst_b	Asserts when the peripheral WDOG2 timeouts
wdog3_wakeupmix_rst_b	Asserts when the peripheral WDOG3 timeouts
wdog4_ca55_rst_b	Asserts when the peripheral WDOG4 timeouts
wdog5_ca55_rst_b	Asserts when the peripheral WDOG5 timeouts
tempsense_reset	Asserts when the Temper Sensor requests a reset
Jtag_sw_rst	Assert when the debugger asserts software reset by JTAG

25.2.11 Boot sequence

The Boot MODE from the pins can be latched in the SRC SBMR2 register. If BOOT_MODE[3]=0, CA55 is the boot core. The MIXs boot status varies depending on the boot core selected. Refer to the table below for details.

MIX SLICE Index	Resource Name	CA55 boot
0	EdgeLock Enclave	ON
1	AONMIX	ON
2	WAKEUPMIX	ON
3	DDRMIX	ON
4	DDRPHY	ON
6	NICMIX	ON
7	HSIOMIX	ON
8	MEDIAMIX	OFF
10	CA55 Core 0	ON
12	CA55 Cluster	ON

All MIXs are by default OFF before the fuse loading is completed. After fuse loading is completed, the MIXs will power up or still be in OFF state depending on the FUSE or BOOT_MODE pin values. The power up sequence is as follows:

1. MIX power on
2. Memory power on
3. Reset release
4. iso_en = 0
5. Clock enable
6. EdgeLock Enclave handshake
7. System boot up

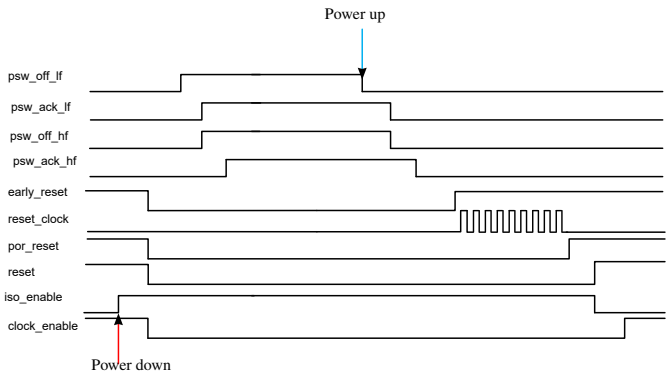

Figure 65. Power Up and Power down Sequence

25.2.12 Reset control

25.2.12.1 Reset CA55 except debug component

The CA55 cannot be warm reset. The following power down and power up sequence is required to reset the CA55.

1. Power down CA55.

2. Set CA55_CPUWAIT[CPUn_WAIT] bit to 1 in the blk_ctrl_s_aonmix block. Once the CPUn_WAIT bit is set to 1, the CA55 core stops working.
3. Power up CA55.
4. The CA55 core will continue to stop working, until the WAIT reset is released.
5. Set CA55_CPUWAIT[CPUn_WAIT] bit to 0 in the blk_ctrl_s_aonmix block. Once the CPUn_WAIT bit is set to 0, the CA55 core works normally.

25.2.13 Low-power mode transition

All SRC slices can be powered off. A fixed power off/on sequence is adopted in this chip. Refer to Figure 65 for the power up and power down sequence.

25.2.13.1 Control of slice power-off

There are two ways to power off a slice.

- GPC mode (by setting AUTHEN_CTRL[LPM_MODE] = 1)
- Software (SW) mode (by setting AUTHEN_CTRL[LPM_MODE] = 0). Refer to Software controller for additional details.

NOTE

Do not change AUTHEN_CTRL[LPM_MODE] value, when the slice is in power off/on sequence or is already in power off state.

In the GPC mode, the SRC powers off the slice under the control of the GPC. Each Core can be mapped to any of the 16 domains by the TRDC via GPC_CPUn_DOMAIN_ASSIGNMENT register. In SRC, each slice can be assigned to any of the 16 domains via AUTHEN_CTRL[WHITE_LIST] bits. When the bit is set, the domain's mapped Core's power state transition is considered as a low power trigger, else the transition is ignored.

NOTE

The CPU3_domain cannot assign to CA55 core 0 slice domain.

Because a slice can be assigned to 16 domains at most, a unified arbitration rule is defined for each slice.

- The slice enters power-off sequence with the last active Core power state transition, if several cores (of domain's assigned domains' mapping Cores) request the slice to power off.
- The slice enters power-on sequence with the first active Core power state transition, if any one core (of domain's assigned domains' mapping Cores) requests the slice to power on while the slice is in power-off status.

25.2.14 Clocks

The table below describes the relevant SRC clock sources.

Table 133. Clocks

Clock	Description
ipg_clk	Main SRC clock. This clock originates from the 24MHz RCOSC and can be turned off.
32k_clk	32KHz clock.

25.3 External Signals

This table describes the SRC external signals.

Table 134. External Signals

Signal	Direction	Description
POR_B	I	Power on reset input pin, active low.
BOOT_MODE[3:0]	I	Boot mode selection pins. The values are sampled during system reset and can be read in the SBMR2 register. See the boot chapter for specific boot configuration settings, and the pin mux chapter for pin assignments.

25.4 Register access permissions

The SRC uses the AUTHEN_CTRL register to control register access permissions.

- The AUTHEN_CTRL[WHITE_LIST] field is used to configure which domain IDs can write to the registers.
- The AUTHEN_CTRL[TZ_USER] and AUTHEN_CTRL[TZ_NS] fields configure privilege and security permissions.
- The AUTHEN_CTRL[LOCK_CFG] field locks configuration fields which should only be set at initialization.

25.5 Memory Map and register definition

This section includes the SRC module memory map and detailed descriptions of all registers.

25.5.1 SRC GENERAL register descriptions

25.5.1.1 SRC General Registers memory map

Fields

Field	Description
31-16 WHITE_LIST	Domain ID white list Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write to this register. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the given power slice. 0000_0000_0000_0001 - Core with domain ID=0 can write General registers. 0000_0000_0000_0010 - Core with domain ID=1 can write General registers. 0000_0000_0000_0100 - Core with domain ID=2 can write General registers. 0000_0000_0000_1000 - Core with domain ID=3 can write General registers. 0000_0000_0001_0000 - Core with domain ID=4 can write General registers. 0000_0000_0010_0000 - Core with domain ID=5 can write General registers. 0000_0000_0100_0000 - Core with domain ID=6 can write General registers. 0000_0000_1000_0000 - Core with domain ID=7 can write General registers. 0000_0001_0000_0000 - Core with domain ID=8 can write General registers. 0000_0010_0000_0000 - Core with domain ID=9 can write General registers. 0000_0100_0000_0000 - Core with domain ID=10 can write General registers. 0000_1000_0000_0000 - Core with domain ID=11 can write General registers. 0001_0000_0000_0000 - Core with domain ID=12 can write General registers. 0010_0000_0000_0000 - Core with domain ID=13 can write General registers. 0100_0000_0000_0000 - Core with domain ID=14 can write General registers. 1000_0000_0000_0000 - Core with domain ID=15 can write General registers.
15	White list lock

Table continues on the next page...

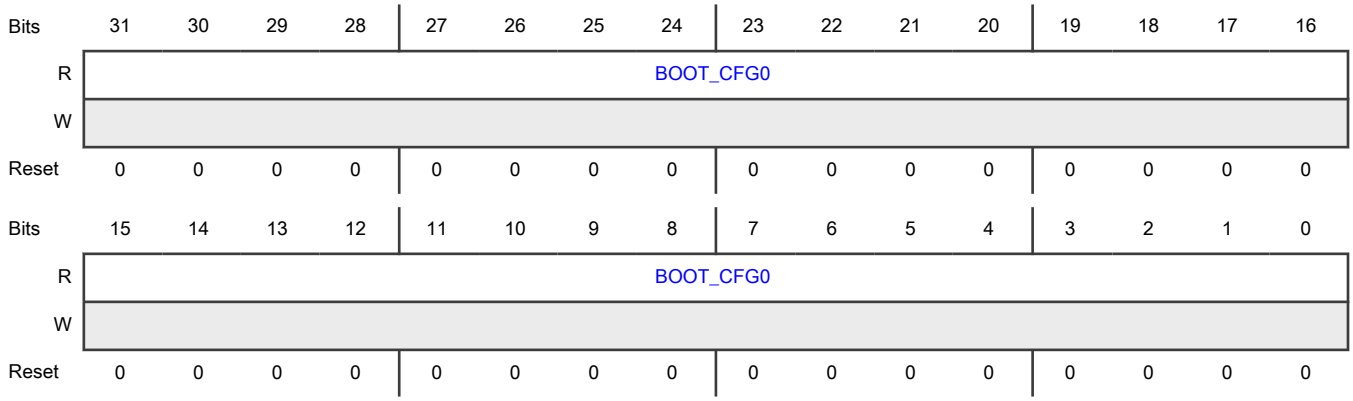
25.5.1.9 SRC Boot Mode Register 1 (SBMR1)

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip and some boot related fuse bits. Reset by POR not system early reset.

Offset

Register	Offset
SBMR1	40h

Diagram



Fields

Field	Description
31-0 BOOT_CFG0	This bit field stores the BOOT_CFG8 fuse values. Please refer to the Fusemap for the fuse details.

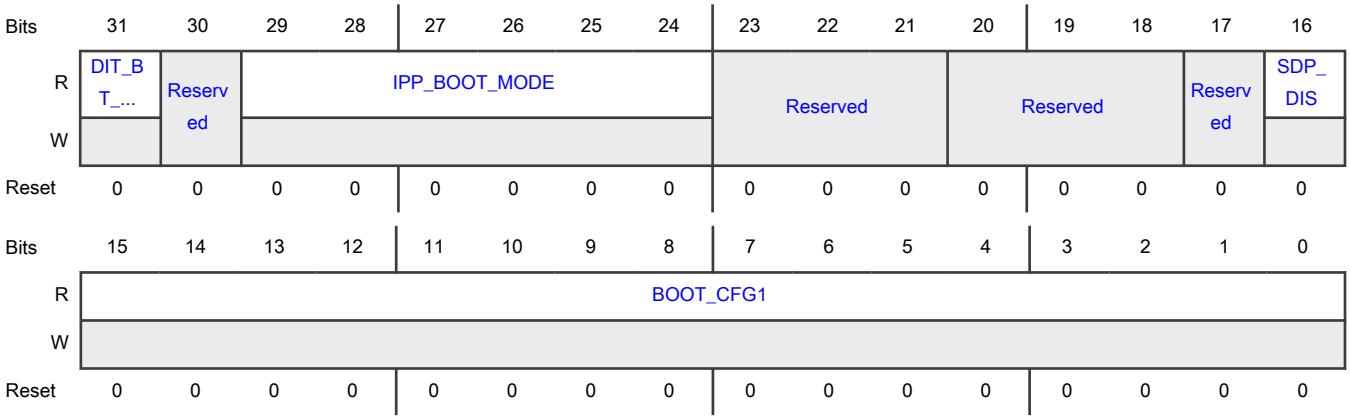
25.5.1.10 SRC Boot Mode Register 2 (SBMR2)

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip and some boot related fuse bits. Reset by POR not system early reset.

Offset

Register	Offset
SBMR2	44h

Diagram



Fields

Field	Description
31 DIT_BT_DIS	Please see the fusemap for fuse details.
30 —	Reserved
29-24 IPP_BOOT_MODE	Boot mode from pins IPP_BOOT_MODE[3:0] shows the latched state of the BOOT_MODE[3:0] signals on the rising edge of POR_B. See the Boot Mode pins section of the System Boot chapter for additional details.
23-21 —	Reserved
20-18 —	Reserved
17 —	Reserved
16 SDP_DIS	Please see the fusemap for fuse details.
15-0 BOOT_CFG1	This bit field stores the BOOT_CFG0[15:0] fuse values. Please refer to the Fusemap for the fuse details.

25.5.1.11 SRC Reset Status Register (SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. Writing zero does not have any effect. Writing one will clear the corresponding bit. Reset by POR not system early reset.

Offset

Register	Offset
SRSR	50h

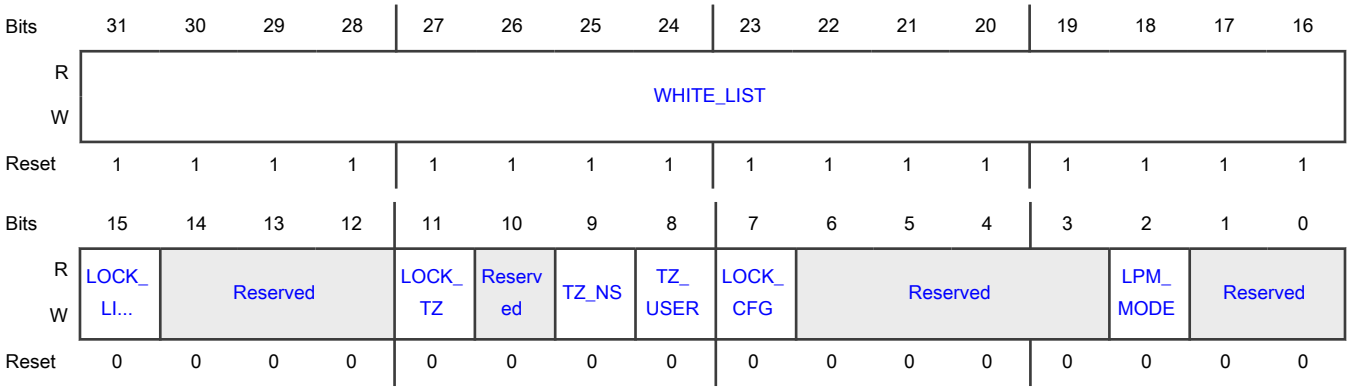
25.5.3.2 Authentication Control (AUTHEN_CTRL)

When GPC_DOMAIN[CPUx_DOMAIN] bit is 1, the MIX SLICE will be power switch with the corresponding CPU.

Offset

Register	Offset
AUTHEN_CTRL	4h

Diagram



Fields

Field	Description
31-16 WHITE_LIST	Domain ID white list Each master(Core or non-Core) can be assigned to any domains among 0-15 through TRDC and through GPC domain assignment register. Once its domains are assigned in TRDC, then its accesses will have its unique domain ID. Each bit in this field represent for one domain. Bit 16-31 represent domains 0-15 respectively. Only the TRDC domains whose corresponding bits are 1 can write this General registers. Write violation will fail without any exception or information. Read violation can still get read data. In LPM mode, only the GPC domains whose corresponding bits are 1 can trigger the powering down of the given power slice. 0000_0000_0000_0001 - Core with domain ID=0 can write SRC MIX SLICE registers. 0000_0000_0000_0010 - Core with domain ID=1 can write SRC MIX SLICE registers.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0000_0000_0000_0100 - Core with domain ID=2 can write SRC MIX SLICE registers. 0000_0000_0000_1000 - Core with domain ID=3 can write SRC MIX SLICE registers. 0000_0000_0001_0000 - Core with domain ID=4 can write SRC MIX SLICE registers. 0000_0000_0010_0000 - Core with domain ID=5 can write SRC MIX SLICE registers. 0000_0000_0100_0000 - Core with domain ID=6 can write SRC MIX SLICE registers. 0000_0000_1000_0000 - Core with domain ID=7 can write SRC MIX SLICE registers. 0000_0001_0000_0000 - Core with domain ID=8 can write SRC MIX SLICE registers. 0000_0010_0000_0000 - Core with domain ID=9 can write SRC MIX SLICE registers. 0000_0100_0000_0000 - Core with domain ID=10 can write SRC MIX SLICE registers. 0000_1000_0000_0000 - Core with domain ID=11 can write SRC MIX SLICE registers. 0001_0000_0000_0000 - Core with domain ID=12 can write SRC MIX SLICE registers. 0010_0000_0000_0000 - Core with domain ID=13 can write SRC MIX SLICE registers. 0100_0000_0000_0000 - Core with domain ID=14 can write SRC MIX SLICE registers. 1000_0000_0000_0000 - Core with domain ID=15 can write SRC MIX SLICE registers.
15 LOCK_LIST	White list lock This field is write once and can lock the value of the WHITE_LIST field. 0 - WHITE_LIST value can be changed. 1 - WHITE_LIST value cannot be changed.
14-12 —	Reserved
11 LOCK_TZ	Lock NONSECURE and USER This field is write once and can lock the TZ_NS and TZ_USER fields. 0 - TZ_NS and TZ_USER value can be changed. 1 - TZ_NS and TZ_USER value cannot be changed.
10 —	Reserved
9 TZ_NS	Allow non-secure mode access Allow either secure mode or non-secure mode to write this MIX SLICE registers. 0 - This MIX SLICE registers can only be written in secure mode. 1 - This MIX SLICE registers can be written either in secure mode or non-secure mode.
8	Allow user mode access Allow either privilege mode or user mode to write this MIX SLICE registers.

Table continues on the next page...

Table continued from the previous page...

Field	Description
TZ_USER	0 - This MIX SLICE registers can only be written in privilege mode. 1 - This MIX SLICE registers can be written either in privilege mode or user mode.
7 LOCK_CFG	Configuration lock This field is write once and can lock value of the low power configuration fields. 0 - Low power configuration fields are not locked. 1 - Low power configuration fields are locked.
6-3 —	Reserved
2 LPM_MODE	Low power control mode **NOTE** This bit cannot be written for SRC.src_edgelock_slice. 0 - Low power mode controlled by software 1 - Low power mode controlled by GPC hardware
1-0 —	Reserved

Chapter 26
Battery-Backed Non-Secure Module (BBNSM)

26.1 Chip-specific BBNSM information

NOTE

The BBNSM output “pmic_en_b” is active-low, but PMIC_ON_REQ PAD is active-high. There is an inverter between them. PMIC_ON_REQ starts low but is driven high after NVCC_BBSM_1P8 is turned on.

NOTE

Accessing BBNSM registers will block the access of AONMIX peripherals(SAI1, MQS1, CAN1, LPSPI1/2, LPSPI1/2, I3C1, TPM1/2) temporarily. For peripherals that need real time, should avoid accessing BBNSM registers when they are working.

Table 135. Reference links to related information

Topic	Related module	Reference
Full description	Arm Cortex A55 Platform (A55)	Overview
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes one instance of BBNSM module.

NOTE

The BBNSM output “pmic_en_b” is active-low, but PMIC_ON_REQ PAD is active-high. There is an inverter between them. PMIC_ON_REQ starts low but is driven high after NVCC_BBSM_1P8 is turned on.

26.2 Overview

BBNSM serves as non-volatile logic and storage for the system.

26.2.1 Block diagram

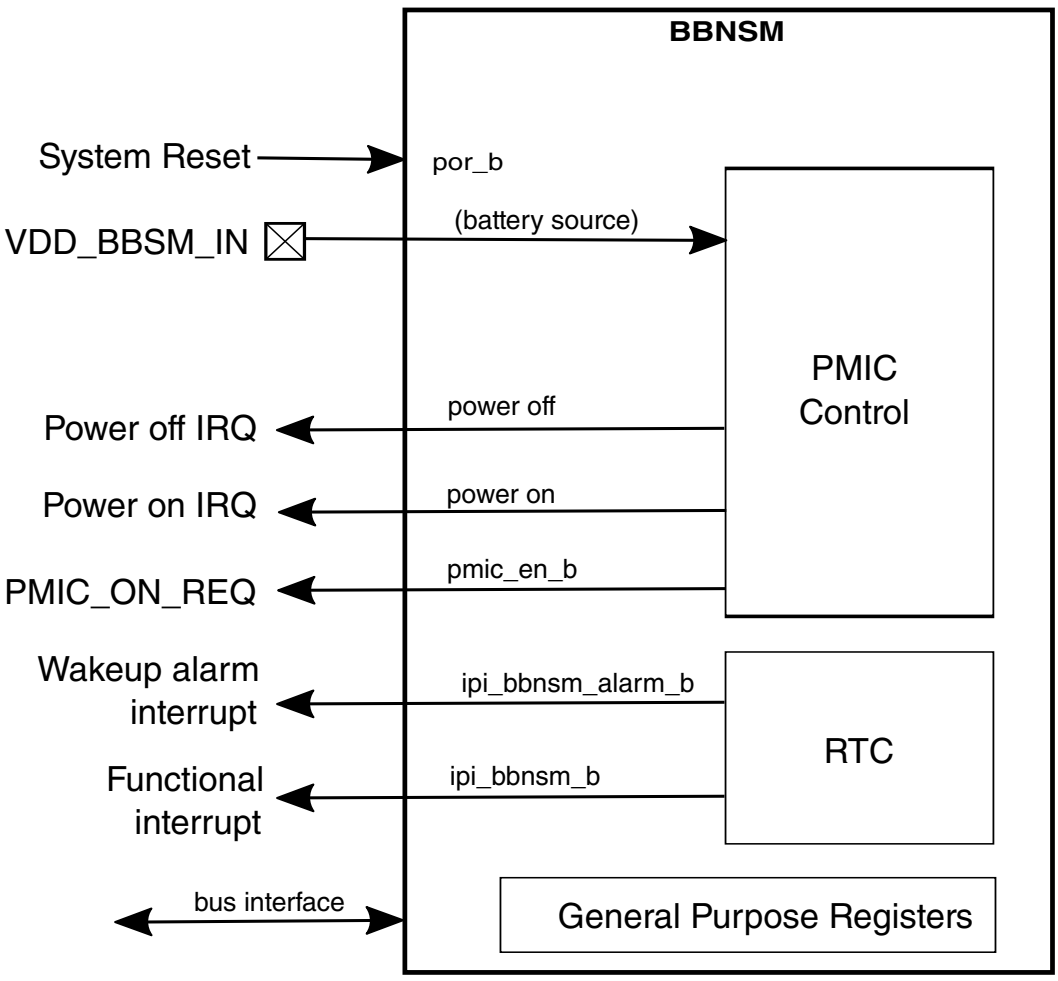

Figure 66. BBNSM block diagram

26.2.2 Features

BBNSM implements the following features:

Table 136. BBNSM feature list

Feature	Description
Non-volatile storage and logic (PMIC logic)	• If the BBNSM power input is connected to an uninterrupted power supply: — BBNSM register values are maintained even when the main SoC is powered off — BBNSM logic continues to operate even when the main SoC is powered off
General-purpose register	• The general-purpose register is available to software to store data. It is 8 registers of 32 bits each by default.

Table continues on the next page...

Table 136. BBNSM feature list (continued)

Feature	Description
Real-time counter (RTC)	• Triggers an interrupt if the RTC reaches its maximum value. • A time alarm can be programmed to generate an interrupt at a specific time.
On/Off Control	• Allows connectivity to a Power Management Integrated Circuit (PMIC) or other voltage regulator devices. • Configurable debounce support for button presses.

26.3 Functional description

The following sections describe functional details of the BBNSM module.

26.3.1 Real-Time Counter (RTC)

BBNSM implements a real-time counter that:

- Retains its state and continues counting even when the main chip is powered down. The BBNSM power input is connected to an uninterrupted power supply
- Generates an interrupt when it reaches the maximum value of all ones. It will then rollover and continue to count
- Generates a functional interrupt request at a particular time by setting the desired time in the Time Alarm register and setting BBNSM_CTRL[TA_EN]
- Can be written at any time
- Can be calibrated so that its count frequency tracks some other time source
- Can be configured to capture the time of a security violation

26.3.1.1 Time Counter Calibration

The real-time counter accuracy may suffer from a drift in the clock, which is used to increment the RTC register. To compensate for this drift, a clock calibration mechanism can adjust the RTC value. It is up to the system processor to decide whether calibration is required or not. If RTC correction is required, enable the mechanism and set the calibration value in the control register. The calibration value (BBNSM_CTRL[CAL_VAL]) includes the sign bit, which is implemented in twos' complement.

If the calibration mechanism is enabled, the calibration value is added or subtracted from the RTC on a periodic basis, once per 32768 cycles of the RTC clock. Positive calibration values will not work with the time alarm feature.

The following table shows the available correction range.

Table 137. Real-time counter calibration settings

Calibration setting (BBNSM_CTRL[CAL_VAL])	Correction in counts per 32768 cycles of the counter clock
01111	+15
...	...
00010	+2
00001	+1
00000	0

Table continues on the next page...

Table 137. Real-time counter calibration settings (continued)

Calibration setting (BBNSM_CTRL[CAL_VAL])	Correction in counts per 32768 cycles of the counter clock
11111	-1
11110	-2
...	...
10001	-15
10000	-16

26.3.1.2 Time Alarm

A time alarm is generated once the most significant 32 bits of the real-time counter match the value in the Time Alarm register. The time alarm can generate interrupts to alert the host processor and can wake up the host processor from one of its low-power modes. This alarm can also wake up the entire system in the power-down mode by asserting the wake-up external output signal.

26.3.2 On/Off Control

The on/off logic inside the BBNSM allows for connecting directly to a PMIC or other voltage regulator device. The module has a button input signal and a wakeup request input signal. It also has two interrupts (power off and power on) and an active-low PMIC enable (pmic_en_b) output. The module can function in two different modes of operation (Dumb PMIC mode and Smart PMIC mode).

26.3.2.1 Smart PMIC Mode

In Smart PMIC mode, BBNSM can generate interrupt outputs (power off and power on) like in Dumb PMIC mode. However, the pmic_en_b signal is a pulse and active-high signal in Smart PMIC mode instead of a level and active-low signal in Dumb PMIC mode. The only configuration option available for this mode is the debounce configuration, which is used for the power off and power on interrupts in the same way as Dumb PMIC mode.

26.3.2.1.1 Smart PMIC Enable Control

The active-high pmic_en_b output asserts if either condition occurs:

- the button input signal asserts
- the wakeup alarm triggers when system power has failed (isolation enable is asserted)

26.3.2.2 Dumb PMIC Mode

In Dumb PMIC mode, BBNSM can generate interrupt outputs (power off and power on) and control the active-low PMIC enable output (pmic_en_b).

26.3.2.2.1 Dumb PMIC Enable Control

The pmic_en_b signal is active (ON state) at reset. In the ON state, the pmic_en_b is deactivated (to OFF state) if either condition occurs:

- the button input signal asserts longer than the BBNSM_CTRL[BTN_TIMEOUT] configuration
- the BBNSM_CTRL[TOSP] bit is set

In the OFF state, the pmic_en_b is activated (to ON state) if either condition occurs:

- the button input signal asserts longer than the BBNSM_CTRL[TURN_ON_TIME] configuration
- the external wakeup request signal asserts

- the wakeup alarm triggers from programming the time alarm and enabling the real-time counter

The behavior of the pmic_en_b signal is described in the state machine below.

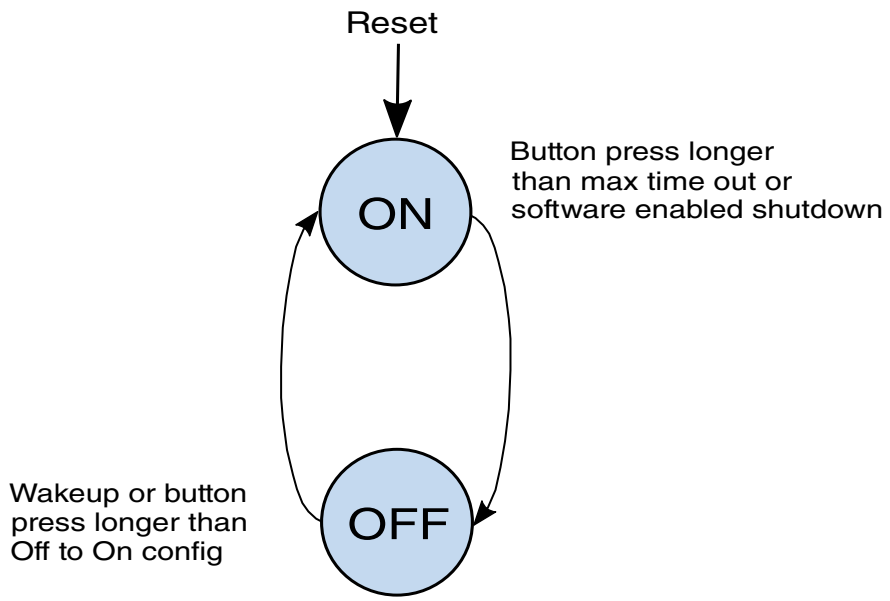

Figure 67. PMIC Enable State Machine (Dumb PMIC Mode)

26.3.3 Clocking

Table 138. BBNSM Clock

Clock	Description
32kHZ RTC clock	Clock is used by BBNSM real-time counter. This clock does not need to be synchronous with other clocks

26.3.4 Reset

Table 139. BBNSM Reset

Reset	Description
por_b	Power-on reset

26.3.5 Interrupts and Alarms

BBNSM provides the following interrupts and alarms:

Table 140. Interrupts and alarms summary

Interrupt/Violation	Event	Default configuration[1]	Configuration options
Functional interrupt (ipi_bbnsm_b)	RTC rollover	Disable	Enable/disable

Table continues on the next page...

Table 140. Interrupts and alarms summary (continued)

Interrupt/Violation	Event	Default configuration[1]	Configuration options
Wakeup alarm interrupt (ipi_bbnsm_alarm_b)	RTC time alarm	Disable	Enable/disable
Power off interrupt	Button input signal	50 msec debounce	Debounce time
Power on interrupt	Button input signal	50 msec debounce	Debounce time

1. Default configuration refers to the state after reset.

26.3.5.1 PMIC Interrupts

The interrupts behave identically in Smart and Dumb PMIC modes.

The power on asserts if:

- system power has failed (isolation enable is asserted), **and**
- the button input signal asserts longer than the BBNSM_CTRL[DEBOUNCE] configuration

The power off asserts if:

- system power has not failed (isolation enable is not asserted), **and**
- the button input signal asserts longer than the BBNSM_CTRL[DEBOUNCE] configuration in the condition of no alarm from BBNSM and tamper event asserted

26.4 External Signals

The table below lists the external signals to the BBNSM.

Table 141. BBNSM external signals

Signal	Description	Direction
ONOFF (btn)	Active-high external on/off button	Input
PMIC_ON_REQ (pmic_en_b)	ONOFF button/PAD has two functions: 1. It can impact the PMIC_ON_REQ value via BBNSM ON-OFF FSM in Dumb PMIC mode or directly pass through the ONOFF button/PAD in Smart PMIC mode. 2. It can generate IRQs which are routed to M33/A55/M7 cores, and also routed to GPC to wake up the system. When PMIC_ON_REQ=1, 1. If ONOFF button was pressed for a "short" time, it can trigger IRQ "set_pwr_off_irq" if it's pressed longer than debounce time the debounce time which is configured in BBNSM_CTRL[19:16]. 2. If you want to toggle PMIC_ON_REQ, then you need to press it longer, the press time length is configured in BBNSM_CTRL[17:16]. When PMIC_ON_REQ=0,	Output

Table continues on the next page...

Table 141. BBNSM external signals (continued)

Signal	Description	Direction
	1. If ONOFF button was pressed for a "short" time, it can trigger IRQ "set_pwr_on_irq" if it's pressed longer than debounce time. The debounce time is configured in BBNSM_CTRL[19:18]. 2. If you want to toggle PMIC_ON_REQ, then you need to press it longer, the press time length is configured in BBNSM_CTRL[21:20].	

26.5 Initialization

There are no initialization steps.

26.6 Memory Map and register definition

This section includes the BBNSM module memory map and detailed descriptions of all registers.

26.6.1 BBNSM register descriptions

26.6.1.1 BBNSM memory map

BBNSM base address: 4444_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)
0	BBNSM Version ID Register (BBNSM_VID)	32	R	0001_013E
4	BBNSM Features Register (BBNSM_FEATURES)	32	R	0000_0020
8	BBNSM Control Register (BBNSM_CTRL)	32	RW	0100_0005
10	BBNSM Interrupt Enable Register (BBNSM_INT_EN)	32	RW	0000_0005
14	BBNSM Events Register (BBNSM_EVENTS)	32	RW	0000_0005
24	BBNSM External Pad Control Register (BBNSM_PAD_CTRL)	32	RW	0000_0000

300 - 31C	General Purpose Register Word a (GPR0 - GPR7)	32	RW	0000_0000

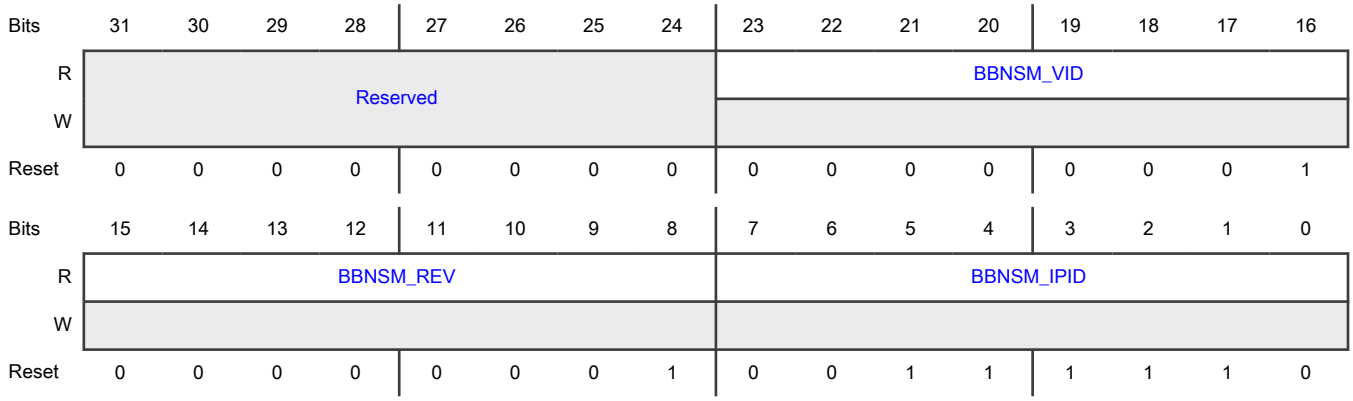
26.6.1.2 BBNSM Version ID Register (BBNSM_VID)

The BBNSM Version ID register can be used by software to differentiate between different versions of the BBNSM and determine what options are implemented in this version of BBNSM. The bit assignments of this register appear below.

Offset

Register	Offset
BBNSM_VID	0h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 BBNSM_VID	BBNSM Version ID Version identifier or major version ID of the BBNSM.
15-8 BBNSM_REV	BBNSM Revision Revision number or minor version ID of the BBNSM.
7-0 BBNSM_IPID	BBNSM IP ID Identifier for the Battery-Backed Non-Secure Module.

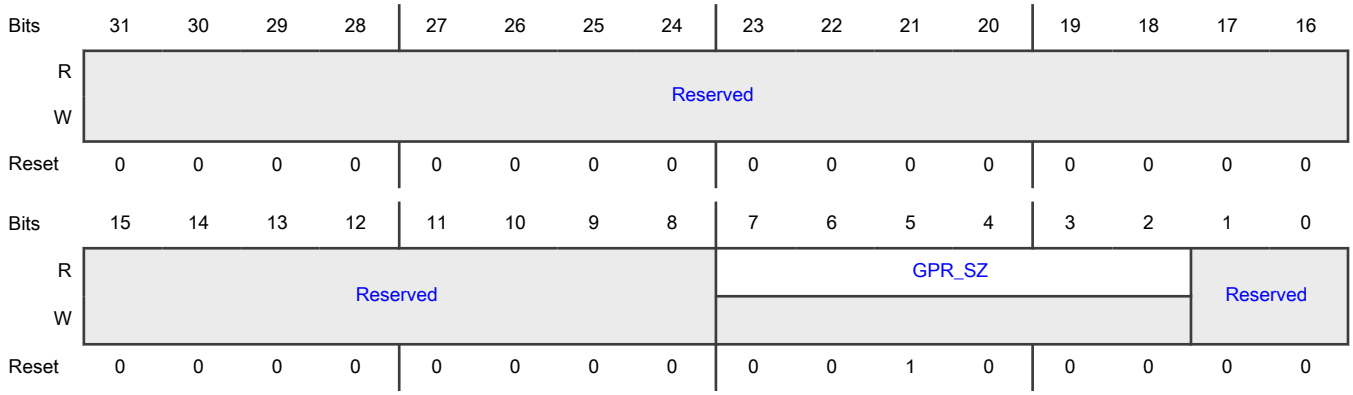
26.6.1.3 BBNSM Features Register (BBNSM_FEATURES)

The BBNSM Features register indicates which optional features are implemented in this version of BBNSM. The bit assignments of this register appear below.

Offset

Register	Offset
BBNSM_FEATURES	4h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-2 GPR_SZ	GPR Register Array Size BBNSM implements a register array of 32-bit words that ELKe firmware can use to retain the GPR values across ELKe power cycles. 00_0000 - This version of BBNSM does not implement a general-purpose register array. All other values - The number of 32-bit words implemented in the general-purpose register array.
1-0 —	Reserved

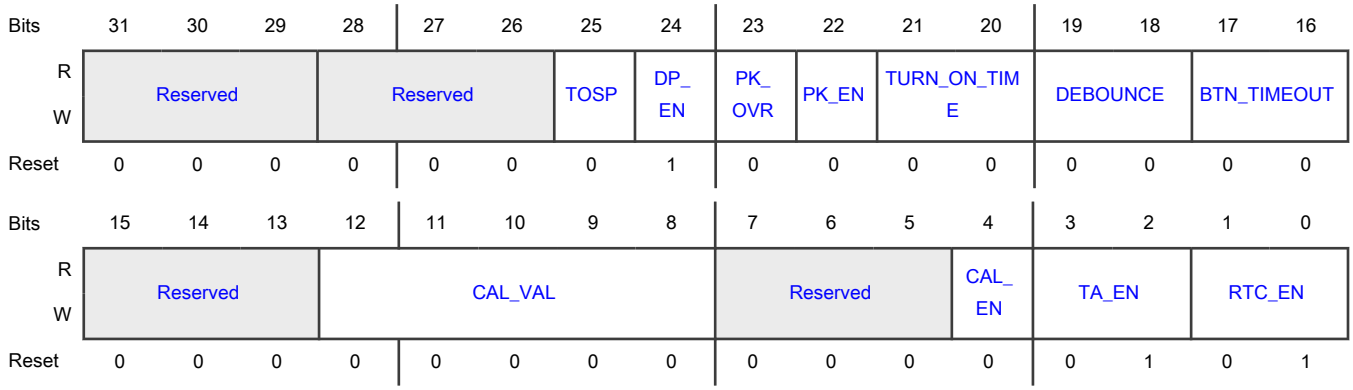
26.6.1.4 BBNSM Control Register (BBNSM_CTRL)

The BBNSM Control register is used to enable features such as the real-time counter and the time alarm. It can also be used to calibrate the RTC or control the on/off logic for connecting to a PMIC.

Offset

Register	Offset
BBNSM_CTRL	8h

Diagram



Fields

Field	Description
31-29 —	Reserved
28-26 —	Reserved
25 TOSP	Turn Off System Power When set, a signal is sent to the PMIC to turn off the system power. This bit will clear once power is off. This bit is only valid when Dumb PMIC is enabled. 0 - Leave system power on. 1 - Turn off system power when Dumb PMIC is enabled.
24 DP_EN	Dumb PMIC Enable When set, software can control the system power. When cleared, the system requires a Smart PMIC to automatically turn power off. 0 - Smart PMIC is enabled. 1 - Dumb PMIC is enabled.
23 PK_OVR	PMIC On Request Override The value written to PK_OVR will be asserted on output signal bbnsm_pk_override. That signal is used to override the IOMUX control for the PMIC I/O pad. 0 - PMIC On Request Override is disabled. 1 - PMIC On Request Override is enabled.
22 PK_EN	PMIC On Request Enable The value written to PK_EN will be asserted on output signal bbnsm_pk_en. That signal is used to turn off the pullup/pulldown circuitry in the PMIC I/O pad. 0 - PMIC On Request is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - PMIC On Request is enabled.
21-20 TURN_ON_TIME	Turn-On Time Amount of time that button is pressed before pmic_en_b is asserted to turn on the SoC power. 00 - 500 milliseconds. 01 - 50 milliseconds. 10 - 100 milliseconds. 11 - 0 milliseconds.
19-18 DEBOUNCE	Debounce Time Amount of debounce time for the BTN input signal. 00 - 50 milliseconds. 01 - 100 milliseconds. 10 - 500 milliseconds. 11 - 0 milliseconds.
17-16 BTN_TIMEOUT	Button Press Timeout Time it takes to hold the button to request a power down in the condition of no alarm from BBNSM and tamper event asserted. 00 - 5 seconds. 01 - 10 seconds. 10 - 15 seconds. 11 - Timeout disabled. Long button presses will not request a power down.
15-13 —	Reserved
12-8 CAL_VAL	Calibration Value Defines signed calibration value for the RTC. This field can be programmed only when RTC calibration is disabled. This is a 5-bit twos' complement value. Hence, the allowable calibration values are in the range from -16 to +15 counts per 32768 ticks of the counter clock. Positive calibration values will not work with the time alarm feature. 0_0000 - +0 counts per each 32768 ticks of the counter clock. 0_0001 - +1 counts per each 32768 ticks of the counter clock. 0_0010 - +2 counts per each 32768 ticks of the counter clock. 0_1111 - +15 counts per each 32768 ticks of the counter clock. 1_0000 - -16 counts per each 32768 ticks of the counter clock. 1_0001 - -15 counts per each 32768 ticks of the counter clock.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1_1110 - -2 counts per each 32768 ticks of the counter clock. 1_1111 - -1 counts per each 32768 ticks of the counter clock.
7-5 —	Reserved
4 CAL_EN	Calibration Enable Enables the RTC calibration mechanism when set. This bit cannot be changed once set. 0 - RTC Time calibration is disabled. 1 - RTC Time calibration is enabled.
3-2 TA_EN	Time Alarm Enable 01 - Disable the time alarm. 10 - Enable the time alarm. A time alarm event occurs if the value in the real-time counter register is equal to the value in the time alarm register.
1-0 RTC_EN	Real-Time Counter Enable 01 - Disable the real-time counter. 10 - Enable the real-time counter.

26.6.1.5 BBNSM Interrupt Enable Register (BBNSM_INT_EN)

The BBNSM Interrupt Enable Register is used to enable interrupt generation when a status event has occurred in BBNSM. Interrupts supported include RTC rollover and time alarm. The bit assignments of this register appear below.

Offset

Register	Offset
BBNSM_INT_EN	10h

Chapter 27
External Memories

27.1 Overview

This chip has these external memory interfaces and controllers:

- High Performance DRAM Interface
- SD/eMMC/SDIO Interface
- Flexible Serial Peripheral Interface (FlexSPI)

27.2 High Performance DRAM Interface (DDR)

The chip includes one 16-bit DRAM controller with LPDDR4 memory technology. Maximum supported capacity is 2GByte.

27.3 eMMC/SD/SDIO

This chip has three Ultra Secured Digital Host Controller (uSDHC) modules for SD/eMMC interface with simultaneous support for all three of 1x eMMC, 1x SD Card and 1x SDIO (for WIFI connectivity). It provides the interface between the host system and the SD/SDIO/eMMC cards.

The key features include:

- Support SD/SDIO standard, up to version 3.0
- Support eMMC standard, up to version 5.1
- Support 3.3V and 1.8V

27.4 Flexible Serial Peripheral Interface

The chip has one FlexSPI block that acts as an interface to one external Octal SPI or Quad SPI serial flash device, each with up to four bidirectional data lines. Both Serial NOR flash and Serial NAND flash are supported (both for boot and runtime operation).

The key features include:

- Channel A can be configured as 1/2/4/8-bit operation
- Support both dual-channel or single-channel operation
- Support both SDR mode and DDR mode
- Support up to 166MHz SDR Mode and 166MHz DDR Mode (with external Flash device DQS input)
- Support up to 133MHz SDR Mode and 66MHz DDR Mode (with internal DQS loopback through DQS pad mode)
- Support On-The-Fly AES Decryption (OTFAD) with 4 keys.

16-bit	16 Gb/2GB	single rank, single channel device with 17-row addresses (R0 - R16)	Byte-mode LPDDR4 devices (x16 channel internally split between two dies, x8 each) of any density are not supported therefore, the numbers are applicable only to devices with x16 internal organization (referred to as "standard" in the JEDEC specification). The chip also supports dual

Table continues on the next page...

Table 144. LPDDR4 - maximum supported densities

Max Data bus width	Maximum density	Assumed memory organization	Notes
			rank single channel devices therefore, 16Gb/2GB density can be also achieved by using a dual rank single channel device with 16-row addresses (R0 - R15).

28.2 Overview

DDRC includes:

- In-line ECC that detects and corrects single-bit errors for reliable memory operation.
- Dynamic Power Management and Global Auto-Precharge modes that simplify system memory design.
- A large set of special features, including ECC error injection and rapid system debug support.

28.2.1 Block diagram

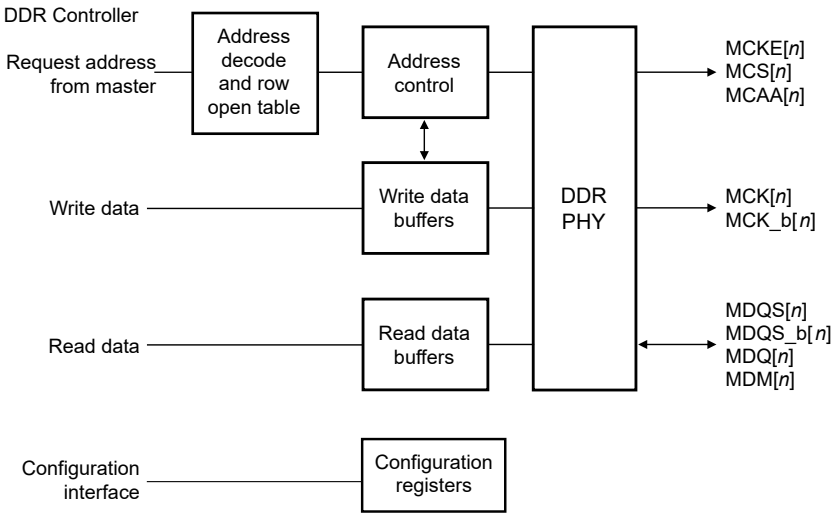

Figure 68. Block diagram

28.2.2 Features

- Support for DDR SDRAM standards:
  - LPDDR4

NOTE

DDRC is designed to support LPDDR4 SDRAMs that are compliant with JESD209-4B as of February 2017.

- Support for the following data-bus widths:
  - 16-bit
- Programmable settings to meet all DDR SDRAM timing parameters

- Support for the following DDR SDRAM configurations:

  NOTE

  Please refer Chip-specific DDR information section for details on the configurations supported.

  — As many as two ranks, each rank independently addressable. Rank interleaving is also supported.

  — 1-Gbit to 16-Gbit for single channel LPDDR4 devices depending on the internal device configuration

  — x16 data ports

- Data mask signals and read-modify-write operations for subdoubleword writes (a read-modify-write sequence is only necessary when in-line ECC is enabled)
- SECDED in-line ECC
- Open-page management (dedicated entry for each logical bank)
- Automatic DDR SDRAM initialization sequence
- Automatic DDR SDRAM data initialization via the PHY
- Sleep power management
- Error injection
- Performance monitor counters that track the number of occurrences of specific events and generate an interrupt when an event count threshold is exceeded

28.3 Functional description

28.3.1 Overview

DDRC controls processor and I/O interactions with system memory. The memory system allows a wide range of memory devices to be mapped to any arbitrary rank, and provides support for discrete DRAMs .

DDRC receives read and write requests and decodes the transaction address to generate the rank, bank, row, and column addresses. DDRC compares the request's decoded address with values in the row-open table to determine if the address maps to an open page. If the transaction does not map to an open page, DDRC issues an ACTIVATE command.

Programmable parameters allow for a variety of memory organizations and timings.

Optional ECC protection is provided for the DDR SDRAM data bus. DDRC uses ECC to:

- Detect and correct all single-bit errors within the data bus.
- Detect all double-bit errors within the data bus.
- Detect most errors within a nibble.

DDRC allows you to open a dedicated page for each available DDR SDRAM bank. You can use DDR_SDRAM_INTERVAL[BSTOPRE] to control the amount of time (in clock cycles) that pages remain open.

Error management explains how DDRC handles errors.

28.3.2 Modes of operation

Table 145. Modes of operation

Mode	Description
Dynamic Power Management	In this mode, DDRC can reduce power consumption by negating the DDR SDRAM MCKE signal when no transactions are pending to the DDR SDRAM. This applies to LPDDR4, only.
Global Auto-Precharge	In this mode, DDRC issues an auto-precharge command with every read or write transaction. To enter this mode: • Write 0 to DDR_SDRAM_INTERVAL[BSTOPRE]. • For separate ranks, write 1 to CS_CONFIG*n*[AP_EN]. See Page-related modes and rank retention for more details.
Open-Page	In this mode, DDRC retains the currently active DDR SDRAM page by not issuing a precharge command. See Page-related modes and rank retention for more details.

28.3.3 Remapping regions

You can use the REMAP_*n*A and REMAP_*n*B registers to remap four regions.

You cannot:

- Overlap regions using REMAP_*n*A and REMAP_*n*B.
- Overlap a mapped region using REMAP_*n*A and REMAP_*n*B with an unmapped region.
- Enable a region for a register if all the regions below that register are enabled as well. This means that:
  - If you write 1 to REMAP_1A[REG_1_REMAP_EN], you must also write 1 to REMAP_0A[REG_0_REMAP_EN].
  - If you write 1 to REMAP_2A[REG_2_REMAP_EN], you must also write 1 to REMAP_0A[REG_0_REMAP_EN] and REMAP_1A[REG_1_REMAP_EN].
  - If you write 1 to REMAP_3A[REG_3_REMAP_EN], you must also write 1 to REMAP_0A[REG_0_REMAP_EN], REMAP_1A[REG_1_REMAP_EN], and REMAP_2A[REG_2_REMAP_EN].

The comparison with Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) occurs after DDRC remaps the AXI addresses mentioned in Remap Region 0B Configuration (REMAP_0B), Remap Region 1B Configuration (REMAP_1B), and Remap Region 2B Configuration (REMAP_2B) to the addresses mentioned in Remap Region 0A Configuration (REMAP_0A), Remap Region 1A Configuration (REMAP_1A) and Remap Region 2A Configuration (REMAP_2A) respectively. You must program Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) to match the addresses after remapping. After remapping, you can access the addresses (programmed in the REMAP_[0-3]A registers) only via the AXI addresses captured in the REMAP_[0-3]B registers. Mapped and nonmapped regions cannot overlap.

ECC is generated based on the AXI address that DDRC receives. DDR_SDRAM_CFG_2[D_INIT] must be 0 so that there is no data initialization in progress, and none scheduled. After writing 1 to DDR_SDRAM_CFG[MEM_EN], execute a write-only memory test on the entire DDR memory region to initialize ECC. If the AXI addresses being remapped are noncontiguous, ensure that the memory test starts from the lowest address range.

For example, if Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) indicates a memory range of 8000_0000h–81FF_FFFFh, program the REMAP registers for mapping 7A00_0000h–7BFF_FFFFh (REMAP_*n*B) to 8000_0000h–81FF_FFFFh (REMAP_*n*A). The ECC calculation uses the AXI address received (7A00_0000h–7BFF_FFFFh).

28.3.4 Timing parameters spanning multiple fields

28.3.4.1 Precharge-to-activate interval (t_{RP})

Calculate t_{RP}, in clock cycles, using this equation:

$$t_{RP} = \text{TIMING_CFG_3[EXT_PRETOACT]} \times 16d + \text{TIMING_CFG_1[PRETOACT]}$$

where TIMING_CFG_1[PRETOACT] must not be 0000

Equation 1. Precharge-to-activate interval (t_{RP})

28.3.4.2 Activate-to-precharge interval (t_{RAS})

Calculate t_{RAS}, in clock cycles, using the following table. The table demonstrates that the minimum value for t_{RAS} is 4.

Table 146. Activate-to-precharge interval (t_{RAS})

When TIMING_CFG_3[EXT_ACTTOPRE] is:	and TIMING_CFG_1[ACTTOPRE] is:	t_{RAS} equals:
000b	0000b	16
	0001b	17
	0010b	18
	0011b	19
	0100b–1111b	TIMING_CFG_1[ACTTOPRE]
001b–111b	0000b–1111b	TIMING_CFG_3[EXT_ACTTOPRE] × 16d + TIMING_CFG_1[ACTTOPRE]

28.3.4.3 Activate-to-read-or-write interval (t_{RCD})

Calculate t_{RCD}, in clock cycles, using this equation:

$$t_{RCD} = \text{TIMING_CFG_3[EXT_ACTTORW]} \times 16d + \text{TIMING_CFG_1[ACTTORW]}$$

where TIMING_CFG_1[ACTTORW] must not be 0

Equation 2. Activate-to-read-or-write interval (t_{RCD})

28.3.4.4 Refresh recovery time (t_{RFC})

Calculate t_{RFC}, in clock cycles, using this equation:

$$t_{RFC} = \text{TIMING_CFG_3[EXT_REFREC]} \times 16d + \text{TIMING_CFG_1[REFREC]} + 8$$

where TIMING_CFG_3[EXT_REFREC] must be less than 11_0000b

Equation 3. Refresh recovery time (t_{RFC})

28.3.4.5 CAS latency

CAS latency is the number of clock cycles between the registration of DDR SDRAM's READ command and the availability of the first output data. For example, if DDRC registers a READ command at clock edge *n* and the latency is *m* clocks, data is available nominally coincident with clock edge *n* + *m*. The largest-possible CAS latency is 44 clock cycles.

Calculate the latency using this equation:

$$\text{CAS latency} = \text{TIMING_CFG_3[EXT_CASLAT]} \times 8d + \text{TIMING_CFG_1[CASLAT]} + 1$$

Equation 4. CAS latency

28.3.4.6 Minimum write recovery interval (n_{WR})

n_{WR} specifies the number of clock cycles from the last data associated with a write command until a precharge command is allowed. Calculate n_{WR} using this equation:

$$n_{WR} = \text{TIMING_CFG_3[EXT_WRREC]} \times 16d + \text{TIMING_CFG_1[WRREC]}$$

Equation 5. Minimum write recovery interval (n_{WR})

28.3.4.7 Minimum MCKE pulse width (t_{CKE})

Calculate t_{CKE}, in clock cycles, using this equation:

$$t_{CKE} = \text{TIMING_CFG_3[EXT_CKE_PLS]} \times 8d + \text{TIMING_CFG_2[CKE_PLS]}$$

Equation 6. Minimum MCKE pulse width (t_{CKE})

28.3.4.8 Four-activate window (t_{FAW})

t_{FAW} is the time during which you can issue no more than four activate commands. Calculate t_{FAW}, in clock cycles, using this equation:

$$t_{FAW} = \text{TIMING_CFG_3[EXT_FOUR_ACT]} \times 64d + \text{TIMING_CFG_2[FOUR_ACT]}$$

where TIMING_CFG_2[FOUR_ACT] must not be 0

Equation 7. Four-activate window (t_{FAW})

28.3.4.9 Precharge power-down exit timing (t_{XP})

t_{XP} defines how long DDRC must wait after exiting precharge power-down before issuing a command to the DDR SDRAM. Calculate t_{XP}, in clock cycles, using this equation:

$$t_{XP} = \text{TIMING_CFG_0[EXT_PRE_PD_EXIT]} \times 16d + \text{TIMING_CFG_0[PRE_PD_EXIT]}$$

where TIMING_CFG_0[PRE_PD_EXIT] must not be 0

Equation 8. Precharge power-down exit timing (t_{XP})

28.3.4.10 Activate-to-activate interval (t_{RRD})

Calculate t_{RRD}, in clock cycles, using this equation:

$$t_{RRD} = \text{TIMING_CFG_3[EXT_ACTTOACT]} \times 16d + \text{TIMING_CFG_1[ACTTOACT]}$$

Equation 9. Activate-to-activate interval (t_{RRD})

where TIMING_CFG_1[ACTTOACT] must not be 0.

28.3.4.11 Write-to-read delay (t_{WTR})

Calculate t_{WTR}, in clock cycles, using this equation:

$$t_{WTR} = \text{TIMING_CFG_3[EXT_WRTORD]} \times 16d + \text{TIMING_CFG_1[WRTORD]}$$

Equation 10. Write-to-read delay (t_{WTR})

where TIMING_CFG_1[WRTORD] must not be 0.

28.3.4.12 Read-to-write turnaround

Calculate the read-to-write turnaround, in clock cycles, using this equation:

$$\text{Read-to-write turnaround} = \text{TIMING_CFG_0[RWT]} + \text{TIMING_CFG_4[EXT_RWT]} \times 4d + CL - WL + (BL \div 2) + 5$$

Equation 11. Read-to-write turnaround

where:

- CL = the CAS latency rounded up to the next integer
- WL = the programmed write latency
- BL = the burst length

28.3.4.13 Write-to-read turnaround

Calculate the write-to-read turnaround, in clock cycles, using this equation:

$$\text{Write-to-read turnaround} = \text{TIMING_CFG_0[WRT]} + \text{TIMING_CFG_4[EXT_RWT]} \times 4d + CL - WL + (BL \div 2) + 1$$

Equation 12. Write-to-read turnaround

where:

- CL = the CAS latency rounded up to the next integer
- WL = the programmed write latency
- BL = the burst length

28.3.4.14 Read-to-read turnaround

Calculate the read-to-read turnaround, in clock cycles, using this equation:

$$\text{Read-to-read turnaround} = \text{TIMING_CFG_0[RRT]} + \text{TIMING_CFG_4[EXT_RRT]} \times 4d + (BL \div 2) + 1$$

Equation 13. Read-to-read turnaround

where BL is the burst length.

28.3.4.15 Write-to-write turnaround

Calculate the write-to-write turnaround, in clock cycles, using this equation:

$$\text{Write-to-write turnaround} = \text{TIMING_CFG_0[WWT]} + \text{TIMING_CFG_4[EXT_WWT]} \times 4d + (BL \div 2)$$

Equation 14. Write-to-write turnaround

where BL is the burst length.

28.3.4.16 Total write latency

Calculate the total write latency, in clock cycles, using this equation:

Total write latency = TIMING_CFG_3[EXT_WR_LAT_2] × 32d + TIMING_CFG_2[EXT_WR_LAT] × 16d + TIMING_CFG_2[WR_LAT]

Equation 15. Total write latency

Follow these restrictions:

- The total write latency must be:
  - 34 cycles or less.
  - At least four clock cycles.
- Do not write 0b–101b to TIMING_CFG_2[WR_LAT] unless TIMING_CFG_2[EXT_WR_LAT] = 1.

28.3.5 Memory-test address restrictions

DDRC has restrictions for any individual memory test when you use the value of DDR_MTCR[MT_ADDR_EN] to limit the address range to be tested. In this case, neither of the following concatenated values (specified by curly brackets) can be less than the value used during the previous test:

- Starting address {DDR_MT_ST_EXT_ADDR[MT_ST_EXT_ADDR], DDR_MT_ST_ADDR[MT_ST_ADDR]}
- Ending address {DDR_MT_END_EXT_ADDR[MT_END_EXT_ADDR], DDR_MT_END_ADDR[MT_END_ADDR])}

28.3.6 Burst-oriented accesses

Read and write accesses to memory are burst-oriented—accesses start at a selected location and continue for a programmed burst (16 data beats). Accesses to closed pages begin with the registration of an ACTIVATE command, followed by a READ or WRITE command. To access an open page, you do not need an ACTIVATE command.

The address coincident with the ACTIVATE command specifies the logical bank and row to be accessed.

The address coincident with the READ or WRITE command specifies the logical bank and starting column for the burst access.

28.3.7 DDR SDRAM interface operation

DDRC supports the DDR SDRAM configurations shown in Supported DDR SDRAM configurations. The Command Address bus (CA) signals support numerous device densities. The CS signals (see External signals) support up to two ranks of memory. The data path to individual ranks is 16 bits wide.

DDRC supports ranks up to max 16 Gbit per device channel for LPDDR4,.

The ranks can be constructed using memory devices that are internally organized as x16 memory devices. The MDM signals provide byte selection for memory accesses.

NOTE

A 16-bit DDR SDRAM device has two MDM signals associated with specific halves of the 16 data signals (DQ[0:7] and DQ[8:15]).

When ECC is enabled, DDRC performs all memory accesses on doubleword boundaries (that is, all MDM signals assert simultaneously). However, when ECC is disabled, the memory system uses the MDM signals for byte lane selection when using x16 devices.

28.3.7.1 Relationship of byte lanes to data for x16 devices

Table 147. Relationship of byte lanes to data for x16 devices

Data byte lane	Data bus mask	Data bus strobe	Data bus
0	MDM[0]	MDQS[0] and MDQS_B[0]	MDQ[0:7]
1	MDM[1]	MDQS[1] and MDQS_B[1]	MDQ[8:15]

28.3.7.2 Supported DDR SDRAM configurations

28.3.7.2.1 LPDDR4

NOTE

Byte-mode LPDDR4 devices (x16 channel internally split between two dies, x8 each) of any density are not supported therefore, the numbers are applicable only to devices with x16 internal organization (referred to as "standard" in the JEDEC specification).

NOTE

Dual rank single channel devices are supported therefore, 16Gb/2GB density can be also achieved by using a dual rank single channel device with 16-row addresses (R0 - R15). The tables below always assume single rank configurations.

Table 148. LPDDR4, x16 device, single 16-bit channel

Device capacity (Gbit)	Device configuration	Row × column × bank bits
1	64 Mbit × 16	13 × 10 × 3
2	128 Mbit × 16	14 × 10 × 3
4	256 Mbit × 16	15 × 10 × 3
8	512 Mbit × 16	16 × 10 × 3
16	1 Gbit × 16	17 × 10 × 3

28.3.7.2.2 Transaction request outside of the programmed address range

If DDRC receives a transaction request and the address does not lie within any of the programmed address ranges for an enabled rank, DDRC reports a memory-select error. See Error management for a detailed description of errors.

28.3.7.2.3 Firmware configures DDRC

System firmware uses the memory-boundary registers to configure DDRC to map the size of each rank in memory.

DDRC uses its bank map to assert the appropriate MCS*n*_b signal for memory accesses according to the provided rank starting and ending addresses. You are not required to map the ranks to a contiguous address space.

28.3.8 DDR SDRAM address multiplexing

This section shows the address bit encodings for the supported DDR SDRAM configurations.

The address and bank address are encoded within the DDR SDRAM command that is presented on the MCAA pins.

NOTE

For LPDDR4, memories, the DDR SDRAM command includes the MA bits described in this section.

28.3.8.1 LPDDR4 , 16-bit data bus, no interleaving

Table 149. LPDDR4 , 16-bit data bus, no interleaving

		High bit	Address from core master																														Low bit
Row × col		32	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
17 × 10 × 3	MCAA ROW			16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
	MCAA BA																				2	1	0											
	MCAA COL																							9	8	7	6	5	4	3	2	1	0	
16 × 10 × 3	MCAA ROW				15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0														
	MCAA BA																				2	1	0											
	MCAA COL																							9	8	7	6	5	4	3	2	1	0

	MCAA BA																				2	1	0											
	MCAA COL																							9	8	7	6	5	4	3	2	1	0	
13 × 10 × 3	MCAA ROW							12	11	10	9	8	7	6	5	4	3	2	1	0														
	MCAA BA																				2	1	0											
	MCAA COL																							9	8	7	6	5	4	3	2	1	0	

28.3.9 DDR SDRAM refresh

DDRC supports auto-refresh and self-refresh commands.

Normal operation uses auto-refresh. You control this command by using DDR_SDRAM_INTERVAL[REFINT].

Use self-refresh only when you configure DDRC to enter a sleep power-management state.

The REFINT value:

- Specifies the number of memory bus clock cycles between refresh cycles
- Must accommodate possible outstanding transactions to complete before a refresh request is sent to the memory after the REFINT value is reached

If a memory transaction is in progress when REFINT is reached, the refresh cycle waits for the transaction to complete. In the worst-case scenario, the refresh cycle must wait for the number of bus clock cycles that the longest programmed access requires. Therefore, NXP recommends that the programmed REFINT value be less than what the DDR SDRAM requires. This ensures that a memory transaction does not cause any latency that could violate the device refresh period,

When a refresh cycle is required, DDRC:

1. Completes all current memory requests.
2. Closes all open pages by issuing a PRECHARGE-ALL command to each DDR SDRAM bank with an open page (as indicated by the row open table).
3. Issues one or more auto-refresh commands to each of the DDR SDRAM banks, as identified by their MCS signals, to refresh one row in each bank of the selected rank.

DDRC staggers the auto-refresh commands across the possible banks to reduce the system's instantaneous power requirements. When the memory is populated with two ranks, DDRC issues two sets of auto-refresh commands on consecutive cycles. DDRC also staggers the initial PRECHARGE-ALL commands in two groups for convenience. For this entire refresh sequence, no cycle optimization occurs for the usual case where fewer than two ranks are installed.

When the refresh sequence completes, DDRC initiates any pending memory requests after an inactive period specified by TIMING_CFG_1[REFREC] and TIMING_CFG_3[EXT_REFREC]. DDRC also supports posted refreshes that allow you to use a longer refresh interval.

28.3.9.1 DDR SDRAM refresh timing

You specify the DDR SDRAM refresh timing using TIMING_CFG_1[REFREC].

After reset, you must configure the refresh timing (TIMING_CFG_1[REFREC]) and the extended refresh recovery time (TIMING_CFG_3[EXT_REFREC]) before attempting to access the DDR SDRAM.

28.3.9.2 DDR SDRAM self-refresh and power-saving modes

In normal operation, DDRC issues auto-refresh commands based on the refresh timing (TIMING_CFG_4[EXT_REFINT], DDR_SDRAM_INTERVAL[REFINT]). In low-power modes, DDRC must issue self-refresh commands to preserve the data. You control when DDRC performs a self-refresh by:

- Setting the self-refresh idle threshold (DDR_SR_CNTR[SR_IT]).
- Writing 1 to DDR_SDRAM_CFG_2[FRC_SR].

In the absence of refresh support, you must preserve DDR SDRAM data—for example, by copying the data to disk.

For LPDDR4 , Dynamic Power Management mode offers tight control of the memory system's power consumption by trading power for performance. This mode uses the MCKE signal to dynamically power down the DDR SDRAM when there is no system memory activity. The MCKE signal deasserts when both of the following conditions are met:

- DDRC has not scheduled any memory refreshes.
- DDRC has not scheduled any memory accesses.

The MCKE signal asserts when a new access or refresh is scheduled. You control this mode by using DDR_SDRAM_CFG[DYN_PWR].

Powering up the DDR SDRAM when a new memory reference is scheduled causes an access latency penalty, depending on:

- Whether you use active or precharge powerdown.
- The settings of TIMING_CFG_0[ACT_PD_EXIT] and TIMING_CFG_0[PRE_PD_EXIT].

28.3.10 DDR SDRAM data beat ordering

DDRC always performs transfers to and from memory in 16-beat bursts. For transfer sizes other than 16 beats, the data transfers still operate as 16-beat bursts. If you enable ECC and either the access is not doubleword aligned or the size is not a multiple of a doubleword (8 byte), DDRC performs a full read-modify-write operation for a write to the DDR SDRAM. If you disable ECC or both accesses are doubleword-aligned with a size that is a multiple of a doubleword, you can use the data-mask signals to prevent the writing of unwanted data to the DDR SDRAM. DDRC also uses data masks to prevent the writing of all unintended full double words to the DDR SDRAM. For example, if you want a one-doubleword (8-byte) write transaction (in 16-bit channel), the remaining 12 beats of data are not written to the DDR SDRAM.

All writes to LPDDR4, memory align to beat 0 of the DDR SDRAM.

28.3.11 Page-related modes and rank retention

DDRC manages pages differently in Global Auto-Precharge mode and in Open-Page mode.

In Global Auto-Precharge mode, DDRC uses the DDR SDRAM auto-precharge feature. This feature allows DDRC to indicate that the DDR SDRAM must automatically close the page after the read or write access. This access is performed by using MA[10] of the address during the COMMAND phase of the access to enable auto-precharge. Auto-precharge is nonpersistent—you enable or disable it for each individual READ or WRITE command. You can, however, enable or disable auto-precharge separately for each rank. You disable Global Auto-Precharge mode by either of the following:

- Write 0 to DDR_SDRAM_INTERVAL[BSTOPRE]
- Write 1 to CS_CONFIG[AP_EN]

In Open-Page mode, DDRC allows an open page for each DDR SDRAM rank. In Open-Page mode, DDRC also retains the currently active DDR SDRAM page by not issuing a precharge command. The page remains opens until one of the following conditions occurs:

- The refresh interval completes.
- The time specified in DDR_SDRAM_INTERVAL[BSTOPRE] elapses.
- A bank row collision occurs with another transaction that DDRC just received.

Open-Page mode can dramatically reduce access latencies for page hits. Depending on the memory system design and timing parameters, using Open-Page mode can save several clock cycles for subsequent burst accesses that hit an active page. You can also obtain better performance by using more ranks.

28.3.12 ECC

DDRC supports ECC for the data path between the core and the system memory. The memory detects all double-bit errors and corrects all single-bit errors. It may detect other errors as well but not correct them. Double-bit errors are always reported when error reporting is enabled. When a single-bit error occurs, DDRC:

- Increments ERR_SBE[SBEC].
- Compares ERR_SBE[SBEC] to ERR_SBE[SBET].
- Reports an error if these values are equal.

You can program Single-Bit ECC Memory Error Management (ERR_SBE) in a way that DDRC corrects and ignores minor memory faults, but a catastrophic memory failure generates an interrupt.

For writes that are smaller than 64 bits, DDRC:

1. Performs a double-word read from system memory of the address for the write, checking for errors.
2. Merges the write data with the data read from memory.
3. Generates a new ECC code for the merged double word.
4. Writes the data and ECC code to memory.

If DDRC detects a multi-bit error after the read, the transaction completes the read-modify-write operation to prevent DDRC from hanging. However, the corrupt data is masked on the write, so the original contents in the DDR SDRAM remain unchanged.

28.3.13 Error management

28.3.13.1 Overview

DDRC detects these types of errors:

- Single-bit
- Multi-bit[1]
- Memory-select

This section and its subsections assume that you enabled all the relevant error detection, correction, and reporting functions as described in:

- Memory Error Address Capture (CAPTURE_ADDRESS)
- Memory Error Attributes Capture (CAPTURE_ATTRIBUTES)
- Memory Error Extended Address Capture (CAPTURE_EXT_ADDRESS)
- Memory Data Path Read Capture High (CAPTURE_DATA_HI)
- Memory Data Path Read Capture Low (CAPTURE_DATA_LO)
- Memory Data Path Read Capture ECC (CAPTURE_ECC)
- Memory Error Detect (ERR_DETECT)
- Memory Error Disable (ERR_DISABLE)
- Memory Error Interrupt Enable (ERR_INT_EN)

28.3.13.2 Error summary

Table 150. Error summary

Category	Error	Description	Action
Notification	Single-bit ECC threshold	The number of ECC errors has reached the threshold specified in Single-Bit ECC Memory Error Management (ERR_SBE).	If you enable interrupts, DDRC reports the error by generating the appropriate interrupt.
Access error	Multi-bit ECC error	A multi-bit ECC error is detected during a read or read-modify-write memory operation.	
	Memory-select error	Read or write address does not fall within the address range of any of the memory banks.	

[1] DDRC uses SECDED ECC, which corrects single-bit errors and detects double-bit errors. Detection of errors of more than two bits is not guaranteed. In this chapter, "multi-bit errors" refers to double-bit errors.

28.3.13.3 Single-bit errors

DDRC counts and reports single-bit errors depending on how you program Single-Bit ECC Memory Error Management (ERR_SBE). DDRC does this when it detects a single-bit error:

1. Corrects the data.
2. Increments ERR_SBE[SBEC].
3. Generates a critical interrupt if ERR_SBE[SBEC] = ERR_SBE[SBET].
4. Completes the transaction normally.

28.3.13.4 Multi-bit errors

DDRC does this when it detects a multi-bit error for a read operation:

1. Logs the error in ERR_DETECT[MBE].
2. Optionally generates the machine-check or critical interrupt (if you enable these as described in Memory Error Disable (ERR_DISABLE)).

28.3.13.5 Memory-select errors

These errors occurs when the address from the memory request does not fall into any of the enabled, programmed rank address ranges. DDRC does this when it detects a memory-select error:

1. Logs the error.
2. Optionally generates a critical interrupt (if you enable it as described in Memory Error Detect (ERR_DETECT)).

For all memory-select errors, DDRC does not issue any transactions onto the pins after the first read returns data strobes.Writes are not issued to the ADDR/CMD pins, but reads are issued to the first enabled rank. Write transaction is issued to the DRAM and the read transaction is not issued to the DRAM.

28.3.14 Performance monitoring

Performance monitor counters (PMC0–PMC10) are used to count events specified by the performance monitor local control registers.

- PMC0 (PMC0a and PMC0b) is a 64-bit counter that counts only clock cycles.
- PMC1–PMC10 are 32-bit counters that can monitor 64 counter-specific events in addition to counting 64 reference events.

The following figure shows the performance monitoring components, which consist of:

- One global control register (PMGC0)
- One 64-bit counter (PMC0)
- Ten 32-bit counters (PMC1–PMC10)
- Two local control registers for each counter

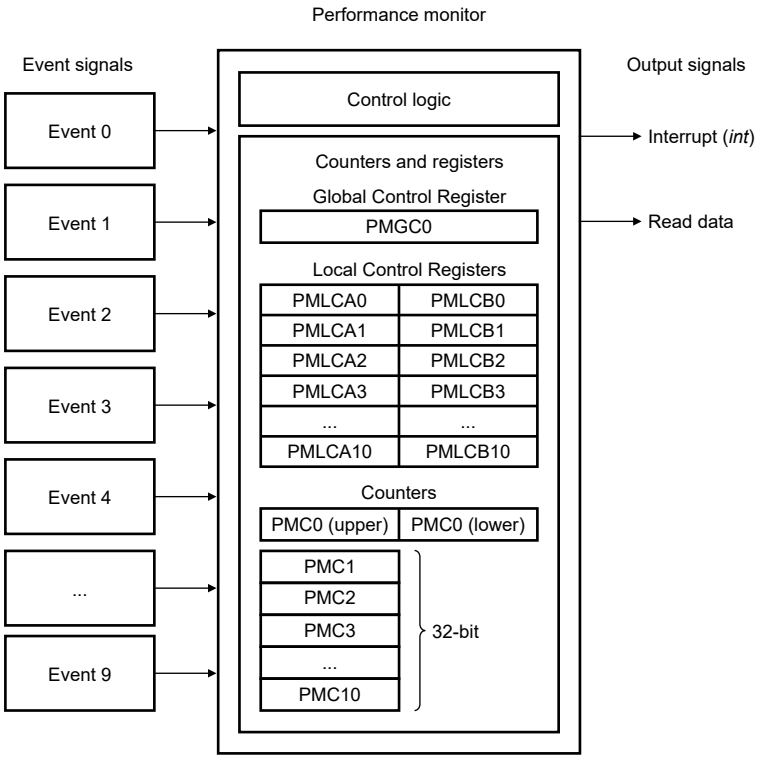

Figure 69. Performance monitor block diagram

The global control register, PMGC0, affects all counters and takes priority over local control registers.

The local control registers are divided into two groups:

- Local control A registers specify:
  - Counter freezing
  - Overflow condition enable
  - Event selection
  - Burstiness

  Local control register PMLCA0, which controls counter PMC0, does not contain event selection because PMC0 counts only cycles.
- Local control B registers:
  - Start and stop triggering
  - Contain the counters' threshold values
  - Contain the threshold multiplier

  Local control register PMLCB0, which controls PMC0, does not contain threshold information because PMC0 only counts cycles.

Performance monitor events are signaled by the functional blocks in DDRC and are selectively recorded in the counters.

- 64 of the events, called reference events, can be counted on any of the ten counters.
- The remaining events, called counter-specific events, can be counted only on the counter where the event is defined.

The performance monitor can generate an interrupt upon a counter overflow. The PMCs can also be programmed to freeze when an interrupt is signaled.

28.3.14.1 Performance monitor interrupt

PMCs can generate an interrupt on an overflow when the most significant bit of a counter transitions to 1. For the interrupt to be signaled, the condition enable field for the counter (PMLCA*n*[CE]) and performance monitor interrupt enable field (PMGC0[PMIE]) must both be 1.

When an interrupt is signaled and the freeze-counters-on-enabled-condition-or-event field (PMGC0[FCECE]) is 1, PMGC0[FAC] is set to 1 by hardware and all of registers are frozen. Software can clear the interrupt condition by resetting the performance monitor and writing 0 to the most significant bit of the counter that generated the overflow.

28.3.14.2 Event counting

PMC1–PMC10 can count the occurrences of specific events. PMC0 is designated to count only clock cycles. However, to provide flexibility, a total of 64 reference events can be counted on any of the 32-bit PMCs (PMC1–PMC10). Additionally, up to 64 unique events can be counted on each 32-bit counter.

You must reset the performance monitor before event-counting sequences. Reset the performance monitor by first freezing one or more counters and then clearing the freeze condition to enable the counters to count according to the register settings. You can freeze counters individually by writing 1 to PMLCA*n*[FC], or simultaneously by writing 1 to PMGC0[FAC]. Writing 0 to these fields enables the performance monitor to begin counting based on the register settings.

Using PMLCA*n*[FC] to reset the performance monitor resets only counter *n*.

28.3.14.3 Threshold events

The threshold feature allows characterization of events that can take a variable number of clock cycles to complete. A threshold event is counted only if the latency is greater than the threshold value specified in PMLCB*n*[THRESHOLD].

There are two types of threshold events:

- Duration threshold events
- Quantity threshold events

28.3.14.3.1 Duration threshold events

For duration threshold events, the 32-bit PMCs increment only when the duration of the event is equal to or greater than the threshold value. The threshold value is scaled by a multiple specified in PMLCB*n*[TBMULT].

A threshold event requires two signals:

- One signal indicates when a threshold event sequence begins.
- A second signal indicates when the event ends.

An internal counter determines when the threshold count is exceeded and when the PMC can increment. This internal counter decrements during a threshold event sequence until it reaches the value of one. A new sequence cannot begin until the current one completes.

Additional threshold start signals are ignored during a sequence until a threshold stop signal occurs. When both a start and stop signal are asserted during the same cycle in a current sequence, the stop terminates the current sequence and the start signals the beginning of a new one. However, if both signals are asserted during the same cycle while not in a current event sequence, both signals are ignored. The following figure is a timing diagram for duration threshold event counting.

Several illegal conditions for threshold counting cause undefined behavior. An illegal condition exists if the threshold value obtained from PMLCB*n*[THRESHOLD] and PMLCB*n*[TBMULT] is less than two. Under these conditions, the intent of threshold counting is ambiguous.

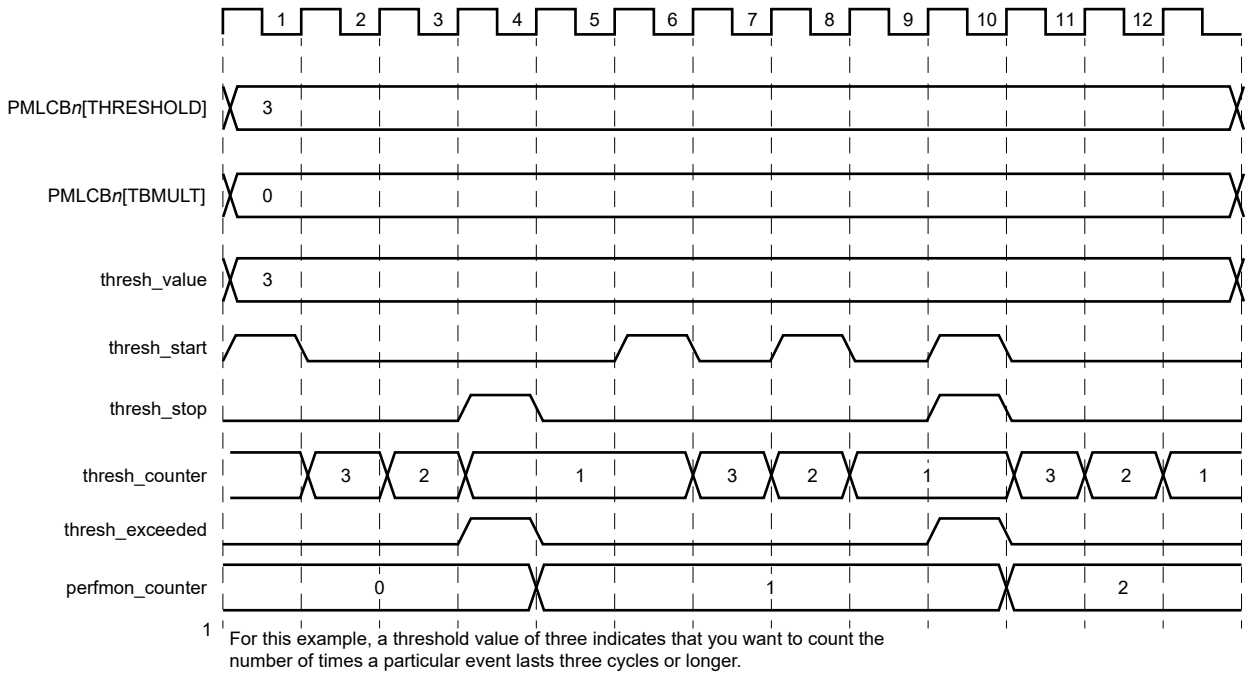

Figure 70. Duration threshold event sequence timing diagram

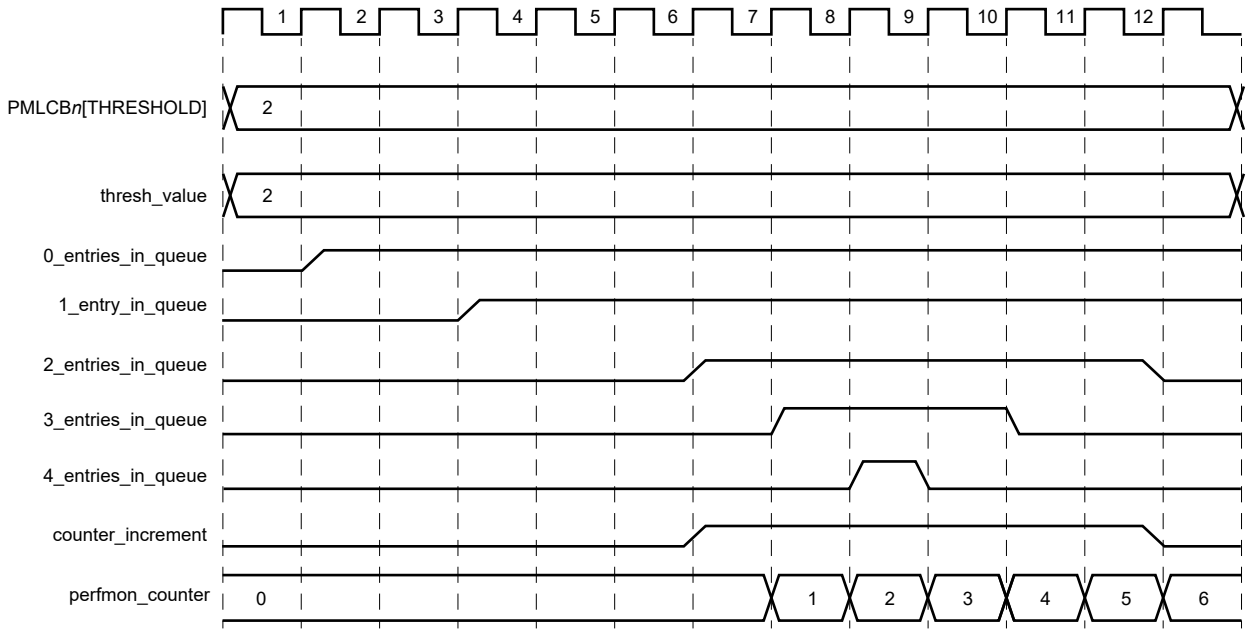
28.3.14.3.2 Quantity threshold events

For quantity threshold events, the performance monitor counter is only incremented when the specified threshold event exceeds the threshold value. These events do not use the multiplier register field (PMLCB*n*[TBMULT]) like the duration threshold events. This type of threshold event is generally used to monitor the usage of buffers and queues. For example, the usage of a specific queue could be characterized by measuring the amount of time the queue is completely full or partially full. For this example, the threshold field would be used to specify how many entries are required to be valid in the queue for that event to be counted. The following figure shows a timing diagram for quantity threshold event counting.



Note: For this example, a threshold value of two indicates that you want to count the number of cycles. There are at least two valid entries in a particular queue.

Figure 71. Quantity threshold event sequence timing diagram

28.3.14.4 Event signals table

Table 151. Event signals

Event ID	Event type	Counter(s)	PMLCA*n*[EVENT] value[1] (h)	Description
REF_12	Reference	C1–C10	0C	Number of read-modify-writes that are required due to ECC
REF_13	Reference	C1–C10	0D	Number of times a read is reordered ahead of another transaction
REF_14	Reference	C1–C10	0E	Number of times a write is reordered ahead of another transaction
REF_15	Reference	C1–C10	0F	Number of internal controller cycles the DDR controller samples data from the DDR PHY for reads
REF_17	Reference	C1–C10	11	Number of pipelined reads that were page misses
REF_18	Reference	C1–C10	12	Number of pipelined reads or writes that were page misses
REF_19	Reference	C1–C10	13	Number of non-pipelined reads that were page misses
REF_22	Reference	C1–C10	16	Number of non-pipelined reads or writes that were page misses
REF_23	Reference	C1–C10	17	Number of pipelined reads that were page hits
REF_24	Reference	C1–C10	18	Number of pipelined reads or writes that were page hits
REF_25	Reference	C1–C10	19	Number of non-pipelined reads that were page hits
REF_26	Reference	C1–C10	1A	Number of non-pipelined reads or writes that were page hits

Table continues on the next page...

Table 151. Event signals (continued)

Event ID	Event type	Counter(s)	PMLCA*n*[EVENT] value[1] (h)	Description
REF_27	Reference	C1–C10	1B	Number of precharges issued to DRAM that are not caused by a refresh
REF_28	Reference	C1–C10	1C	Number of page misses for oldest transaction
REF_31	Reference	C1–C10	1F	Number of page hits for oldest transaction
REF_59	Reference	C1–C10	3B	Number of precharges including PRE_ALL commands for refreshes
REF_61	Reference	C1–C10	3D	Number of precharges due to bank collision
REF_63	Reference	C1–C10	3F	Number of cycles that commands are stalled due to lack of resources for DRAM access timings
PMC2_72	Counter	C2	48	Number of cycles the scheduler is empty
PMC2_73	Counter	C2	49	Number of filtered write data beats
PMC3_72	Counter	C3	48	Number of cycles the scheduler is full
PMC3_73	Counter	C3	49	Number of filtered read data beats per mask 0
PMC4_72	Counter	C4	48	Number of transactions that load a read for a read-modify-write
PMC4_73	Counter	C4	49	Number filtered read data beats per mask 1
PMC5_72	Counter	C5	48	Number of times medium priority read is loaded to scheduler
PMC5_73	Counter	C5	49	Number of filtered read data beats per mask 2
PMC6_64	Counter	C6	40	Number of cycles interface is blocked for a refresh (only valid for all-bank refresh)
PMC6_72	Counter	C6	48	Number of times low-priority read is loaded to scheduler
PMC7_64	Counter	C7	40	Number of cycles the scheduler is half full
PMC7_65	Counter	C7	41	Number of times a write is loaded to scheduler
PMC8_64	Counter	C8	40	This signal asserts each time the read/write bias is switched for arbitration
PMC8_65	Counter	C8	41	Number of cycles the scheduler is 1/4 full
PMC9_66	Counter	C9	42	Number of cycles the scheduler is 3/4 full
PMC10_66	Counter	C10	42	Number of times high priority read is loaded to scheduler

1. All values not listed are reserved.

28.3.14.5 Chaining

By configuring one counter to increment each time another counter overflows, several counters can be chained together to provide event counts larger than 32 bits. Each counter in a chain adds 32 bits to the maximum count. The register chaining sequence is not arbitrary and is specified indirectly by selecting the register overflow event to be counted. Selecting an event has the effect of selecting a source register because all available chaining events, are dedicated to specific registers.

The chaining overflow event occurs when the counter reaches its maximum value and wraps, not when the register's most significant bit transitions to 1. For this overflow to occur, PMLCA*n*[CE] must be zero to avoid signaling an interrupt when the

counter's most significant bit transitions to 1. Several cycles may be required for the chained counters to reflect the true count because of the internal delay between when an overflow occurs and a counter increments.

28.3.14.6 Triggering

Triggering allows one counter to start or stop counting on the change of another counter or on the overflow of another counter. More specifically, if PMC1 is set to start or stop counting as a result of a change or overflow in counter PMC2, then counter PMC2 must be identified in the local control register of counter PMC1. This is done by appropriately setting the trigger-on select bit or trigger-off select bit (PMLCB1[TRIGONSEL] or PMLCB1[TRIGOFFSEL]). Additionally, the condition that triggers the counter must be selected by configuring the corresponding control bits (PMLCB1[TRIGONCNTL] or PMLCB1[TRIGOFFCNTL]). Assuming the counter is enabled by other control register settings, the counter increments (or freezes) when its specified event occurs after the trigger-on (or off) condition occurs.

When trigger on and trigger off are both selected, the trigger-off condition is ignored until the trigger-on condition has occurred. Furthermore, when a trigger-off condition occurs, the counter state is preserved; it is not restarted by subsequent trigger-on conditions.

Triggering is disabled when the counter's trigger-select bits specify itself as the trigger source. Similarly, triggering is disabled when the trigger control bits are cleared.

28.3.14.7 Burstiness counting

The burstiness counting feature makes it easier to characterize events that occur in rapid succession followed by a relatively long pause. As shown in the table below, event bursts are defined by size, granularity, and distance.

Table 152. Burstiness counting

Parameter	Description	Register field
Size	The minimum number of events constituting a burst	PMLCA*n*[BSIZE]
Granularity	The maximum time between individual events counted as members of the same burst	PMLCA*n*[BGRAN]
Distance	The minimum time between bursts	PMLCA*n*[BDIST] × PMLCB*n*[TBMULT]

The figure below shows the relationships between size, granularity, and distance. Burstiness counting can be performed for all events except threshold events.

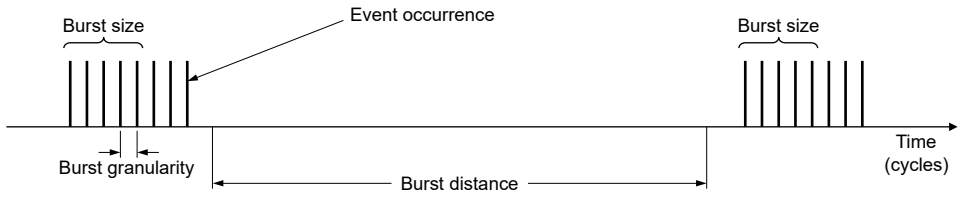


Figure 72. Burst size distance granularity and burstiness counting

The burstiness size field (PMLCA*n*[BSIZE]) specifies the minimum number of event occurrences that constitute a burst. A burst is identified when the number of event occurrences equals or exceeds PMLCA*n*[BSIZE]. Furthermore, these individual event occurrences must be separated by no more clock cycles than the value in the burstiness granularity field (PMLCA*n*[BGRAN]). Although a burst is identified when the minimum number of events occurs, it is not counted until the burst sequence has ended. A burst sequence ends when the specified burstiness granularity is exceeded, at which point the last valid event has occurred for that sequence.

PMLCA*n*[BGRAN] specifies the maximum number of cycles between individual events for them to qualify as members of the same burst sequence.

The burstiness distance field (PMLCA*n*[BDIST]) and threshold/burstiness multiplier field (PMLCB*n*[TBMULT]) specify the acceptable number of cycles between the end of a burst sequence and the beginning of a new sequence for a group of event occurrences to be counted as an individual burst.

The product of the burstiness distance field and the threshold/burstiness multiplier field determine the burstiness distance value used to determine when another burst sequence can begin. Note that the burst distance count begins when a new burst sequence ends and the PMC is incremented. No new burst sequence may begin until the burst distance count has reached zero. After the burst distance count reaches zero, it holds the zero value indicating that a new burst sequence can be counted. The burst distance count begins again when a new burst sequence is identified and counted.

Burstiness counting is disabled when the definition of a burst is ambiguous, that is, when the burst size field is less than two, or the burst distance is zero. When burstiness counting is disabled, regular counting is allowed.

Figure 73 shows that the burst distance is measured from the end of one burst sequence and that a new burst sequence may not begin until the burst distance count expires.

Three internal counters track the different values required for burstiness counting.

- Burstiness size is monitored by a counter. It is loaded with the value specified in the local control register when the burst granularity counter and the burst distance counters reach zero, and no new event is occurring. It always decrements when the following conditions occur: its value is not already zero, an event occurs, and the burst distance count equals zero.
- Burstiness granularity is monitored by a counter that is loaded with the specified value in the local control register on the rising edge of an event occurrence whenever the burst distance count equals zero. The granularity counter is decremented (if it has not already reached zero) when an event is not occurring and burst distance count equals zero.
- Burstiness distance is measured by a counter (burst_dist_ctr) that is loaded with the product of PMLCB*n*[BDIST] and PMLCB*n*[TBMULT] when a burst sequence has been identified and counted. This counter is decremented when burstiness counting is enabled (and the counter has not already reached zero).

A burst is counted at the end of a burst sequence when the three burst parameter counters are all zero. Figure 73 shows a burstiness counting example.

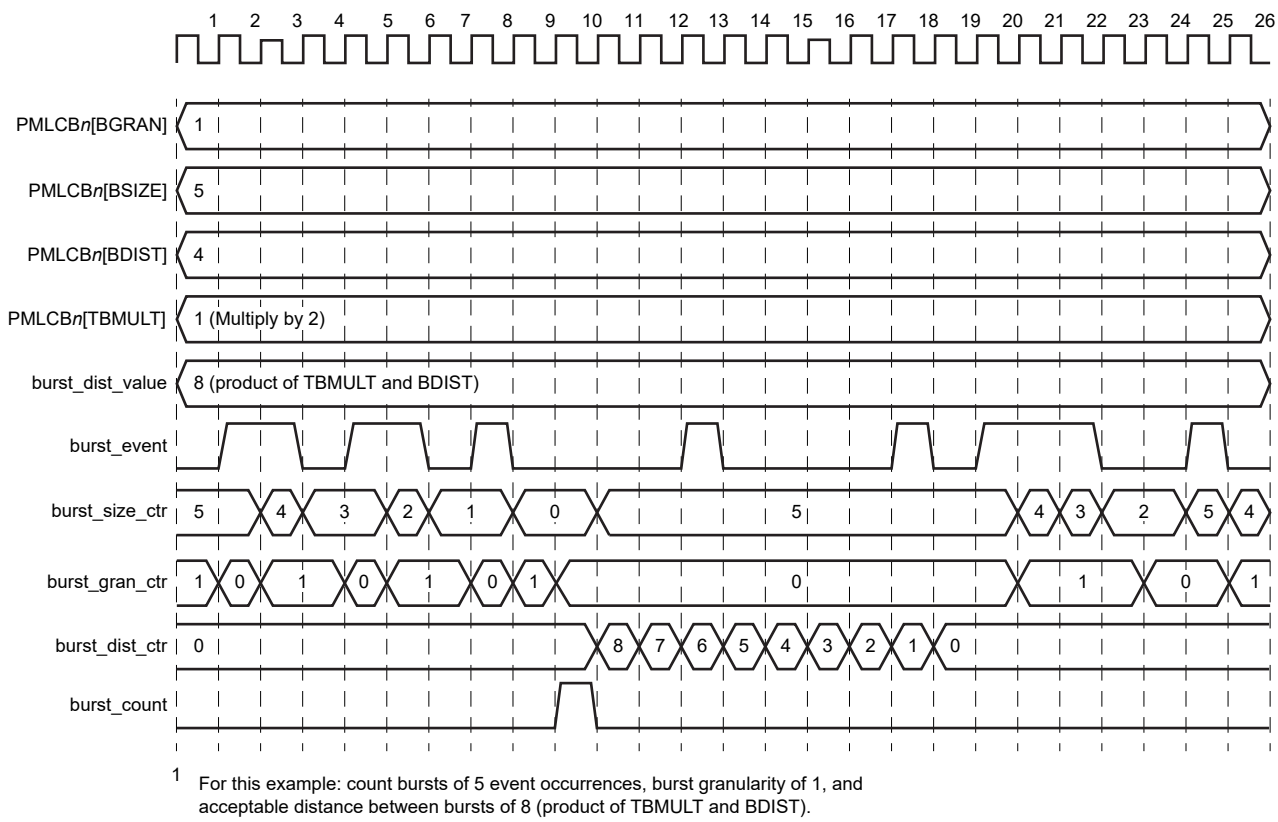

Figure 73. Burstiness counting timing diagram

28.3.15 Clocking

This module has no clocking considerations.

28.3.16 Interrupts

This section describes the interrupts generated by DDR.

Interrupts are generated in the following cases:

- Performance monitor counters generate an interrupt when an event count threshold is exceeded.
- Catastrophic memory failure.
- In case of a single-bit error if ERR_SBE[SBEC] = ERR_SBE[SBET], critical interrupt is generated. See Single-Bit ECC Memory Error Management (ERR_SBE) for details.
- In case of a multi-bit error if ERR_DISABLE[MBED] = 0, ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] = 1, machine-check or critical interrupt is generated. See Memory Error Disable (ERR_DISABLE), Memory Error Interrupt Enable (ERR_INT_EN) and for details.
- In case of Memory-select errors if ERR_DETECT[MBE], ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] = 1
- The performance monitor signals an interrupt when PMGC0[FCECE] = 1
- Writing 1 to PMCn[PMCn] may cause immediate interrupt
- ERR_INT_EN[MSEE, SBEE, MBEE, SSBE12E, REFRATEEE, UPDTMTEE,] enables ECC interrupts or memory-select error interrupts

28.4 External signals

This section provides a summary and details of DDRC external signals.

See the chip data sheet for:

- A pinout diagram showing pin numbers
- Electrical and mechanical specifications

28.4.1 Signal summary LPDDR4

Table 153. Signal summary

Name	Description	Reset	Pins	Input or output
MCAA[5:0]	LPDDR4, address and command	All zeros	6	Output
MCK	DDR SDRAM clock output	0	1	Output
MCK_b	DDR SDRAM clock output (complement)	1	1	Output
MCKE[0:1]	DDR SDRAM clock enable		2	Output
MCS[1:0]_b	CS	All ones	2	Output
MDM[1:0]	Data mask	All zeros	2	Output
MDQ[15:0]	Data bus	All zeros	16	Input or output
MDQS[1:0]	Data strobes	All zeros	2	Input or output
MDQS[1:0]_b	Complement data strobes	All ones	2	Input or output
ZN	Driver impedance calibration	See the chip data sheet	1	Input or output

28.4.2 Signal details LPDDR4

Table 154. Signal details

Signals	Description	
LPDDR4 address and command bus MCAA[5:0]	These signals control DDRC outputs for the DDR SDRAM. MA0 is the least-significant bit of the DDRC address output. A is for channel A.	
	Input	—
	Output	These signals represent the address that DDRC drives. They contain different portions of the address depending on the memory size and the DDR SDRAM command that DDRC issues. See DDR SDRAM address multiplexing for a complete mapping of these signals. When DDRC is enabled, it always drives the address, which is valid when a transaction is driven to DDR SDRAM. The signals are in the high-impedance state when DDRC is disabled.
DDR SDRAM clock outputs • MCK	These signals comply with the JEDEC DDR SDRAM specifications, which require true and complement clocks. The DDR SDRAM sees a clock edge when the true and complement signal waveforms cross.	

Table continues on the next page...

Table 154. Signal details (continued)

Signals	Description	
• MCK_b	Input	—
	Output	These signals provide the DDR SDRAM clock output and its complement.
Clock enable MCKEA	This signal enables the clock for the DDR SDRAM. You can deassert it to stop clocking the DDR SDRAM. You must connect this signal for the same memory rank as the corresponding MCK and MCK_b pair.	
	Input	—
	Output	Assertion of this signal indicates that clocking for the DDR SDRAM is enabled. Deassertion of this signal indicates that clocking for the DDR SDRAM is disabled and the DDR SDRAM must ignore MCK or MCK_b signal transitions. MCK and MCK_b become irrelevant during MCKE deassertion. This signal asserts when you write 1 to DDR_SDRAM_CFG[MEM_EN]. DDRC: • Negates this signal when DDRC enters Dynamic Power Management mode or performs a self-refresh. • Asserts this signal again when DDRC exits Dynamic Power Management mode or finishes a self-refresh.
Chip selects MCSA[1:0]_b	These signals select a physical DDR SDRAM rank to perform a memory operation as described in Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) and Rank n Configuration (CS0_CONFIG - CS1_CONFIG).	
	Input	—
	Output	DDRC asserts these signals to begin a memory cycle and negates them when no DDR SDRAM action occurs during the current cycle. The transaction must follow the timing constraints defined in the TIMING_CFG_*n* registers.
DDR SDRAM data output masks MDM[1:0]	These signals mask unwanted bytes of data transferred during a write. You need these signals to support sub-burst-size transactions (such as single-byte writes) on DDR SDRAM where all input and output occurs in multi-byte bursts. MDM0 corresponds to the least-significant byte and MDM1 corresponds to the most-significant byte. Relationship of byte lanes to data for x16 devices shows byte lane encodings. The timing of these signals is the same as that of MDQ*n*.	
	Input	—
	Output	Asserting these signals prevents writing to the DDR SDRAM. Deasserting these signals allows you to read or write the corresponding byte in the DDR SDRAM.
Data bus MDQ[15:0]	These signals provide a bidirectional data bus for DDRC's input and output signals.	

Table continues on the next page...

Table 154. Signal details (continued)

Signals	Description	
	When these signals are in the high-impedance state, no READ or WRITE commands are in progress, and neither DDRC nor the DDR SDRAM drives any data.	
	Input	The signals represent the data that the external DDR SDRAMs drive during a READ transaction.
	Output	The signals represent the data that DDRC drives when writing to the DDR SDRAM.
Data strobes • MDQS[1:0] • MDQS[1:0]_b	These are differential signals that indicate when the MDQ signals convey valid data. See DDR SDRAM interface operation for byte-lane assignments.	
	Input	These signals are driven high when positive capture data is received and driven low when negative capture data is received. If a READ command is registered at clock edge *n*, and you program the latency in TIMING_CFG_1[CASLAT] to be *m* clocks, data strobes at the DDR SDRAM assert coincidentally with the data on clock edge *n*+*m*.
	Output	These signals are driven high when positive capture data is transmitted and driven low when negative capture data is transmitted. If a WRITE command is registered at clock edge *n*, data strobes at the DDR SDRAM assert centered in the data eye on clock edge *n*+1.
Driver impedance calibration ZN	This signal is used for automatic driver calibration. See the chip data sheet for the proper value and connection of the ZN resistor.	
	Input	DDRC drives this signal for four DDR SDRAM cycles at a time when DDRC executes the automatic driver compensation.
	Output	

28.5 Initialization

28.5.1 Fields to initialize at startup

Your boot code must configure the following fields at system reset or startup.

Table 155. Fields to initialize at startup

Register	Fields

28.6.2 Rank n Memory Bounds (CS0_BNDS - CS1_BNDS)

Defines the starting and ending address of the memory space that corresponds to rank *n*.

When writing to this register, you must ensure that:

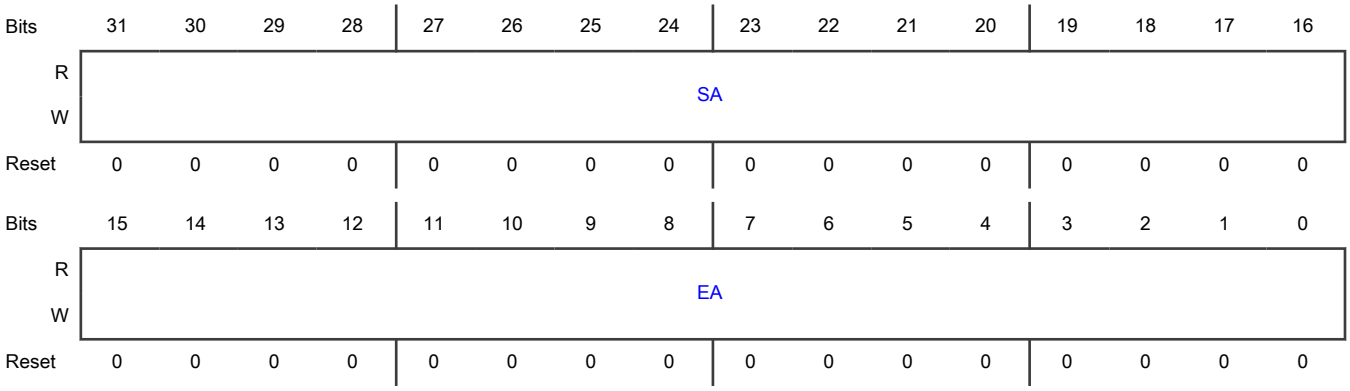
- The memory-space size you specify must equal the size of the physical DDR SDRAM.
- EA is greater than or equal to SA.

When you enable rank interleaving, DDRC uses only the fields in the lower interleaved rank to define the memory space, and does not use the other ranks' CS*n*_BNDS registers. For example, if ranks 0 and 1 are interleaved, DDRC uses CS0_BNDS but does not use CS1_BNDS.

Offset

Register	Offset
CS0_BNDS	0h
CS1_BNDS	8h

Diagram



Fields

Field	Description
31-16 SA	Starting Address Specifies the starting address for rank *n*. DDRC compares the lower 8 bits of this field with the 8 most-significant bits of the 32-bit address. You must write 0b to the upper 8 bits of this field.
15-0 EA	Ending Address Specifies the ending address for rank *n*. DDRC compares the lower 8 bits of this field with the 8 most-significant bits of the 32-bit address. You must write 0b to the upper 8 bits of this field.

28.6.3 Remap Region 0A Configuration (REMAP_0A)

Works with Remap Region 0B Configuration (REMAP_0B) to enable a region that you can remap to a different memory region as DDRC receives the remap address. See Remapping regions for what you can and cannot do when remapping.

The comparison with Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) occurs after DDRC remaps the AXI address mentioned in REMAP_[0-3]B registers on the address mentioned in REMAP_[0-3]A registers. You must program Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) to match the address after remapping. The addresses after remapping (programmed in REMAP_[0-3]A registers) can be accessed only via AXI addresses captured in REMAP_[0-3]B registers. Mapped and nonmapped regions cannot overlap.

Field	Description
—	
23-18 ROW0_OVRD	Row 0 Override Indicates the placement of row bit 0 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
17-16 —	Reserved
15-10 COL10_OVRD	Col 10 Override Indicates the placement of col bit 10 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
9-8 —	Reserved
7-2 COL9_OVRD	Col 9 Override Indicates the placement of col bit 9 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
1-0 —	Reserved

28.6.16 DDRC Address Decode 5 (DDR_ADDR_DEC_5)

Defines how the specified bits of the DDR SDRAM address are mapped to the original address of the transaction when you enable address decode overrides via DDR_ADDR_DEC_9[ADDR_DEC_OVRD].

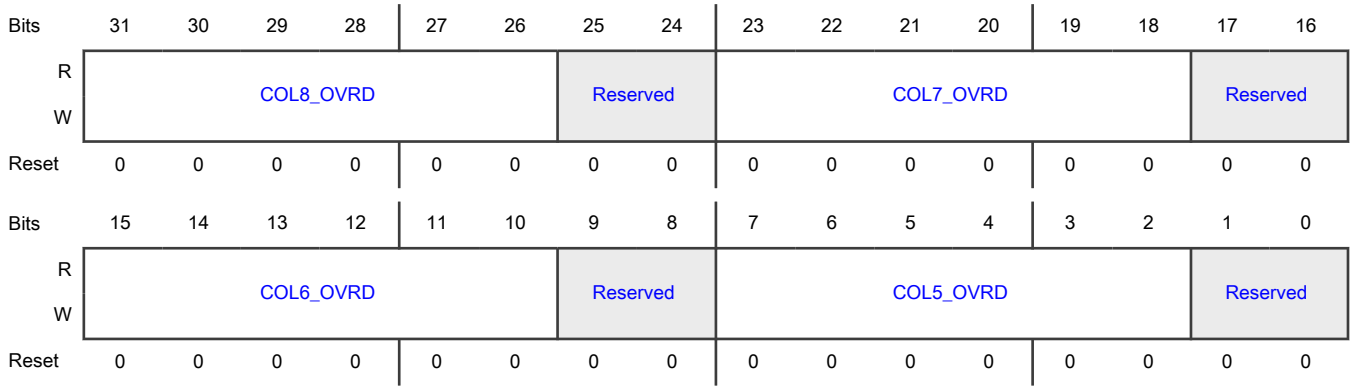
NOTE

When inline ECC is used for LPDDR4, we cannot override, lowest 7 Column bits and upper 3 row bits when ECC is enabled.

Offset

Register	Offset
DDR_ADDR_DEC_5	54h

Diagram



Fields

Field	Description
31-26 COL8_OVRD	Col 8 Override Indicates the placement of col bit 8 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
25-24 —	Reserved
23-18 COL7_OVRD	Col 7 Override Indicates the placement of col bit 7 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
17-16 —	Reserved
15-10 COL6_OVRD	Col 6 Override Indicates the placement of col bit 6 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
9-8 —	Reserved
7-2 COL5_OVRD	Col 5 Override Indicates the placement of col bit 5 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
1-0 —	Reserved

28.6.17 DDRC Address Decode 6 (DDR_ADDR_DEC_6)

Defines how the specified bits of the DDR SDRAM address are mapped to the original address of the transaction when you enable address decode overrides via DDR_ADDR_DEC_9[ADDR_DEC_OVRD].

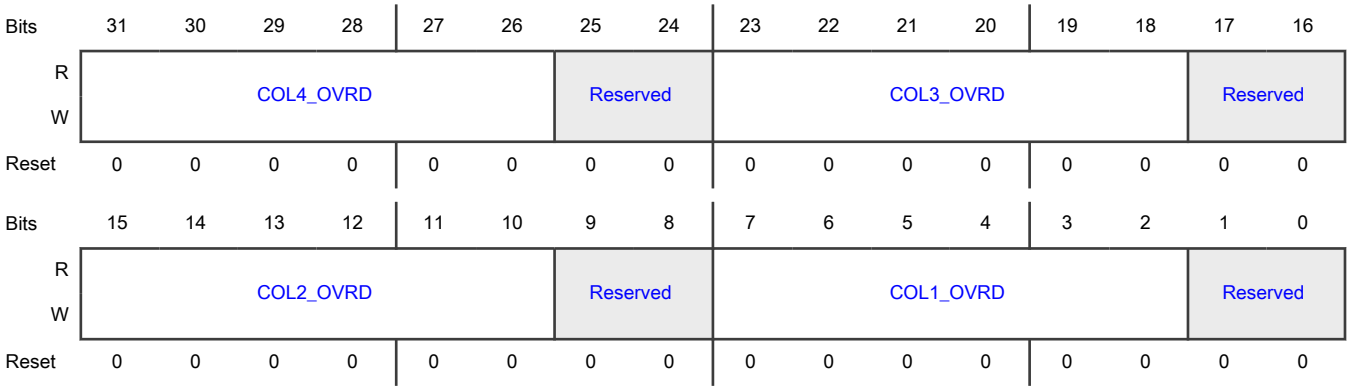
NOTE

When inline ECC is used for LPDDR4, we cannot override, lowest 7 Column bits and upper 3 row bits when ECC is enabled.

Offset

Register	Offset
DDR_ADDR_DEC_6	58h

Diagram



Fields

Field	Description
31-26 COL4_OVRD	Col 4 Override Indicates the placement of col bit 4 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1. You must write 100b to this field for a 64-bit bus, and 11b for a 32-bit bus.
25-24 —	Reserved
23-18 COL3_OVRD	Col 3 Override Indicates the placement of col bit 3 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1. You must write 101b to this field for a 32-bit bus.
17-16 —	Reserved
15-10 COL2_OVRD	Col 2 Override Indicates the placement of col bit 2 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1. You must write 101b to this field for a 64-bit bus, and 100b for a 32-bit bus.
9-8 —	Reserved
7-2 COL1_OVRD	Col 1 Override Indicates the placement of col bit 1 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	You must write 100b to this field for a 64-bit bus, and 11b for a 32-bit bus.
1-0 —	Reserved

28.6.18 DDRC Address Decode 7 (DDR_ADDR_DEC_7)

Defines how the specified bits of the DDR SDRAM address are mapped to the original address of the transaction when you enable address decode overrides via DDR_ADDR_DEC_9[ADDR_DEC_OVRD].

NOTE

When inline ECC is used for LPDDR4, we cannot override, lowest 7 Column bits and upper 3 row bits when ECC is enabled.

Field	Description
31-26 CID0_OVRD	CID 0 Override Indicates the placement of CID bit 0 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
25-24 —	Reserved
23-18 CS1_OVRD	Interleaved Rank 1 Override Indicates the placement of interleaved rank bit 1 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
17-16 —	Reserved
15-10 CS0_OVRD	Interleaved Rank 0 Override Indicates the placement of interleaved rank bit 0 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
9-8 —	Reserved
7-2 BG1_OVRD	Bank Group 1 Override Indicates the placement of bank group bit 1 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
1-0 —	Reserved

28.6.20 DDRC Address Decode 9 (DDR_ADDR_DEC_9)

Defines how the specified bits of the DDR SDRAM address are mapped to the original address of the transaction when you enable address decode overrides via DDR_ADDR_DEC_9[ADDR_DEC_OVRD].

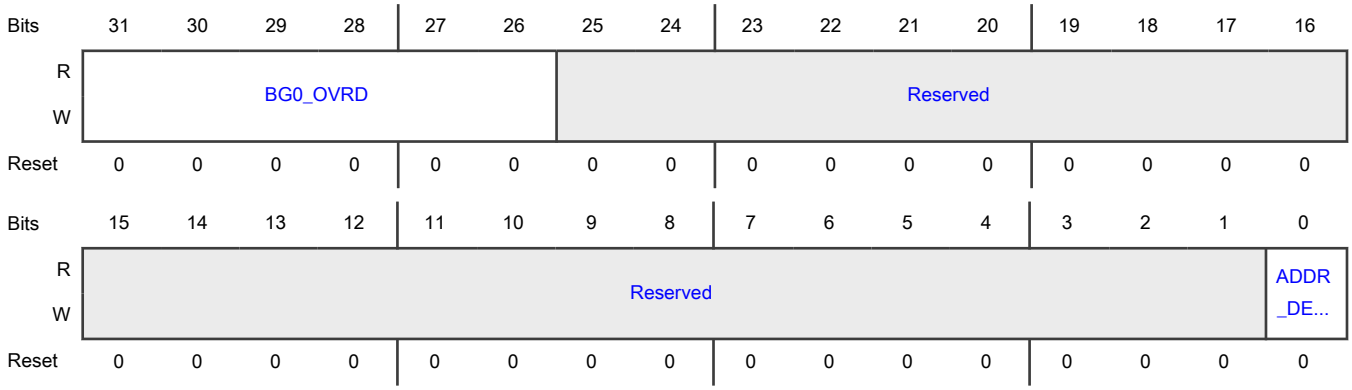
NOTE

When inline ECC is used for LPDDR4, we cannot override, lowest 7 Column bits and upper 3 row bits when ECC is enabled.

Offset

Register	Offset
DDR_ADDR_DEC_9	64h

Diagram



Fields

Field	Description
31-26 BG0_OVRD	Bank Group 0 Override Indicates the placement of bank group bit 0 in the address when DDR_ADDR_DEC_9[ADDR_DEC_OVRD] = 1.
25-1 —	Reserved
0 ADDR_DEC_OVRD	Address Decode Override Enables the DDR_ADDR_DEC_*n* registers to define the address decode scheme. If this field is enabled, you can implement all the fields of the DDR_ADDR_DEC_*n* registers while leaving a proper field for memory controller interleaving. When using a 16-bit bus, the least-significant bit of the address does not have an override bit mapped to it, and when using a 32-bit bus, the two least-significant bits of the address do not have an override bit mapped to them. When using inline ECC, you cannot alter the lower 7 column bits from their standard placement via the address decode registers.

28.6.21 Rank n Configuration (CS0_CONFIG - CS1_CONFIG)

Enables the DDR SDRAM rank and sets the number of row and column bits used for the rank.

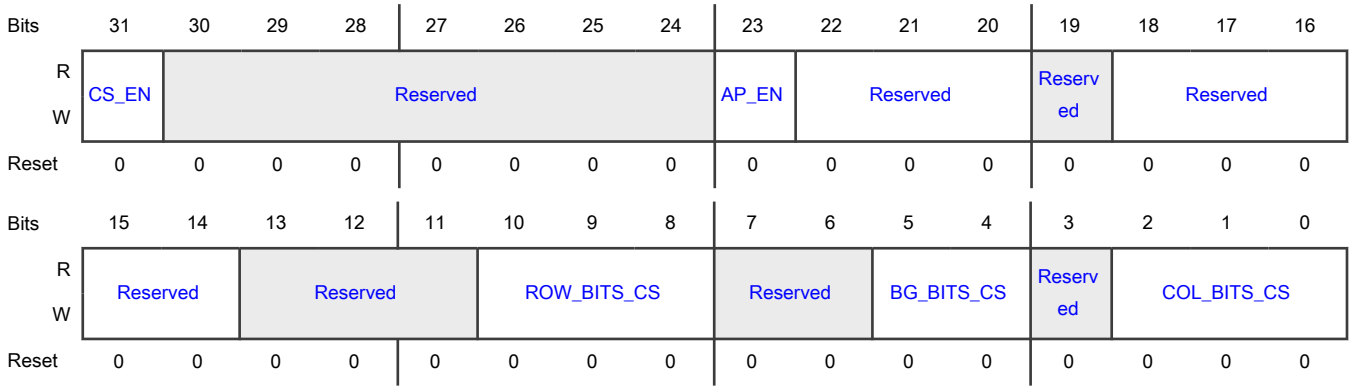
You must write the correct number of row and column bits for each DDR SDRAM to this register.

Because ROW_BITS_CS and COL_BITS_CS establish address multiplexing, you must ensure that you wrote the correct values.

Offset

Register	Offset
CS0_CONFIG	80h
CS1_CONFIG	84h

Diagram



Fields

Field	Description
31 CS_EN	Rank Enable Enables rank *n*. When CS_EN = 1, the rank assumes the state defined in Rank n Memory Bounds (CS0_BNDS - CS1_BNDS). The DDR PHY initialization begins when you write 1 to this field and completes when DDRC changes DDRDSR_2[PHY_INIT_CMPLT] to 1. You must write 1 to DDR_SDRAM_CFG[MEM_EN] after the initialization completes. 0 - Disables 1 - Enables
30-24 —	Reserved
23 AP_EN	Auto-Precharge Enable Enables the auto-precharge command for rank *n*. The rank: • Precharges automatically only if you enabled Global Auto-Precharge mode (DDR_SDRAM_INTERVAL[BSTOPRE] = 0). • Always issues an auto-precharge command for read and write transactions. 0 - Disables 1 - Enables
22-20 —	Reserved
19 —	Reserved

Fields

Field	Description
31-30 RWT	Read-To-Write Turnaround To Different Ranks Specifies clock cycles that combine with TIMING_CFG_4[EXT_RWT] to define the read-to-write turnaround (see Read-to-write turnaround) to different ranks.
29-28	Write-To-Read Turnaround To Different Ranks

Table continues on the next page...

Table continued from the previous page...

Field	Description
WRT	Specifies clock cycles that combine with TIMING_CFG_4[EXT_WRT] to define the read-to-write turnaround (see Write-to-read turnaround) to different ranks.
27-26 RRT	Read-To-Read Turnaround To Different Ranks Specifies clock cycles that combine with TIMING_CFG_4[EXT_RRT] to define the read-to-read turnaround (see Read-to-read turnaround) to different ranks.
25-24 WWT	Write-To-Write Turnaround To Different Ranks Specifies the number of extra cycles to be added between writes to different ranks. Specifies clock cycles that combine with TIMING_CFG_4[EXT_WWT] to define the write-to-write turnaround (see Write-to-write turnaround) to different ranks.
23-20 ACT_PD_EXIT	Active Powerdown Exit Specifies clock cycles that combine with TIMING_CFG_0[EXT_ACT_PD_EXIT] to wait after exiting an active power-down before issuing a command to the DDR SDRAM. 0000 - Reserved All other values - Clock cycles as defined in the description
19-16 PRE_PD_EXIT	Precharge Power-Down Exit Specifies clock cycles that combine with TIMING_CFG_0[EXT_PRE_PD_EXIT] to define t_{XP} (see Precharge power-down exit timing (t_{XP})). 0000 - Reserved All other values - Clock cycles as defined in the description
15-14 EXT_PRE_PD_EXIT	Extended Precharge Power-Down Exit Enables you to add extra clock cycles that combine with PRE_PD_EXIT to define t_{XP} (see Precharge power-down exit timing (t_{XP})).
13 —	Reserved
12 EXT_ACT_PD_EXIT	Extended Active Power-Down Exit Enables you to add extra clock cycles that combine with ACT_PD_EXIT to define t_{XP} (see Precharge power-down exit timing (t_{XP})).
11-6 —	Reserved
5-0 MRS_CYC	MRW Cycle Time Specifies the number of idle clock cycles that must pass between an MRW command and any other command. Write the greater of t_{MRD} and t_{MRW} to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	00_0000 - Reserved All other values - Clock cycles as defined in the description

28.6.24 DDR SDRAM Timing Configuration 1 (TIMING_CFG_1)

Sets the number of clock cycles between various DDR SDRAM control commands.

Offset

Register	Offset
TIMING_CFG_1	108h

27-24 ACTTOPRE	Activate-To-Precharge Time Specifies clock cycles that combine with TIMING_CFG_3[EXT_ACTTOPRE] to define t_{RAS} (see Activate-to-precharge interval (t_{RAS})).
23-20 ACTTORW	Activate To Read Or Write Specifies clock cycles that combine with TIMING_CFG_3[EXT_ACTTORW] to define t_{RCD} (see Activate-to-read-or-write interval (t_{RCD})).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0000 - Reserved All other values - Clock cycles as defined in the description
19-17 CASLAT	CAS Latency Specifies clock cycles that combine with TIMING_CFG_3[EXT_CASLAT] to define the CAS latency (see CAS latency).
16 —	Reserved
15-12 REFREC	Refresh Recovery Specifies clock cycles that combine with TIMING_CFG_3[EXT_REFREC] to define t_{RFC} (see Refresh recovery time (t_{RFC})).
11-8 WRREC	Write Recovery Specifies clock cycles that combine with TIMING_CFG_3[EXT_WRREC] to define n_{WR} (see Minimum write recovery interval (n_{WR})). The value 0b is reserved when TIMING_CFG_3[EXT_WRREC] = 0.
7-4 ACTTOACT	Activate-To-Activate Interval Specifies the number of clock cycles from an activate command until another activate command is allowed for a different logical bank in the same physical bank. This field indicates the activate-to-activate interval (t_{RRD}). 0000 - Reserved All other values - Clock cycles as defined in the description
3-0 WRTORD	Write-To-Read Interval Specifies the number of clock cycles between the last write data pair and the subsequent read command to the same physical bank. This field indicates the last write data pair to read command issue interval (t_{WTR}) for LPDDR4. 0000 - Reserved All other values - Clock cycles as defined in the description

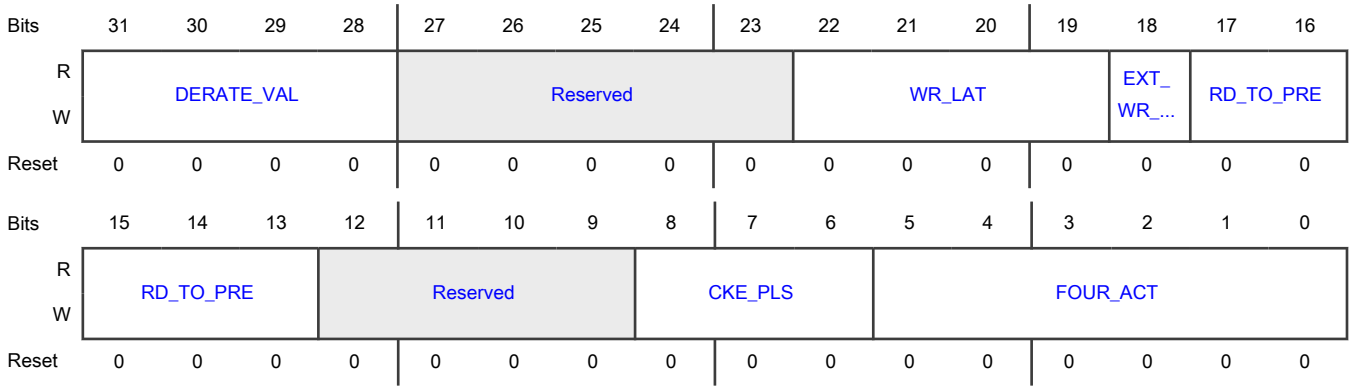
28.6.25 DDR SDRAM Timing Configuration 2 (TIMING_CFG_2)

Sets the clock delay to data for writes.

Offset

Register	Offset
TIMING_CFG_2	10Ch

Diagram



Fields

Field	Description
31-28 DERATE_VAL	Derate Value Enables you to specify the number of cycles used for de-rating DDR SDRAM timing parameters when you set the dynamic refresh rate DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] and the monitored rate requires timing parameter de-rating.
27-23 —	Reserved
22-19 WR_LAT	Write Latency Specifies clock cycles that combine with TIMING_CFG_2[EXT_WR_LAT] and TIMING_CFG_3[EXT_WR_LAT_2] to define the total write latency (see Total write latency).
18 EXT_WR_LAT	Extended Write Latency Enables you to add extra clock cycles that combine with TIMING_CFG_2[WR_LAT] and TIMING_CFG_3[EXT_WR_LAT_2] to define the total write latency (see Total write latency).
17-13 RD_TO_PRE	Read-To-Precharge Time Specifies the read-to-precharge time n_{RTP}) in clock cycles for LPDDR4. 0_0000 - Reserved All other values - Clock cycles as defined in the description
12-9 —	Reserved
8-6 CKE_PLS	MCKE Pulse Specifies clock cycles that combine with TIMING_CFG_3[EXT_CKE_PLS] to define t_{CKE} (see Minimum MCKE pulse width (t_{CKE})).
5-0 FOUR_ACT	Four Activate Specifies clock cycles that combine with TIMING_CFG_3[EXT_FOUR_ACT] to define t_{FAW} (see Four-activate window (t_{FAW})).

28.6.26 DDR SDRAM Control Configuration (DDR_SDRAM_CFG)

Enables:

- The DDR SDRAM interface logic.
- Operating features such as self-refresh, error check and correction, and dynamic power management.

Offset

Register	Offset
DDR_SDRAM_CFG	110h

Diagram

31 MEM_EN	DDRC Enable If DDRC is disabled, you must not enable it until you configure all other memory configuration parameters appropriately. 0 - Disables 1 - Enables
30 SREN	Self-Refresh Enable Enables the DDR SDRAM self-refresh function during sleep. 0 - Disables 1 - Enables
29 —	Reserved
28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
27 —	Reserved
26-24 SDRAM_TYPE	DDR SDRAM Type Specifies the type of DDR SDRAM device to be used. Use this field to issue the automatic hardware initialization sequence to the DDR SDRAM via the MRW and extended-MRW commands. 100 - LPDDR4, SDRAM All other values are reserved.
23-22 —	Reserved
21 DYN_PWR	Dynamic Power Management Controls whether DDRC is in Dynamic Power Management mode. In this mode, the DDR SDRAM CKE signal is negated if there is no ongoing memory activity. 0 - No 1 - Yes
20-19 DBW	DDR SDRAM Data Bus Width Specifies the DDR SDRAM data bus width. 10 - 16 bits All other values are reserved.
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved
14-8 BA_INTLV_CTL	Rank Interleaving Control Is used for rank interleaving and indicates whether external ranks are interleaved. Below, the unlisted field values are reserved, and an "x" denotes a don't-care value. 000_0000 - No external ranks are interleaved.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	100_0000 - External ranks 0 and 1 are interleaved. All other values are reserved.
7-4 —	Reserved
3 —	Reserved
2 —	Reserved
1 MEM_HALT	DDRC Halt Specifies whether DDRC accepts new data read or write transactions. When this field is 1, DDRC does not accept any new transactions for DDR SDRAM until the field becomes 0. This field can be used when bypassing initialization and forcing MRW commands. 0 - Accepts new transactions 1 - Completes any remaining transactions and remains halted until you write 0 to this field
0 BI	Bypass Initialization Controls bypass initialization. You must write 1 to this field because the DDR PHY programs MRW commands. 0 - Reserved; do not use 1 - Initialization routine is bypassed

28.6.27 DDR SDRAM Control Configuration 2 (DDR_SDRAM_CFG_2)

Provides additional control configuration for DDRC.

Offset

Register	Offset
DDR_SDRAM_CFG_2	114h

30 —	Reserved
29-28 —	Reserved
27-24 MCK_DIS	MCK Disable Can be used to disable up to 4 MCK clock pairs, if available, according to the following table.

When you have:	MCK_DIS bit 3:	MCK_DIS bit 2:	MCK_DIS bit 1:	MCK_DIS bit 0:
MCK0	Disables or enables the MCK0 clock pair	Does nothing		
MCK0 and MCK1		Disables or enables the MCK1 clock pair	Does nothing	
MCK0, MCK1, and MCK2			Disables or enables the MCK2 clock pair	Does nothing
MCK0, MCK1, MCK2, and MCK3				Disables or enables the MCK3 clock pair

NOTE

- MCK_DIS bit 0 is register bit 24, MCK_DIS bit 1 is register bit 25, and so on.
- In this chip, only MCK0 pair is available, hence only bit 3 is applicable.

0b - Enable the clock pair

1b - Disable the clock pair

Table continued from the previous page...

Field	Description
—	
7 —	Reserved
6-5 —	Reserved
4 D_INIT	DDR SDRAM Data Initialization Indicates the status of data initialization. You write 1 to this field, and DDRC writes 0 to it. If you write 1 before DDRC is enabled, DDRC automatically initializes the DDR SDRAM after DDRC is enabled. DDRC automatically writes 0 to the field after the initialization is complete. You can only write 1 to this field when DDRC is idle and DDR_MTCR[MT_EN] = 0. This field remains enabled until the initialization is complete. DDR SDRAM Data Initialization (DDR_DATA_INIT) initializes the DDR SDRAM. 0 - No data initialization in progress, and none scheduled 1 - DDRC to initialize the DDR SDRAM after DDRC is enabled
3 —	Reserved
2 —	Reserved
1 —	Reserved. NXP recommends writing 1 to this field.
0 —	Reserved

28.6.28 DDR SDRAM Mode Control (DDR_SDRAM_MD_CNTL)

Enables you to:

- Issue an MRW command to a particular rank.
- Force the MCKE signals to a specific value.

Table 156. DDR_SDRAM_MD_CNTL field settings

Field	MRW	Refresh	Precharge
MD_EN	1	0	0
SET_REF	0	1	0

Table continues on the next page...

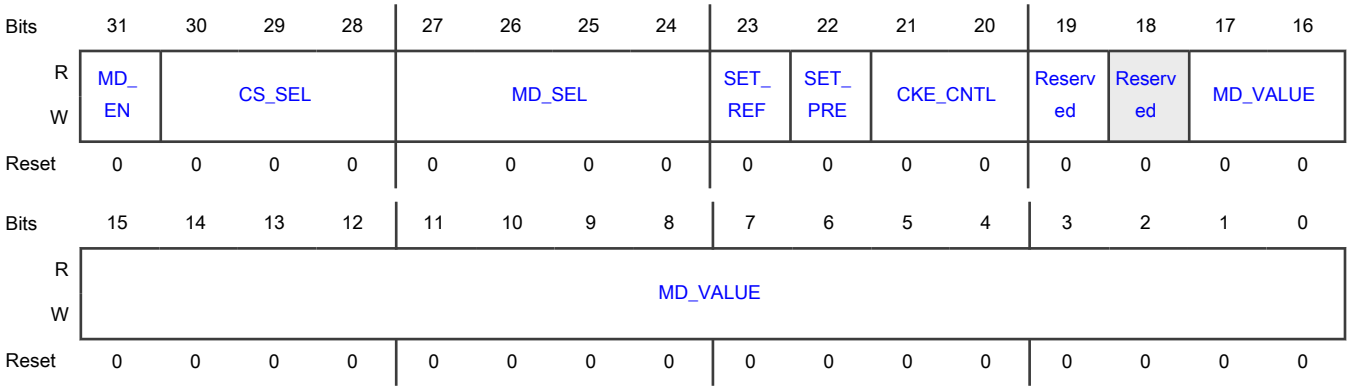
Table 156. DDR_SDRAM_MD_CNTL field settings (continued)

Field	MRW	Refresh	Precharge
SET_PRE	0	0	1
CS_SEL	Chooses rank		
MD_SEL	Selects the mode register	-	Selects a logical bank and bank group
MD_VALUE	Indicates the value written to the mode register	-	Only bit 7 is significant
CKE_CNTL	0	0	0

Offset

Register	Offset
DDR_SDRAM_MD_CNTL	120h

Diagram



Fields

Field	Description
31 MD_EN	Mode Enable This field specifies that valid data in DDR_SDRAM_MD_CNTL[MD_VALUE] is ready to be written to the DDR SDRAM via an MRW command. DDR_SDRAM_MD_CNTL[MD_SEL] selects the specific mode register. Additionally, you must select the rank by writing 1 to DDR_SDRAM_MD_CNTL[CS_SEL]. You write 1 to this field and DDRC writes 0 to it after the selected command is issued. **NOTE** You must not write 1 to this field unless DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] is 0. 0 - Does not need to be issued

Table continues on the next page...

Field	Description
	1 - Valid data contained in the register ready to be issued as an MRW command
30-28 CS_SEL	Select Rank Specifies the rank that is driven active because of a command that you force in this register. 000 - 0 001 - 1 100 - 0 and 1 All other values are reserved.
27-24 MD_SEL	Mode Register Select Selects: • The DDR SDRAM mode register to be changed during a mode select command. • The DDR SDRAM logical bank to be precharged during a precharge command. The precharge-all and refresh commands ignore this field. MD_SEL[0:1] is not used with LPDDR4 DDR SDRAM. 0000 - MR 0001 - EMR 0010 - EMR2 0011 - EMR3
23 SET_REF	Set Refresh Specifies whether a refresh command must be issued. Forces an immediate refresh to be issued to the rank, as specified by DDR_SDRAM_MD_CNTL[CS_SEL]. You write 1 to this field and DDRC writes 0 to it after the command is issued. LPDDR4 DDR SDRAM does not support this field. 0 - No 1 - Yes
22 SET_PRE	Set Precharge Specifies whether a precharge command must be issued. Forces a precharge or precharge-all command (depending on the value of DDR_SDRAM_MD_CNTL[MD_VALUE]) to be issued to the rank, as specified by DDR_SDRAM_MD_CNTL[CS_SEL]. You write 1 to this field and DDRC writes 0 to it after the command is issued. LPDDR4 DDR SDRAM does not support this field. 0 - No 1 - Yes
21-20	Clock Enable Control

Table continues on the next page...

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>CKE_CNTL</td><td>Specifies the value to which MCKE signals are forced.
This field enables you to globally assert or deassert all the MCKE signals issued to the DDR SDRAM.
After you force a value to MCKE, DDRC continues to force that value until one of the following occurs:
• You write 0 to this field.
• Another event (for example, self-refresh entry or exit, or power-down entry or exit) causes the MCKE signals to change.
00 - Not forced
01 - Forced to a lower value
10 - Forced to a higher value
11 - Reserved</td></tr>
<tr><td>19
—</td><td>Reserved</td></tr>
<tr><td>18
—</td><td>Reserved</td></tr>
<tr><td>17-0
MD_VALUE</td><td>Mode Register Value
Specifies the value that is presented on the DDRC memory-address pins during an MRW command.
This field is significant only when this register is used to issue an MRW, precharge, or precharge-all command.
The two most-significant bits do not affect the MRW commands to the DDR SDRAM because A[17:16] of the DDR SDRAM's MR registers are reserved.
For an MRW command, this field contains the data to be written to the selected mode register. When using LPDDR4 DDR SDRAM, the bits of this field, 17:0, map to the DDR SDRAM command as follows: When using LPDDR4 DDR SDRAM, the bits of this field, 17:0, map to the DDR SDRAM command as follows:
Table 157. LPDDR4 MD_VALUE description
<table>
<tr><th>MD_VALUE bits</th><th>Mapped to</th></tr>
<tr><td>17–14</td><td>Unused</td></tr>
<tr><td>13–6</td><td>OP7–OP0</td></tr>
<tr><td>5–0</td><td>MA5–MA0</td></tr>
</table>
For a precharge command, only bit 5 of this field is significant.</td></tr>
</table>

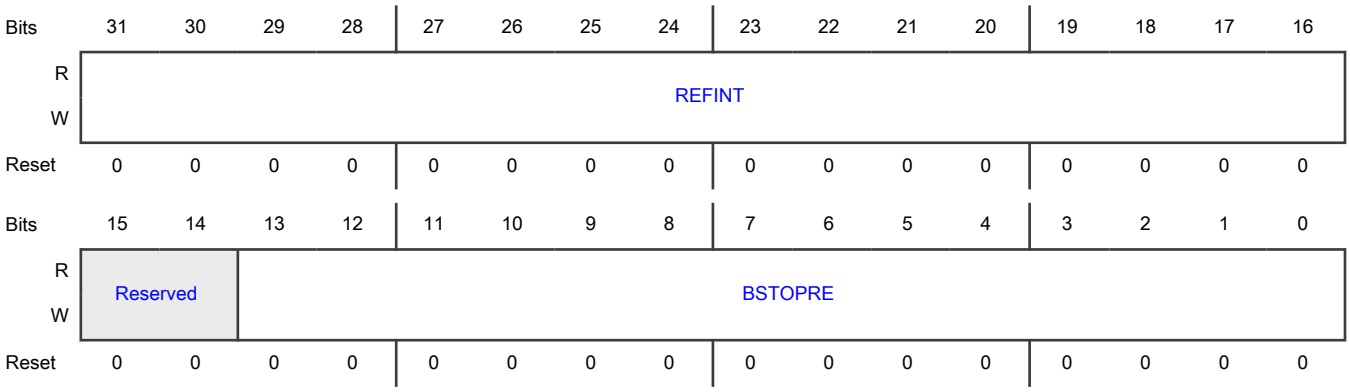
28.6.29 DDR SDRAM Interval Configuration (DDR_SDRAM_INTERVAL)

Specifies the number of DDR SDRAM clock cycles between refreshes issued to the DDR SDRAMs. Additionally, the register provides the number of DDR SDRAM cycles for which a page is retained after being accessed.

Offset

Register	Offset
DDR_SDRAM_INTERVAL	124h

Diagram



Fields

Field	Description
31-16 REFINT	Refresh Interval Represents the number of memory bus clock cycles between refresh cycles. This way, the field controls auto-refresh. Writing 0 to this field turns off auto-refresh. **NOTE** This field should be REFINT*NUM_PR when DDR_SDRAM_CFG2[NUM_PR] is > 1. Depending on DDR_SDRAM_CFG_2[NUM_PR], some quantity of rows is refreshed in each DDR SDRAM rank during each refresh cycle. The value of this field depends on the specific DDR SDRAM used and the interface clock frequency. This field is concatenated with TIMING_CFG_4[EXT_REFINT] to obtain a 17-bit value for the total refresh interval.
15-14 —	Reserved
13-0 BSTOPRE	Precharge Interval Sets the duration (in memory bus clocks) that a page is retained after a DDR SDRAM access. If this field is 0, DDRC: • Leaves Open-Page mode. • Enters Global Auto-Precharge mode. • Uses auto-precharge read and write commands.

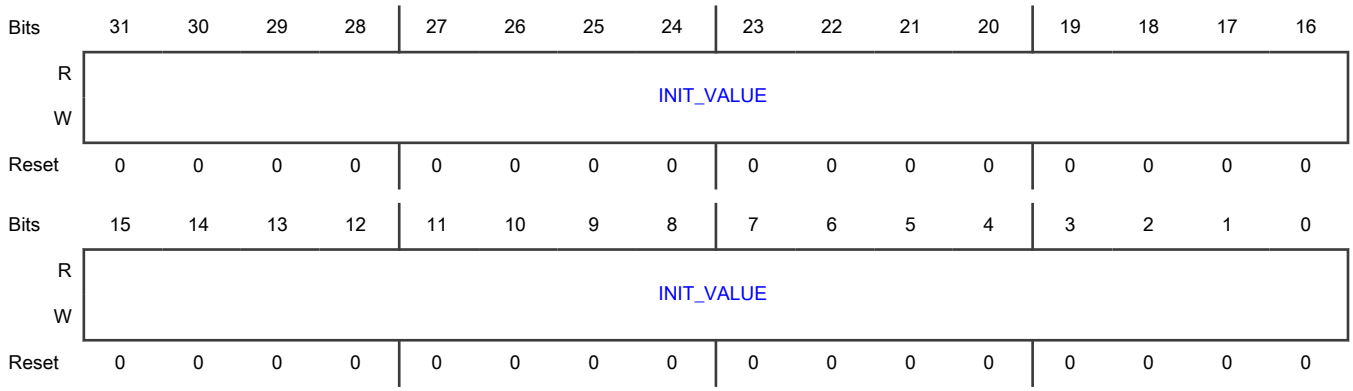
28.6.30 DDR SDRAM Data Initialization (DDR_DATA_INIT)

Provides the value that is used to initialize memory when DDR_SDRAM_CFG_2[D_INIT] = 1.

Offset

Register	Offset
DDR_DATA_INIT	128h

Diagram



Fields

Field	Description
31-0 INIT_VALUE	Initialization Value Represents the value that DDR SDRAM is initialized with when DDR_SDRAM_CFG_2[D_INIT] = 1.

28.6.31 DDR SDRAM Timing Configuration 4 (TIMING_CFG_4)

Provides additional timing fields for turnaround clocks, refresh recovery, and (DLL) lock time.

Offset

Register	Offset
TIMING_CFG_4	160h

Fields

Field	Description
31-28 RWT	Read-To-Write Turnaround For Same Rank Specifies the number of clock cycles to be added between a read-to-write turnaround for transactions to the same rank. When you select zero clock cycles, DDRC uses the value used for transactions to different ranks, as defined in TIMING_CFG_0[RWT], for calculating the number of additional clock cycles. Regardless of the value defined in this field, the value that TIMING_CFG_0[RWT] defines is also considered before issuing a write command.
27-24 WRT	Write-To-Read Turnaround For Same Rank Specifies the number of clock cycles to be added between a write-to-read turnaround for transactions to the same rank. When you select zero clock cycles, DDRC uses the value that is used for transactions to different ranks, as defined in TIMING_CFG_0[WRT], for calculating the number of additional clock cycles. TIMING_CFG_0[WRT] provides the minimum number of clock cycles that DDRC uses, regardless of its value.
23-20 RRT	Read-To-Read Turnaround For Same Rank Specifies the number of clock cycles to be added between reads to the same rank as follows: Number of cycles = BL/2 + RRT If you select zero clock cycles, DDRC uses the formula BL/2 to calculate the number of clock cycles required between read commands to the same rank. DDRC must wait for four clock cycles between read-to-read transactions to the same rank.
19-16 WWT	Write-To-Write Turnaround For Same Rank Controls the number of clock cycles to be added between writes to the same rank as follows: Number of cycles = BL/2 + WWT If you select zero clock cycles, DDRC uses the formula BL/2 to calculate the number of clock cycles required between write commands to the same rank.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	DDRC must wait for four clock cycles between write-to-write transactions to the same rank.
15-14 EXT_RWT	Extended Read-To-Write Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[RWT] to define the read-to-write turnaround (see Read-to-write turnaround).
13-12 EXT_WRT	Extended Write-To-Read Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[WRT] to define the write-to-read turnaround (see Write-to-read turnaround).
11-10 EXT_RRT	Extended Read-To-Read Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[RRT] to define the read-to-read turnaround (see Read-to-read turnaround).
9-8 EXT_WWT	Extended Write-To-Write Turnaround Specifies extra clock cycles that combine with TIMING_CFG_0[WWT] to define the write-to-write turnaround (see Write-to-write turnaround).
7-5 —	Reserved
4 EXT_REFINT	Extended Refresh Interval Specifies the number of memory bus clock cycles between refresh cycles. Depending on the setting of DDR_SDRAM_CFG_2[NUM_PR], some number of rows are refreshed in each DDR SDRAM physical bank during each refresh cycle. EXT_REFINT is concatenated with DDR_SDRAM_INTERVAL[REFINT] to obtain a 17-bit value for the total refresh interval, {EXT_REFINT, REFINT}. This combined refresh interval depends on the specific SDRAMs used and the interface clock frequency. Refreshes are not issued when {EXT_REFINT, EFINT} = 0. 0 - 0 1 - 65,536
3-2 —	Reserved
1-0 DLL_LOCK	DDR SDRAM DLL Lock Time Specifies the number of clocks that it takes for the DDR SDRAM to be available after exiting Self-Refresh mode. DDRC waits for the number of cycles that this field specifies before issuing any commands after exiting POR or after a self-refresh completes (t_{XSR}). 10 - 1024 clocks 11 - 2048 clocks

Table continues on the next page...

Table continued from the previous page...

Field	Description
	All other values are reserved.

28.6.32 DDR SDRAM Timing Configuration 7 (TIMING_CFG_7)

Provides the required CKE-related timing fields.

Offset

Register	Offset
TIMING_CFG_7	16Ch

Fields

Field	Description
31-30 —	Reserved
29-28 CKE_RST	MCKE Reset Time Specifies the number of clock cycles for which DDRC must wait after a reset and assertion of MCKE until the first MRW command. This field indicates MCKE reset time (t_{XPR}), and determines t_{XS} when exiting Self-Refresh mode. Therefore, if t_{XPR} and t_{XS} are different for a particular memory, you must select the greater of these two values and write that value to this field. 00 - 200 01 - 256 10 - 512 11 - 4096

Table continues on the next page...

Table continued from the previous page...

Field	Description
27-24 CKSRE	Clock After Self-Refresh Entry Specifies the number of clock cycles for which DDRC must drive valid MCK and MCK_b values after entering Self-Refresh mode before the clocks are allowed to stop. This field indicates the number of valid clock cycles after entering Self-Refresh mode (t_{CKSRE}). When using an LPDDR4, memory, you must write t_{ESCKE} to this field. 0000,1010 - 15 0001 - 6 0010 - 7 0011 - 8 0100 - 9 0101 - 10 0110 - 11 0111 - 12 1000 - 13 1001 - 14 1011 - 16 1100 - 17 1101 - 18 1110 - 19 1111 - 32
23-20 CKSRX	Clock After Self-Refresh Exit Specifies the number of clock cycles during which DDRC must drive valid MCK and MCK_b values before exiting Self-Refresh mode and before the clocks are allowed to stop. This field indicates a valid number of clock cycles after exiting Self-Refresh mode (t_{CKSRX}). When using LPDDR4 DDR SDRAM, you must write t_{SR} to this field. 0000,1010 - 15 0001 - 6 0010 - 7 0011 - 8 0100 - 9 0101 - 10 0110 - 11 0111 - 12 1000 - 13

28.6.33 DDR SDRAM ZQ Calibration Control (DDR_ZQ_CNTL)

Enables the controls required for ZQ calibration.

When using ZQ calibration, the following define the limitations for DDR SDRAM timing parameters:

- DDR_ZQ_CNTL[ZQOPER]
- DDR_ZQ_CNTL[ZQCS]
- TIMING_CFG_1[PRETOACT]
- TIMING_CFG_1[REFREC]
- DDR_SDRAM_INTERVAL[REFINT]
- Number of enabled ranks

A refresh command can be skipped after a self-refresh completes if this condition is true:

(ZQOPER + ZQCS) × (# of enabled ranks) + PRETOACT + REFREC + $2t_{ck}$ > REFINT

In this scenario, you could use either of these options:

- Posted refreshes to extend the refresh interval
- DDR SDRAM Mode Control (DDR_SDRAM_MD_CNTL) to force an extra refresh to each rank after exiting Self-Refresh mode

However, timing parameters for most chips and frequencies do not allow missed refreshes.

Offset

Register	Offset
DDR_ZQ_CNTL	170h

Diagram

Fields

Field	Description
31 ZQ_EN	ZQ Calibration Enable Determines if ZQ calibration is used. If it is used, DDRC issues a ZQCL command after POR and anytime DDRC completes a self-refresh. A ZQCS command is issued after every 32 refresh sequences to account for VT variations. 0 - Not used 1 - Used
30-28 —	Reserved
27-24 ZQINIT	ZQ Calibration Initialization Time Determines the number of clock cycles allowed for DDR SDRAM ZQ calibration at POR. This field signifies POR ZQ calibration time (t_{ZQinit}). Each rank is calibrated separately, and this time must elapse after DDRC issues a ZQCL command to the DDR SDRAM for each rank before a separate command may be issued. When using LPDDR4 DDR SDRAM, you must write t_{ZQCAL} to this field. 0111 - 128 1000 - 256 1001 - 512 1010 - 1024 1011 - 2048

Table continues on the next page...

Table continued from the previous page...

Field	Description
23-20 —	Reserved
19-16 ZQOPER	ZQ Calibration Operation Time Determines the number of clock cycles that DDR SDRAM requires to complete the ZQ calibration when exiting Self-Refresh mode. This field signifies normal operation full calibration time (t_{ZQoper}). Each CS is calibrated separately, and this time must elapse after DDRC issues a ZQCL command to the DDR SDRAM for each CS before a separate command may be issued. When using LPDDR4 memories, you must write t_{ZQCAL} to this field. 0111 - 128 1000 - 256 1001 - 512 1010 - 1024 1011 - 2048
15-12 —	Reserved
11-8 ZQCS	ZQ Calibration Short Time Determines the number of clock cycles allowed for DDR SDRAM ZQ calibration during dynamic calibration, which is issued after every refresh sequence that DDR_ZQ_CNTL[ZQCS_INT] defines. This field signifies normal operation short calibration time (t_{ZQCS}). Each CS is calibrated separately, and this time must elapse after DDRC issues a ZQCS command for each CS before a separate command may be issued. When using LPDDR4 DDR SDRAM, you must write t_{ZQLAT} to this field. 0000 - 1 0001 - 2 0010 - 4 0011 - 8 0100 - 16 0101 - 32 0110 - 64 0111 - 128 1000 - 256 1001 - 512
7-4	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
3-0 ZQCS_INT	ZQCS Interval Determines the number of refresh sequences that are to pass between each ZQCS calibration. 0000 - 32 0001 - 64 0010 - 128 0011 - 256 0100 - 512 0101 - 1024 0110 - 2048 0111 - 4096 1000 - 8192 1001 - 16384 1010 - 32768 1111 - ZQCS calibration disabled All other values are reserved.

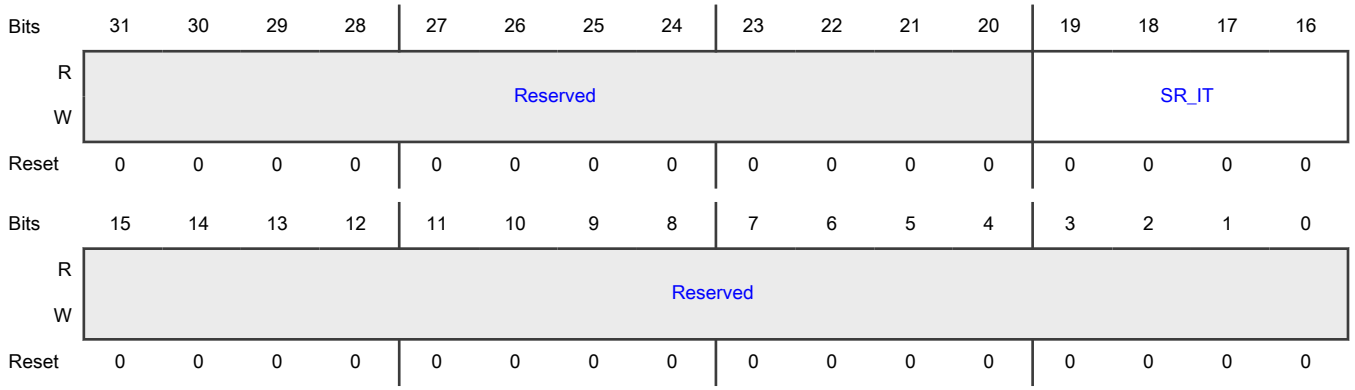
28.6.34 DDR SDRAM Self-Refresh Counter (DDR_SR_CNTR)

Enables you to force DDRC to perform a self-refresh after a predefined period of idle time.

Offset

Register	Offset
DDR_SR_CNTR	17Ch

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 SR_IT	Self-Refresh Idle Threshold Defines the number of DDR SDRAM clock cycles that must pass when DDRC is idle before it enters Self-Refresh mode, according to the following equation: Number of clock cycles = $2^{(8 + SR_IT \times 2)}$ **NOTE** SR_IT values 1-7 are not supported. Anytime you issue a transaction to DDRC, it exits Self-Refresh mode and resets its internal counter. • When this field is 0, this power-saving feature is disabled. • If you write a non-zero value to this field, DDRC exits Self-Refresh mode anytime a transaction is issued, regardless of the reason it entered this mode. However, when writing a non-zero value to this field, DDR_SDRAM_CFG_3[SR_FAST_WK_EN] must be 1.
15-0 —	Reserved

28.6.35 DDR SDRAM Timing Configuration 8 (TIMING_CFG_8)

Provides additional timing fields .

Offset

Register	Offset
TIMING_CFG_8	250h

31-26 —	Reserved
25-16	Refresh Recovery Per-Bank Refresh

Table continues on the next page...

Table continued from the previous page...

Field	Description
REFREC_PB	Refresh recovery time for per-bank refresh. Controls the number of clock cycles from a refresh command to an activate for the same bank. Note that hardware adds an additional 8 clock cycles to the final, 7-bit value of the refresh recovery, such that it (t_{RFCpb}) is calculated as follows: 00_0000_0000 - 8 clocks 00_0000_0001 - 9 clocks 00_0000_0010 - 10 clocks 10_1111_1110 - 774 clocks 10_1111_1111 - 775 clocks
15-12 —	Reserved
11-10 —	Reserved
9-0 REFTOREF_PB	Refresh-to-refresh interval for per-bank refresh. Note that hardware adds an additional 8 clock cycles to the final, 7-bit value of this field, such that it ($t_{pbR2pbR}$) is calculated as follows: 00_0000_0000 - disable PB refresh 00_0000_0001 - 9 clocks 00_0000_0010 - 10 clocks 10_1111_1110 - 774 clocks 10_1111_1111 - 775 clocks

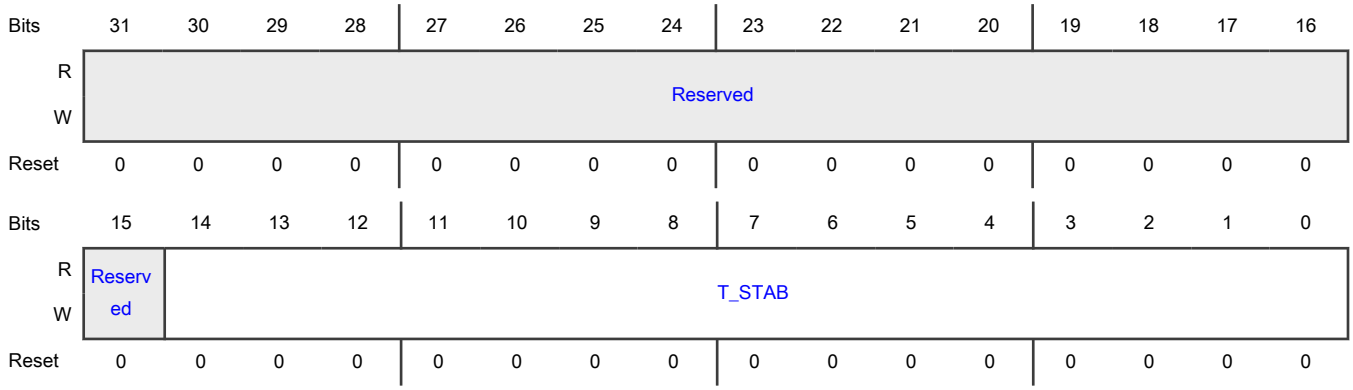
28.6.37 DDR SDRAM Timing Configuration 10 (TIMING_CFG_10)

Provides an additional timing field required to support wake up time for self refresh mode.

Offset

Register	Offset
TIMING_CFG_10	258h

Diagram



Fields

Field	Description
31-15 —	Reserved
14-0 T_STAB	Stabilization Wait Time Defines the stabilization wait time (in MCK clock cycles) when exiting self refresh in slow wakeup mode. If you write 0 to this field, DDRC ignores this constraint. **NOTE** Be aware of a special constraint if you expect the temperature to drift by more than 20 degrees Celsius. In this case, the value you write to this field must be t_{STAB} or 10 µs, whichever is greater, during self-refresh.

28.6.38 DDR SDRAM Timing Configuration 11 (TIMING_CFG_11)

Provides additional timing fields required to support LPDDR4.

Offset

Register	Offset
TIMING_CFG_11	25Ch

Fields

Field	Description
31 DDRC_RST	DDRC Reset Specifies whether DDRC operates normally or is undergoing reset. You must write 1 to this field if you want to reset DDRC. This resets all state machines and internal FIFOs. The field does not reset DDRC's configuration registers. Before you write 1 to this field, you must write 0 to DDR_SDRAM_CFG[MEM_EN]. This field returns to 0 by itself. Therefore, you must poll this field and wait until it returns to 0 before re-enabling DDRC. 0 - Operating normally 1 - Undergoing reset
30	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
29-28 —	Reserved
27-24 —	Reserved
23-22 —	Reserved
21-20 —	Reserved
19 —	Reserved
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved
14-12 DM_CFG	Data Mask Configuration Determines how DDRC uses the MDM pins. When DM_CFG = 100b, DDRC supports both DBI and data masks. You can use this configuration only with LPDDR4 DDR SDRAM. For more information on value 000b below, see DDR_SDRAM_CFG[SDRAM_TYPE]. 000 - Normal data masks based on the settings defined in DDR_SDRAM_CFG[SDRAM_TYPE] 010 - DBI 011 - Neither data masks nor DBI 100 - DBI with data masks All other values are reserved.
11	Drain Queues For Self-Refresh

Table continues on the next page...

Table continued from the previous page...

Field	Description
DRAIN_FOR_SR	Forces DDRC to drain its main command queue before servicing a self-refresh request. This field is only used for: • Software-initiated, self-refresh requests via DDR_SDRAM_CFG_2[FRC_SR] • Sleep requests • Self-refresh requests enabled in DDR_SR_CNTR[SR_IT] 0 - Do not drain 1 - Drain
10 —	Reserved
9-8 —	Reserved
7 DYN_REF_RATE_EN	Dynamic Refresh Rate Enable Enables only the dynamic refresh rate adjustments for LPDDR4 DDR SDRAM. If you write 1 to this field, DDRC polls the MR4 register every 64 refresh sequences to determine a proper refresh rate. If two ranks are enabled, DDRC alternates between polling rank 0 and rank 1, and uses the lesser of the two refresh intervals. You can find the results of the previous MR4 reads in DDR Refresh Rate (DDR_SDRAM_REF_RATE). This feature cannot be used with rank 2 or rank 3 enabled. 0 - Disables 1 - Enables
6 —	Reserved
5-4 —	Reserved
3 NON_PWR_2	Non Power of 2 Enable This field controls whether a non-power of 2 density DRAM is used. For example, 3Gbit, 6Gbit, and 12Gbit DRAMs are considered non-power of 2 DRAMs. You must program the CSn_BNDS to include the full data available when using a non-power of 2 DRAM. 0 - Disables 1 - Enables
2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
1 SR_FAST_WK_EN	Self Refresh Fast Wakeup Enable Controls the type of wakeup enable (slow or fast) used after a self-refresh. **NOTE** If you will ever use self refresh with this bit cleared after a given reset, then you must clear this bit during the initial configuration of the DDRC. 0 - Slow 1 - Fast
0 —	Reserved

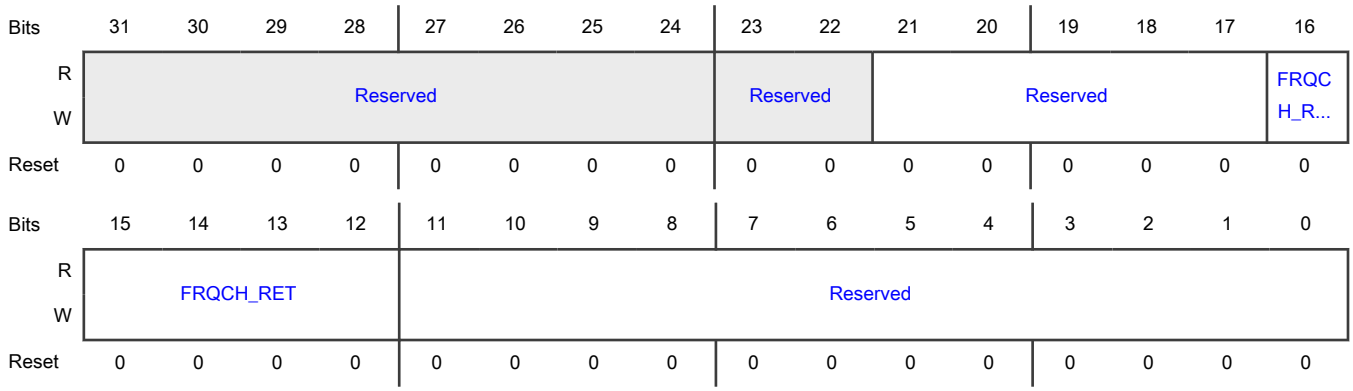
28.6.40 DDR SDRAM Control Configuration 4 (DDR_SDRAM_CFG_4)

Provides more control configuration for DDRC, along with timings for blocking certain accesses.

Offset

Register	Offset
DDR_SDRAM_CFG_4	264h

Diagram



Fields

Field	Description

Fields

Field	Description
31-30 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
29-24 PRETOACT_HS	Precharge-To-Activate Time For Half Speed Defines clock cycles to define t_{RP} when operating at half frequency. 00_0000 - Reserved All other values - Clock cycles as defined in the description
23 —	Reserved
22-16 ACTTOPRE_HS	Activate-To-Precharge Time For Half Speed Defines clock cycles to define t_{RAS} when operating at half frequency.
15-14 —	Reserved
13-8 ACTTORW_HS	Activate To Read Or Write For Half Speed Defines clock cycles that define t_{RCD} when operating at half frequency. 00_0000 - Reserved All other values - Clock cycles as defined in the description
7-6 —	Reserved
5-0 CASLAT_HS	CAS Latency For Half Speed Defines clock cycles that define the CAS latency when operating at half frequency. This field must be programmed to 1 less than the desired CAS latency, similar to {TIMING_CFG_3[EXT_CASLAT], TIMING_CFG_1[CASLAT]}.

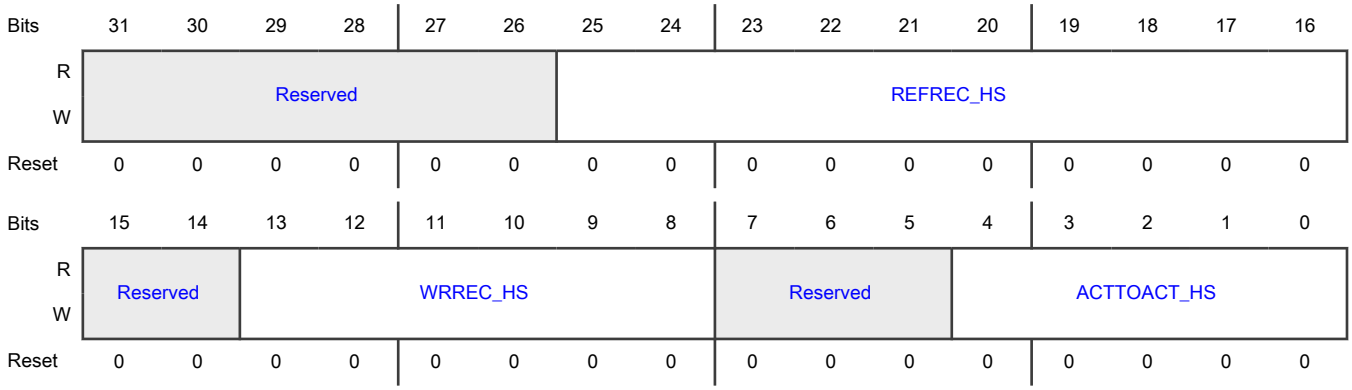
28.6.43 DDR SDRAM Timing Configuration 13 (TIMING_CFG_13)

Provides additional timing fields required to support half-frequency operation when dynamically switching the clock frequency.

Offset

Register	Offset
TIMING_CFG_13	304h

Diagram



Fields

Field	Description
31-26 —	Reserved
25-16 REFREC_HS	Refresh Recovery For Half Speed Defines clock cycles to define t_{RFC} when operating at half frequency. Note that the DDRC adjusts this field by 8 cycles, similar to {TIMING_CFG_3[EXT_REFREC], TIMING_CFG_1[REFREC]}.
15-14 —	Reserved
13-8 WRREC_HS	Write Recovery For Half Speed Defines clock cycles to define n_{WR} when operating at half frequency. The value 0b is reserved. 00_0000 - Reserved All other values - Clock cycles as defined in the description
7-5 —	Reserved
4-0 ACTTOACT_HS	Activate-To-Activate Interval For Half Speed Specifies the number of clock cycles from an activate command until another activate command is allowed for a different logical bank in the same physical bank when operating at half frequency. This field indicates the activate-to-activate interval (t_{RRD}). 0_0000 - Reserved All other values - Clock cycles as defined in the description

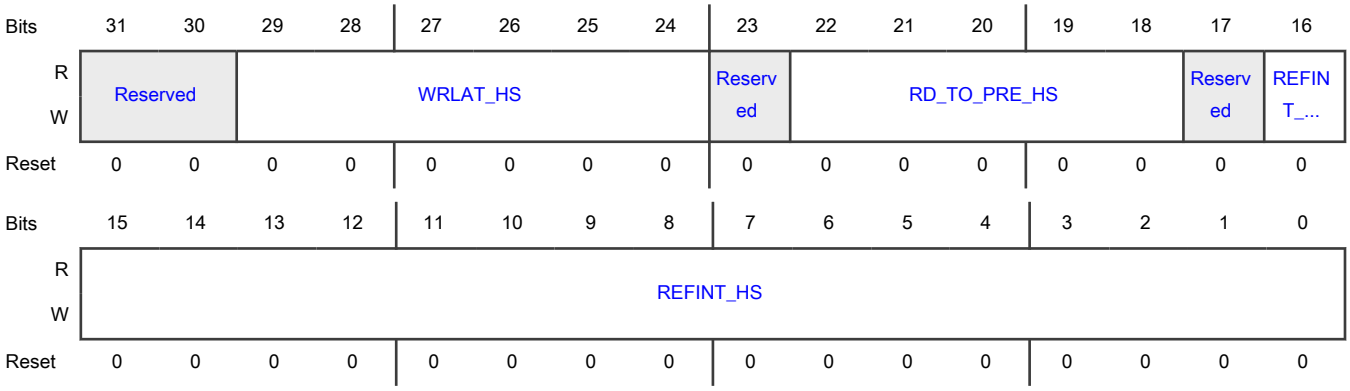
28.6.44 DDR SDRAM Timing Configuration 14 (TIMING_CFG_14)

Provides additional timing fields required to support half-frequency operation when dynamically switching the clock frequency.

Offset

Register	Offset
TIMING_CFG_14	308h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-24 WRLAT_HS	Write Latency For Half Speed Indicates the number of clock cycles used to determine the write latency when operating at half frequency. The maximum write latency supported is 34 clocks.
23 —	Reserved
22-18 RD_TO_PRE_HS	Read-To-Precharge Time For Half Speed Specifies the number of clock cycles indicating read-to-precharge (n_{RTP}) when operating at half frequency. The value 0b is reserved. 0_0000 - Reserved All other values - Clock cycles as defined in the description
17 —	Reserved
16-0 REFINT_HS	Refresh Interval For Half Speed Represents the number of memory bus clock cycles between refresh cycles when operating at half frequency. This way, the field controls auto-refresh. Writing 0 to this field turns off auto-refresh.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Depending on DDR_SDRAM_CFG_2[NUM_PR], some quantity of rows is refreshed in each DDR SDRAM physical bank during each refresh cycle. The value of this field depends on the specific DDR SDRAM used and the interface clock frequency.

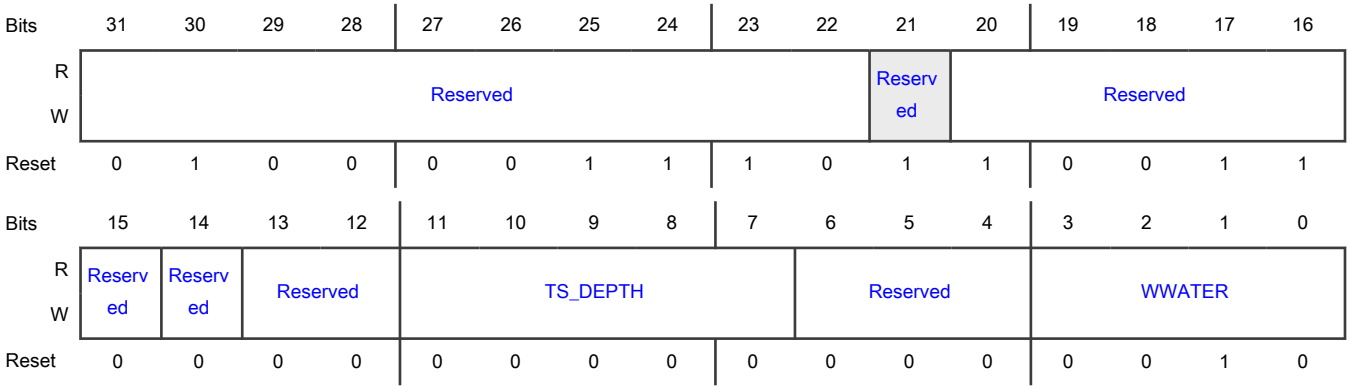
28.6.45 Transaction Configuration Register 1 (TX_CFG_1)

This register contains miscellaneous settings to fine-tune arbitration performance.

Offset

Register	Offset
TX_CFG_1	800h

Diagram



Fields

Field	Description
31-22 —	Reserved
21 —	Reserved
20-15 —	Reserved
14 —	Reserved
13-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
11-7 TS_DEPTH	Transaction Scheduler Depth This field determines the depth of the Transaction Scheduler. A value of 0b00000 provides the maximum number of entries. You must program the depth to 0b11010 or less if ERR_EN[INLINE_ECC_EN] is set.
6-4 —	Reserved
3-0 WWATER	Write Watermark. Write queue level before writes allowed to arbitrate. This field must be set to 0b0000 if ERR_EN[INLINE_ECC_EN] is set.

28.6.46 DDR SDRAM Debug Status 2 (DDRDSR_2)

Contains the current settings of the driver impedance.

NOTE

Rapid Clear is done only on memory range selected by MTCR register. Rapid memory status bits must be cleared before accessing memory again.

Offset

Register	Offset
DDRDSR_2	B24h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31 IDLE	Memory controller idle (read only). 0 - Memory controller is busy. 1 - Memory controller is idle.
30 NML	No Modified Lines Indicates whether modified lines exist in the ECC cache. 0 - Exist 1 - Do not exist
29-3 —	Reserved
2 PHY_INIT_CMPLT	DDR PHY Initialization Complete Specifies whether PHY initialization is complete. DDRC changes this field to 1 after the DDR PHY initialization is complete. You must wait until this field becomes 1 before writing 1 to DDR_SDRAM_CFG[MEM_EN]. 0 - Not complete 1 - Complete
1 RPD_ST	Rapid Clear Of Memory Start Specifies whether the rapid clear of memory function has started. If the rapid clear of memory feature is available for DDRC, this field indicates that the sequence has started. After the sequence starts, writes to DDRC's memory-mapped registers do not affect this register's contents. 0 - Not started 1 - Started
0 RPD_END	Rapid Clear Of Memory End Specifies whether the rapid clear of memory function is complete. If the rapid clear of memory feature is available for DDRC, this field indicates a successful end of the rapid clear sequence. 0 - Not complete 1 - Complete

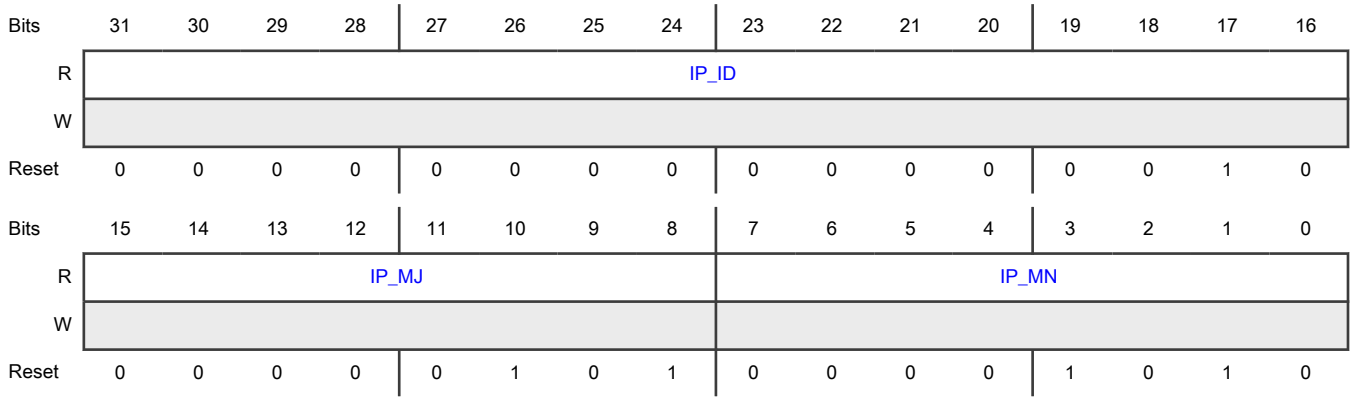
28.6.47 DDRC Revision 1 (DDR_IP_REV1)

Provides the DDRC ID, major revision, and minor revision.

Offset

Register	Offset
DDR_IP_REV1	BF8h

Diagram



Fields

Field	Description
31-16 IP_ID	IP Block ID For DDRC, this value is 2h.
15-8 IP_MJ	Major Revision This is the major revision for DDRC.
7-0 IP_MN	Minor Revision For DDRC, this value is 8'd10h.

28.6.48 DDR SDRAM Memory Test Control (DDR_MTCR)

Enables the controls for an automatic memory test.

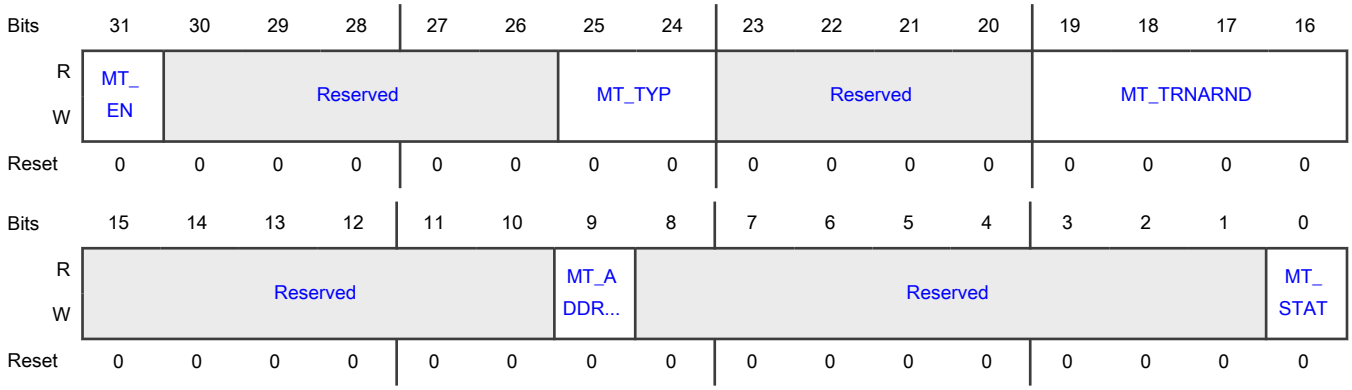
NOTE

You must clear the fields in this register after running a memory test.

Offset

Register	Offset
DDR_MTCR	D00h

Diagram



Fields

Field	Description
31 MT_EN	Memory Test Enable Determines the status of the memory test. You can write 1 to this field to enable the memory test. Depending on the value of DDR_MTCR[MT_TYP], DDRC issues only reads, only writes, or both reads and writes. DDRC writes 0 to this field after the memory test is complete. DDRC: • Issues transactions throughout the memory, as defined by Rank n Configuration (CS0_CONFIG - CS1_CONFIG) and Rank n Memory Bounds (CS0_BNDS - CS1_BNDS). • Checks the data during the memory test. If ECC is enabled, you must read Memory Error Detect (ERR_DETECT) after the memory test to determine whether any ECC errors occurred during the test. Then: • If an ECC error is detected, the error capture registers hold the address, data, and attributes captured for the first fail. • If no ECC errors are detected and the test fails (for a data miscompare), the capture registers hold information for the transaction that caused the first data miscompare. Transactions that fail with ECC errors are prioritized in capture registers. DDRC writes 0 to this field after the memory test is complete. You can write 1 to this field in either of these conditions: • Before DDR_SDRAM_CFG[MEM_EN] becomes 1 • After the memory controller is enabled and idle You cannot write 1 to this field while the DDRC is processing other transactions. You cannot write 1 to this field when DDR_SDRAM_CFG_2[D_INIT] = 1. 0 - Disables 1 - Enables
30-26	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
25-24 MT_TYP	Memory Test Type Determines whether the memory test uses only reads, only writes, or both reads and writes. You must not use the only-read test unless you have already initialized the memory. 00 - Both writes and reads 01 - Only writes 10 - Only reads 11 - Reserved
23-20 —	Reserved
19-16 MT_TRNARND	Memory Test Turnaround Determines the number of writes issued during the memory test before reads to the same addresses are issued. This field allows longer streams of writes and reads, and it can be used to test the write→read and read→write turnarounds. The field is only relevant if DDR_MTCR[MT_TYP] = 0. 0000 - Entire memory is written to before read transactions are issued. 0001 - Total write and read streams are one transaction each. 0010 - Total write and read streams are two transactions each. 0011 - Total write and read streams are four transactions each. All other values are reserved.
15-10 —	Reserved
9 MT_ADDR_EN	Memory Test Address Range Enable Specifies the memory range used for the memory test. • If this field is 0, the full memory range defined by Rank n Memory Bounds (CS0_BNDS - CS1_BNDS) is used. • If this field is 1, the address range defined by DDR SDRAM Memory Test Start Extended Address (DDR_MT_ST_EXT_ADDR), DDR SDRAM Memory Test Start Address (DDR_MT_ST_ADDR), DDR SDRAM Memory Test End Extended Address (DDR_MT_END_EXT_ADDR), and DDR SDRAM Memory Test End Address (DDR_MT_END_ADDR) is used. To use this field to limit the address range to be tested, for any individual test, the value of neither of the following can be less than that used during the previous test: • The starting address (DDR_MT_ST_EXT_ADDR || DDR_MT_ST_ADDR) • The ending address (DDR_MT_END_EXT_ADDR || DDR_MT_END_ADDR)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Additionally, you cannot write 1 to this field if DDR_MTCR[MT_TRNARND] = 0. 0 - Memory range that the CSn_BNDS registers define 1 - Memory range that the DDR_MT_ST_EXT_ADDR, DDR_MT_ST_ADDR, DDR_MT_END_EXT_ADDR, and DDR_MT_END_ADDR registers define
8-1 —	Reserved
0 MT_STAT	Memory Test Status Specifies whether a fail or data miscompare is detected during the memory test. After DDRC writes 0 to DDR_MTCR[MT_EN], this field becomes 1 in case of a data mismatch during a memory test read. In case of a failure during the memory test (that is, a data miscompare), this field becomes 1 at the same time DDR_MTCR[MT_EN] becomes 0. You can write 0 to this field after DDRC writes 1 to it to indicate a data mismatch. **NOTE** You must ignore this status bit if ERR_EN[INLINE_ECC_EN] is set. If you enable inline ECC, then the ERR_DETECT register can be monitored for detected errors during the memory test. 0 - No fail detected 1 - Data miscompare detected

28.6.49 DDR SDRAM Memory Test Pattern n (DDR_MTP0 - DDR_MTP9)

Provides the data pattern that is written during the *n*th set of 32 bits of each 40-byte memory test pattern.

This field works with DDR_MTCR[MT_EN] to enable the memory write and read test.

The memory test read compares data that is written to this register.

Offset

For n = 0 to 9:

Register	Offset
DDR_MTPn	D20h + (n × 4h)

Fields

Field	Description
31-0 MT_ST_ADDR	Memory Test Start Address Specifies the starting address that is used for memory testing when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

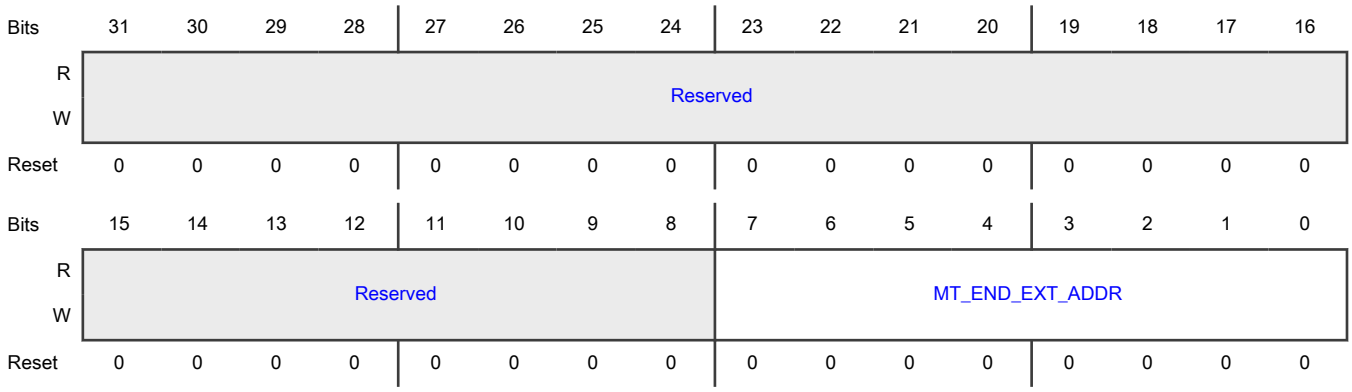
28.6.52 DDR SDRAM Memory Test End Extended Address (DDR_MT_END_EXT_ADDR)

Works with DDR_MTCR[MT_ADDR_EN] to specify the DDR memory test end extended address.

Offset

Register	Offset
DDR_MT_END_EXT_ADDR	D68h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-0 MT_END_EXT_ADDR	Memory Test End Extended Address Specifies the ending extended address that is used when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

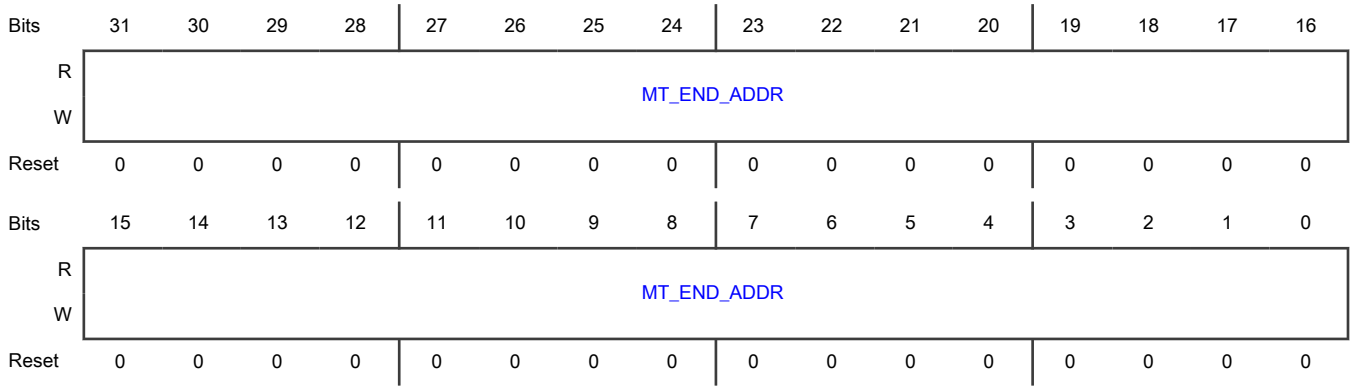
28.6.53 DDR SDRAM Memory Test End Address (DDR_MT_END_ADDR)

Works with DDR_MTCR[MT_ADDR_EN] to specify the DDR memory test end address.

Offset

Register	Offset
DDR_MT_END_ADDR	D6Ch

Diagram



Fields

Field	Description
31-0 MT_END_ADDR	Memory Test End Address Specifies the ending address that is used when DDR_MTCR[MT_ADDR_EN] = 1. See Memory-test address restrictions for restrictions on what you can specify.

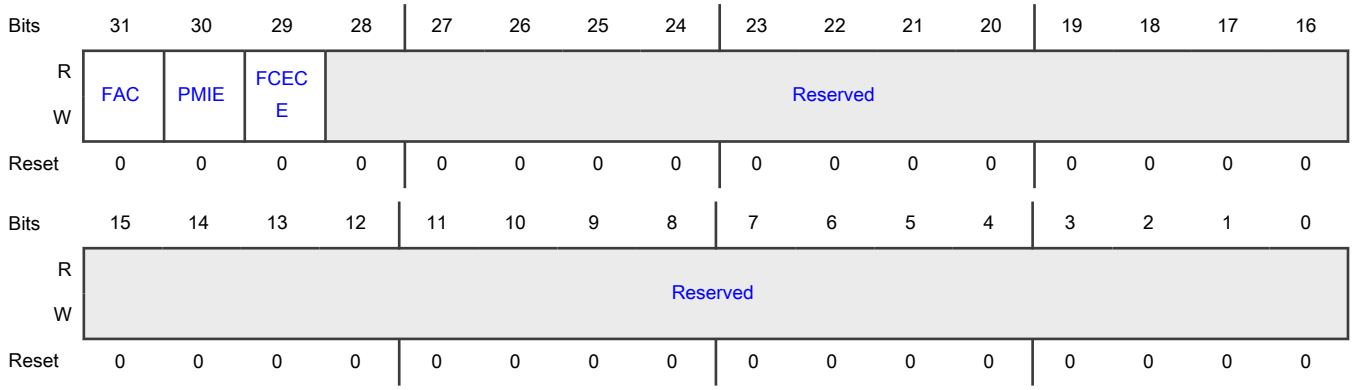
28.6.54 Performance Monitor Global Control (PMGC0)

Controls all PMC's.

Offset

Register	Offset
PMGC0	E00h

Diagram



Fields

Field	Description
31 FAC	Freeze All Counters Specifies whether PMCs are incremented. They are if PMLCA*n*[FC] permits. If PMCs are not incremented, the performance monitor signals an interrupt when PMGC0[FCECE] = 1. 0 - Incremented 1 - Not incremented
30 PMIE	Performance Monitor Interrupt Enable Enables performance monitor interrupts that PMC overflows lead to. Interrupts are enabled and occur when an enabled condition or event occurs. 0 - Disables 1 - Enables
29 FCECE	Freeze Counters On Enabled Condition Or Event Specifies when PMCs can be incremented. These are the conditions: • If PMLCA*n*[CE] is enabled • If the most-significant bit of the counter is 1, that is, when PMC*n* = 1 The use of the trigger and freeze counter conditions depends on the enabled condition. 0 - Enabled if PMLCAn[CE] = 1, until an event or condition occurs. 1 - Enabled if PMLCAn[CE] = 1, until an event or condition occurs. At this point, if PMGC0[FAC] = 1, you must write 0 to it.
28-0 —	Reserved

28.6.55 Performance Monitor Local Control A0 (PMLCA0)

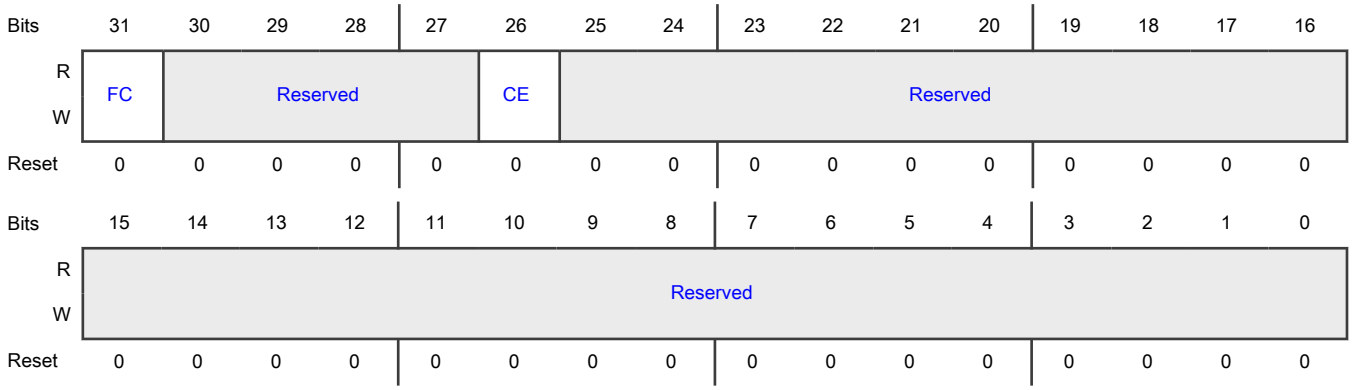
Works with Performance Monitor Local Control B0 (PMLCB0) to associate with an individual counter for specifying the usage of that counter and the event monitored on the counter.

This register controls the operations of the PMC0*n* registers.

Offset

Register	Offset
PMLCA0	E10h

Diagram



Fields

Field	Description
31 FC	Freeze Counter Indicates whether PMCs are enabled and incremented. They are if PMGC0[FAC] permits. This field enables the corresponding PMC*n* register to increment. 0 - Enabled 1 - Disabled
30-27 —	Reserved
26 CE	Condition Enable Controls counter overflow conditions. You must write 0 to this field when PMC0*n* is used as a trigger or is selected for chaining. 0 - Counter overflow conditions for PMC0n cannot occur (PMC0n cannot cause interrupts or freeze counters) 1 - Counter overflow conditions occur when the most-significant bit of PMC0n is 1
25-0 —	Reserved

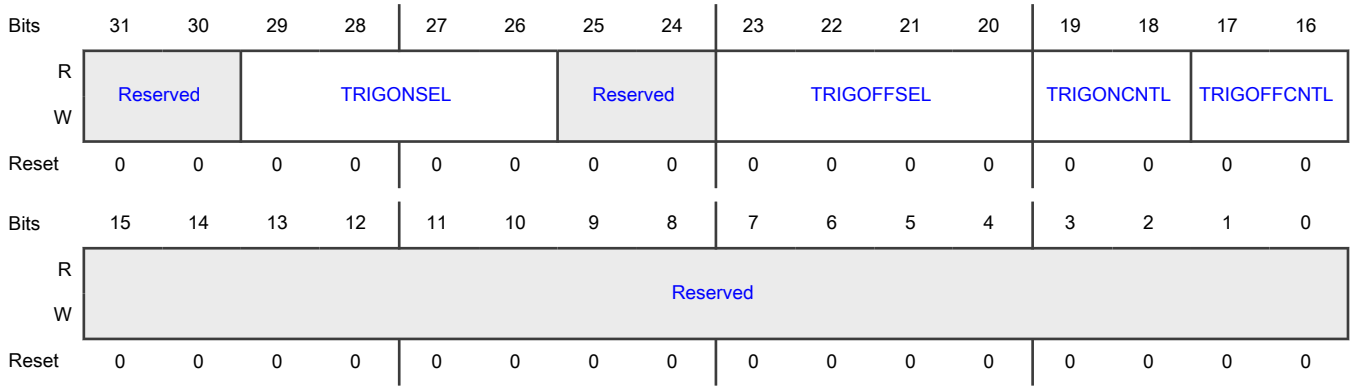
28.6.56 Performance Monitor Local Control B0 (PMLCB0)

Associates with counter 0 to specify how the counter is used and the events monitored on the counter.

Offset

Register	Offset
PMLCB0	E14h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-26 TRIGONSEL	Trigger-On Select Specifies the number of the counter that starts event counting. When the corresponding TRIGONCNTL event overflows, the current counter begins counting. No triggering occurs if the value of this field is self-referential, that is, when the value of this field is set to the current counter number.
25-24 —	Reserved
23-20 TRIGOFFSEL	Trigger-Off Select Specifies the number of the counter that stops event counting. When the corresponding TRIGONCNTL event overflows, the current counter stops counting. No triggering occurs if the value of this field is self-referential, that is, when the value of this field is set to the current counter number.
19-18 TRIGONCNTL	Trigger-On Control Indicates the condition that triggers the counting to start. 00 - Triggering off (no triggering to start) 01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
17-16 TRIGOFFCNTL	Trigger-Off Control Indicates the condition that triggers the counting to stop. 00 - Triggering off (no triggering to start)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
15-0 —	Reserved

28.6.57 PMC 0a (PMC0a)

Holds the lower 32 bits of a 64-bit clock-cycle counter. PMC 0b (PMC0b) holds the upper 32 bits of that counter. This counter counts events that Performance Monitor Local Control A (PMLCA1 - PMLCA10) and Performance Monitor Local Control B (PMLCB1 - PMLCB10) select.

Offset

Register	Offset
PMC0a	E18h

Fields

Field	Description
31-0 PMC0	Counter 0 Counts only clock cycles. This field specifies a read-write counter, which you can program with an initial value to count from.

28.6.59 Performance Monitor Local Control A (PMLCA1 - PMLCA10)

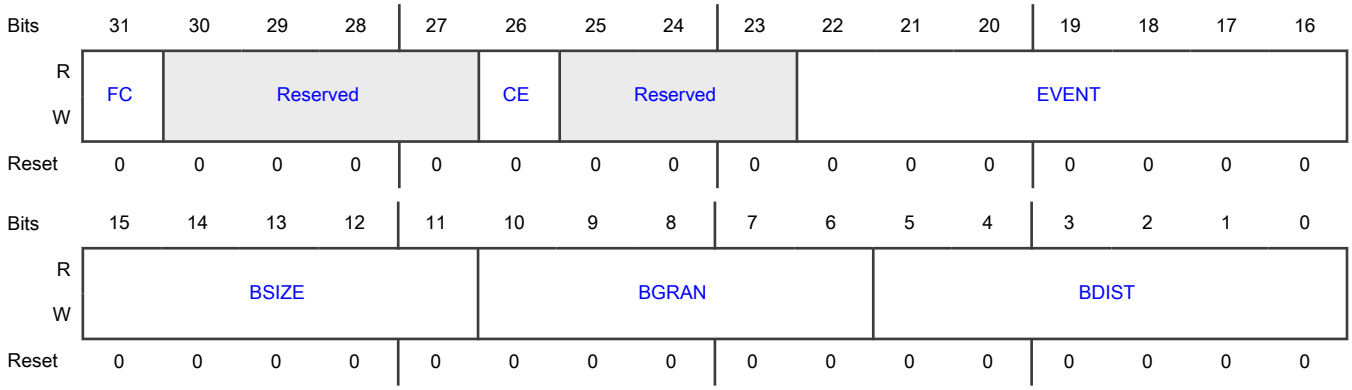
Controls the operation of the PMC*n* registers.

Offset

For a = 1 to 10:

Register	Offset
PMLCAa	E10h + (a × 10h)

Diagram



Fields

Field	Description
31 FC	Freeze Counter Indicates whether PMCs are enabled and incremented. They are if PMGC0[FAC] permits. This field enables the corresponding PMC*n* register to increment. 0 - Enabled 1 - Disabled
30-27 —	Reserved
26 CE	Condition Enable Controls the counter overflow conditions for PMC0. These conditions occur when the most-significant bit of PMC*n* is 1. When the conditions do not occur, they cannot cause interrupts or freeze counters. You must write 0 to this field when PMC0 is used as a trigger or is selected for chaining. 0 - Counter overflow conditions cannot occur 1 - Counter overflow conditions occur
25-23 —	Reserved
22-16 EVENT	Event Selector Selects events to be counted. See Event signals table for a list of events, counters, and the corresponding EVENT field values.
15-11 BSIZE	Burst Size Represents the fewest event occurrences that constitute a burst, which means, a rapid sequence of events followed by a relatively long pause. A value less than two events implies regular event counting. Any non-threshold, regular event may be counted in a bursty fashion.

Table continues on the next page...

Table continued from the previous page...

Field	Description
10-6 BGRAN	Burst Granularity Represents the maximum number of clock cycles between events that are considered part of a single burst.
5-0 BDIST	Burst Distance Specifies the burst distance, which is the number of clock cycles between bursts. This field works with PMLCB*n*[TBMULT] and must have a value greater than PMLCA*n*[BSIZE] for proper burstiness counting behavior. Writing 0 to this field indicates regular counting.

28.6.60 Performance Monitor Local Control B (PMLCB1 - PMLCB10)

Associates with counter 0 to specify how the counter is used and the events monitored on that counter.

Offset

For a = 1 to 10:

Register	Offset
PMLCBa	E14h + (a × 10h)

Diagram

Fields

Field	Description
31-30 —	Reserved
29-26	Trigger-On Select

Table continues on the next page...

Table continued from the previous page...

Field	Description
TRIGONSEL	Specifies the number of the counter that starts event counting. When the corresponding TRIGONCNTL event overflows, the current counter begins counting. No triggering occurs if the value of this field is self-referential, that is, when it is set to the current counter number.
25-24 —	Reserved
23-20 TRIGOFFSEL	Trigger-Off Select Specifies the number of the counter that stops event counting. When the corresponding TRIGONCNTL event overflows, the current counter stops counting. No triggering occurs if the value of this field is self-referential, that is, when it is set to the current counter number.
19-18 TRIGONCNTL	Trigger-On Control Indicates the condition that triggers the counting to start. 00 - Triggering off (no triggering to start) 01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
17-16 TRIGOFFCNTL	Trigger-Off Control Indicates the condition that triggers the counting to stop. 00 - Trigger off (no triggering to start) 01 - Trigger on change 10 - Trigger on overflow 11 - Reserved
15-11 —	Reserved
10-8 TBMULT	Threshold And Burstiness Multiplier Represents threshold and burstiness multiplier. Threshold events are counted when the event duration exceeds a specified threshold value. The threshold is scaled based on the settings of this field, which is also used to scale the burst distance for burstiness counting. For all events that scale the threshold, the threshold field is multiplied from 1 to 128. This field is not used to scale the threshold value for quantity threshold events. 000 - 1 001 - 2 010 - 4 011 - 8

Table continues on the next page...

Table continued from the previous page...

Field	Description
	100 - 16 101 - 32 110 - 64 111 - 128
7-6 —	Reserved
5-0 THRESHOLD	Threshold Specifies a value that is used as an indicator to start counting events. When used, only those events are counted for which the value exceeds this programmed threshold value. For example, if PMC2 counts events for which the duration exceeds the threshold, you can obtain the distribution of those events for a given program by monitoring the program repeatedly, using a different threshold value each time.

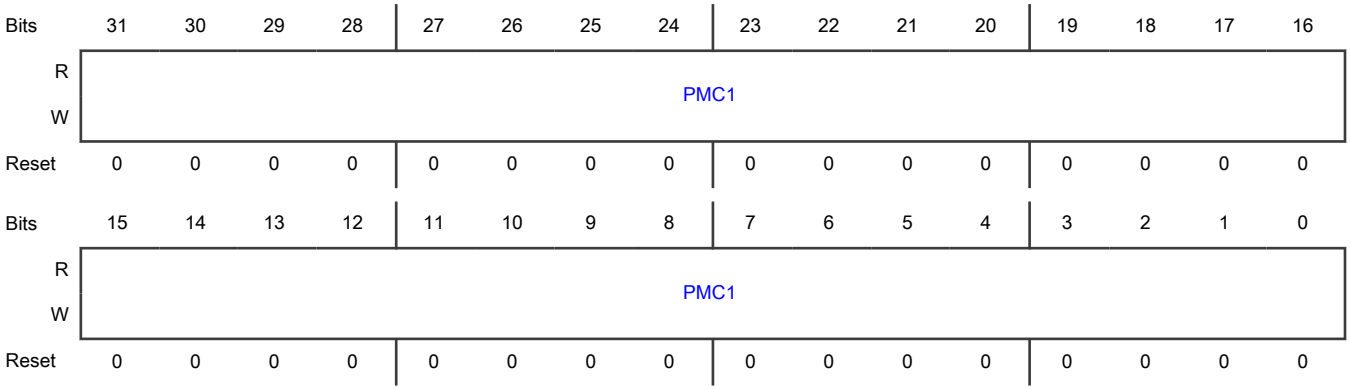
28.6.61 Performance Monitor Counter (PMC1)

Specifies counters that can monitor 64 unique events in addition to the 64 reference events that the full set of PMC*n* registers can count.

Offset

Register	Offset
PMC1	E28h

Diagram



Fields

Field	Description
31-0	Event Count

Table continues on the next page...

Field	Description
PMC1	Indicates an overflow when the most-significant bit of this counter is 1. Writing 1 to this field may cause an immediate interrupt.

28.6.62 Performance Monitor Counter (PMC2)

Specifies counters that can monitor 64 unique events in addition to the 64 reference events that the full set of PMC*n* registers can count.

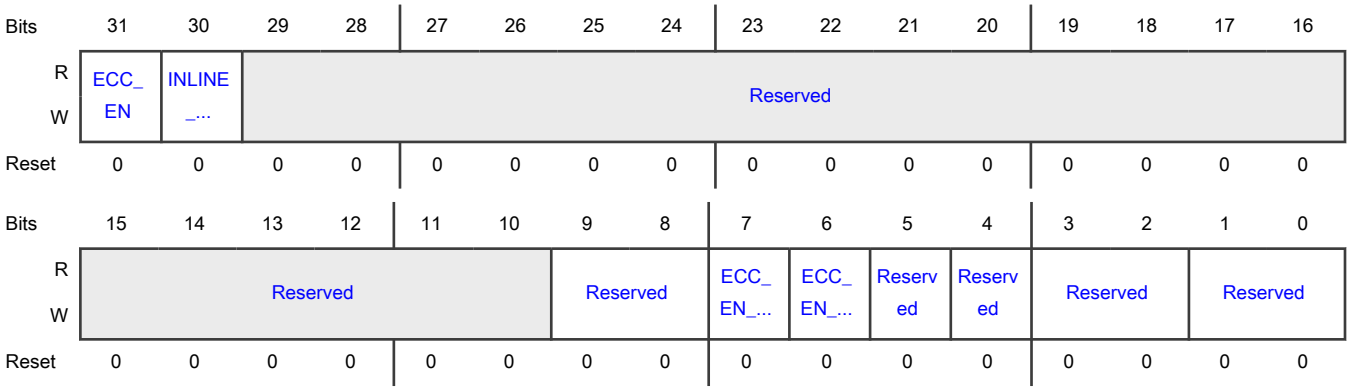
28.6.71 Error Enable (ERR_EN)

Enables controls for many errors that can be reported and injected.

Offset

Register	Offset
ERR_EN	1000h

Diagram



Fields

Field	Description
31 ECC_EN	ECC Enable Enabled global ECC protection for the DDR SDRAM space. This field is the global DDR SDRAM ECC enable. If this field is 0, no ECC errors are reported and no ECC interrupts are generated unless one or more ECC regions are enabled, refer to ECC Region Configuration registers ECC_REG_0 to ECC_REG_7. If this field is 1, the entire DDR SDRAM space is ECC protected. In case protection is enabled only for certain regions, you must program these registers to enable ECC: • ECC Region 0 Configuration (ECC_REG_0) • ECC Region 1 Configuration (ECC_REG_1) • ECC Region 2 Configuration (ECC_REG_2) • ECC Region 3 Configuration (ECC_REG_3) • ECC Region 4 Configuration (ECC_REG_4) • ECC Region 5 Configuration (ECC_REG_5) • ECC Region 6 Configuration (ECC_REG_6) • ECC Region 7 Configuration (ECC_REG_7) Uncorrectable read errors may cause an interrupt. 0 - Disables 1 - Enables
30 INLINE_ECC_EN	Inline ECC Enable Enables inline ECC. You can write 1 to this field only if all of the following conditions are met: • The memory has at least 13 row bits, 10 column bits, and 3 bank bits. • You have enabled data masks (DDR_SDRAM_CFG_3[DM_CFG]) • Either of these conditions is true: — ERR_EN[ECC_EN] = 1. — Certain ECC regions are enabled. When using two ranks of memory, each rank must use the same amount of memory with the same number of row, column, and bank address fields if inline ECC is enabled. When using a 17x10x3 configuration for the DRAM, after DRAM has valid data and ECC, you must read the initial 32k of DRAM, starting with the first defined address. This will load the internal ECC cache with valid data. This is only required for this maximum row/col/bank configuration. **NOTE** Use of inline ECC will reduce overall memory bandwidth. 0 - Disables 1 - Enables

Fields

Field	Description
31-0 EIML	Error Injection Mask Low Data Bit Used to test ECC by forcing errors on the low word of the data bit. Writing 1 to a bit in this field causes the corresponding data-path bit to be inverted on memory bus writes.

28.6.74 Memory Data Path Error Injection Mask ECC (ERR_INJECT)

Enables you to:

- Set the ECC mask.
- Enable errors to write to the ECC memory.
- Enable the ECC byte to mirror the most-significant data byte.
- Inject a single address-parity error.

Offset

Register	Offset
ERR_INJECT	1108h

Fields

Field	Description
31-0 ECLD	Error Capture Low Data Path Captures the low word of the data path when errors are detected.

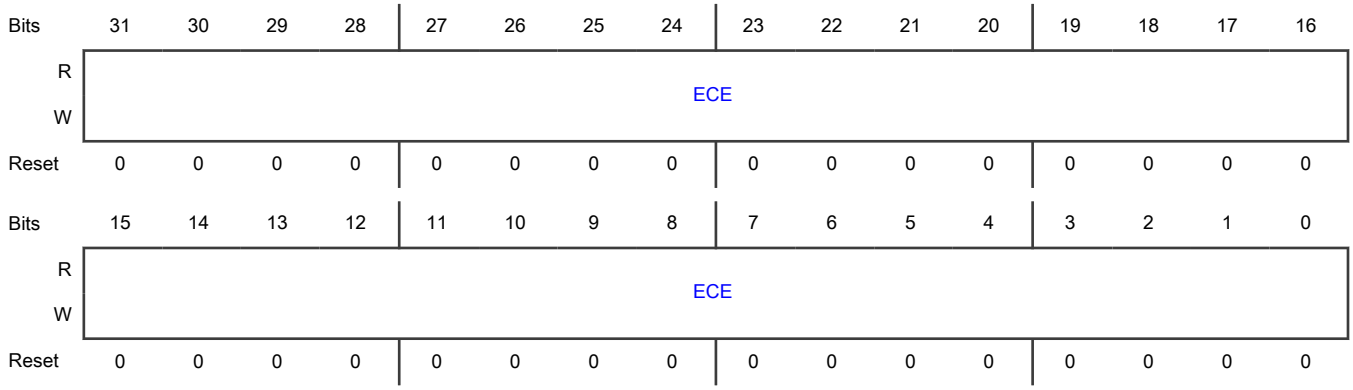
28.6.80 Memory Data Path Read Capture ECC (CAPTURE_ECC)

Stores the ECC syndrome bits that are on the data bus when an error is detected.

Offset

Register	Offset
CAPTURE_ECC	1128h

Diagram



Fields

Field	Description
31-0 ECE	Error Capture ECC Captures the ECC bits on the data path whenever errors are detected. ECC is always generated or checked on 64-bit data chunks. The bits of this field mean the following:

ECE bit numbers	Meaning
0–7	Show the 8-bit ECC for the fourth 64 bits of a 32-byte granule
8–15	Show the 8-bit ECC for the third 64 bits of a 32-byte granule
16–23	Show the 8-bit ECC for the second 64 bits of a 32-byte granule
24–31	Show the 8-bit ECC for the first 64 bits of a 32-byte granule

28.6.81 Memory Error Detect (ERR_DETECT)

Stores the detection fields for multiple-memory errors, single- and multiple-bit ECC errors, and memory-select errors.

You can determine the type of memory error by examining the contents of this register. If an error is disabled using Memory Error Disable (ERR_DISABLE), the corresponding error is never detected or captured in Memory Error Detect (ERR_DETECT).

NOTE

SSBE2, SMBE2 bits are not applicable for LPFLASH.

Offset

Register	Offset
ERR_DETECT	1140h

7 REFRATEE	Refresh rate error. Cleared by software writing a 1. 0 - A refresh rate error has not been detected. 1 - A refresh rate error has been detected.
6 —	Reserved
5 —	Reserved
4 —	Reserved
3	Multiple-Bit Error Indicates whether DDRC detected a multiple-bit error.

Table continues on the next page...

Table continued from the previous page...

Field	Description
MBE	0 - Not detected 1 - Detected
2 SBE	Single-Bit ECC Errors Indicates whether the number of detected single-bit ECC errors crossed the threshold defined in ERR_SBE[SBET]. 0 - Did not cross 1 - Crossed
1 —	Reserved
0 MSE	Memory-Select Error Indicates whether a memory-select error is detected. This error occurs if a transaction arriving at DDRC does not match any valid rank windows. 0 - Not detected 1 - Detected

28.6.82 Memory Error Disable (ERR_DISABLE)

Allows selective disabling of DDRC's error-detection circuitry.

Disabled errors are not detected or reported.

Offset

Register	Offset
ERR_DISABLE	1144h

Table continues on the next page...

Table continued from the previous page...

Field	Description
3 MBED	Multiple-Bit ECC Error Disable Indicates if multiple-bit ECC errors are detected or reported. Multiple-bit ECC errors are detected if ERR_EN[ECC_EN] = 1. They are reported if ERR_INT_EN[MBEE] = 1. See Error management for more information. To ensure that an interrupt is generated: • This field must be 0. • ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] must be 1. 0 - Detected 1 - Not detected or reported
2 SBED	Single-Bit ECC Error Disable Enables single-bit ECC errors. 0 - Enables 1 - Disables
1 —	Reserved
0 MSED	Memory-Select Error Disable Enables memory-select errors. 0 - Enables 1 - Disables

28.6.83 Memory Error Interrupt Enable (ERR_INT_EN)

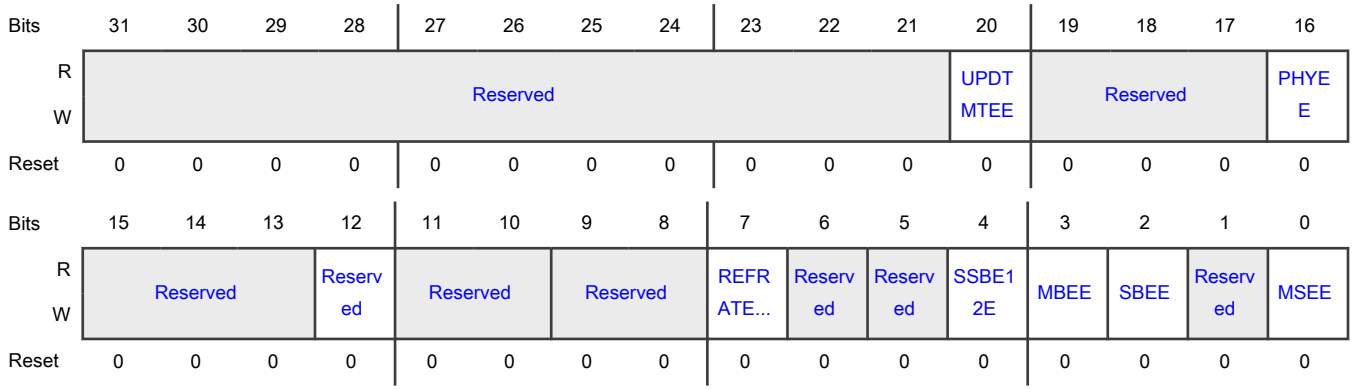
Enables ECC interrupts or memory-select error interrupts.

When an enabled interrupt condition occurs, DDRC generates an interrupt.

Offset

Register	Offset
ERR_INT_EN	1148h

Diagram



Fields

Field	Description
31-21 —	Reserved
20 UPDTMTEE	Update Timeout Interrupt Enable Specifies whether a training update timeout causes an interrupt. 0 - No 1 - Yes
19-17 —	Reserved
16 PHYEE	PHY error interrupt enable. 0 - PHY errors cannot generate interrupts. 1 - PHY errors generate interrupts.
15-13 —	Reserved
12 —	Reserved
11-10 —	Reserved
9-8 —	Reserved
7 REFRATEEE	Refresh Rate Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Specifies whether a reported refresh rate that is outside the defined temperature range causes an interrupt. You should only set this bit if also setting DDR_SDRAM_CFG_3[DYN_REF_RATE_EN] 0 - No 1 - Yes
6 —	Reserved
5 —	Reserved
4 SSBE12E	SRAM Single-Bit Error Interrupt Enable Indicates whether SRAM SBE1 or SRAM SBE2 errors generate interrupts. 0 - No 1 - Yes
3 MBEE	Multiple-Bit ECC Error Interrupt Enable Indicates whether multiple-bit ECC errors generate interrupts. Uncorrectable read errors may lead to interrupts. To ensure that an interrupt is generated, these conditions must be true: • ERR_DISABLE[MBED] must be 0. • ERR_INT_EN[MBEE] and ERR_EN[ECC_EN] must be 1 if one or more ECC regions are enabled. See Error management for more information. 0 - No 1 - Yes
2 SBEE	Single-Bit ECC Error Interrupt Enable Indicates whether single-bit ECC errors generate interrupts. 0 - No 1 - Yes
1 —	Reserved
0 MSEE	Memory-Select Error Interrupt Enable Indicates whether memory-select errors generate interrupts. 0 - No 1 - Yes

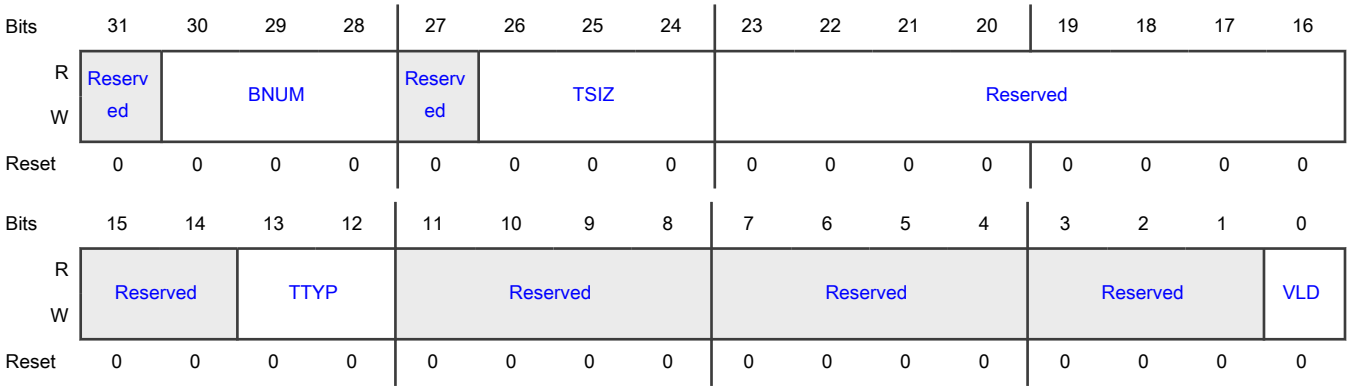
28.6.84 Memory Error Attributes Capture (CAPTURE_ATTRIBUTES)

Defines attributes of the originating read and write transactions that cause errors related to type, size, source, and others.

Offset

Register	Offset
CAPTURE_ATTRIBUTES	114Ch

Diagram



Fields

Field	Description

Fields

Field	Description
31-8 —	Reserved
7-0 CEADDR	Captured Extended Address Captures the 8 most-significant bits of the transaction address when an error is detected.

28.6.87 Single-Bit ECC Memory Error Management (ERR_SBE)

Stores:

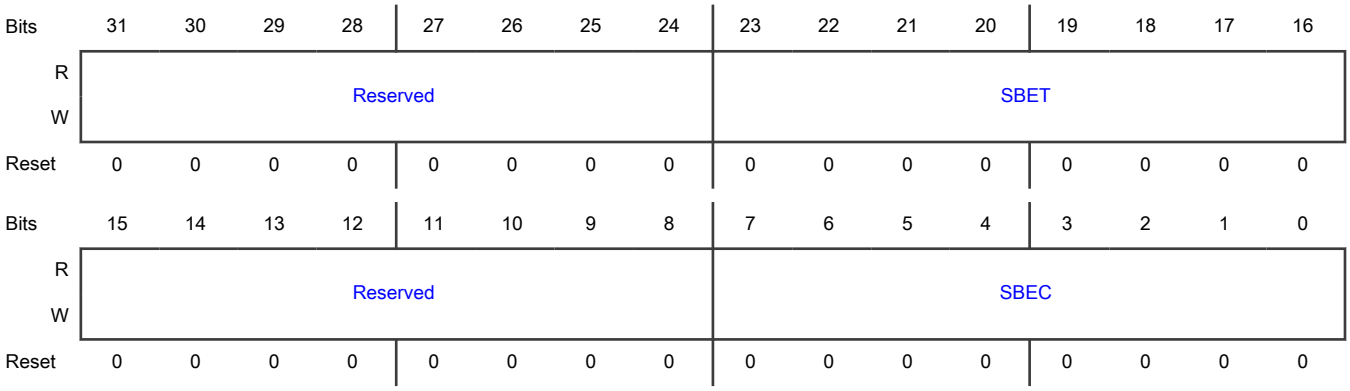
- The threshold value for reporting SBEs.
- The number of SBEs counted since the last error report.

ERR_SBE[SBEC] resets when it reaches the threshold. If necessary, you must reset the counter after it manages the error.

Offset

Register	Offset
ERR_SBE	1158h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 SBET	SBE Threshold Establishes the number of SBEs that must be detected before an error condition is reported.

Table continues on the next page...

Table continued from the previous page...

Field	Description
15-8 —	Reserved
7-0 SBEC	SBE Counter Indicates the number of SBEs detected and corrected since the last error report. If you enable SBE reporting, an error is reported and an interrupt is generated when the value of this field equals that of ERR_SBE[SBET]. This field becomes 0 when it reaches its threshold value.

28.6.88 ECC Region 0 Configuration (ECC_REG_0)

Provides bits 31:20 for the starting and ending addresses of a region to be enabled for ECC. The region must be defined only if:

- You enable specific ECC regions.
- ERR_EN[ECC_EN] = 0.

NOTE

ECC region registers should not be programmed without first programming this register. If per region ECC enablement is used for any region, then you must have region 0 enabled.

Offset

Register	Offset
ECC_REG_0	1240h

28.7 Glossary

Bank	A collection of memory-cell rows and columns
CS	Chip select
DBI	Data bus inversion
DLL	Delay-locked loop
ECC	Error checking and correction
FFI	Freedom from interference
MRW	Mode register write
ODT	On-die termination
Page	A synonym for row, usually used in the context of Open-Page mode
PIC	Programmable interrupt controller
PMC	Performance monitor counter
POR	Power-on reset
Posted refresh	In a posted refresh, more than one refresh command can be performed at a time. For example if you set the posted refresh to 5, then at each refresh interval 5 consecutive refreshes are issued, keeping the DDR interface blocked until all 5 refreshes are completed. this allows for a longer period of uninterrupted operation in DDR.
SBE	Single-bit error
SECDED	Single-error correcting, double-error detecting

Chapter 29
Flexible Serial Peripheral Interface (FlexSPI)

29.1 Chip-specific FLEXSPI information

Table 158. Reference links to related information

Topic	Related module	Reference
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
Full description	FLEXSPI	FLEXSPI
System memory map		System memory map
Signal multiplexing	Port control	Signal multiplexing

The chip includes one instance of FLEXSPI with support for one channel.

29.1.1 Module instances

This device has one instance of the FLEXSPI module.

29.1.2 Master ID Assignments

To enable FlexSPI to view different IDs from different masters, follow the steps shown below:

- Set AHBCR[HMSTRIDREMAP] =1 to enable master ID mapping
- Configure HMSTRxCR[MSTRID] using the table below (The “n” should be masked by the mask value. Other bits can be selectively masked to group some masters into one AHB buffer region):

Table 159. Master IDs

Module	4-bit Master ID
Cortex-A55 cores	000n
Reserved	0010 - 0111
Reserved	1000
Reserved	1001
Edgelock	1010
eDMA3_1(AHB)	1011
eDMA3_1(AXI)	1100
Reserved	1101 - 1110
All other bus masters	1111

NOTE

After reset, the FlexSPI sees all masters IDs as zero.

29.1.3 AHB Memory Map Address Range

The table below shows the address range calculations for the FlexSPI:

Table 160. Memory Map Address Ranges

Description	FlexSPI1
Address range mapped for AHB read access to FLEXSPI RX FIFO	0x4742_0000 – 0x4742_01FF
Address range mapped for AHB write access to FLEXSPI TX FIFO	0x4743_0000 – 0x4743_03FF
AHB Memory for Serial Flash memory access	0x2800_0000 - 0x2FFF_FFFF
AHB RX Buffer size	2 KByte
AHB TX Buffer size	64 Bytes
FLEXSPI RX FIFO	512 KByte
FLEXSPI TX FIFO	1 KByte

NOTE

- FLEXSPI command should be able to access Flash address space which is greater than 128MB.
- AHB command cannot access Flash address space which is greater than 128MB, it can only access within 128MB.
- But for IP command, AHB/IPS BUS both can access IP RX/TX FIFO(different reg configuration will choose IPS or AHB), which means IPS/AHB bus both can access greater than 128MB flash address space indirectly by IP RX/TX FIFO in IP command mode only.

29.2 Overview

FlexSPI supports one SPI channel and up to two external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

The FlexSPI configuration depends on the chip configuration. See the system-level section for boot information and pinmux for chip-specific information regarding the modes and number of devices supported.

FlexSPI supports communication with both serial flash memory and serial RAM devices. While many of the descriptions, registers, and fields specifically reference flash memory, almost all information can also be applied to serial RAM. Flash memory is used as an example in the tables and figures in this chapter.

NOTE

Terminology in this chapter has been updated to align with JEDEC standard *Expanded Serial Peripheral Interface (xSPI) for Non Volatile Memory Devices, Version 1.0*.

Table 161. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

29.2.1 Block diagram

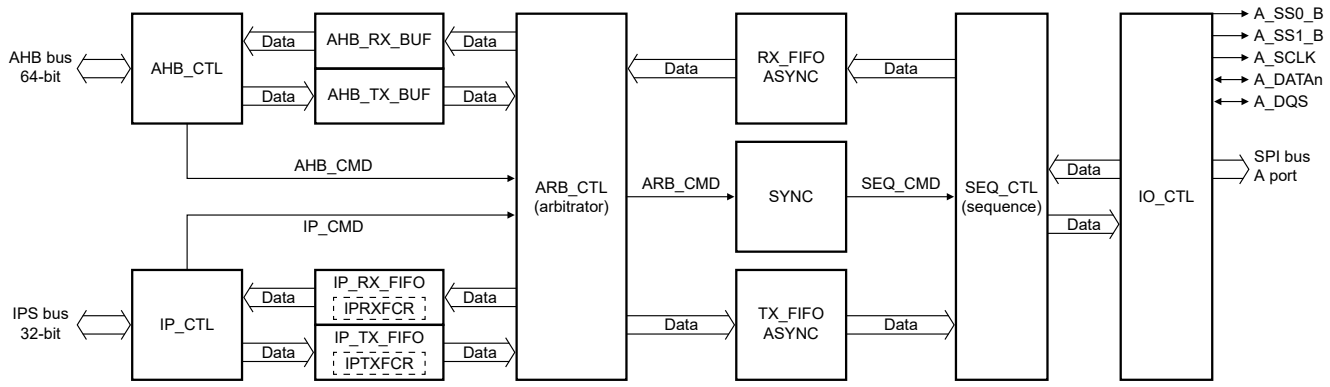

Figure 74. Block diagram

29.2.2 Features

FlexSPI supports:

- Flexible sequence engine (lookup table) to support various vendor devices
  - Serial NOR flash memory and other devices with SPI protocol similar to serial NOR flash memory
  - Serial NAND flash memory
  - HyperBus devices (HyperFlash/HyperRAM)
  - XCCELA devices
  - FPGA devices
- Flash memory access modes
  - Single, Dual, Quad, Octal mode
  - Single Data Transfer Rate (SDR) and Double Data Transfer Rate (DDR) mode
  - Individual mode
- Sampling clock mode
  - Internal dummy read strobe looped back internally
  - Internal dummy read strobe looped back from pad
  - Flash-memory-provided read strobe
- Automatic data learning to select the correct sample clock phase
- Memory mapped read and write access by AHB bus
  - AHB receive buffer implemented to reduce read latency. See the chip-specific section for AHB buffer size.
  - 16 AHB controllers with programmable priority for read access from each
  - 8 flexible and configurable buffers in AHB receive buffer
  - AHB transmit buffer implemented to buffer all write data from one AHB burst. See the chip-specific section for AHB buffer size.

NOTE

All AHB controllers share this AHB transmit buffer. There is no AHB controller number limitation for write access.

- Software-triggered flash memory read and write access by IP bus
  - IP receive FIFO implemented to buffer all read data from external devices. FIFO size: 512 bytes
  - IP transmit FIFO implemented to buffer all write data to external devices. FIFO size: 1024 bytes
  - DMA support to read IP receive FIFO
  - DMA support to fill IP transmit FIFO
  - SCLK stops when IP receive FIFO is full during reading flash memory data
  - SCLK stops when IP transmit FIFO is empty during writing flash memory data

29.3 Glossary for FlexSPI module

Table 162. Glossary

Term	Definition
AHB Command	AHB Command is one or several Serial Flash Memory access command sequences triggered by AHB read/write access to AHB address ranged mapped for Serial Flash Memory.
ASFM_BASE	Base address of AHB address space mapped to Serial Flash Memory.
ARDF_BASE	Base address of AHB address space mapped to IP RX FIFO.
ATDF_BASE	Base address of AHB address space mapped to IP TX FIFO.
Set	Write 1 to register bit to establish logic level one on the bit.
Clear	Write 0 to register bit to establish logic level zero on the bit.
Command Sequence	A command sequence is 4*32 bits sequence code consisting of up to 8 instructions. Command sequence should be programmed in LUT according to Flash command. When a command sequence executed, the chip selection signal becomes asserted. When a command sequence execution finished, the chip selection signal becomes negated.
DDR	Dual data transfer rate for flash access mode Flash receive data on both SCLK rise and fall edge and transmit data on both SCLK rise and fall edge.
Endianness	Byte Ordering scheme.
Field	Two or more register bits grouped together.
Fill	To add entries to a FIFO by software or hardware.
Instruction Code	16 bits code defining the type of command to be executed on FlexSPI interface.
IP Command	IP Command is one or several Serial Flash Memory access command sequences triggered by set register bit IPCMD.TRG.
Negated	A signal that is negated is in its inactive state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.
SDR	Single data transfer rate for flash access mode

Table continues on the next page...

Table 162. Glossary (continued)

Term	Definition
	Flash receive data on SCLK rise edge and transmit data on SCLK fall edge.
Set	To set a bit or bits means to establish logic level one on the bit or bits.
SFM	Serial Flash Memory
Individual Mode	Access to a single, individual serial flash device at a time.
Memory Command	Serial access Command for reading/programming/configuring. A memory command may consist one or several command sequences, for each command sequence the Chip selection signal will be asserted and deasserted once.
LUT	Look-up table to preserve command sequence. LUT is programmed by software with command sequences which is used to issue memory commands.

29.4 Functional description

29.4.1 Flash connection

There is one FlexSPI interface port (port A) that supports up to two flash devices by providing two chip select outputs.

NOTE

FlexSPI configuration depends on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

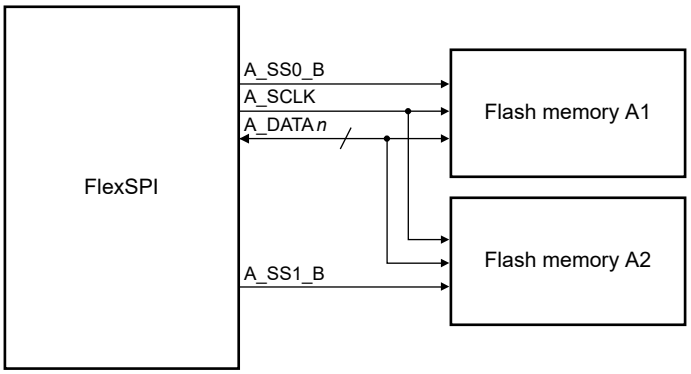

Figure 75. FlexSPI connection diagram with two devices.

NOTE

- Flash A1 and Flash A2 can be two flash chip packages or two flash dies in the same package.
- In individual mode, flash devices cannot be accessed at the same time. But these two devices can be accessed separately.

29.4.2 Flash memory access mode

29.4.2.1 SPI clock mode

FlexSPI only supports SPI clock mode 0: clock polarity (CPOL) = 0 and clock phase (CPHA) = 0. When the SPI bus is idle, SCLK stays at a logic low state.

29.4.2.2 Individual mode

In individual mode, read and write data are received and transmitted on port A or port B.

NOTE

FlexSPI does not support 16-bit read and write for the SPI interface.

29.4.2.3 SDR mode and DDR mode

In SDR mode, flash memory receives data on the rising edge of SCLK and transmits data on the falling edge of SCLK.

In DDR mode, flash memory receives and transmits data on both the rising and falling edges of SCLK.

The instruction (opcode) in the LUT sequence dynamically determines SDR and DDR modes. There is no static configuration register field setting for SDR and DDR modes. See FlexSPI input timing and FlexSPI output timing for details about input and output timing.

29.4.2.4 Single, Dual, Quad, and Octal mode

In Single mode, FlexSPI transmits and receives data on one data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, FlexSPI transmits and receives data on two data pins (DATA0–DATA1 for both transmitting and receiving).

In Quad mode, FlexSPI transmits and receives data on four data pins (DATA0–DATA3 for both transmitting and receiving).

In Octal mode, FlexSPI transmits and receives data on eight data pins (DATA0–DATA7 for both transmitting and receiving).

Instruction (num_pads) in the LUT sequence dynamically determine Single, Dual, Quad, and Octal modes. There is no static configuration register field setting for Single, Dual, Quad, and Octal modes.

29.4.3 Modes of operation

FlexSPI operates with these modes.

Table 163. Operating modes

Mode	Description
Module Disable	This mode is a low-power mode for FlexSPI. In Module Disable mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock domain is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, and IP transmit FIFO cannot be accessed. Serial memory access is also not available. Write 1 to MCR0[MDIS] to enter this mode. Write 0 to MCR0[MDIS] to exit this mode.
Doze	This mode is a low-power mode for the chip. When the chip requires FlexSPI to enter Doze mode and MCR0[DOZEEN] = 1, FlexSPI enters Doze mode after all transactions are completed (STS0[ARBIDLE] = 1). In Doze mode, the AHB clock and serial clock domains are gated off internally, but the IPS bus clock is not gated off. Read and write access to the control and status register are available, but the LUT, IP receive FIFO, the IP transmit FIFO cannot be accessed. Serial memory access is also not available.

Table continues on the next page...

Table 163. Operating modes (continued)

Mode	Description
	This mode is entered via system request, and exited by deasserting this system request.
Stop	This mode is a low-power mode for the chip. When the chip requires the FlexSPI to enter Stop mode, FlexSPI waits for all transactions to complete (STS0[ARBIDLE] = 1) and return ACK handshake to the system. After the ACK handshake is returned, FlexSPI gates off the AHB clock and serial clock domains internally. The system can gate off the AHB bus clock, IPS bus clock, and serial clock at the system level. This mode is entered via system request. This mode is exited by deasserting this system request, and the ACK handshake message is also deasserted immediately.
Normal	No clock is gated off internally. Normal register access and serial memory access are available.

29.4.4 AHB access memory map

FlexSPI allocates AHB memory space for each memory device starting from the FlexSPI region base address of the system memory map. The FLSHxCR0[FLSHSZ] field determines the amount of memory allocated for each memory device in KB, Fx_SIZE. The memory is then allocated sequentially and contiguously.

NOTE

See the chip-specific section for the maximum flash size supported.

When MCR2[SAMEDEVICEEN] = 1:

- FA1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FA2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHA1CR0[FLSHSZ] × 1 KB

When MCR2[SAMEDEVICEEN] = 0:

- FA1_SIZE = FLSHSZ × 1 KB
- FA2_SIZE = FLSHA2CR0[FLSHSZ] × 1 KB
- FB1_SIZE = FLSHB1CR0[FLSHSZ] × 1 KB
- FB2_SIZE = FLSHB2CR0[FLSHSZ] × 1 KB

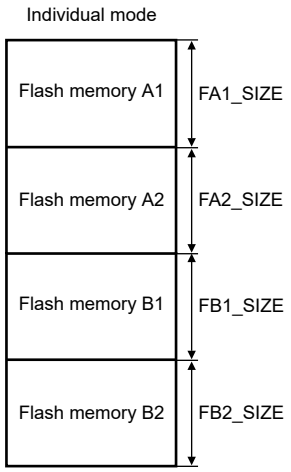

Figure 76. AHB access memory map in individual mode

AHB access memory map in individual mode:

- Flash A1 address range: 0000_0000h to FA1_SIZE
- Flash A2 address range: FA1_SIZE to (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: (FA1_SIZE + FA2_SIZE + FB1_SIZE) to (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

NOTE

The address used in equations in this topic is the address presented to the memory. The base address for FlexSPI in the system memory map has already been removed, so it not used or shown here.

29.4.4.1 Flash address sent to flash memory devices

The AHB address (AHB command) or IPCR0[SFAR] (IP command) determines the flash memory access start address. See Flash memory access via AHB command and Flash memory access via IP command for more details.

For AHB commands, the FlexSPI controller removes the flash memory base address automatically when sending flash addresses to flash devices. The flash address is sent to devices in two parts: row address and column address. For flash devices that do not support the column address, set FLSHxCR1[CAS] to 0. This setting causes all flash address bits to be sent to flash devices as row addresses.

For word-addressable flash devices, the last bit of the address is not needed, because flash memory is read and programmed in terms of two bytes.

29.4.5 Lookup table (LUT)

The LUT is an internal memory that preserves a number of preprogrammed sequences. Each sequence consists of up to eight instructions which are executed sequentially. When an IP command or an AHB command triggers a flash memory access, the FlexSPI controller:

1. Fetches the sequence from LUT (sequence index or number).
2. Executes the flash memory access to generate a valid flash transaction on the SPI interface.

Figure 77 shows the LUT structures, sequences, and instructions.

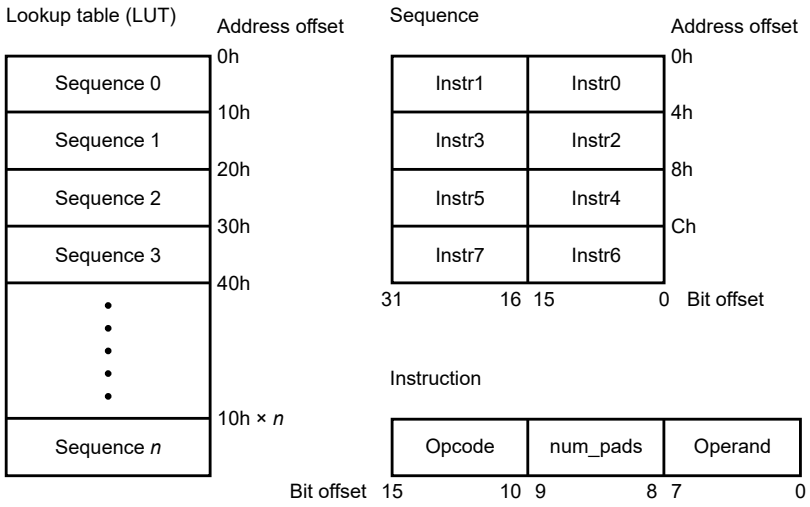

Figure 77. LUT structure, sequences, and instructions

NOTE

If the number of instructions needed for a flash transaction is less than eight, the STOP instruction (code 0000_0000h) must be programmed for unneeded instructions.

For IP and AHB write commands, the FlexSPI controller always executes from instruction pointer 0. For AHB read commands, the FlexSPI controller executes from a saved instruction start pointer. The FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointers are zero before the JMP_ON_CS instruction is executed. When the JMP_ON_CS instruction is executed, the operand in the JMP_ON_CS instruction is saved as instruction start pointer. See Execute-In-Place (XIP) enhanced mode.

The reset value of the LUT is unknown because it is implemented as internal memory. The LUT must be programmed according to the connected device. To protect its contents during a code runover, the LUT can be locked or unlocked to prevent unwanted changes after the LUT has been configured. The key to lock or unlock the LUT is **5AF05AF0h**.

To lock the LUT:

1. Write the key (5AF05AF0h) to LUT Key (LUTKEY).
2. Write 1 to LUTCR[LOCK] and write 0 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

To unlock the LUT:

1. Write the key (5AF05AF0h) to the LUT Key Register LUT Key (LUTKEY).
2. Write 0 to LUTCR[LOCK] and write 1 to LUTCR[UNLOCK]. When there is another register write access to FlexSPI between these two write accesses, this LUT is not successfully locked.

The lock status of the LUT can be read from LUTCR[LOCK] and LUTCR[UNLOCK].

29.4.6 Programmable sequence engine

The FlexSPI controller implements a programmable sequence engine that executes the sequence from the LUT. The FlexSPI controller executes the instructions sequentially, and generates flash transactions on the SPI interface accordingly. Table 164 is a complete list of the supported instructions.

Table 164. Instruction set

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
CMD_SDR	00_0001h	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Transmit command code to flash memory	Command code: Operand[7:0]	Bit number: 8
CMD_DDR	00_0021h				
RADDR_SDR	00_0002h		Transmit row address to flash memory See Flash address sent to flash memory devices	Row_Address[31:0] Row_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Row_Address.
RADDR_DDR	00_0022h				
CADDR_SDR	00_0003h		Transmit column address to flash memory. See Flash address sent to flash memory devices.	Column_Address[31:0] Column_Address comes from AHB bus (AHB command) or IPCR0[SFAR] (IP command).	Bit number: operand[7:0] Value of operand determines number of bits sent in Column_Address.
CADDR_DDR	00_0023h				
MODE1_SDR	00_0004h		Transmit mode bits to flash memory	Mode bits: Operand[0]	Bit number: 1
MODE1_DDR	00_0024h				
MODE2_SDR	00_0005h			Mode bits: Operand[1:0]	Bit number: 2
MODE2_DDR	00_0025h				
MODE4_SDR	00_0006h			Mode bits: Operand[3:0]	Bit number: 4
MODE4_DDR	00_0026h				
MODE8_SDR	00_0007h			Mode bits: Operand[7:0]	Bit number: 8
MODE8_DDR	00_0027h				
WRITE_SDR	00_0008h		Transmit program data to flash device	Program data in IP_TX_FIFO or AHB_TX_BUF	AHB burst size and burst type (AHB command) or IPCR1[IDATSZ] (IP command) determines byte number (data size). For details about flash read or program data size, see Flash memory access via AHB command and Flash memory access via IP command.
WRITE_DDR	00_0028h				
READ_SDR	00_0009h		Receive read data from flash device Read data is put into AHB_RX_BUF or IP_RX_FIFO.	-	
READ_DDR	00_0029h				
DATSZ_SDR	00_000Bh		Transmit read or program data size	Internal logic	Bit number: operand[7:0]
DATSZ_DDR	00_002Bh				

Table continues on the next page...

Table 164. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
			(byte number) to flash device	Read or program data size for current command sequence	Never set operand to zero or greater than 64 for DATSZ instruction.
DUMMY_SDR	00_000Ch		Leave data lines undriven by FlexSPI controller. Turnaround cycles are provided from host driving to device driving. num_pads determines number of pads in input mode.	-	Dummy cycle number (in serial root clock): Operand[7:0] Dummy cycle (N), described in data sheet of flash device, is in number of SCLK cycles. This number may be configurable. In SDR mode, SCLK cycle is same as serial root clock. Operand value must be set to N. In DDR mode, SCLK cycle is double serial root clock cycle. Operand value must be set to 2N, 2N-1 or 2N+1 depending on definition of dummy in data sheet of flash device. See Flash memory access sequence examples and dummy cycle definition in data sheet of external memory.
DUMMY_DDR	00_002Ch				
DUMMY_RWDS_SDR	00_000Dh		Similar to DUMMY_SDR/ DUMMY_DDR instruction. Difference is in dummy cycle number. DQS pin is called RWDS in HyperBus specification. See Dummy instruction for details. **Set operand to "Latency count" for HyperBus devices.**	-	For read command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 1) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 1) if RWDS (DQS pin) is low; For write command, dummy cycle number (in serial root clock): (operand[7:0] × 4 - 2) if RWDS (DQS pin) is high; (operand[7:0] × 2 - 2) if RWDS (DQS pin) is low;
DUMMY_RWDS_DDR	00_002Dh				

Table continues on the next page...

Table 164. Instruction set (continued)

Name	Opcode	num_pads	Action on SPI interface	Transmit data	Bits/bytes/cycle number
LEARN_SDR	00_000Ah	00h - one pad (Single mode) 01h - two pads (Dual mode) 02h - four pads (Quad mode) 03h - eight pads (Octal mode)	Receive read data or preamble bit from flash device FlexSPI controller compares data line bits with the DLPR register to determine a correct sampling clock phase.	-	Bit number: operand[7:0] Never set operand to zero for LEARN instruction. Value of operand indicates number of bits to receive and compare to DLPR value. For example, 8-bit pattern 5Ah on each data line must set operand to 8.
LEARN_DDR	00_002Ah				
JMP_ON_CS	00_001Fh	Num_pads setting ignored.	Stop execution, deassert CS and save operand[7:0] as instruction start pointer for next sequence. Normally this instruction is used to support Execute-In-Place enhanced mode. See Execute-In-Place (XIP) enhanced mode. This instruction is only allowed for AHB read commands. When using this instruction in IP command or AHB write command, interrupt status flag set (INTR[IPCMDERR] or INTR[AHBCMDERR]).	-	No transaction on SPI interface.
STOP	00_0000h		Stop execution and deassert CS. Next command sequence (to same flash device) starts from instruction pointer 0.	-	

The programmable sequence engine allows configuration of the LUT according to the connected external serial device. The flexible LUT structure easily adapts to new command or protocol changes from different vendors.

The DDR sequence is a flash memory access sequence that contains DDR instructions other than DUMMY_DDR, and may contain SDR instructions. The output and input timing on FlexSPI differs for SDR and DDR sequences. When included as part of a DDR sequence, SDR instructions execute differently from SDR instructions in an SDR sequence. See FlexSPI input timing and FlexSPI output timing.

29.4.6.1 Executing instructions on SPI interface

This section describes the execution of instructions on the SPI interface. For all instructions that receive bits from or transmit bits to flash devices:

- The bit order in one byte is higher on DATA7 than DATA0.
- The bit order is higher on port B than port A.

This order is shown in Figure 78.

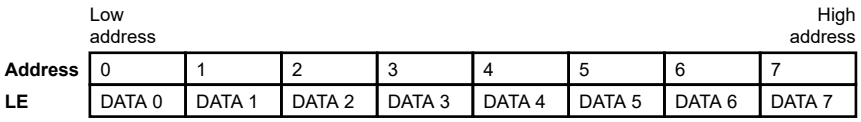

Figure 78. Bus bit order

Table 165. SPI instructions

Instructions	Description
Command (CMD_SDR, CMD_DDR)	Normally used to transmit a command code to the external device. The command code is the 8-bit operand in the instructions. See Flash memory access sequence examples.
Address (RADDR_SDR, RADDR_DDR, CADDR_SDR, CADDR_DDR)	Normally used to send the flash memory access start address (row address or column address) to an external device. FlexSPI determines the bits of the row address or column address according to the AHB access address or IP command address. See Flash address sent to flash memory devices. The operand value in the instruction code represents the number of address bits to send. For example, when NUM_PADSn = 8, a memory reading the flash memory address on four SCK edges requires the sum of bits in CADDR and RADDR instructions to be 32. Otherwise, FlexSPI does not generate four SCK edges of address phase. See Flash memory access sequence examples.
Mode (MODEx_SDR, MODEx_DDR)	Normally used to send mode bits to external devices. Mode bits are the lower bits of an operand. For example, the bit number is 1 for MODE1_SDR and MODE1_DDR, 2 for MODE2_SDR and MODE2_DDR, 4 for MODE4_SDR and MODE4_DDR, and 8 for MODE8_SDR and MODE8_DDR. The pad number should not be greater than the mode bit number. For example, you cannot set NUM_PADSn to 11b (Octal mode) for MODE4_* instructions. See Flash memory access sequence examples for more details.
Data Size (DATSZ_SDR, DATSZ_DDR)	Used to send the size of program data or read data (byte number) to external devices. This instruction is normally used in FPGA applications where the memory space in external device acts like a FIFO. The external device requires data size information to determine how much data are popped from or pushed into the internal FIFO. The operation value in the data size instructions is the bit number. See Flash memory access sequence examples.

Table continues on the next page...

Table 165. SPI instructions (continued)

Instructions	Description
Write (WRITE_SDR, WRITE_DDR)	Normally used to send program data to external device. Programming data is fetched from IP_TX_FIFO (IP Command) or AHB_TX_Buffer (AHB command). For details about flash program data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for program data is always from low to high. See Flash memory access sequence examples for more details.
Read (READ_SDR, READ_DDR)	Normally used to receive flash memory data from external devices. Received data is put into IP_RX_FIFO (IP Command) or AHB_RX_Buffer (AHB command). For information about flash memory read data size, see Flash memory access via AHB command and Flash memory access via IP command. The byte order for reading data is always from low to high. See Flash memory access sequence examples.
Dummy (DUMMY_SDR, DUMMY_DDR, DUMMY_RWDS_SDR, DUMMY_RWDS_DDR)	Used to provide turnaround cycles on the SPI interface. During dummy instruction, the FlexSPI controller and external devices do not drive the SPI interface. See Programmable sequence engine for details about dummy cycle number. DUMMY_RWDS_DDR can be used for a HyperBus device that uses RWDS pin to indicate whether extra latency is needed. DUMMY_RWDS_SDR is reserved. The FlexSPI controller checks the DQS pin input level at the fourth cycle after SCLK output toggling is enabled. The DQS pin is called RWDS in HyperBus specification. See Flash memory access sequence examples. **NOTE** FlexSPI releases the bus after at least one cycle. To avoid data contention, the NUM_PADSn value for the dummy commands should be configured to match the number of data lines used for the external memory.
Learn (LEARN_SDR, LEARN_DDR)	Used to determine the correct sample clock phase for flash memory read data sampling. External device drives read data (or data learning pattern) bits on the FlexSPI interface. The FlexSPI controller compares the data line bits to the DLPR register to determine a correct sampling clock phase. Clock phase selection is automatically updated after executing learn instructions. See Data learning for more details. The operand value in learn instructions is the byte number. FlexSPI checks the same data pattern on each data line. The byte order is byte 0, byte 1, byte 2, byte 3, byte0, byte 1, and so on. • Byte 0 is DLPR register bits 7–0. • Byte 1 is DLPR register bits 15–8. • Byte 2 is DLPR register bits 23–16. • Byte 3 is DLPR register bit 31–24. The bit order is from high to low in each byte. See Flash memory access sequence examples.

29.4.6.2 Flash memory access sequence examples

Diagrams below all assume MCR0[SERCLKDIV] = 0.

Figure 79 shows an example SDR single I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

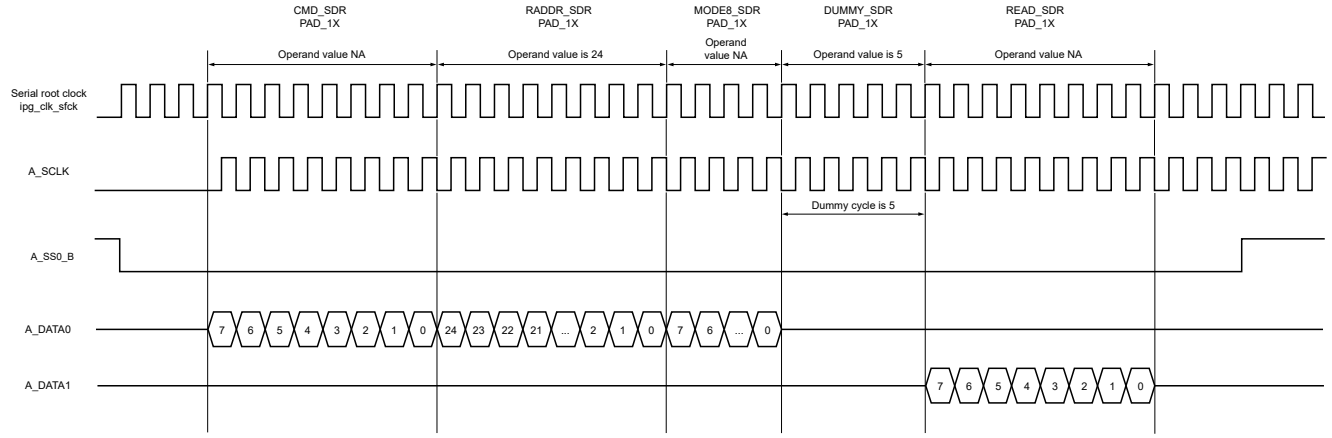

Figure 79. Flash memory access sequence example (SDR single I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 80 shows an example SDR quad I/O read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

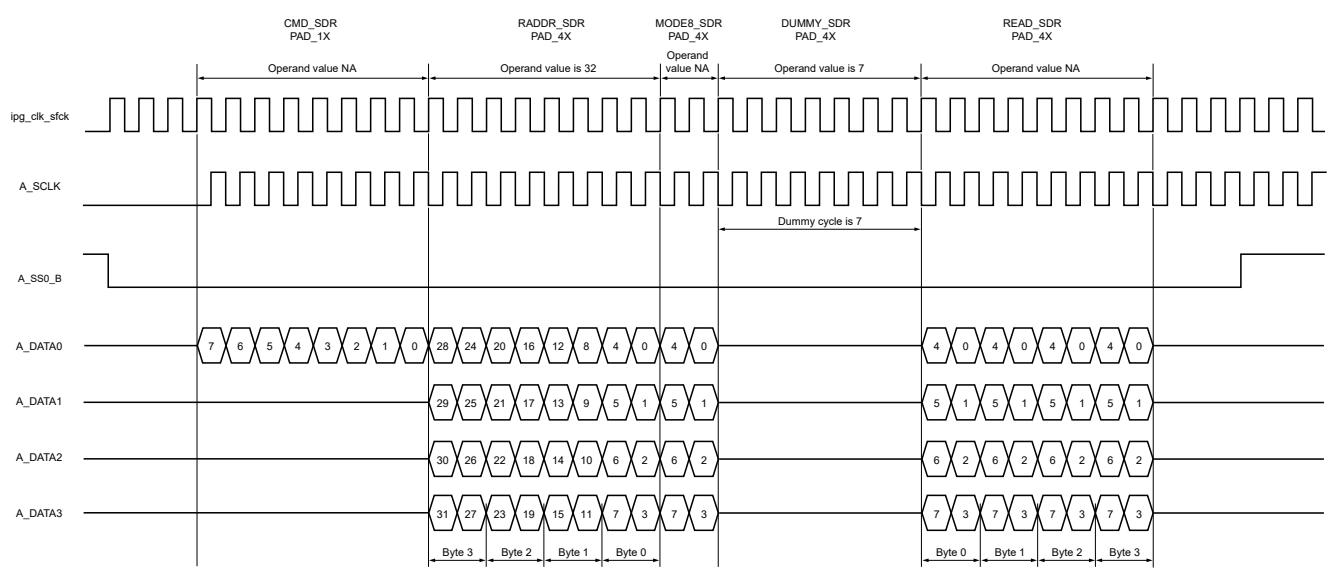

Figure 80. Flash memory access sequence example (SDR quad I/O read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK (on Cypress S25FS512S data sheet).

Figure 81 shows an example learn instruction (not for a specified flash device) in individual mode.

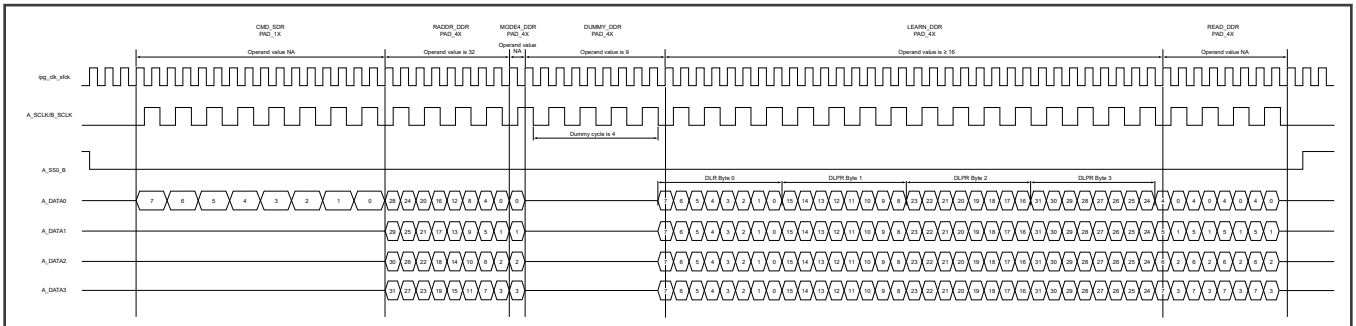

Figure 81. Flash memory access sequence example (data learning)

NOTE

- FlexSPI dummy instruction starts and ends at the rising edge of serial root clock.
- Device dummy cycle starts and ends at the falling edge of SCLK.
- The operand value of DUMMY_DDR instruction is odd because the total cycle number before DUMMY_DDR cycle is odd.

Figure 82 shows an example HyperBus device read transaction (single latency count) in individual mode.

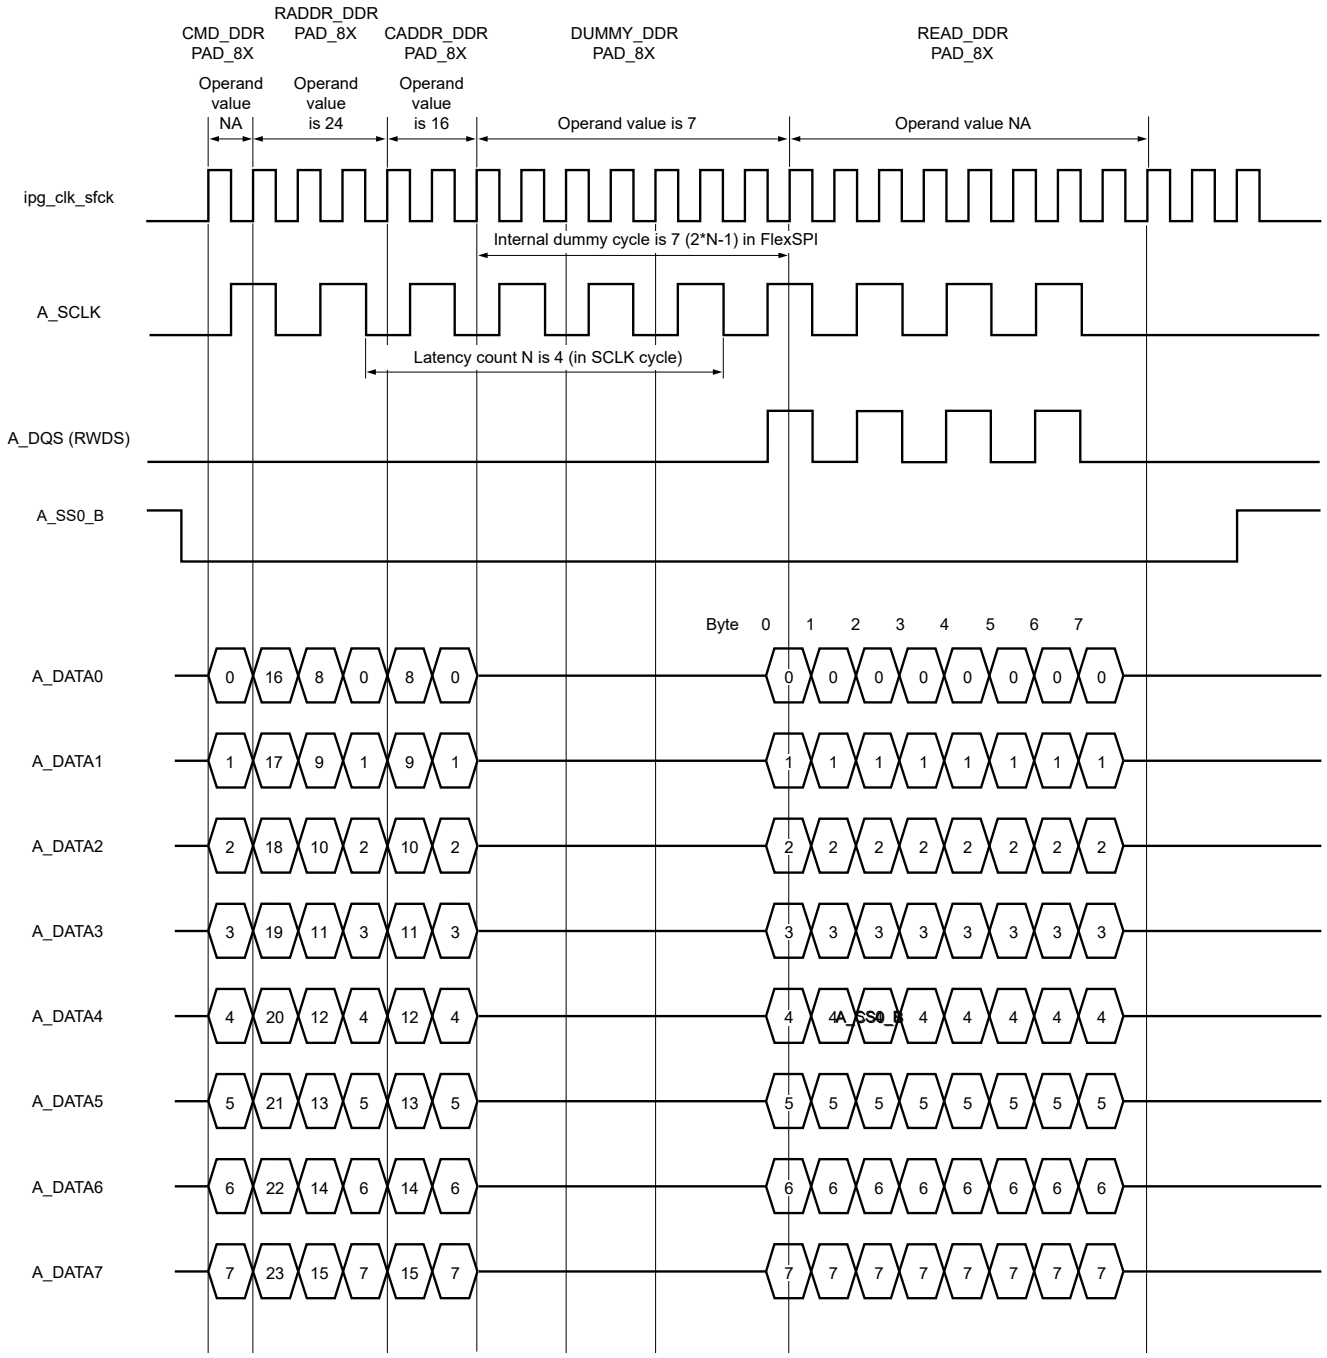

Figure 82. HyperBus device read transaction with single latency count

NOTE

FlexSPI continues to drive the clock until it has latched all of the read data it is expecting. On-chip delay for the data to reach FlexSPI can increase the number of SCK clock pulses.

Figure 83 shows an example HyperBus device read transaction (additional latency count) in individual mode.

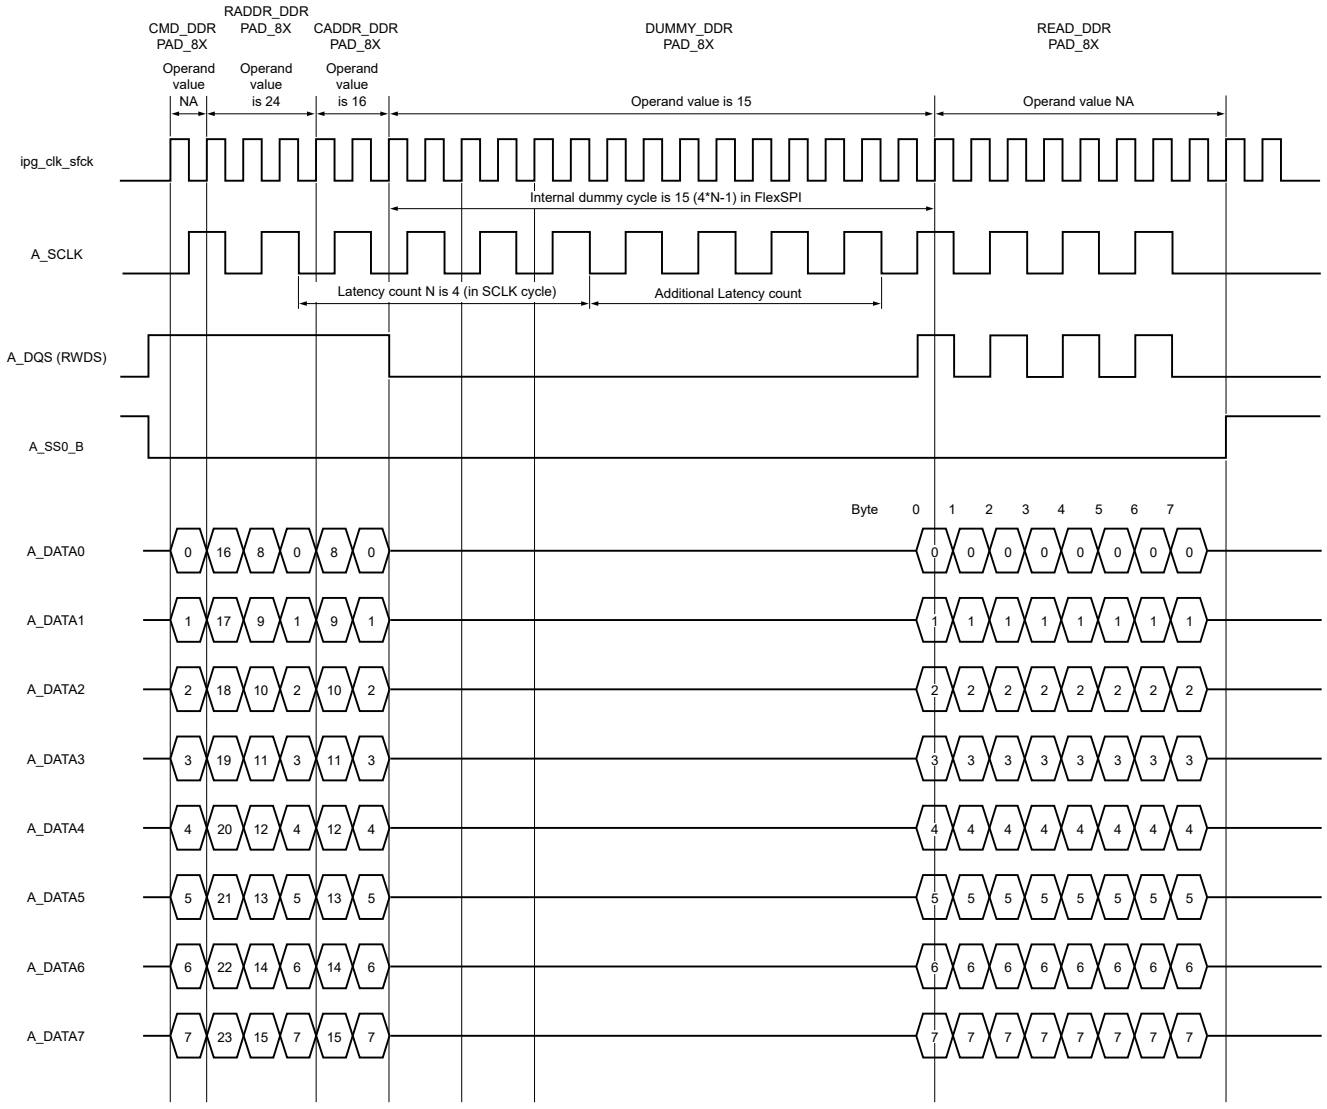

Figure 83. HyperBus device read transaction with additional latency count

Figure 84 shows an example HyperBus device write transaction (single latency count) in individual mode.

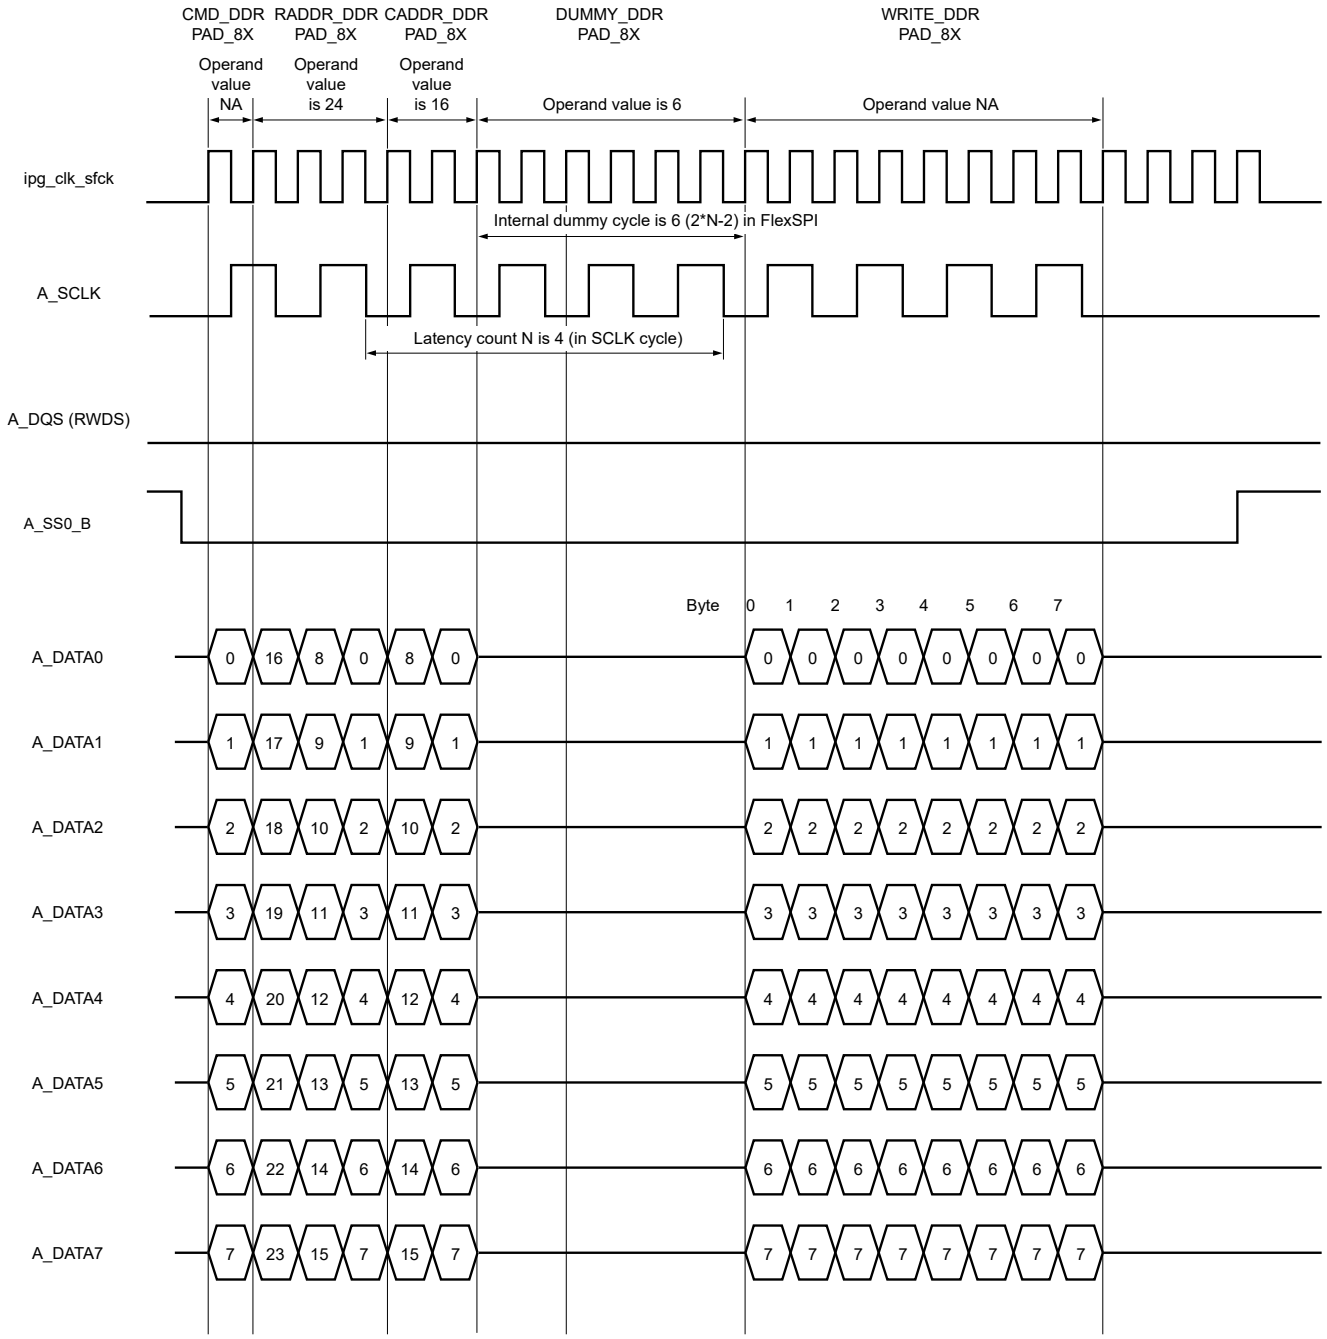

Figure 84. HyperBus device write transaction with single latency count

Figure 85 shows an example HyperBus device write transaction (additional latency count) in individual mode.

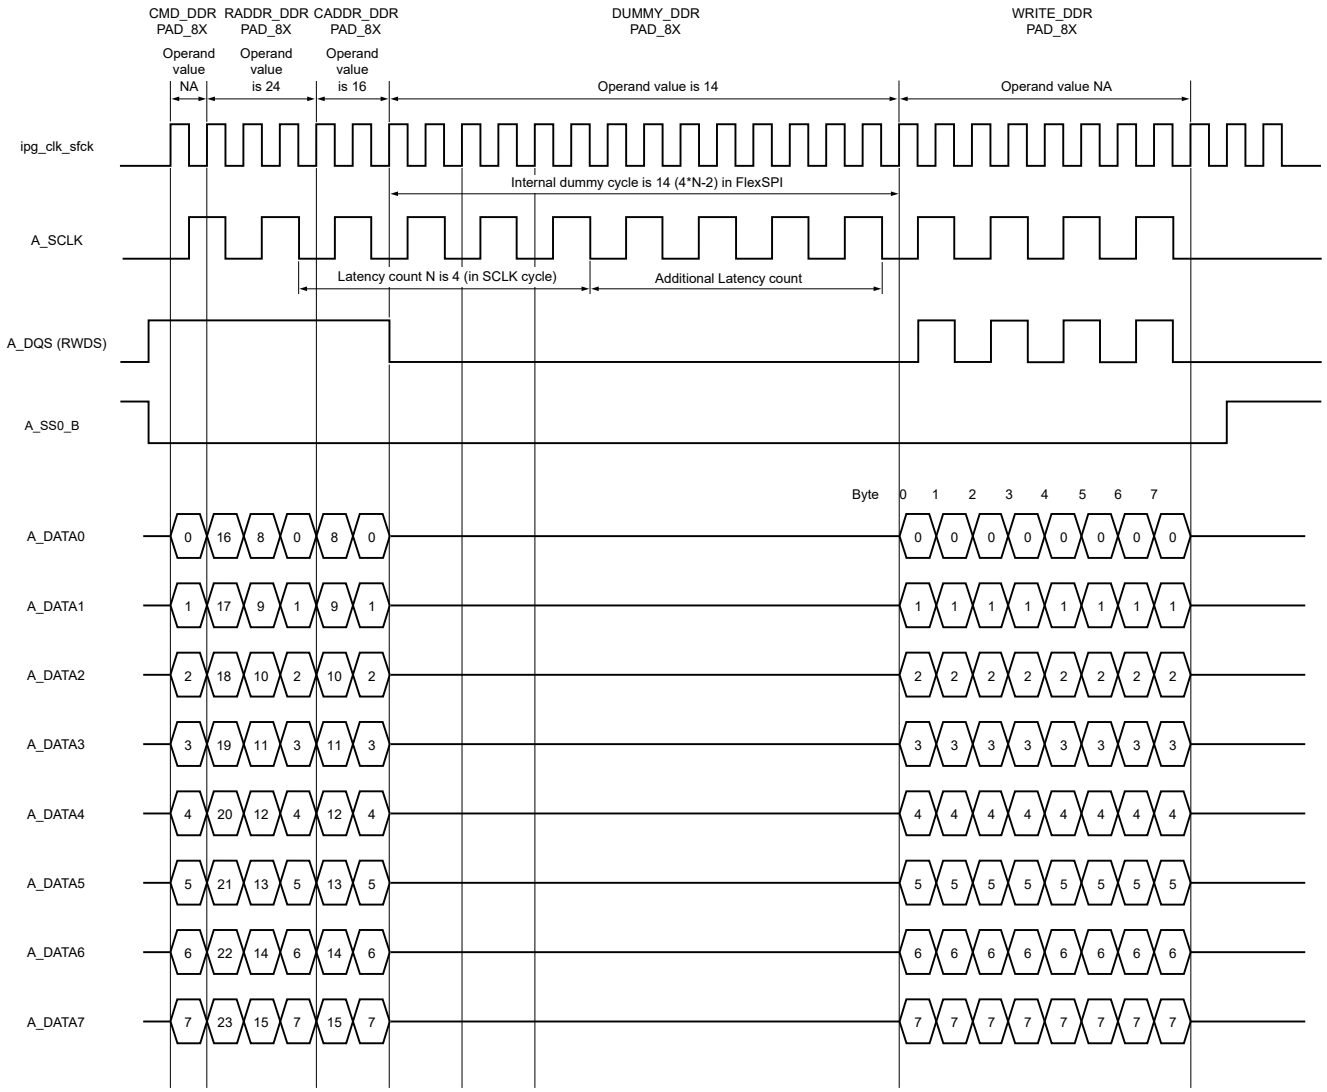

Figure 85. HyperBus device write transaction with additional latency count

29.4.7 Clocking

This section describes FlexSPI clocks and special clocking requirements.

Table 166. Clock usage

Clock name	Description	Comment
serial clock root (ipg_clk_sfck)	Root clock for Serial domain	FlexSPI core clock, used to generate the serial clock output. The clock is optionally divided using MCR0[SERCLKDIV] to obtain the SCLK.

Table continues on the next page...

Table 166. Clock usage (continued)

Clock name	Description	Comment
		Its frequency is same as SPI SCK frequency in SDR mode if MCR0[SERCLKDIV] = 0.
ahb clock (hclk)	AHB bus clock	hclk frequency is higher than 1/4 of serial root clock, so internal async FIFO is never full. This clock is used for internal logic in FlexSPI.
ipg clock (ipg_clk)	IPS bus clock	Register access clock. ipg_clk must be equal to hclk or an integer division of hclk. For example, ipg_clk = hclk/2.
SCLK	FlexSPI serial clock. Output clock on SCLK pin	Half clock frequency of serial clock root in DDR mode, and same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
DQS_OUT	Dummy Read Strobe output	Same frequency as SCLK. Clock output toggles during READ and LEARN instructions. The DQS ensures that the data can be strobed correctly. It is only used for data strobe, instead of command or address strobe. The data includes useful read data and data learning patterns.
DQS_IN	Sample clock for receive data	Same frequency as SCLK. Sample clock comes from looped-back dummy read strobe, looped-back SCLK, or flash-memory-provided read strobe.

29.4.8 Interrupts

Table 167 describes all interrupts that FlexSPI generates.

Table 167. Flash memory address, row address, and column address

Interrupt	Enable	Condition
IP command done	INTEN[IPCMDDONEEN]	An IP command is finished.
IP command grant error	INTEN[IPCMDGEEN]	An IP command grant timeout occurs (bus not granted after MCR0[IPGRANTWAIT] × 1024 AHB clock cycles). See Overview of error categories, flags, and triggered sources.
AHB command grant error	INTEN[AHBCMDGEEN]	An AHB command grant timeout occurs (bus not granted after MCR0[AHBGRANTWAIT] × 1024 AHB

Table continues on the next page...

Table 167. Flash memory address, row address, and column address (continued)

		clock cycles). See Overview of error categories, flags, and triggered sources.
IP command error	INTEN[IPCMDERREN]	A command check error or a command execution error for an IP command occurs. See Overview of error categories, flags, and triggered sources.
AHB command error	INTEN[AHBCMDERREN]	A command check error or a command execution error for AHB command occurs. See Overview of error categories, flags, and triggered sources.
IP_RX_FIFO watermark available	INTEN[IPRXWAEN]	The fill level of IP_RX_FIFO reaches the watermark level (IPRXFCR[RXWMRK]).
IP_TX_FIFO watermark empty	INTEN[IPTXWEEN]	The empty level of IP_TX_FIFO reaches the watermark level (IPTXFCR[TXWMRK]).
Data learning failed	INTEN[DATALEARNFAILEN]	No valid sample clock phase found after LEARN instruction is executed. See Overview of error categories, flags, and triggered sources.
Sequence execution timeout	INTEN[SEQTIMEOUTEN]	A sequence execution time exceeds the timeout wait time (MCR1[SEQWAIT]). For example, the following flash memory read command sequence lasts about 800_0000h cycles (ipg_clk_sfck). If SEQWAIT is set to FFFFh, a sequence timeout interrupt is generated. • IP command triggers timeout. • Flash memory read data size is 100_0000h bytes. • Flash memory accesses in single mode and SDR mode.
AHB bus error	INTEN[AHBBUSERROREN]	AHB bus response timeout occurs, or AHB read access occurs while OTFAD is enabled and FlexSPI is still fetching the key blob. For example, AHB read sequence is not configured properly in LUT (such as without a READ instruction). No data is read from the external device. As a result, FlexSPI cannot reach the read data in AHB_RX_Buffers for the AHB read command.
Write command stops SCLK	INTEN[SCKSTOPBYWREN]	IP_TX_FIFO is empty while executing a write command sequence. FlexSPI

Table continues on the next page...

Table 167. Flash memory address, row address, and column address (continued)

		stops SCLK output clock toggling and waits for write data filling.
Read command stops SCLK	INTEN[SCKSTOPBYRDEN]	IP_RX_FIFO is full while executing a read command sequence. FlexSPI stops SCLK output clock toggling and waits to read the data from IP_RX_FIFO.
Key done	INTEN[KEYDONEEN]	OTFAD is enabled and key blob processing is enabled, key blob processing is done, and no error is detected.
Key error	INTEN[KEYERROREN]	OTFAD is enabled and key blob processing is enabled, and an error occurs during key blob processing. Once this interrupt is set, only reset can clear it.

29.4.9 On-The-Fly AES Decryption (OTFAD) support

After power-up, if OTFAD and key fetches are enabled in the system, FlexSPI automatically starts fetching the key blobs from location 0 of flash A1. The key fetches continue until OTFAD receives and processes all key blobs. During the fetch operation, any AHB access causes an error response, and INTR[AHBBUSERROR] is set. No IPS access is allowed during the fetching of key blobs. INTR[KEYDONE] or INTR[KEYERROR] represents the key blob processing result.

After OTFAD processes all key blobs, the OTFAD engine decrypts any reads from FlexSPI and returns them on the AHB bus. When OTFAD is enabled, FlexSPI always enables prefetch; only AHBCR[READSZALIGN] can disable the prefetch. The Read Resume function is also disabled. All read access addresses are eight-byte-aligned automatically, regardless the setting of AHBCR[READADDROPT]. If OTFAD is enabled, the prefetch never crosses the 1 KB boundary.

29.4.10 Flash memory access via IP command

Follow these steps to trigger a flash memory access via IP command.

1. If this command is a programing command, fill the IP transmit FIFO with programming data (for instance, programming flash data and flash memory status registers.)
2. Write the flash memory access start address to IPCR0[SFAR].
3. Write the read or program data size to IPCR1[IDATSZ]. Write the sequence index to IPCR1[ISEQID]. Write the sequence number to IPCR1[ISEQNUM].
4. Write 1 to IPCMD[TRG] to trigger a flash memory access command.
5. Wait for the INTR[IPCMDDONE] flag to set or for the IP command done interrupt to fire, indicating the command has completed on the FlexSPI interface.

NOTE

- The IP transmit FIFO can be filled before or after writing the IPCR0, IPCR1, and IPCMD registers. If the SFM command starts with the IP transmit FIFO empty, FlexSPI stops SCLK toggling to wait for transmit data ready automatically.
- The IPCMD register must be written after writing the IPCR0 and IPCR1 registers.
- One IP command can issue up to eight command sequences.
- You cannot issue another IP command before the previous IP command is finished. Performing this action results in unknown behavior.

If this command is a read command, all read data from flash memory is put into the IP receive FIFO. Software must read data from the IP receive FIFO via AHB bus or IP bus. When the IP receive FIFO is full and the flash device still contains data to read, FlexSPI stops SCLK toggling until the FIFO has free space. See SCLK stop.

A triggered serial flash command contains:

- A flash memory access start address. IPCR0[SFAR] determines this address.
- A flash chip select. The flash memory access address and flash memory size setting (FLSHxCR0[FLSHSZ]) determine the chip select.
- A flash command sequence index and sequence number. FlexSPI sequentially executes the sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT.
- Flash individual memory access mode:
- The flash memory read or program data size, in bytes.
  - If the value of IPCR1[IDATSZ] is nonzero, the data size is IPCR1[IDATSZ].
  - If the value of IPCR1[IDATSZ] is zero, the operand value in the read or write instruction determines the data size.

NOTE

- Software must ensure that the last sequence index never exceeds the LUT sequence number. That is, IPCR1[ISEQID] + IPCR1[ISEQNUM] must be less than 32.
- For sequence numbers greater than one, the data size is applied to every command sequence.
- If there is no write or read instruction in the command sequence, the data size is ignored.

The IP command request is sent to the arbitrator after software triggers it. It is not executed on the FlexSPI interface until the arbitrator grants it. See Command arbitration.

29.4.10.1 Reading data from IP receive FIFO

FlexSPI puts read data from the external device into the IP receive FIFO for IP commands.

The data stored in the IP receive FIFO can be read using IPS and register or system and AHB bus transactions:

- Via IP bus
- Via AHB bus

If MCR0[ARDFEN] = 1, only the AHB bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using IP bus always returns with data zero, and no bus error occurs.

If MCR0[ARDFEN] = 0, only the IPS bus can read the read data in the IP receive FIFO. Read access to the IP receive FIFO using the AHB bus triggers a bus error.

FlexSPI pushes read data into the IP receive FIFO in sets of 64 bits each time it receives 64 bits of data from an external device. When the number of read data bits is not 64-bit-aligned, FlexSPI pushes additional zero bits into the IP receive FIFO for the last push.

The processor or DMA can read the IP receive FIFO.

29.4.10.1.1 Reading via processor

To read data from the IP receive FIFO via processor, configure the items below.

- Write 0 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPRXWAEN] to enable the IP receive FIFO watermark available interrupt (optional).

The processor must poll INTR[IPRXWA] or wait for the IP receive FIFO watermark available interrupt before reading data from the FIFO. Waiting ensures that a watermark level amount of data is filled in the IP receive FIFO before reading.

After reading a watermark level amount of data from the FIFO, software must set the INTR[IPRXWA] flag to pop that data from the FIFO.

Figure 86 shows the reading flow from the IP receive FIFO via processor.

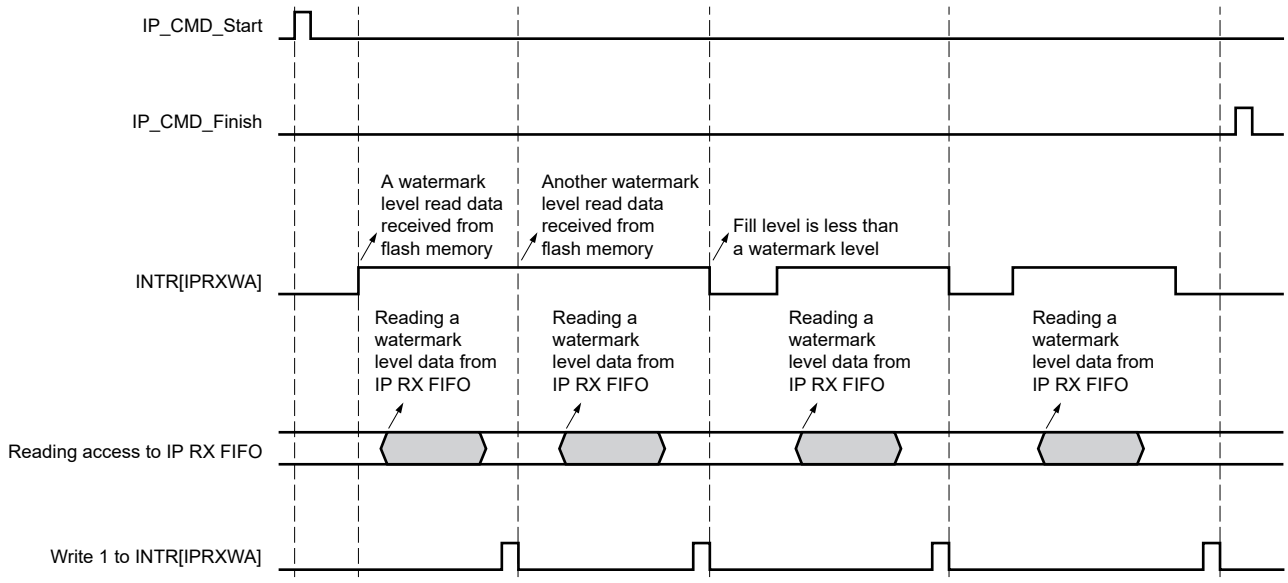

Figure 86. Reading IP receive FIFO via processor

NOTE

- The processor must read a watermark level of data from the IP receive FIFO before setting the INTR[IPRXWA] flag.
- The total flash read or program data size is not required to be a multiple of the watermark level. When the reading data size from the FIFO is less than a watermark level for the last time, software polls IPRXFSTS[FILL], not INTR[IPRXWA]. After all data from the FIFO are copied and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), software sets IPRXFCR[CLRIPRXF] to clear the FIFO. If the FIFO is not cleared, the reading data will be incorrect for the next reading command to flash memory.
- Setting the INTR[IPRXWA] flag pops the IP receive FIFO data. Each read access to the FIFO does not pop the data.

29.4.10.1.2 Reading via DMA

To read data from the IP receive FIFO via DMA, configure the items below.

- Write 1 to IPRXFCR[RXDMAEN].
- Write the watermark level to IPRXFCR[RXWMRK]. The watermark level is (IPRXFCR[RXWMRK] + 1) × 8 bytes.

- Configure the DMA transfer minor loop size to match the watermark level.

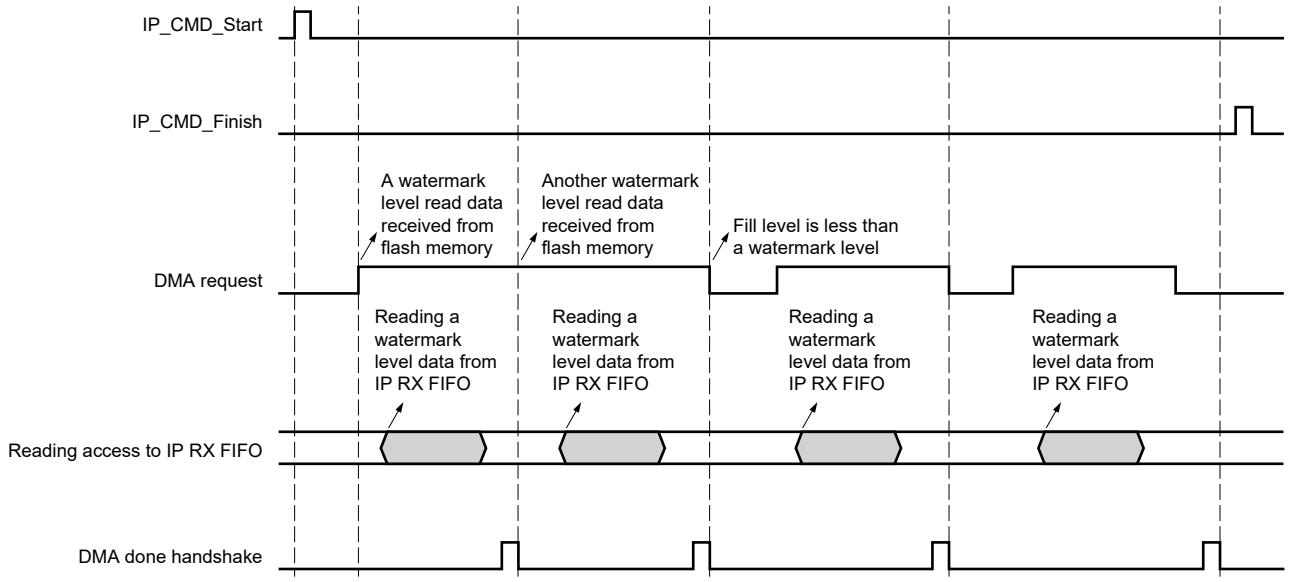

Figure 87. Reading from IP receive FIFO via DMA

NOTE

- When the fill level of the FIFO meets or exceeds the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA reads a watermark level amount of data from the IP receive FIFO each time. (Configure the minor loop size to match the watermark level).
- DMA must return a done handshake (pulse valid) to FlexSPI each time it finishes reading a watermark level amount of data.
- The DMA done handshake (not each read access) pops the IP receive FIFO data.
- The total read and write data size (major loop size) must be a multiple of the watermark level. The DMA does not know when the data is ready for the last reading. When the data size is not a multiple of the watermark level, it is too complex for the DMA driver to poll IPRXFSTS[FILL].

29.4.10.2 Writing data to IP transmit FIFO

The programming data is put into the IP transmit FIFO, then FlexSPI transmits it to the flash memory. IPS or AHB access can write it:

- Via IP bus
- Via AHB bus

To write the programming data into the IP transmit FIFO via AHB bus, write 1 to MCR0[ATDFEN]. The IP bus write access to the FIFO is ignored, but no bus error occurs.

To write the programming data into the IP transmit FIFO via IP bus, write 0 to MCR0[ATDFEN]. The AHB bus write access to the FIFO returns a bus error.

When FlexSPI fetches data to transmit, 64 bits of data from the IP transmit FIFO are popped. If the programming data size is not a multiple of 64 bits, the number of last popped valid bits is less than 64 bits. No error occurs; these invalid bits are not transmitted to the flash memory.

The processor or DMA can fill the IP transmit FIFO with programming data.

29.4.10.2.1 Writing via processor

To write data into the IP transmit FIFO via processor, configure the items below.

- Write 0 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.
- Write 1 to INTEN[IPTXWEEN] to enable the IP transmit FIFO watermark available interrupt (optional).

The processor must poll INTR[IPTXWE] or wait for the IP transmit FIFO watermark empty interrupt before writing data to the FIFO. Waiting ensures that a watermark level amount of data is available in the IP transmit FIFO before writing.

After writing a watermark level amount of data to the FIFO, software must set the INTR[IPTXWE] flag to push that data into the FIFO. (The write pointer is incremented.)

NOTE

Setting the INTR[IPTXWE] flag pushes the IP transmit FIFO data. Each write access to the FIFO does not push the data.

Figure 88 shows the writing flow to the IP transmit FIFO via processor.

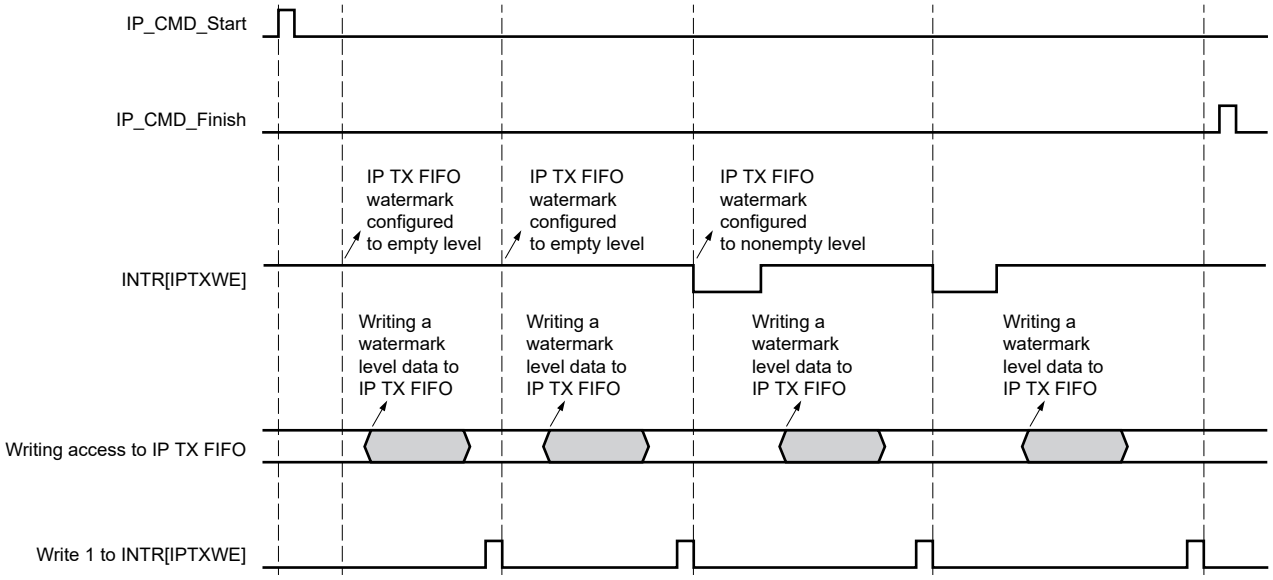

Figure 88. Writing to IP transmit FIFO via processor

NOTE

- The processor must write a watermark level amount of data into the IP transmit FIFO each time.
- The total flash write data size is not required to be a multiple of the watermark level. In this case, the writing data size to the FIFO is less than a watermark level for the last time. After all data to the FIFO are written and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), the processor sets IPTXFCR[CLRIPTXF] to clear the FIFO. If the FIFO is not cleared, the programming data will be incorrect for the next programming command to flash memory.

29.4.10.2.2 Writing via DMA

To write data into the IP transmit FIFO via DMA, configure the items below.

- Write 1 to IPTXFCR[TXDMAEN].
- Write the watermark level to IPTXFCR[TXWMRK]. The watermark level is (IPTXFCR[TXWMRK] + 1) × 8 bytes.

- Configure the DMA transfer minor loop size to match the watermark level.

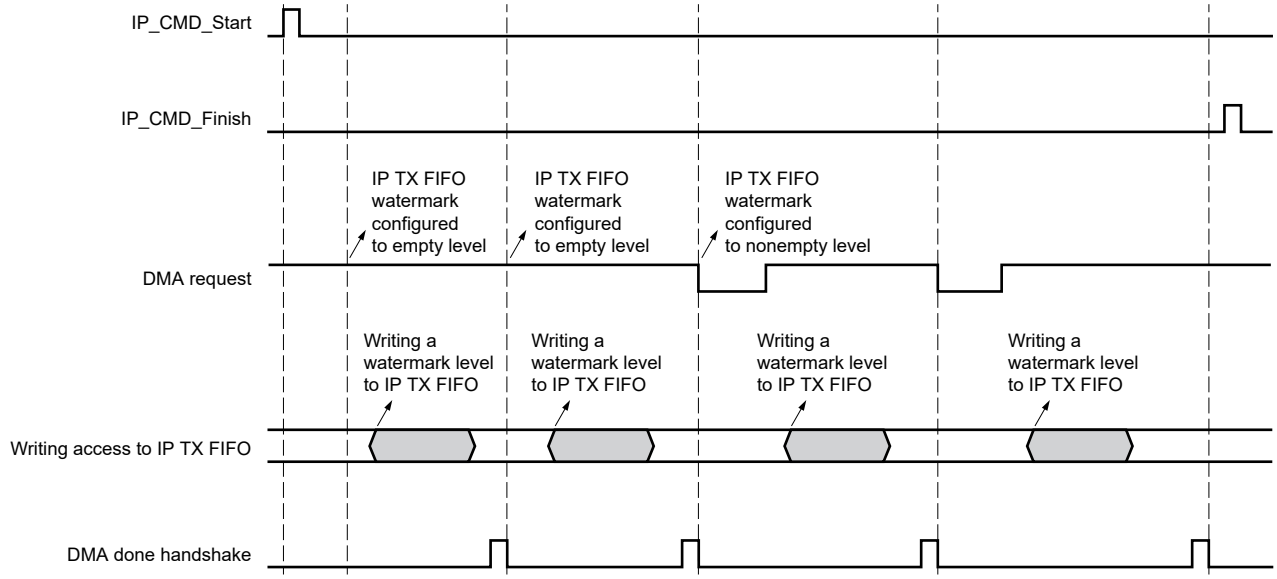

Figure 89. Writing into IP transfer FIFO via DMA

NOTE

- When there is empty space in the IP transmit FIFO greater than the watermark level, a DMA request is generated. This request is level-valid, not pulse-valid.
- DMA writes a watermark level amount of data into the FIFO each time. (Configure the minor loop size to match the watermark level.
- DMA returns a done handshake (pulse valid) to FlexSPI each time it finishes writing a watermark level amount of data.
- The DMA done handshake (not each write access) pushes the IP transmit FIFO data.
- The total program data size (major loop size) is not required to be a multiple of the watermark level. After writing all data into the IP transmit FIFO and all command sequences to flash memory are finished (INTR[IPCMDDONE] = 1), write 1 to IPTXFCR[CLRIPTXF] to clear the FIFO. Failure to clear the FIFO results in incorrect programming data for the next programming command to flash memory.

29.4.11 Flash memory access via AHB command

Flash memory can be accessed via AHB bus directly on the AHB address space. This address space is mapped to serial flash memory in FlexSPI. AHB bus accesses to this address space trigger flash memory access command sequences as needed.

For AHB read access to serial flash memory, FlexSPI fetches data from flash memory into the AHB receive buffer, then returns the data on the AHB bus. For AHB write access to serial flash memory, FlexSPI buffers AHB bus write data into the AHB transmit buffer, then transmits the data to serial flash memory.

No software configuration or polling is needed for AHB commands, except for FlexSPI initialization. As with a normal AHB target, the AHB controller accesses the external flash device transparently.

AHB commands are normally used to access serial flash memory space. IP commands must be used to access the control and status registers or other spaces, such as a one-time programmable (OTP) space in an external flash device.

The AHB commands for read and write access are discussed in detail below.

29.4.11.1 AHB write access to flash memory

For AHB write access to flash memory, FlexSPI buffers the write data from the AHB bus into the internal AHB transmit buffer. FlexSPI then transmits the data to flash memory. FlexSPI only buffers write data for one AHB burst. Figure 90 shows the hardware operation in response to an AHB write access to flash memory.

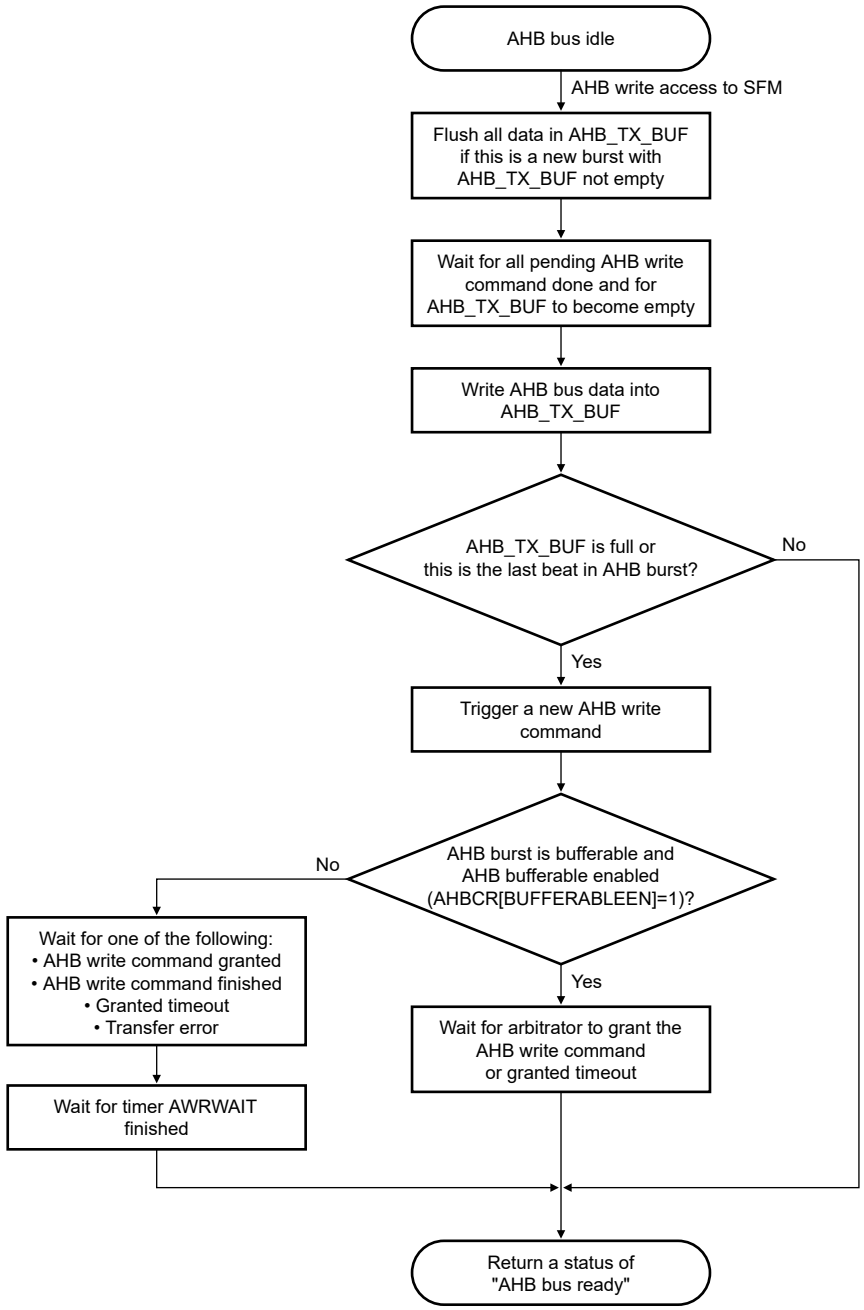

Figure 90. Hardware operation in response to AHB write access to flash memory

NOTE

1. If previous AHB burst is INCR write burst, AHB transmit buffer may not be empty when AHB bus is idle or new burst arrives. A new AHB write command is triggered to flush all data in AHB transmit buffer to external flash device. The new burst is held until this AHB write command finishes.
2. If the current access is bufferable, when the AHB write command is triggered, AHB ready is returned after the write command is granted. If the current access is non-bufferable, AHB ready is returned after the write command finishes.

FlexSPI triggers a new AHB write command in these cases:

- This beat is the last one in the current AHB burst, for any burst type except INCR.
- AHB transmit buffer is full after the current beat data is buffered.
- AHB bus becomes idle or a new burst arrives with the AHB transmit buffer not empty.

Table 168 describes the details of a triggered AHB write command.

Table 168. Triggered AHB write command

Item	Description
Flash memory access start address	Determined by AHB burst address. FlexSPI records the start address for the data in AHB transmit buffer, which is used as flash memory access start address.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip selection.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB write command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual)	
Flash memory data size	Determined by byte number of buffered data in AHB transmit buffer.

The following examples indicate internal logic for AHB write access to flash memory, where AHB_TX_BUF is 64 bytes :

- AHB INCR 64-bit bufferable burst with address sequence 8h, 10h, 18h, 20h, ..., 50h (10 beats total).

  Two AHB write commands are triggered: the first command with flash memory start address 8h and data size 40h; the second command with flash memory start address 48h and data size 10h. See Figure 91.

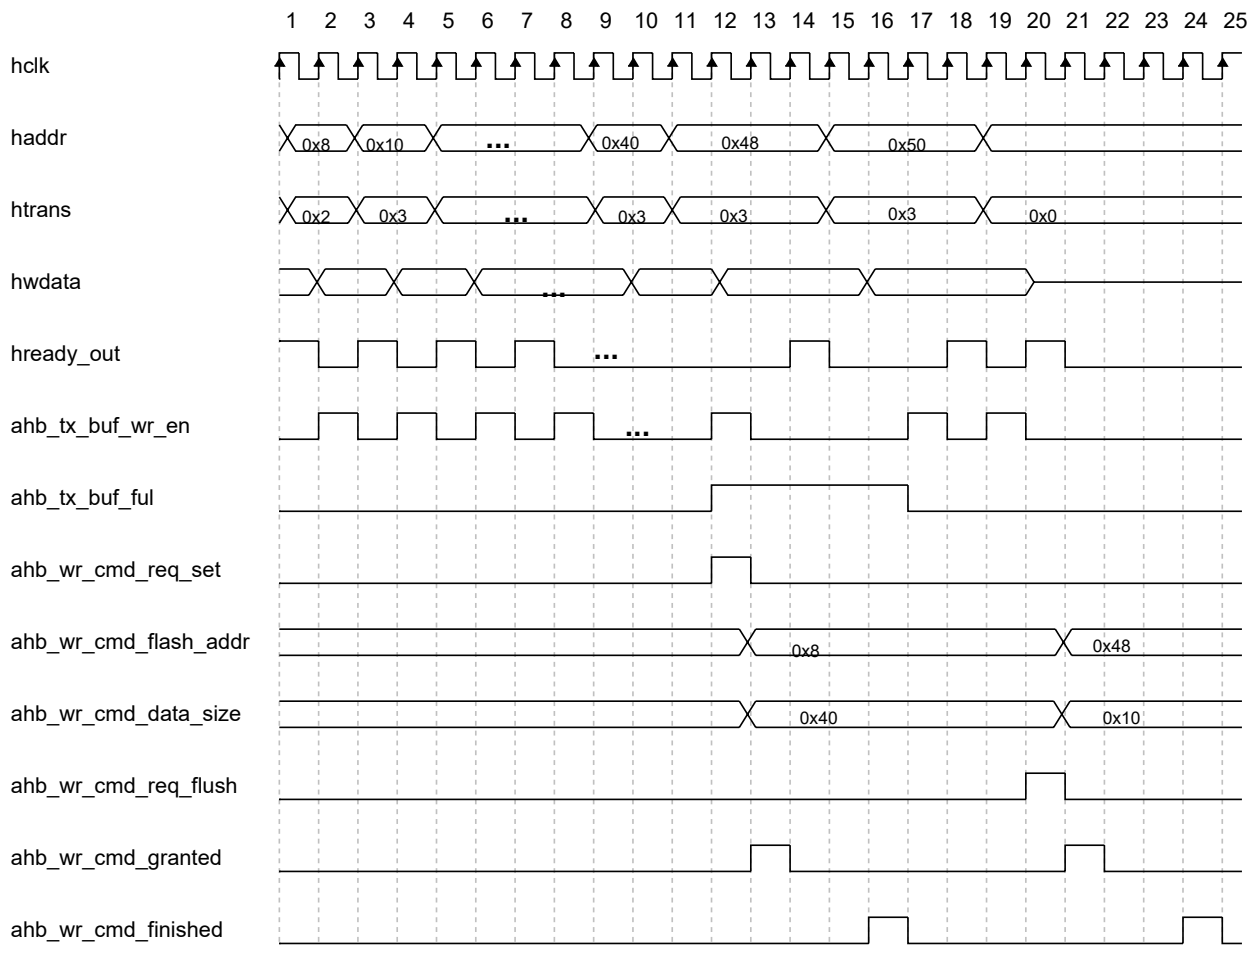

Figure 91. AHB write access (INCR, 64-bit, bufferable)

- AHB WRAP8 64-bit bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h. See Figure 92.

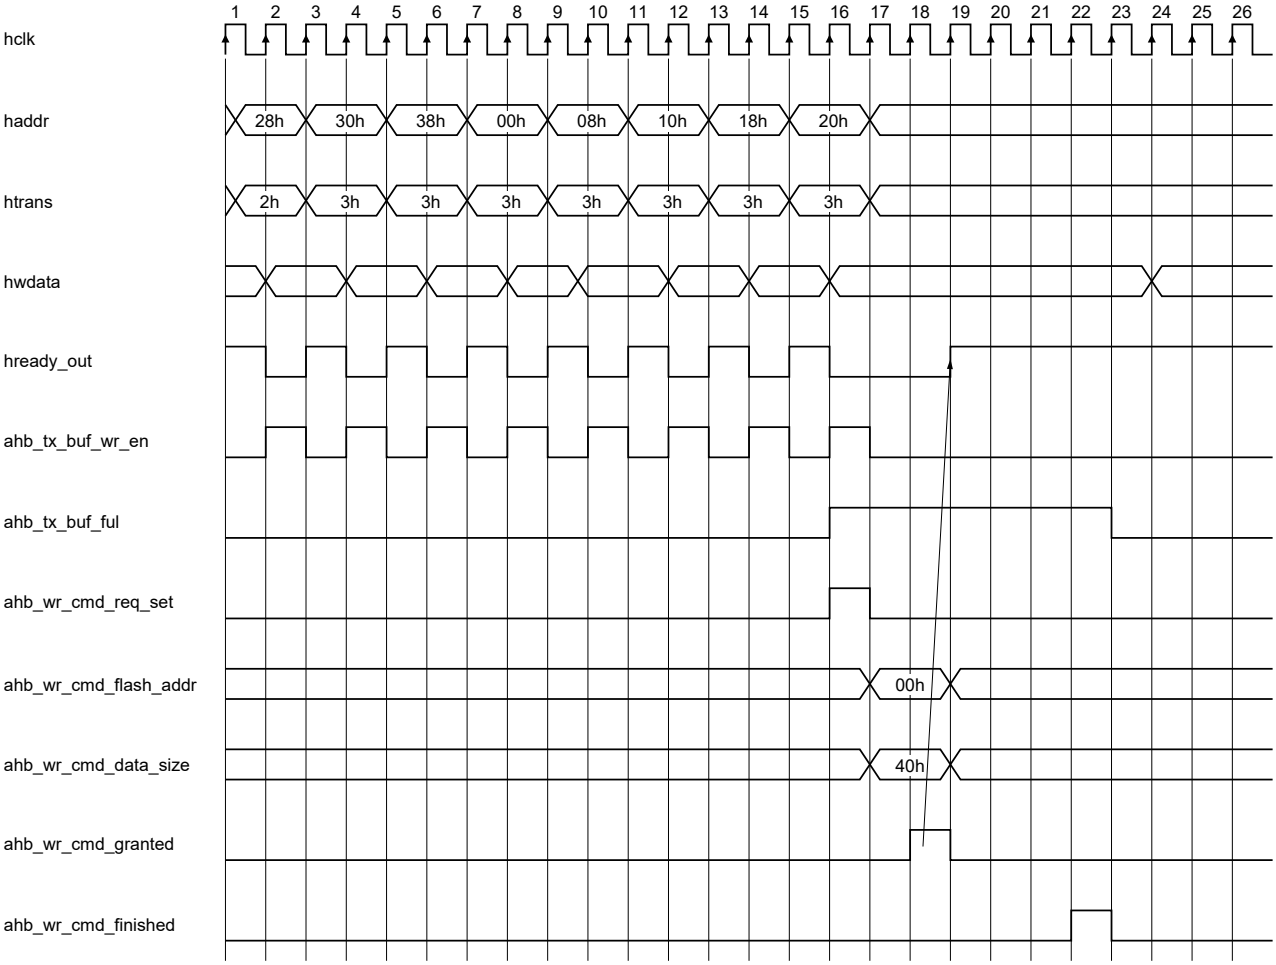

Figure 92. AHB write access (WRAP8, 64-bit, bufferable)

- AHB WRAP8 64-bit non-bufferable burst with address sequence 28h, 30h, 38h, 0h, 8h, 10h, 18h, 20h.

  One AHB write command is triggered with flash memory start address 0h and data size 40h.

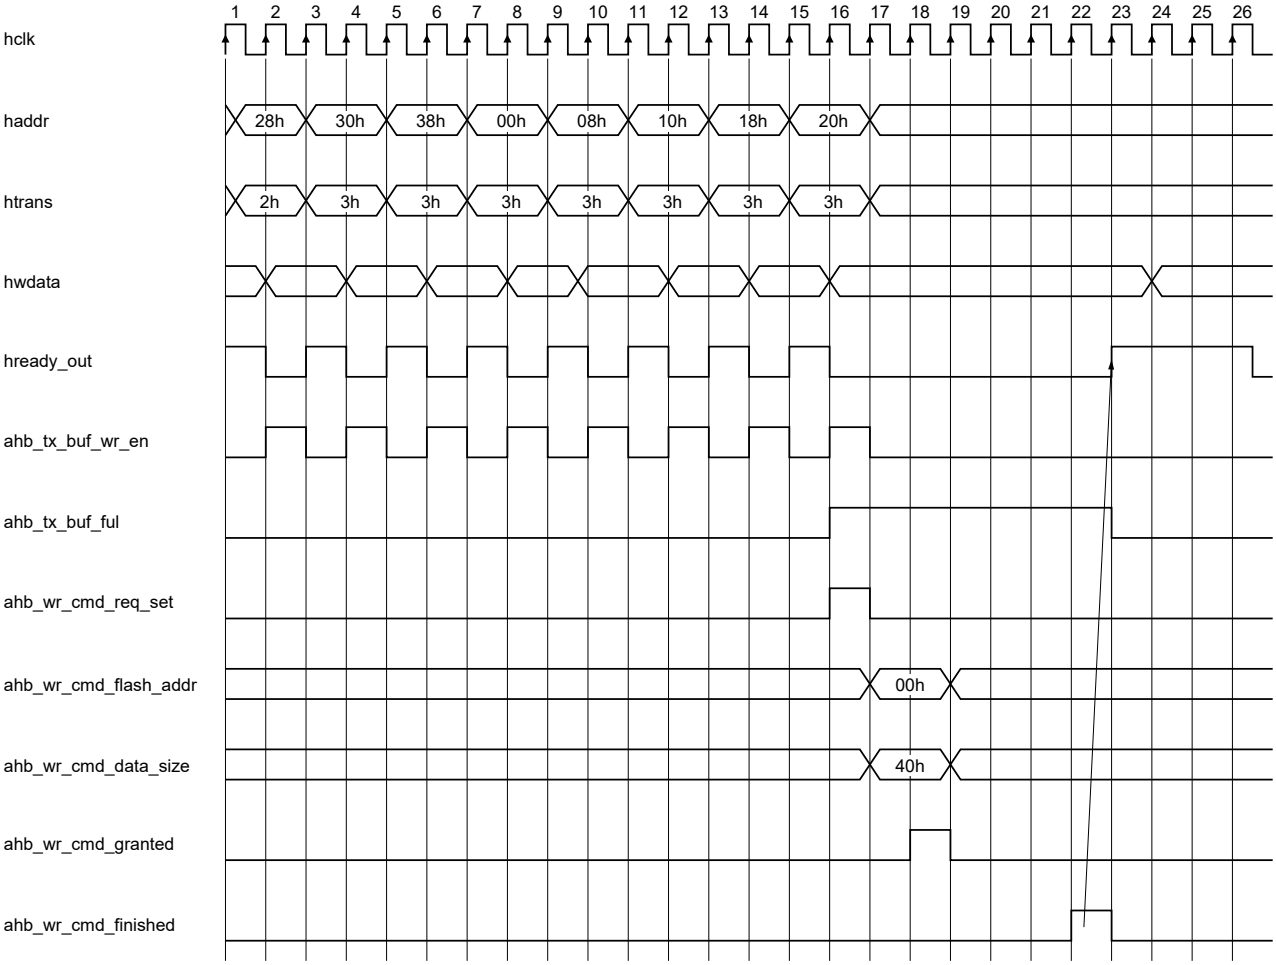

Figure 93. AHB write access (WRAP8, 64-bit, non-bufferable)

NOTE

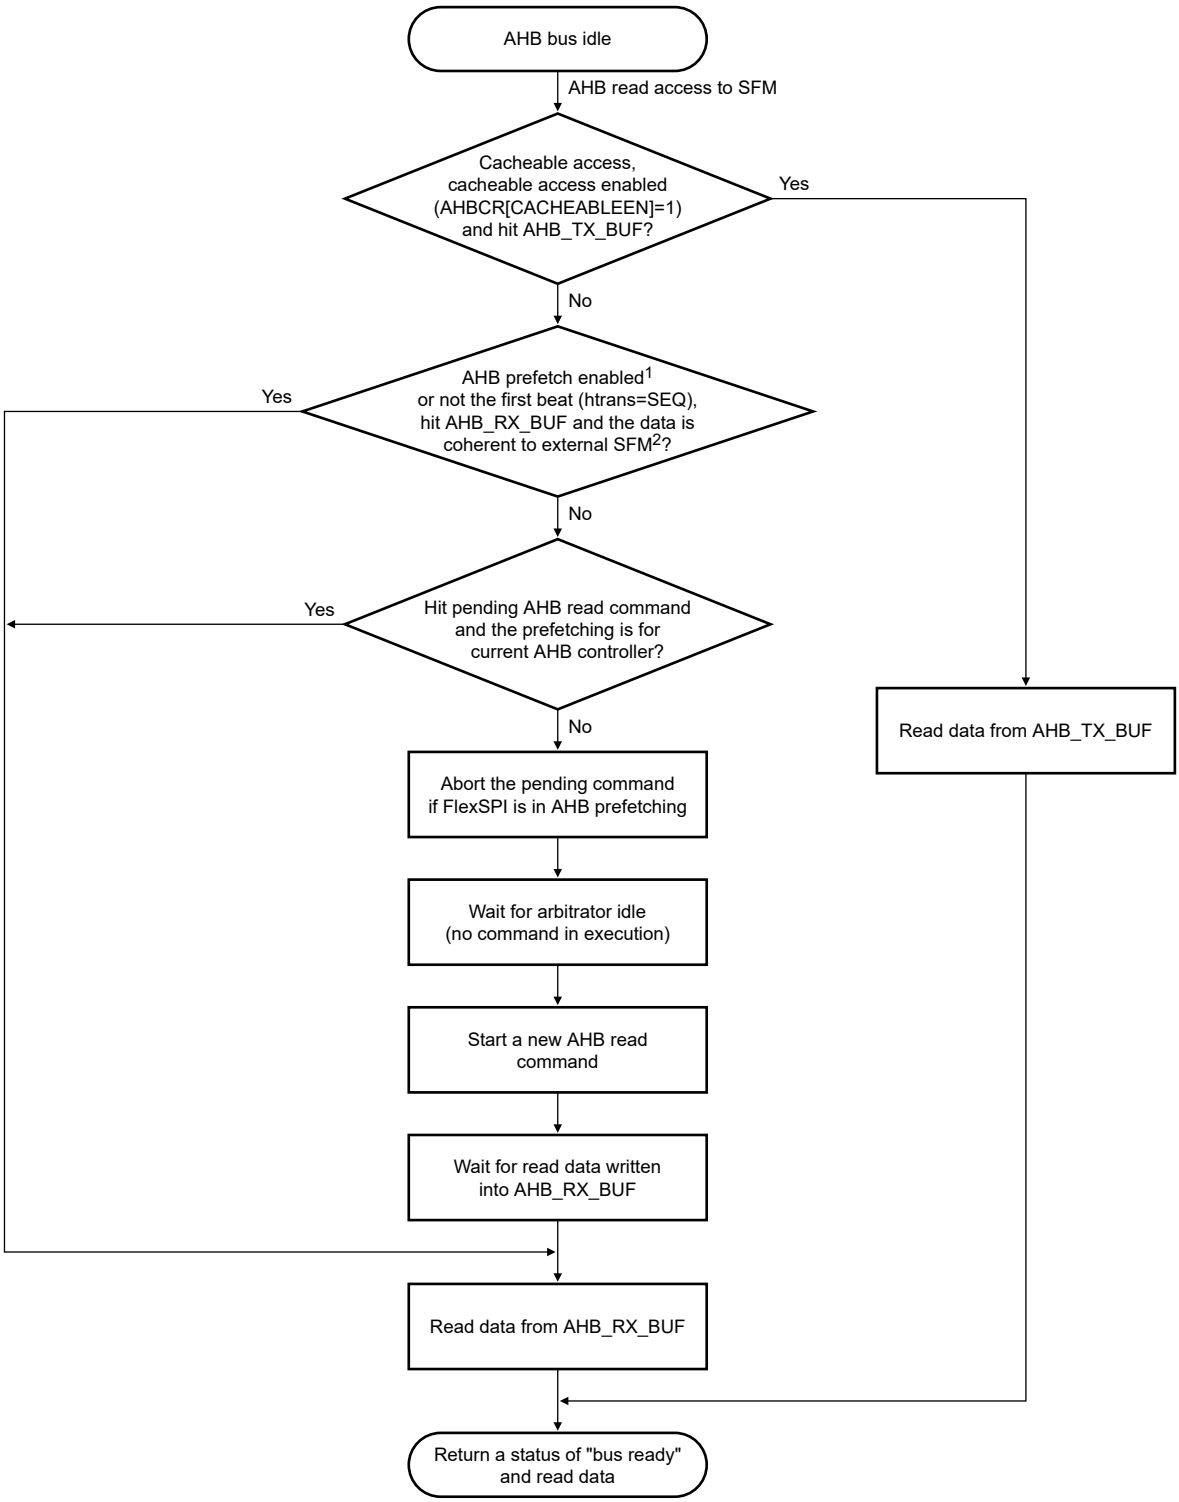
If the burst data size (in bytes) is greater than the AHB transmit buffer size, wrapper burst is not supported. For example, if AHB_TX_BUF is 64 bytes, AHB WRAP16 (16 × 64 bits = 128 bytes) write burst access is not supported.

29.4.11.2 AHB read access to flash memory

For AHB read access to flash memory, FlexSPI checks the burst access type and register setting to determine whether to access these locations:

- The AHB transmit buffer
- The AHB receive buffer
- A pending AHB read command

If all of these options are missed, FlexSPI triggers a new AHB read command to fetch data from flash memory. Figure 94 shows the hardware operation in response to AHB read access to flash memory.



Notes:
1) AHB prefetch is enabled when both AHBCR[PREFETCHEN]=1 and AHBRXBUFxCR0[PREFETCHEN]=1 (x is the AHB RX buffer ID for the current AHB controller) or OTFAD is enabled.
2) The AHB RX buffer holds the data read from flash memory. This data may become incoherent if AHB writes to the same flash-memory address.

Figure 94. Hardware operation in response to AHB read access to flash memory

Table 169 describes the details of a triggered AHB read command.

Table 169. Triggered AHB read command

Item	Description
Flash memory access start address and data size	Determined by AHB address, burst type, and burst size. FlexSPI fetches read data from the start address for the current burst or beat. See Table 170 for details.
Flash memory chip select	FlexSPI uses the settings of the flash memory access start address and flash memory size to determine the chip select.
Flash memory command sequence index	Determined by FLSHxCR2[AWRSEQID].
Flash memory command sequence number	Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero, multiple flash memory access command sequences are triggered every time for an AHB read command. The sequences indexed from AWRSEQID to (AWRSEQID + AWRSEQNUM) in LUT are executed sequentially.
Flash memory access mode (Individual)	

NOTE

- FlexSPI automatically determines which ARDSEQNUM and ARDSEQID fields that the flash device uses as sequence ID for chip selection. See MCR2[SAMEDEVICEEN].
- FlexSPI determines which AHB receive buffer to use for the current AHB read access by controller ID. For details about the AHB receive buffer ID and AHB controller ID mapping, see AHB receive buffer management.
- You cannot allocate the size of the AHB receive buffer to be less than the AHB Burst size. This allocation results in unknown behavior.

Table 170. AHB read command flash memory start address and data size

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [26:0]	Data size
0	Never cross flash boundary, because AHB burst never crosses 1 KB boundary.	SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(hburst_end_address-hbeat_start_address)
		INCR	hbeat_start_address	byte size of current beat For INCR burst with prefetch disabled, each beat is handled same as SINGLE burst.
		WRAP4, WRAP8, WRAP16	hburst_start_address	(hburst_end_address-hburst_start_address)
1	No	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	ahb_rx_buf_sz
	No	WRAP4, WRAP8, WRAP16	hburst_start_address	ahb_rx_buf_sz

Table continues on the next page...

Table 170. AHB read command flash memory start address and data size (continued)

Prefetch enable	Cross flash boundary	Burst type	Flash memory start address [26:0]	Data size
	Yes	INCR, SINGLE, INCR4, INCR8, INCR16	hbeat_start_address	(flash_top_address-hbeat_start_address)
	Yes	WRAP4, WRAP8, WRAP16	hburst_start_address	(flash_top_address-hburst_start_address)

NOTE

- hbeat_start_address is HADDR input from the AHB controller for current beat.
- hburst_start_address (for example 00h) is the lowest address for current burst. hburst_end_address (for example 10h) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 8h, Ch, 0h, 4h.
- ahb_rx_buf_sz is the buffer size in bytes of AHB receive buffer that the current AHB controller uses.
- flash_top_address is the top address of currently accessed flash memory.

29.4.11.3 AHB receive buffer management

There are 8 buffers (Buffer 0–7) in the AHB receive buffer. These buffers are transparent to AHB controllers. FlexSPI fetches flash memory data and returns it on the AHB bus automatically. No status register polling is needed for AHB read access to Serial Flash Memory (SFM).

See the chip-specific section for AHB buffer size.Use AHBRXBUF0CR0[BUFSZ]–AHBRXBUFCR7[BUFSZ] to configure the buffer size of each AHB receive buffer. The buffer size for Buffer 0 to Buffer 7 could be set to 0. If the buffer size is set to 0, FlexSPI ignores the related setting of AHBRXBUFxCR0[MSTRID]. Buffer 7 is used for all AHB controllers not assigned to Buffer 0–6. FlexSPI ignores the Buffer 7 size setting field (AHBRXBUF7CR0[BUFSZ]). Its buffer size is: (AHB receive buffer total size) - (the sum of the sizes of Buffer 0–6).

When an AHB read access to serial flash memory occurs, FlexSPI determines which buffer to use via this method:

1. If the controller ID equals AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 is used.
2. If the controller ID equals AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 is used.
3. If the controller ID equals AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 is used.
4. If the controller ID equals AHBRXBUF3CR0[MSTRID] and AHBRXBUF3CR0[BUFSZ] is not zero, Buffer 3 is used.
5. If the controller ID equals AHBRXBUF4CR0[MSTRID] and AHBRXBUF4CR0[BUFSZ] is not zero, Buffer 4 is used.
6. If the controller ID equals AHBRXBUF5CR0[MSTRID] and AHBRXBUF5CR0[BUFSZ] is not zero, Buffer 5 is used.
7. If the controller ID equals AHBRXBUF6CR0[MSTRID] and AHBRXBUF6CR0[BUFSZ] is not zero, Buffer 6 is used.
8. If all the above cases are not met, Buffer 7 is used.

NOTE

- Software must ensure that the size of each buffer is not less than the maximum burst size of an AHB read access from the AHB controller using this buffer. Otherwise, the behavior is undefined. The minimum buffer size request depends on the chip implementation. For example, if the capability of the chip to send out a maximum burst is 64 bytes, the minimum AHB receive buffer is 64 bytes.
- Assigning multiple buffers to a single AHB controller is not supported, unless the prefetch buffer enhancement feature is being used.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] = 1), the size of the buffer determines the prefetch data size. If it does not cross the flash boundary, FlexSPI fetches data from the external flash device with that buffer size.
- The priority setting of AHB controller (AHBRXBUFxCR0[PRIORITY] = 1) is used only for suspending control of AHB prefetching. See Command abort and suspend.

29.4.12 Command arbitration

There are four flash memory access command sources:

1. AHB command, that AHB write access to serial flash memory space triggers
2. AHB command, that AHB read access to serial flash memory space triggers
3. IP command, that writing IPCMD[TRG] triggers
4. Suspended command, an AHB read prefetch sequence which is suspended

An AHB bus access never triggers a write command and a read command at the same time.

The AHB prefetch sequence is an AHB command sequence triggered via AHB read access when AHB prefetch is enabled. After all read data is fetched for the current AHB read burst, FlexSPI prefetches more data to reduce read latency for the next AHB read access. An AHB command for a read operation is never aborted while fetching read data for the current AHB read burst. However, a new IP command or AHB command request while prefetching data (not for the current read burst) can abort an AHB read command.

When the arbitrator is idle (STS0[ARBIDLE] = 1), the granted priority of these command sources is:

1. AHB command (read or write)
2. IP command
3. Suspended command

NOTE

When the arbitrator is idle and there is no AHB or IP command request, a suspended command is not granted immediately. The arbitrator waits MCR2[RESUMEWAIT] AHB clock cycle idle states before resuming the suspended command to avoid AHB prefetch sequence being resumed and suspended frequently.

If the arbitrator is busy executing AHB or IP commands (not suspended commands), no new command requests are granted. If the grant times out, an AHB or IP command granted error occurs.

If a new AHB or IP command request comes while arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence is aborted (but not immediately). Arbitrator grants the AHB or IP command request after AHB read prefetch sequence is aborted on the FlexSPI interface and saved all internal data pointers.

29.4.12.1 Command abort and suspend

Table 171 describes the command abort and suspend mechanism.

Table 171. Command abort and suspend

Action	Description
Aborting a command	As mentioned above, if a new AHB or IP command request arrives, an AHB read prefetch sequence can be aborted.
Suspending a command	When an AHB read prefetch sequence is aborted on the FlexSPI interface, FlexSPI saves this suspended sequence in the cases listed below. FlexSPI resumes this sequence after the arbitrator has been idle for enough time. • There is no valid suspended command (AHBSPNDSTS[ACTIVE] = 0). This condition can occur when no command is suspended or when the suspended command is resumed. • The priority of aborted AHB read prefetch sequence is higher than the active suspend sequence. **NOTE** FlexSPI ignores and never resumes the original suspended sequence.
Activating a suspended command	The suspended command (internal status) becomes active when an AHB prefetch command is aborted and suspended. It becomes inactive in the following cases: • The arbitrator resumes the suspended command. • The AHB controller triggers a new AHB read command request using the same AHB receive buffer (buffer ID).

Figure 95 shows an example of the flow of command abort, suspend, or resume.

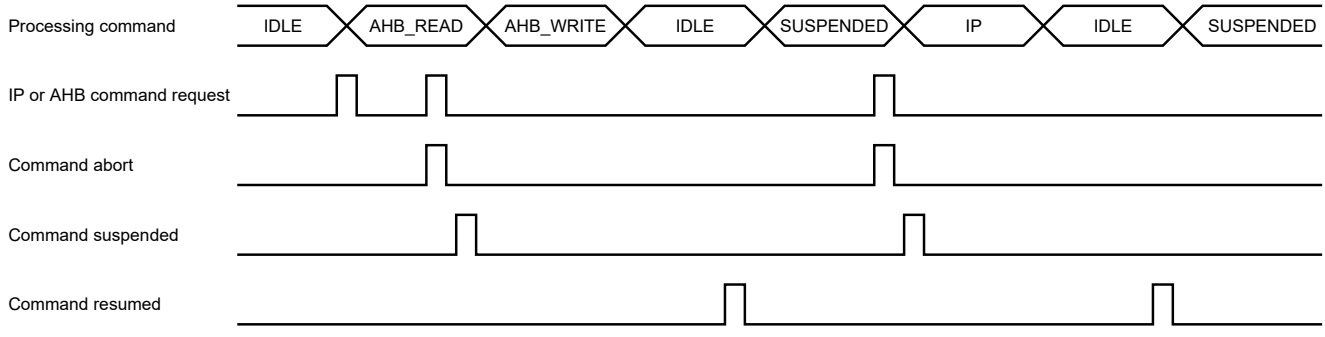


Figure 95. Command instruction execution on FlexSPI interface

NOTE

- The AHB prefetch sequence is aborted, suspended, or resumed twice in Figure 95. A new AHB write command request aborts the sequence the first time, and a new IP command request aborts the sequence the second time.
- The suspended sequence is resumed after a wait time of idle state. If there are frequent IP or AHB command requests and the wait time is not set reasonably, the suspend and resume activities may be triggered frequently.

29.4.13 SCLK stop

FlexSPI stops SCLK output toggling:

- When programming data is not ready for a programming command sequence.
- When an internal FIFO has no space to receive data for reading command sequence.

Certain devices may not support the stopping of SCLK during a command sequence (chip select is valid). SCLK stopping can be avoided via the methods described below.

- For flash memory reading that an IP command triggers:
  - Never trigger a read command with data size larger than IP receive FIFO size.
  - Internal asynchronous FIFO for flash memory reading should never be full.

    FlexSPI pops 64 bits of data per AHB clock cycle from this FIFO, and receives data from FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual mode) determines the receiving speed. For example, in Octal mode, FlexSPI receives 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never full.
- For flash memory programming that an IP command triggers:
  - Never trigger a program command with data size larger than the IP transmit FIFO size. Write all programming data into the IP transmit FIFO before triggering the IP command.
  - The internal asynchronous FIFO for flash memory programming must never be empty.

    FlexSPI fetches 64 bits of programming data per AHB clock cycle into this FIFO, and transmits data to the FlexSPI interface on the serial root clock. The flash memory access mode (Single, Dual, Quad, or Octal mode and Individual mode) determines the transmitting speed. For example, in Octal mode, FlexSPI transmits 16 bits per serial root clock cycle. If the AHB clock frequency is faster than 1/4 of the serial root clock, this asynchronous FIFO is never empty.
- For flash memory reading or programming that an AHB command triggers:
  - The internal asynchronous FIFO for flash memory reading and programming must never be full or empty. The frequency ratio limitation is same as it is for flash memory reading or flash memory programming that an IP command triggers.

NOTE

- FlexSPI never triggers an AHB read command with data size larger than the internal AHB receive buffer size.
- FlexSPI never triggers an AHB program command with data size larger than the internal AHB transmit buffer size.
- All programming data is buffered into the AHB transmit buffer before triggering an AHB program command in FlexSPI.

29.4.14 FlexSPI output timing

29.4.14.1 Output timing between data and SCLK

This section describes the output timing relationship of data (on A_DATA and B_DATA) and SCLK. There are three cases.

- **SDR instruction in SDR sequence**

  An SDR sequence contains only SDR instructions. In this case, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 96 shows the relationship between the serial root clock, data, and SCLK:

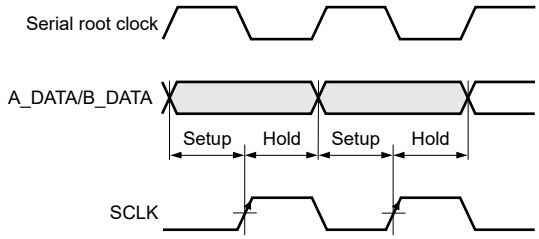

Figure 96. SDR instruction in SDR sequence

- **SDR instructions in a DDR sequence**

  A DDR sequence is a flash memory access command sequence that contains DDR instructions other than DUMMY_DDR. It may contain SDR instructions. If there are SDR instructions in a DDR sequence, all data bits last for two serial root clock cycles on the FlexSPI interface. Figure 97 shows the relationships between the serial root clock, data, and SCLK.

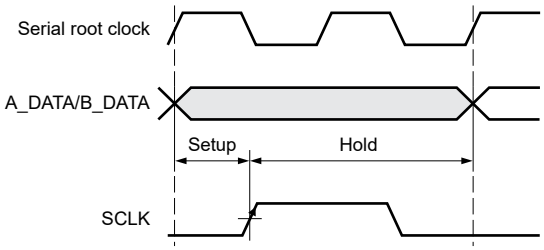

Figure 97. SDR instruction in DDR sequence

- **DDR instructions in a DDR sequence**

  For DDR instructions in a DDR sequence, all data bits last one serial root clock cycle on the FlexSPI interface. Figure 98 shows the relationships between the serial root clock, data, and SCLK.

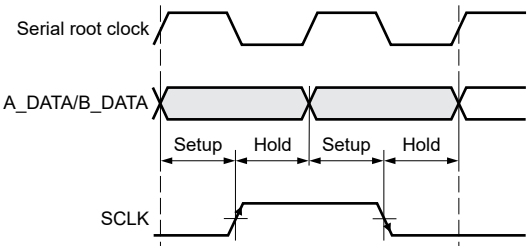

Figure 98. DDR instruction in DDR sequence

29.4.14.2 Output timing between chip select and SCLK

This section describes the output timing relationship between chip select (on A_SS0_B , A_SS1_B, B_SS0_B, and B_SS1_B) and SCLK. The timing relationship for the SDR sequence differs a little from the timing relationship for the DDR sequence.

- **Chip select timing in SDR sequence**

  For an SDR sequence, the delay from chip select assertion to the SCLK rising edge is (FLSHxCR1[TCSS] + 0.5) cycles of the serial root clock. The delay from SCLK falling edge to chip select deassertion is FLSHxCR1[TCSH] cycles of serial root clock. Figure 99 shows the timing relationship between the chip select and SCLK.

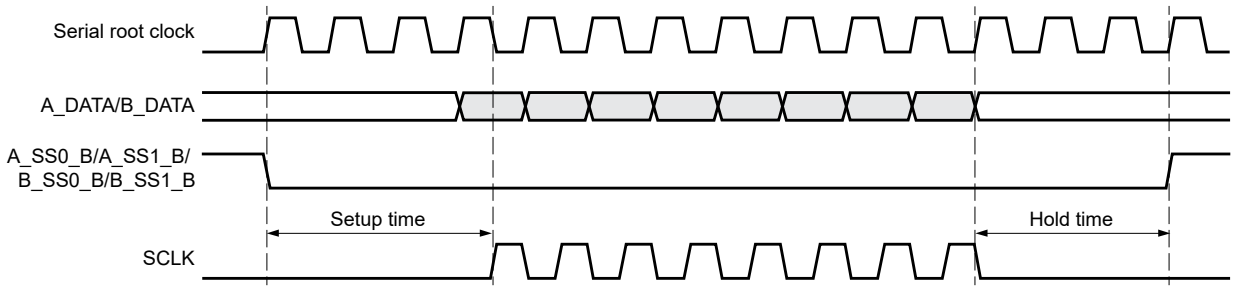

Figure 99. Chip select output timing for SDR sequence

- **Chip select timing in DDR sequence**

  For a DDR sequence, the delay from chip select assertion to the SCLK rising edge is **(FLSHxCR1[TCSS] + 0.5)** cycles of the serial root clock. The delay from the SCLK falling edge to chip select deassertion is **(FLSHxCR1[TCSH] + 0.5)** cycles of serial root clock.

  NOTE

  When AHB receive prefetch is enabled, and prefetch can be aborted, configure TCSH to 1 or greater. Configuring TCSH in this way guarantees a positive chip select hold time after the SCLK falling edge.

  Figure 100 shows the timing relationship between chip select and SCLK.

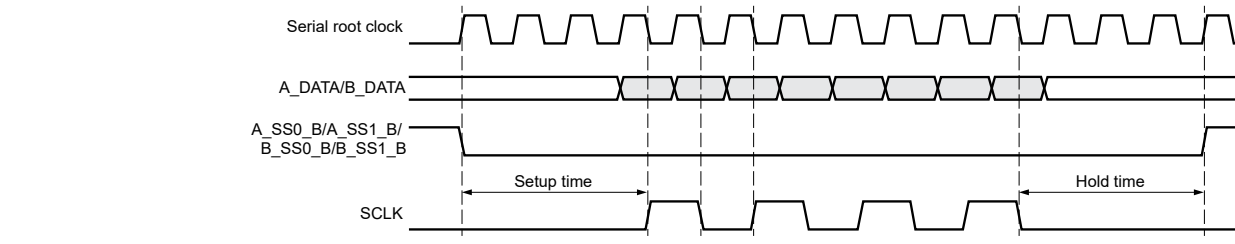

Figure 100. Chip select output timing for DDR sequence

For devices such as an FPGA device, a minimum chip select negation time (time between two chip select assertions) may be required. If the value of FLSHxCR1[CSINTERVAL] is nonzero, FlexSPI ensures a delay between chip select valid assertions. The delay time is CSINTERVAL × 256 cycles of serial root clock for an SDR or DDR sequence. If the external device has no limitation, configure the value of this field to zero. Figure 101 shows the timing of the chip select interval.

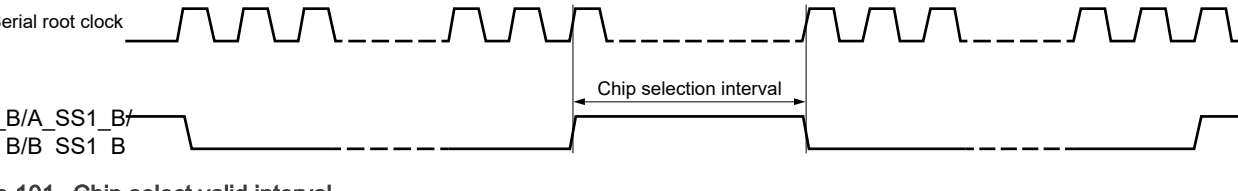

Figure 101. Chip select valid interval

29.4.15 FlexSPI input timing

This section describes the input timing of FlexSPI.

29.4.15.1 Receiving block

This section describes the receiving block in FlexSPI.

FlexSPI decodes instruction code to determine SDR mode or DDR mode. It also determines whether both the rising and falling edges are used for flash data sampling. FlexSPI samples the data line for learn instructions and read instructions.

MCR0[RXCLKSRC] selects the clock source from these four sources for the sampling clock:

- Internal dummy read strobe and looped back internally
- Internal dummy read strobe and looped back from DQS pad
- Flash-memory-provided read strobe

For details about DLL configuration, see DLL configuration for sampling.

Figure 102 shows the sampling block in FlexSPI.

FlexSPI uses both rising and falling edges to sample data from flash_A and flash_B. Two muxes with four clock source inputs generate the signals ipp_ind_io_fa, ipp_ind_io_fb. See Receive clock source features. ipp_ind_io_fa_int and ipp_ind_io_fb_int are reversed from ipp_ind_io_fa and ipp_ind_io_fb. Both sampling flip-flops are used when FlexSPI is in DDR mode. Only the falling edge sampling flip-flop is used in SDR mode.

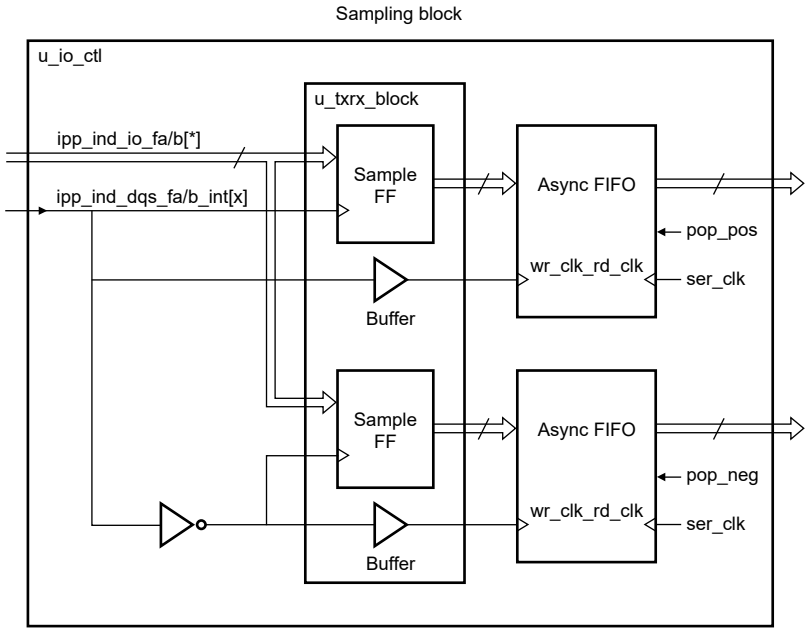

Figure 102. Sampling block in FlexSPI

Figure 103 is the receiving block diagram for data learning.

There are 16 clock phases for sampling data. An internal delay chain delays the clock phases.

See Data learning.

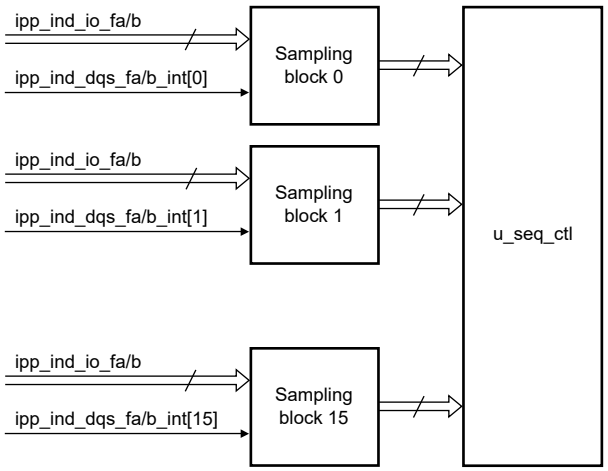

Figure 103. Sampling blocks for data learning

FlexSPI does not support read operations with a zero-turnaround cycle for direction switching on I/O pins. This read operation often occurs in QuadSPI configuration register reads. In Figure 104 and Figure 105, SIO[3:0] is an output from FlexSPI in the CMD phase, and is an input to FlexSPI in the DATA phase. No time remains for FlexSPI to switch the direction. This kind of read is not supported. FlexSPI and flash memory drive the I/O pins at the same time, which may cause a problem. To avoid this behavior on I/O pins, using SPI mode or reading with dummy cycles is required.

NOTE

The cycle numbers are not accurate in the examples below. See the device spec for accurate cycle numbers.

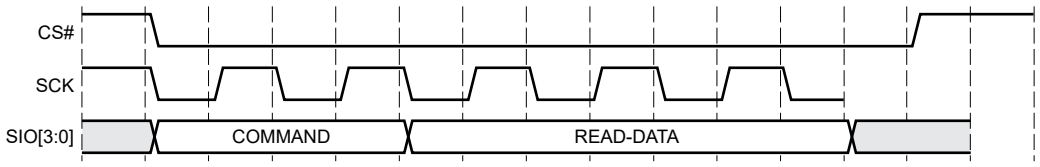

Figure 104. Unsupported read behavior

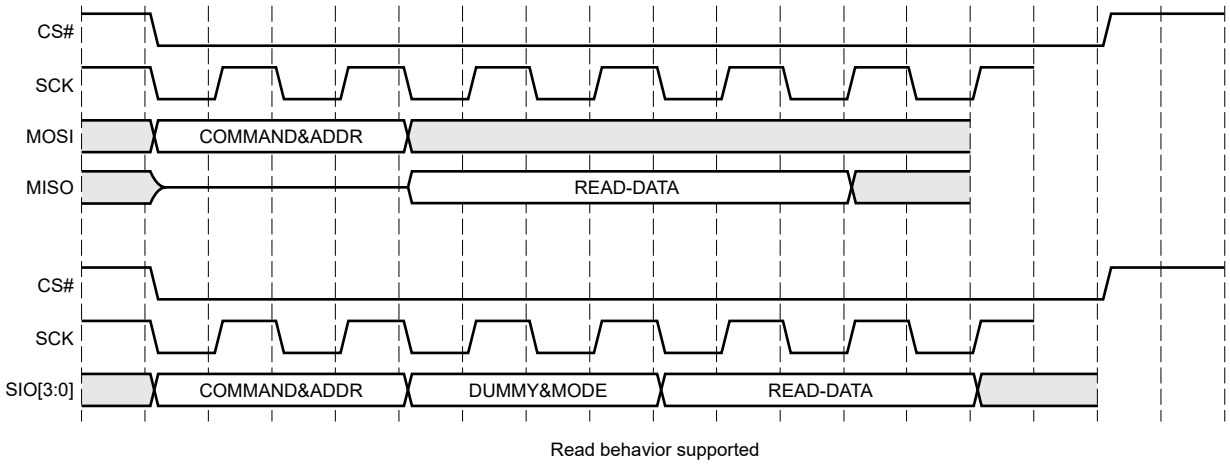

Figure 105. Supported read behavior

29.4.15.2 Receive clock source features

FlexSPI uses a read strobe to sample incoming data. There are several options for generating the read clock strobe that MCR0[RXCLKSRC] selects. Using the receive clock source method has implications for the board connections and can affect the maximum frequency that the interface supports. See the device data sheet for details on the maximum frequency supported for each RXCLKSRC option.

Table 172. RXCLKSRC options

MCR0[RXCLKSRC]	Description	Board connection	Max Frequency
0	Internal dummy read strobe and internal loopback	DQS pin is not used. The DQS pin can be configured for an alternate signal function.	Lowest
1	Internal dummy read strobe and loopback from DQS pad	FlexSPI uses the DQS pin, and it must be configured for its FlexSPI function. The internally generated read strobe is sent to the DQS pin and is sampled at the pin to match more closely the data pin timings. The DQS pin is typically left floating. External capacitance can be added to adjust timing.	Medium
3	Flash-memory-provided read strobe	DQS pin is connected to the DQS or RWDS signal that the memory provides.	Highest

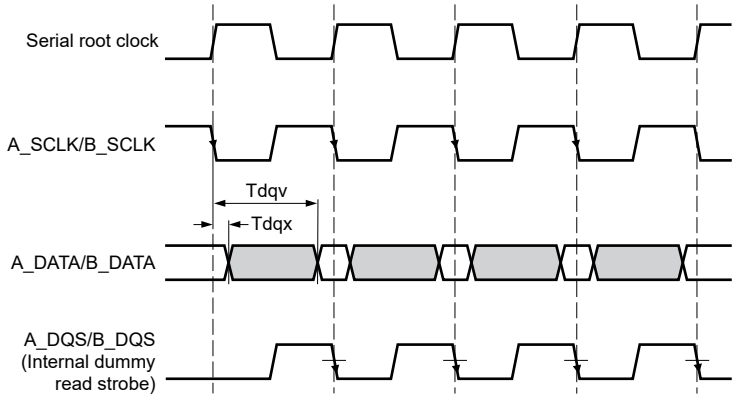
29.4.15.3 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with the internal dummy read strobe (MCR0[RXCLKSRC] = 0 or 1). The timing for sampling with an internal dummy read strobe loopback is very similar to the timing for loopback from pad. Sampling with a dummy read strobe loopback from the DQS pad can achieve a higher read frequency. It compensates for the delay of the SCLK output path and data pin input path.

The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

  For SDR read or learn instructions, FlexSPI samples input data pins with the falling edge of the dummy read strobe. Figure 106 shows the input timing for sampling with dummy read strobe in SDR mode.



Tdqv is the setup time from SCLK to the next valid data.
Tdqx is the hold time from SCLK to the current valid data.

Figure 106. Input timing for sampling with dummy read strobe in SDR mode

- **Input timing for sampling with dummy read strobe in DDR mode**

  For DDR read or learn instructions, FlexSPI samples input data pins on rising and falling edges of the dummy read strobe. Figure 107 shows the input timing for sampling with dummy read strobe in DDR mode.

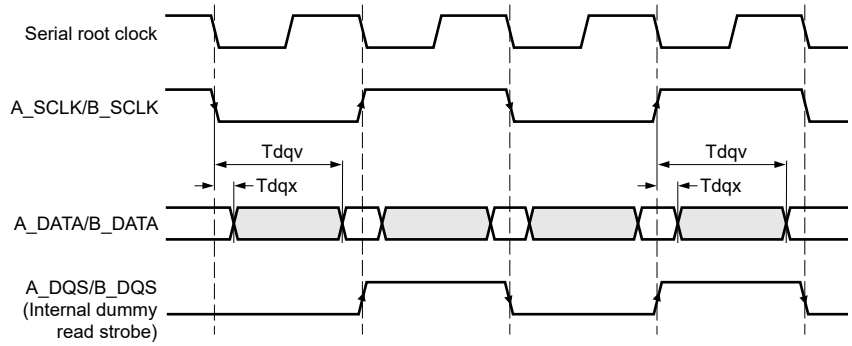


Figure 107. Input timing for sampling with dummy read strobe in DDR mode

29.4.15.4 Input timing for sampling with flash-memory-provided read strobe

This section describes the input timing when sampling with flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3). The input timing is different for SDR mode and DDR mode.

NOTE

There are no known devices that provide a read strobe and support SDR mode operation.

- **Flash-memory-provided read strobe with SCLK**

  Certain flash devices provide both read data and read strobes with SCLK. Then the read strobe edge is aligned with the read data change. The FlexSPI controller delays the read strobe for one half cycle of the serial root clock (with DLL), then samples read data with the delayed strobe. See DLL configuration for sampling. Figure 108 and Figure 109 show the input timing for sampling with flash memory read strobe in SDR mode and DDR mode.

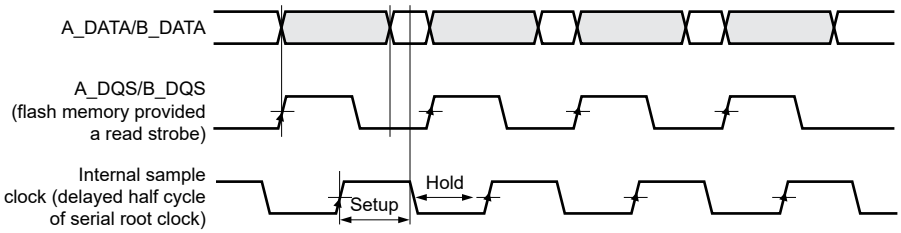

Figure 108. Input timing 2 for flash-memory-provided read strobe in SDR mode

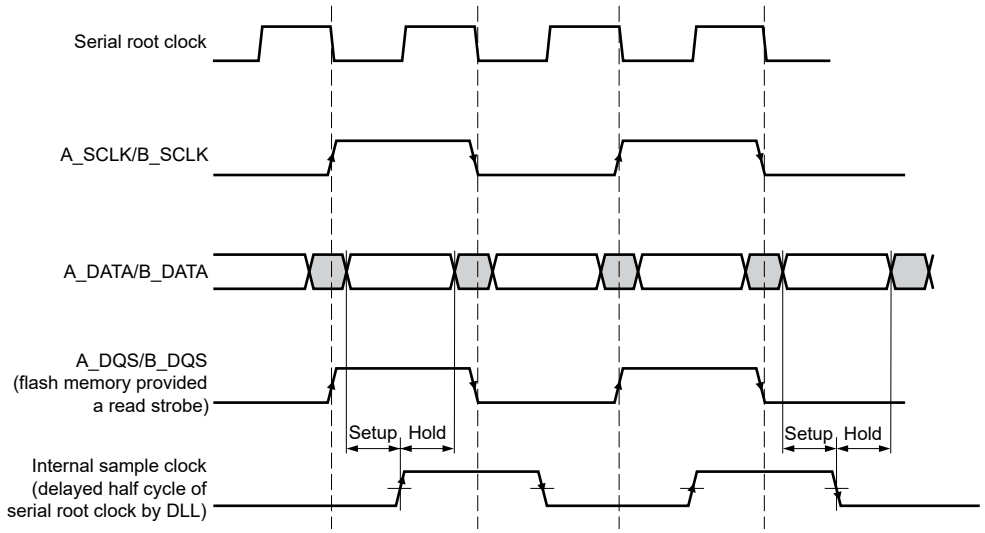

Figure 109. Input timing 2 for flash-memory-provided read strobe in DDR mode

29.4.15.5 DLL configuration for sampling

For the four sampling clock sources described previously, the input timing differs depending on the DLLxCR register configuration, according to the sampling clock source mode. The DLL is a delay-line chain that can be set to a fixed number of delay cells. It can also be auto-adjusted to lock on a certain phase delay to the reference clock.

- DLLxCR must be set to 0000_0100h (one fixed delay cell in DLL delay chain) in the following cases:
  - Sampling data with dummy read strobe looped back internally (MCR0[RXCLKSRC] = 0h)
  - Sampling data with dummy read strobe looped back from DQS pad (MCR0[RXCLKSRC] = 1h)
- When data is sampled with a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h) and flash memory provides the read strobe with SCLK, DLL must be configured as follows (when serial root clock is over 100 Mhz. These settings ensure a lock of the reference clock (serial root clock).
  - DLLxCR[SLVDLYTARGET] is up to flash parameters used.
  - DLLxCR[REFPHASEGAP] = 2h
  - DLLxCR[DLLEN] = 1h
  - DLLxCR[OVRDEN] = 0h
  - Other fields in DLLxCR must be kept at their reset values (all zeroes).

    After the register settings above are completed, set the DLL with following steps.

    1. Reset the DLL(DLLxCR[DLLRESET] or MCR0[SWRESET]).
    2. Wait for STS2[xREFLOCK] and STS2[xSLVLOCK] being asserted.
    3. Wait for equal or more than 512 serial root clock cycles.
    4. Start read or write operation.

NOTE

If the serial root clock is slower than 100 MHz, DLL cannot lock on a half cycle of serial root clock. The delay cell number is limited in the delay chain. DLL must be configured as follows instead:

- DLLxCR[OVRDEN] = 1
- DLLxCR[OVRDVAL] = N

  Each delay cell in DLL is about 75 ps to 225 ps. The delay of DLL delay chain is (N × Delay_cell_delay). N is set based on the maximum DDR frequency (N ≤ equation). This value is calculated based on the MAX_DDR_FREQ parameter. N = 18. This value is a recommended value. If a failure occurs, the value might require adjustment in a real application.

  You can calculate the delay of one delay cell and obtain the value of N. If the serial root clock is lower than 100 MHz, the delay chain can't lock with DLLxCR[SLVDLYTARGET] = 0xF (half cycle of root clock delay). You need to set DLLxCR[SLVDLYTARGET] as 0xE (15/32 cycle delay) or less. When DLL is locked (read STS2[AREFLOCK] and STS2[ASLVLOCK]), the delay cell number = STS2[ASLVSEL] +1 and the delay value (one delay cell) = (total delay)/(delay cell number). Based on delay value, the N can be easily calculated.
- Other fields in DLLxCR must be kept at their reset values (all zeroes).

29.4.16 Data learning

The FlexSPI controller generates 16 clock phases (Phase 0–15) via delay cell line (DCL) with the selected sample clock. Clock phase 0 is the selected sample clock (DQS_IN) with no delay cell. 16 sampling blocks are implemented for Port A.

During a learn instruction, FlexSPI compares the sampled data bits with the internal data learn pattern in the Data Learning Pattern (DLPR) register and determines the correct sampling clock phase. The phase selection is automatically updated after a learn instruction and applied to subsequent read instructions or sequences.

When data learning is disabled (MCR0[LEARNEN] = 0), FlexSPI always uses clock phase 0 to sample FlexSPI data lines. Attempting to execute a learn instruction results in an error flag (INTR[IPCMDERR] or INTR[AHBCMDERR]).

FlexSPI supports data learning in both SDR mode and DDR mode. Data learning is not supported if the sampling clock source is a flash-memory-provided read strobe (MCR0[RXCLKSRC] = 3h).

Data learning can achieve high read frequency, but the flash memory input timing still limits the highest frequency. Flash memory must receive the command code and flash address bits.

When data learning is enabled, FlexSPI uses clock phase 0 after reset and before executing a learn instruction. The clock phase selection is updated after FlexSPI executes the learn instruction. The selected sample clock phase can be polled via STS0[DATALEARNPHASEA]. When data learning fails, the INTR[DATALEARNFAIL] interrupt flag is set, and the previous clock phase selection is kept. You can write 1 to MCR2[CLRLEARNPHASE] to reset the internal clock phase selection to clock phase 0.

29.4.16.1 Data learning with flash-memory-provided preamble bit

Certain flash devices support driving with preamble bits before driving read data in each read command sequence. Preamble bits are also called the data-learning pattern (DLP). The DLP is programmable via configuration register in the flash device.

For the specified read command sequence, flash memory returns preamble bits after dummy cycles and before returning read data.

For these flash devices, the operation flow with data learning is:

1. Configure the data learning pattern in Data Learning Pattern (DLPR) register.
2. Configure the same data learning pattern in the flash device by triggering an IP command.
3. Enable data learning in the flash device by triggering an IP command.
4. Configure LUT sequence with valid read command sequence containing the learn instruction.
5. Trigger a flash memory read command via AHB or IP command as normal.

NOTE

The first four steps are executed only once. They are not needed for every flash memory read command.

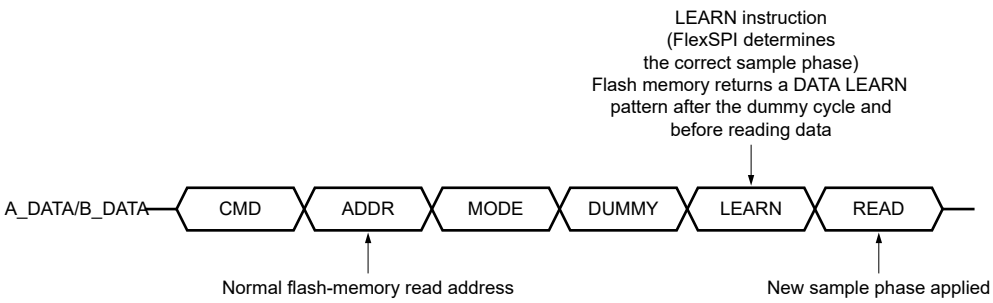

Figure 110. Data learning flow with flash-memory-provided preamble bit

29.4.16.2 Data learning without flash-memory-provided preamble bit

For flash devices that do not provide a preamble bit, the DLP cannot be returned automatically for each read command sequence. For these flash devices, the data learning sequence is:

1. Set data learning pattern in Data Learning Pattern (DLPR) register.
2. Reserve a certain flash memory area and program data (according to data learning pattern and flash memory access mode) to this area via IP command.
3. Configure LUT sequence with read sequence using a learn instruction instead of a read instruction. Trigger the read sequence to the reserved flash memory area via IP command.
4. Trigger the flash memory read command via AHB or IP command as normal. No learn instruction is needed in this read sequence.

NOTE

- The first three steps are executed only once. They are not needed for every flash memory read command.
- Step 4 should be executed with a certain interval to ensure that the internal sampling clock phase is adjusted in time.

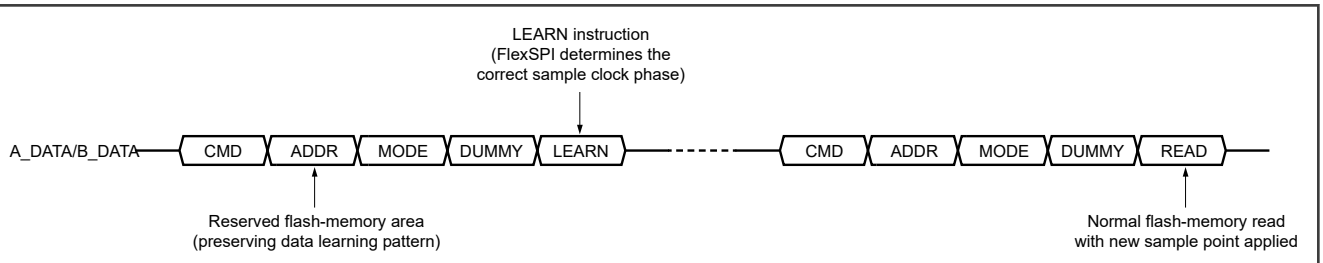

Figure 111. Data learning flow without flash-memory-provided preamble bit

NOTE

- For flash devices that do not provide a preamble bit, software overhead is required to read the reserved flash memory area at the interval.

These items determine the preprogramming data:

- Data Learning Pattern (DLPR register setting)
- DLP bit length

- Individual mode for read command
- Octal, Quad, Dual, or Single mode for read command

Figure 112 shows a preprogramming data example where the DLPR value is 43h, eight bits, and flash memory is read in Quad mode.

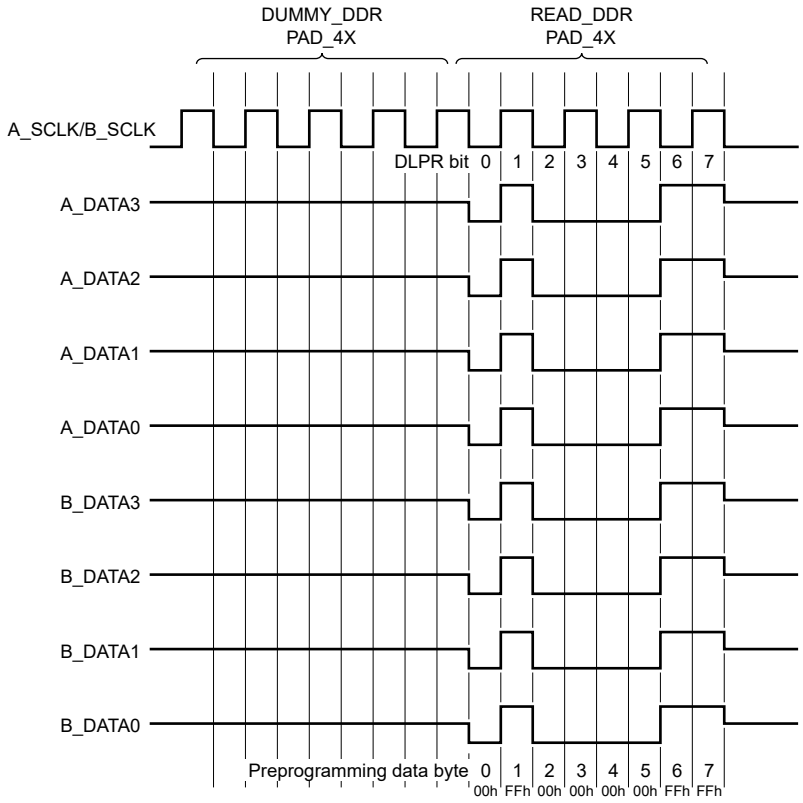

Figure 112. Preprogramming data for data learning

29.4.17 Execute-In-Place (XIP) enhanced mode

FlexSPI always supports XIP, regardless of whether external devices provide XIP enhanced mode. To support XIP, put program codes on an external device, then read or execute these codes directly via AHB read access to serial flash memory space. There is no configuration or status polling needed during AHB read access to the memory of the external device. The AHB receive buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, the command code is only sent in the first read instruction. It saves many cycles for command instructions and improves code execution. Devices enter or exit XIP enhanced mode via a special sequence that external devices specify. See the external device data sheet for more details.

Normally, a device enters XIP enhanced mode via this sequence:

1. Enable XIP enhanced mode in external flash device via IP command.
2. Send the first read sequence to external flash device with correct mode bits. Command code is included in this read sequence.
3. Send the subsequent read sequences to external flash device with correct mode bits. Command code is not included in these read sequences. Mode bits must be sent according to the flash specified; otherwise, the flash exits XIP enhanced mode.

The instruction JMP_ON_CS in FlexSPI must be used to support XIP enhanced mode in external devices. This instruction is only allowed in the AHB read command; otherwise, the instruction generates an IPCMDERR or AHBCDMERR interrupt (when the

interrupt is enabled). When external devices do not support XIP enhanced mode, JMP_ON_CS must never be used. To support XIP enhanced mode:

- The first instruction in the read sequence must be the command instruction.
- The last valid instruction must be JMP_ON_CS (with operand 1h).

For the first AHB read command triggered, FlexSPI executes the instructions from the instruction pointer 0 in the sequence (which is the command instruction). After this sequence is executed, FlexSPI saves the operand in the JMP_ON_CS instruction as the start pointer for the next command to current device internally. For the next AHB read command triggered, FlexSPI executes from the instruction pointer 1h, bypassing the command instruction.

After XIP enhanced mode is started, it is possible to access flash via other commands like program commands. You must, however, use a special sequence to exit enhanced XIP mode before you can run a different command. Figure 113 indicates XIP operation with Flash XIP enhanced mode.

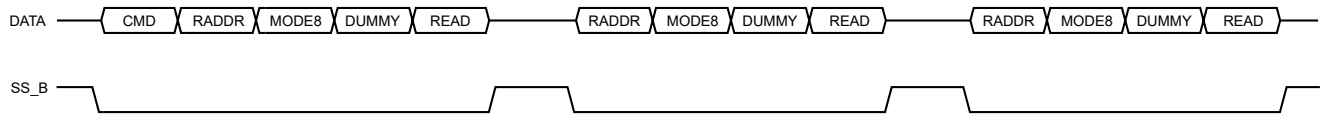

Figure 113. XIP Enhanced Mode Operation

29.4.18 AHB bus blocking

FlexSPI can temporarily block some or all AHB transactions. This feature is useful when IP commands are in progress that could cause a potential conflict with an AHB request. Examples of situations where IP bus blocking would be used are:

- Avoiding RWW (read while write). While programming or erasing flash, reads are not allowed. AHB bus blocking can prevent the AHB bus from requesting a read while IP write commands are in progress.

To block all AHB transactions:

1. Configure blocking for all AHB transactions by writing 1 to IPCR2[IPBLKALLAHB].
2. Request AHB bus blocking by writing 1 to IPCR2[IPBLKAHBREQ].
3. Wait for the AHB bus blocking request to be acknowledged (IPCR2[IPBLKAHBACK] = 1).
4. Perform IP write commands as needed.
5. Request normal operation by writing 0 to IPCR2[IPBLKAHBREQ].
6. Wait for AHB blocking request clear to be acknowledged (IPCR2[IPBLKAHBACK] = 0).

NOTE

AHB bus blocking can only be used to prevent conflicts between AHB and IP transactions. Software must handle conflicts between multiple AHB transactions.

29.5 External signals

This section provides the external signal information for the FlexSPI module.

Table 173. External Signal List

Signal name	Function	Direction	Description
A_SS0_B	Peripheral Chip Select Flash A1	O	Chip select for the serial flash device A1

Table continues on the next page...

Table 173. External Signal List (continued)

Signal name	Function	Direction	Description
A_SCLK	Serial Clock Flash A	O	Serial clock output to the serial flash device A. This clock runs at half the frequency of serial clock root in DDR mode, and at the same frequency as serial clock root in SDR mode. Clock output toggles during the entire flash memory access sequence.
A_DATAn	Serial I/O Flash A	I/O	Data I/O lines to and from the serial flash device A
A_DQS	Data Strobe Signal Flash A	I/O	Data strobe signal for port A. This signal has three functions: • Driven with read strobe by external device. Some flash devices provide the read strobe signal together with read data. In this case, if the external device drives this pad only when reading flash memory data, this pad may require a **pull-down** resistor. • Driven with latency information by external device. Some devices use this pin to indicate the dummy cycles needed (before program or read data transfer) such as HyperRAM or HyperFlash. • Loopback dummy read strobe. The FlexSPI controller provides internal dummy read strobe for flash memory read data. Higher read frequency can be achieved by looping back this dummy read strobe from the pad. This pin can be floated or have some capacitive load added at the board level to compensate for load on DATA or SCLK pins.

29.6 Initialization

The FlexSPI controller initialization sequence is:

1. Enable controller clocks (AHB clock, IP bus clock, or serial root clock) at system level.
2. To enter module stop mode, write 1 to MCR0[MDIS].
3. Configure module control registers: MCR0, MCR1, and MCR2. Do not change MCR0[MDIS].
4. When AHB commands are used, configure AHB Bus Control (AHBCR) and AHB Receive Buffer Control (AHBRXBUFxCR0) registers.
5. Configure flash control registers (FLSHxCR0, FLSHxCR1, or FLSHxCR2) according to external device type.
6. Configure DLL control register (DLLxCR) according to sample clock source selection.
7. To exit module stop mode, write 0 to MCR0[MDIS].
8. Configure LUT as needed for AHB command or IP command.

9. Optionally, to reset controller, write 1 to MCR0[SWRESET].

External devices must be configured via IP command normally after initialization. For example, the WRITE STATUS command performs device configuration for most serial NOR flash memory.

29.7 Application information

This section describes applications that FlexSPI supports.

29.7.1 Application on serial NOR flash device

This section provides the example LUT instruction sequences for serial NOR flash device (Cypress Flash S25FS128S).

29.7.1.1 Write enable command

Table 174 shows the WRITE ENABLE command sequence.

Table 174. WRITE ENABLE command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h	06h	Command name: WREN
1-7	STOP (00h)	0h	00h	

29.7.1.2 Write registers command

Table 175 shows the Write Registers command sequence.

Table 175. Write Registers command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	01h	Command name: WRR
1	WRITE_SDR	0h (Single)	1h or 2h	Data size is 1 byte or 2 bytes. Byte 0 is write data for Status Register 1; Byte 1 is write data for Configuration Register 1. IPCR1[IDATSZ] can override this value.
2-7	STOP (00h)	0h	00h	

29.7.1.3 Page Program command

Table 176 shows Page Program command sequence.

Table 176. PAGE PROGRAM command (Cypress serial NOR flash)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	02h or 12h	Command name: PP or 4PP PP is 3-byte address mode. 4PP is 4-byte address mode.

Table 187 shows DDR Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration register bits CR2V[7] = 0, CR2V[6] = 0, CR2V[3:0] = 8h, Non-QPI mode, Continuous read mode.

Table 187. DDR Quad IO FAST_READ command (Non-QPI mode, Continuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	EDh or EEh	Command name: QIOR_DDR or 4QIOR_DDR QIOR_DDR is 3-byte address mode. 4QIOR_DDR is 4-byte address mode.
1	ADDR_DDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_DDR	2h (Quad)	A0h	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_DDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	LEARN_DDR	2h (Quad)	1h	DLP is 8 bits.
5	READ_DDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
6	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
7	STOP (00h)	0h	00h	

Table 188 shows DDR Quad IO FAST_READ command sequence. This table shows Cypress SPI Configuration Register bits CR2V[7] = 0, CR2V[6] = 1, CR2V[3:0] = 8h, QPI mode, Continuous read mode.

Table 188. DDR Quad IO FAST_READ command (QPI mode, Continuous read mode)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	2h (Quad)	EDh or EEh	Command name: QIOR_DDR or 4QIOR_DDR QIOR_DDR is 3-byte address mode. 4QIOR_DDR is 4-byte address mode.
1	ADDR_DDR	2h (Quad)	18h or 20h	Address bit number (operand value) should be 24 in 3-byte address mode and 32 in 4-byte address mode.
2	MODE8_DDR	2h (Quad)	A0h	Enter continuous read mode or remain in continuous read mode.
3	DUMMY_DDR	2h (Quad)	08h	Dummy cycle is 8 (in serial root clock) as CR2V[3:0] = 8h.
4	LEARN_DDR	2h (Quad)	1h	DLP is 8 bits.
5	READ_DDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size. This value is ignored for AHB command.
6	JMP_ON_CS	0h (or Don't care)	01h	CMD instruction is bypassed after the first read access.
7	STOP (00h)	0h	00h	

29.7.2 Application on HyperBus device

This section provides the example LUT instruction sequences for HyperBus device (Cypress RPC flash, HyperRam, or HyperFlash).

29.7.2.1 HyperFlash

This section provides example sequences for HyperFlash devices (Cypress S26KS series).

Table 189 shows the read status command sequence.

Table 189. Read status command

Seq num	Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0 (Write - Addr = 555h, Data = 70h)	0	CMD_DDR	3h (Octal)	20h	CA bit 47: (R/W# = 0h CA bit 46: (Target) = 0h CA bit 45: (Burst Type) = 1h CA bit 44-40: All reserved = 0h
	1	CMD_DDR	3h (Octal)	00h	Row Address: 0000AAh (24 bit)
	2	CMD_DDR	3h (Octal)	00h

				data size. This value is ignored for AHB command.
5-7	STOP (00h)	0h	00h	

29.7.3 Application on Serial NAND flash device

This section provides example LUT instruction sequences for serial NAND flash device (Micron Flash MT29 series). The operation of serial NAND flash is similar to serial NOR flash.

The read operation sequence is:

- Page read. Transfer the data from the NAND flash array to the cache register.
- Get feature to read the status.
- Random data read

Table 194 shows the page read command sequence.

Table 194. Page Read command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	13h	Command code: 13h
1	RADDR_SDR	1h (Single)	18h	Row address: 24 bit
2-7	STOP (0h)	0h	00h	

Table 195 shows Get Feature command sequence.

Table 195. Get Feature command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	0h (Single)	0Fh	Command code: 0Fh
1	CMD_SDR	1h (Single)	C0h	Status register address (C0h)
2	READ_SDR	0x1 (Single)	02h	2 bytes read data
3-7	STOP (0h)	0h	00h	

Table 196 shows Random Data Read command sequence.

Table 196. Read from Cache x4 command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	6Bh	Command code: 6Bh
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection

Table continues on the next page...

Table 196. Read from Cache x4 command (continued)

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
				is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	DUMMY_SDR	2h (Quad)	08h	Dummy cycle number: 8 (serial root clock)
4	READ_SDR	2h (Quad)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default reading data size.
5-7	STOP (0x0)	0x0	0x00	

The program operation sequence is:

- Write enable
- Program Load. Transfer the write data to the cache register.
- Program Execute
- Get Feature to read the status.

Table 197 shows Program Load command sequence.

Table 197. Program Load command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	02h	Command code: 02h
1	MODE4_SDR	1h (Single)	0h or 1h	If plane selection is one, software should decode the flash address and write 1h to mode bits. If plane selection is zero, software should write 0h to mode bits. Plane selection bit is 18th bit of flash address. If NAND flash size is less than 4 Gbit, plane selection is always zero.
2	CADDR_SDR	1h (Single)	0Ch	Column address: 12 bit
3	WRITE_SDR	1h (Single)	Any nonzero value	If IPCR1[IDATSZ] is zero, this operand value can be used as default writing data size.
4-7	STOP (0h)	0h	00h	

Table 198 shows Program Execute command sequence.

Table 198. Program Execute command

Instruction number	Instruction opcode[5:0]	Instruction num_pads[1:0]	Instruction operand[7:0]	Comment
0	CMD_SDR	1h (Single)	10h	Command code: 10h
1	RADDR_SDR	1h (Single)	18h	Row Address: 24 bit
2-7	STOP (0h)	0h	00h	

29.7.4 Application on FPGA device

An FPGA device can be accessed via both AHB and IP commands. All AHB accesses to FPGA are transparent to the software driver (no software intervention). An FPGA device may have some special requirements.

Table 199. Special requirements for FPGA devices

Condition	How to manage the condition
Device type may be different on A1, A2, B1, or B2.	Write 0 to MCR2[SAMEDEVICEEN] and configure the FLSHxCR0 and FLSHxCR1 registers separately for up to four external devices.
Device requires different wait cycle for programming.	The AHB write wait cycle number can be set separately for these four external devices (via FLSHxCR2[AWRWAIT]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle). FlexSPI holds the AHB bus ready for this wait time; AHB bus performance may decrease when this wait time is very long.
Device requires different wait cycle for reading.	The AHB read sequence index and sequence number can be set separately for these four external devices (via FLSHxCR2[ARDSEQID] and FLSHxCR2[ARDSEQNUM]). Software can configure the sequences in LUT with different dummy instructions (operand determines dummy cycle).
Device may be sensitive to read instruction clock cycle number.	If its internal memory is implemented similar to a FIFO, the device is sensitive to the read instruction clock cycle number. Software can send the data size information to the external device via DATSZ instruction. The FPGA device decodes the data size information and determines how many data bytes must be popped.
Device may require interval time between chip select valid.	This interval can be managed via FLSHxCR1[CSINTERVAL].
Device may use SCLK as reference clock for its internal PLL.	SCLK must be free-running and the clock frequency must be stable. To achieve this configuration, write 1 to MCR0[SCKFREERUNEN] and only use SDR sequences.

29.7.5 Overview of error categories, flags, and triggered sources

Table 200 provides an overview of the categories, flags, and triggered sources of errors in FlexSPI.

Table 200. Error category, triggered sources, and flags

Error Category	Triggered Sources	Description	Error Flags
Command grant error	AHB write command	Command grant timeout	INTR[AHBCMDGE] is set AHB bus error response

Table continues on the next page...

Table 200. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
	AHB read command		INTR[AHBCMDGE] is set AHB bus error response
	IP command		INTR[IPCMDGE] is set
Command check error	AHB write command	• AHB write command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	AHB read command	• Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence	INTR[AHBCMDERR] is set Command is not executed when an error is detected in command check
	IP command	• IP command with JMP_ON_CS instruction used in the sequence • Unknown instruction opcode in the sequence • Instruction DUMMY_SDR or DUMMY_RWDS_SDR used in DDR sequence • Instruction DUMMY_DDR or DUMMY_RWDS_DDR used in SDR sequence • Flash boundary across	INTR[IPCMDERR] is set Command is not executed when an error is detected in command check
Command execution error	AHB write command	Command timeout during execution	INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set An AHB bus error response

Table continues on the next page...

Table 200. Error category, triggered sources, and flags (continued)

Error Category	Triggered Sources	Description	Error Flags
			occurs, except in following cases: • Flush triggers AHB write command (INCR burst ended with AHB_TX_BUF not empty) • AHB bufferable write access and bufferable enabled (AHBCR[BUFFERABLEEN] = 1)
	AHB read command		INTR[AHBCMDERR] is set INTR[SEQTIMEOUT] is set AHB bus error response
	IP command		INTR[IPCMDERR] is set INTR[SEQTIMEOUT] is set
AHB bus timeout	AHB write command	AHB bus timeout (no bus ready return)	AHB bus error response
	AHB read command		
Data learning failed	Any command	No valid sample clock phase found after learn instruction is executed	INTR[DATALEARNFAIL] is set

29.8 Memory map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

29.8.1 Register access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the values of reserved fields in control registers. Changing the values of reserved fields may impact the normal functioning of the controller.

NOTE

When FlexSPI can access sensitive memory contents, the FlexSPI controller should protect those contents using resource isolation such as XRDC or TrustZone. Ensure that only trusted software is allowed to access the FlexSPI controller register interface.

29.8.2 FLEXSPI register descriptions

29.8.2.1 FlexSPI memory map

FLEXSPI1 base address: 425E_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

29.8.2.2 Module Control 0 (MCR0)

Controls basic functions of FlexSPI module

Offset

Register	Offset
MCR0	0h

Diagram

Fields

Field	Description
31-24 AHBGRANTWAIT	Timeouts Wait Cycle for AHB command Grant Sets duration of timeout wait cycle for AHB commands. If the arbitrator does not grant the AHB-triggered command, it times out after (AHBGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is IP-triggered and the read or write data size is too large, this grant timeout may occur. When an AHB command grant timeout occurs, an INTR[AHBCMDGE] interrupt is generated. When INTEN[AHBCMDGEEN] = 1, the arbitrator ignores AHB commands. **NOTE** This field is for debugging only. Do not change the value from its default.
23-16 IPGRANTWAIT	Timeout Wait Cycle for IP Command Grant Sets duration of timeout wait cycle for IP commands. If the arbitrator does not grant the IP-triggered command, it times out after (IPGRANTTIMEOUT × 1024) AHB clock cycles. When the pending command sequence is AHB-triggered and the read or write data size is too large, this grant timeout may occur. When IP command grant timeout occurs, an INTR[IPCMDGE] interrupt is generated. When INTEN[IPCMDGEEN] = 1, the arbitrator ignores IP commands. **NOTE** This field is for debugging only. Do not change the value from its default.
15 LEARNEN	Data Learning Enable Enables data learning feature. When data learning is disabled, the sampling clock phase 0 is always used for receive data sampling, even when a learn instruction is correctly executed. See Data learning. 0 - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable
14 SCKFREERUNEN	SCLK Free-running Enable Enables free-running SCLK output. For FPGA applications, the external device may use SCLK as a reference clock to its internal PLL. 0 - Disable 1 - Enable
13 —	Reserved
12 DOZEEN	Doze Mode Enable Enables Doze mode. When enabled, AHB clock and serial clock are gated off when there is a Doze-mode request from the system. 0 - Disable 1 - Enable
11 HSEN	Half Speed Serial Flash Memory Access Enable Enables the clock divider to provide a half-speed clock to external serial flash devices (A_SCLK/B_SCLK) for all commands in SDR and DDR mode. Write 1 to MCR0[MDIS] before changing the value of this field. Failure to do so may cause issues in the internal logic or state machine. 0 - Disable 1 - Enable
10-8 SERCLKDIV	Serial Root Clock Divider Sets divider value for serial root clock. The serial root clock can be divided inside FlexSPI . See Clocking. **NOTE** Do not modify this field while FlexSPI is active (MCR0[MDIS] = 0). 000 - Divided by 1 001 - Divided by 2 010 - Divided by 3 011 - Divided by 4 100 - Divided by 5 101 - Divided by 6 110 - Divided by 7 111 - Divided by 8
7	AHB Write Access to IP Transmit FIFO Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
ATDFEN	Enables AHB write access to IP transmit FIFO. See Writing data to IP transmit FIFO. 0 - AHB write access disabled. IP bus writes to IP transmit FIFO. AHB bus write access to IP transmit FIFO memory space produces bus error. 1 - AHB write access enabled. AHB bus writes to IP transmit FIFO. IP Bus write access to IP transmit FIFO memory space is ignored and causes no bus error.
6 ARDFEN	AHB Read Access to IP Receive FIFO Enable Enables AHB read access to IP receive FIFO. See Reading data from IP receive FIFO. 0 - AHB read access disabled. IP bus reads IP receive FIFO. AHB Bus read access to IP receive FIFO memory space produces bus error. 1 - AHB read access enabled. AHB bus reads IP receive FIFO. IP Bus read access to IP receive FIFO memory space returns data zero and causes no bus error.
5-4 RXCLKSRC	Sample Clock Source for Flash Reading Selects sampling clock source for flash memory reading. See Receive clock source features. 00 - Dummy Read strobe that FlexSPI generates, looped back internally 01 - Dummy Read strobe that FlexSPI generates, looped back from DQS pad 10 - Reserved 11 - Flash-memory-provided read strobe and input from DQS pad
3-2 —	Reserved
1 MDIS	Module Disable Disables FlexSPI module. When the module is disabled, AHB and serial clock are gated off internally to save power. Only register access is allowed, except for the LUT, IP receive FIFO, and IP transmit FIFO. 0 - No impact 1 - Module disable
0 SWRESET	Software Reset Resets the internal FlexSPI state machine and aborts any transactions in progress. Hardware automatically writes 0 to this field after software reset is done. Configuration registers are not reset. 0 - No impact 1 - Software reset

29.8.2.3 Module Control 1 (MCR1)

Controls basic functions of FlexSPI module

Offset

Register	Offset
MCR1	4h

Diagram

Fields

Field	Description
31-16 SEQWAIT	Command Sequence Wait Sets wait time for command sequence. Command sequence execution times out and aborts after (SEQWAIT × 1024) serial root clock cycles. When this timeout occurs, if the interrupt is enabled (INTEN[SEQTIMEOUTEN] = 1), an INTR[SEQTIMEOUT] interrupt is generated. Also, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.
15-0 AHBBUSWAIT	AHB Bus Wait Sets wait time for AHB bus. When data is not received from or transmitted to serial flash memory space after (AHBBUSWAIT × 1024) AHB clock cycles, the read or write access times out. When this timeout occurs, the AHB bus receives an error response, and an interrupt is generated (INTEN[AHBBUSERROREN]). When INTR[AHBBUSERROREN] = 1, the arbitrator ignores AHB commands. **NOTE** You cannot write 0 to this field.

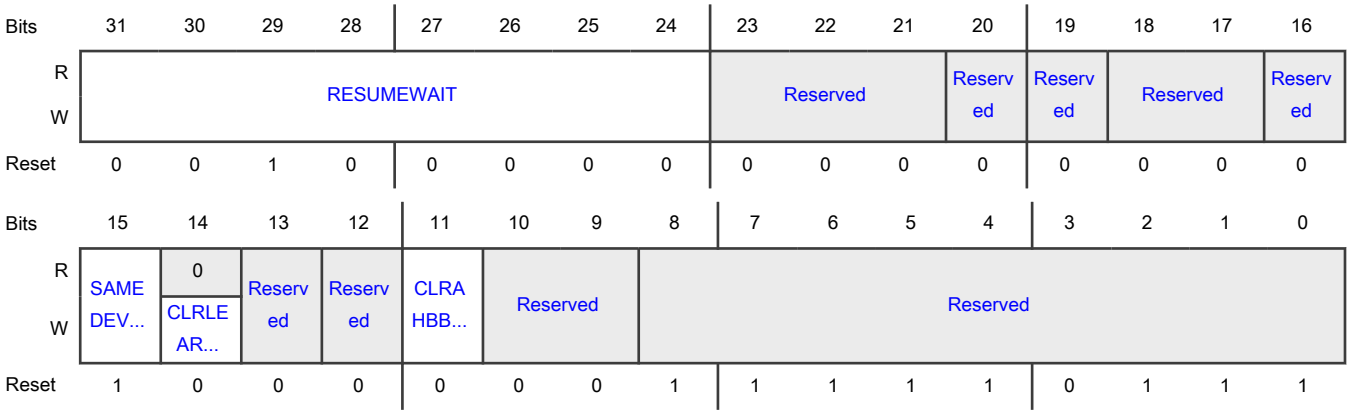
29.8.2.4 Module Control 2 (MCR2)

Controls basic functions of FlexSPI module.

Offset

Register	Offset
MCR2	8h

Diagram



Fields

Field	Description
31-24 RESUMEWAIT	Resume Wait Duration Determines duration (in AHB clock cycles) to remain in idle state before suspended command sequence is resumed. See Command abort and suspend.
23-21 —	Reserved
20 —	Reserved
19 —	Reserved
18-17 —	Reserved
16 —	Reserved
15 SAMEDEVICEEN	Same Device Enable Sets all external devices (A1, A2, B1, and B2) to be the same devices (in type and in size). 0 - In Individual mode, FLSHA1CRx and FLSHA2CRx, FLSHB1CRx and FLSHB2CRx settings are applied to Flash A1, A2, B1, B2 separately.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - FLSHA1CR0, FLSHA1CR1, and FLSHA1CR2 register settings are applied to Flash A1, A2, B1, B2. FLSHA2CRx, FLSHB1CRx, and FLSHB2CRx settings are ignored.
14 CLRLEARNPHASE	Clear Learn Phase Selection Resets the sampling clock phase selection to 0. When 1 is written to this field, it becomes 0 again immediately. 0 - No impact 1 - Reset sample clock phase selection to 0
13 —	Reserved
12 —	Reserved
11 CLRAHBBUFOPT	Clear AHB Buffer Determines whether AHB receive and transmit buffers are cleared automatically when FlexSPI returns Stop mode ACK. If an AHB receive buffer or transmit buffer will be powered off in Stop mode, software should write 1 to this field. Otherwise, an AHB read access after exiting Stop mode may hit either buffer, but their data entries are invalid. 0 - Not cleared automatically 1 - Cleared automatically
10-9 —	Reserved
8-0 —	Reserved

29.8.2.5 AHB Bus Control (AHBCR)

Controls AHB bus interface functions.

Offset

Register	Offset
AHBCR	Ch

Fields

Field	Description
31-27 AFLASHBASE	AHB Memory-Mapped Flash Base Address
26-22 —	Reserved
21-20 ALIGNMENT	AHB Boundary Alignment Configures the size of AHB read and write boundary. All accesses that cross the boundary are divided into smaller sub accesses. 00 - No limit 01 - 1 KB 10 - 512 bytes 11 - 256 bytes
19 —	Reserved
18 —	Reserved
17 —	Reserved
16 —	Reserved
15 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
14-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 READSZALIGN	AHB Read Size Alignment Configures how AHB read size is determined. See Table 170. **NOTE** When 1, data prefetching is disabled regardless of other field settings such as PREFETCH_EN and OTFAD_EN. Read size is rounded up to the nearest eight-byte multiple. For example, if current AHB read size is 12 bytes, it is aligned to 16 bytes. When the fetch size must be eight-byte aligned but no speculative fetching is wanted, write 1 to this field. 0 - Register settings such as PREFETCH_EN and OTFAD_EN determine AHB read size. 1 - AHB read size to up size to 8 bytes aligned, no prefetching
9 —	Reserved
8 —	Reserved
7 RESUMEDISABLE	AHB Read Resume Disable Disables the resumption of AHB read prefetch. **NOTE** When OTFAD is enabled, this field does not affect the resume function; AHB read resume is always disabled. When OTFAD is disabled, suspended AHB read prefetch resumes based on the values of this field and MCR2[RESUMEWAIT]. 0 - Suspended AHB read prefetch resumes when AHB is IDLE. 1 - Suspended AHB read prefetch does not resume once aborted.
6 READADDROPT	AHB Read Address Option Removes AHB burst start address alignment limitation. When the FlexSPI controller is used for FPGA application, this field may be required for FlexSPI to fetch the exact byte number as an AHB burst. In this case, FPGA device should be non-word-addressable and this field must be 0.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When OTFAD is enabled, FlexSPI functions as it does when READADDROPT = 1 regardless the value of this field. 0 - AHB read burst start address alignment is limited when flash memory is accessed in flash is word-addressable. 1 - AHB read burst start address alignment is not limited. FlexSPI fetches more data than the AHB burst requires for address alignment.
5 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch. When enabled, FlexSPI fetches more flash read data than the current AHB burst requires. This action reduces the read latency for next AHB read access. **NOTE** When OTFAD is enabled, the AHB prefetch function is enabled regardless of the value of this field. **NOTE** AHB read prefetch is enabled only when both this field and AHBRXBUFnCR0[PREFETCHEN] are 1. 0 - Disable 1 - Enable
4 BUFFERABLEEN	Bufferable Write Access Enable Enables AHB bus bufferable write access. This field affects the last beat of an AHB write access. See AHB write access to flash memory. 0 - Disabled. For all AHB write accesses (bufferable or nonbufferable), FlexSPI returns AHB Bus Ready after transmitting all data and finishing command. 1 - Enabled. For AHB bufferable write access, FlexSPI returns AHB Bus Ready when the arbitrator grants the AHB command. FlexSPI does not wait for the AHB command to finish.
3 CACHABLEEN	Cacheable Read Access Enable Enables AHB bus cacheable read access. 0 - Disabled. When an AHB bus cacheable read access occurs, FlexSPI does not check whether it hit the AHB transmit buffer. 1 - Enabled. When an AHB bus cacheable read access occurs, FlexSPI first checks whether the access hit the AHB transmit buffer.
2 CLRAHBTXBUF	Clear AHB Transmit Buffer Clears status and pointers of AHB transmit buffer. When the clear operation completes, this field clears automatically, so it always reads as 0. 0 - No impact.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable clear operation.
1 —	Reserved
0 —	Reserved

29.8.2.6 Interrupt Enable (INTEN)

Includes AHB error response, IPS error response, and ECC error interrupt enables. See Interrupts.

Offset

Fields

Field	Description
31 PREFETCHEN	AHB Read Prefetch Enable Enables AHB read prefetch for the controller corresponding to the current AHB receive buffer. The prefetch feature is disabled when AHBCR[PREFETCHEN] is 0. You can use this field to enable or disable prefetch separately for each controller. 0 - Disabled 1 - Enabled when AHBCR[PREFETCHEN] is enabled.
30 REGIONEN	AHB Receive Buffer Address Region Enable Enable prefetch buffer enhancement.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE Only AHBRXBUF 0-3 have this function. 0 - Disabled. The buffer hit is based on the value of MSTRID only. 1 - Enabled. The buffer hit is based on the value of MSTRID and the address within AHBBUFREGIONSTARTn and AHBREGIONENDn.
29-27 —	Reserved
26-24 PRIORITY	AHB Controller Read Priority Configure the priority for the AHB Controller Read to which this AHB receive buffer is assigned. 7 is the highest priority, 0 the lowest. See Command abort and suspend.
23-20 —	Reserved
19-16 MSTRID	AHB Controller ID Configures the ID of the AHB controller to which this AHB receive buffer is assigned. See AHB receive buffer management.
15-9 —	Reserved
8-0 BUFSZ	AHB Receive Buffer Size Configures the size of the AHB receive buffer in multiples of 64 bits. See AHB receive buffer management.

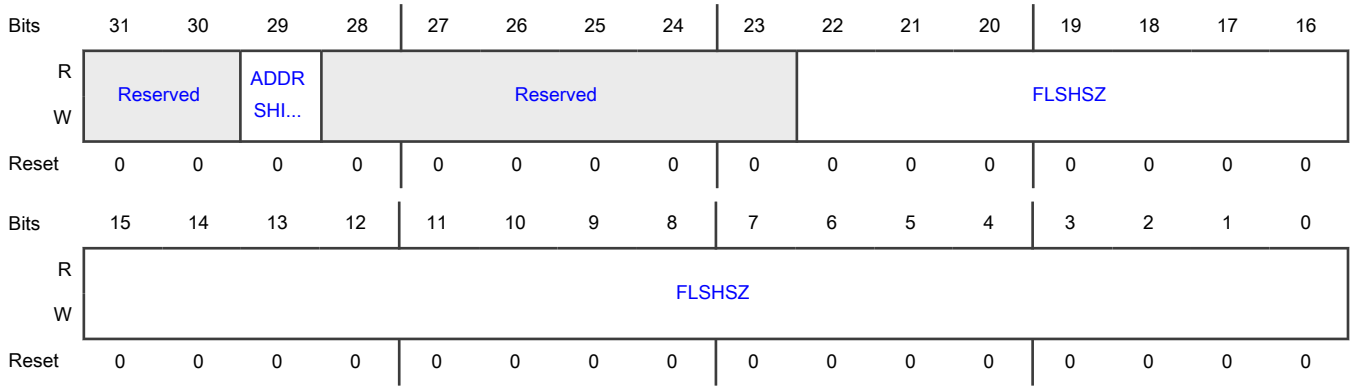
29.8.2.11 Flash Control 0 (FLSHA1CR0 - FLSHB2CR0)

Contains flash memory size setting. FlexSPI determines which device is accessed (Chip Select) via this register.

Offset

Register	Offset
FLSHA1CR0	60h
FLSHA2CR0	64h
FLSHB1CR0	68h
FLSHB2CR0	6Ch

Diagram



Fields

Field	Description
31-30 —	Reserved
29 ADDRSHIFT	AHB Address Shift Function control Used to left-shift five bits for the flash address to support ISSI quad PSRAM. 0 - Disabled 1 - Enabled
28-23 —	Reserved
22-0 FLSHSZ	Flash Size in KB Configures the maximum flash memory size. See the chip-specific section for the maximum flash size supported. When the value of this field is greater than the maximum size, the device flash size is interpreted as the maximum. The maximum flash size is the largest flash size supported for a single device. It is also the maximum total flash size supported for all devices (up to four). If the total flash size is larger than the maximum size, only the maximum flash size address space is accessible. For IPS access, The maximum flash size supported for each device is 4 GB. When the value of this field is greater than 400000h, the device flash size is taken as 4 GB. The max total flash size supported (for all 4 devices) is also 4 GB. If the total flash size is larger than 4 GB, only 4 GB of address space is accessible.

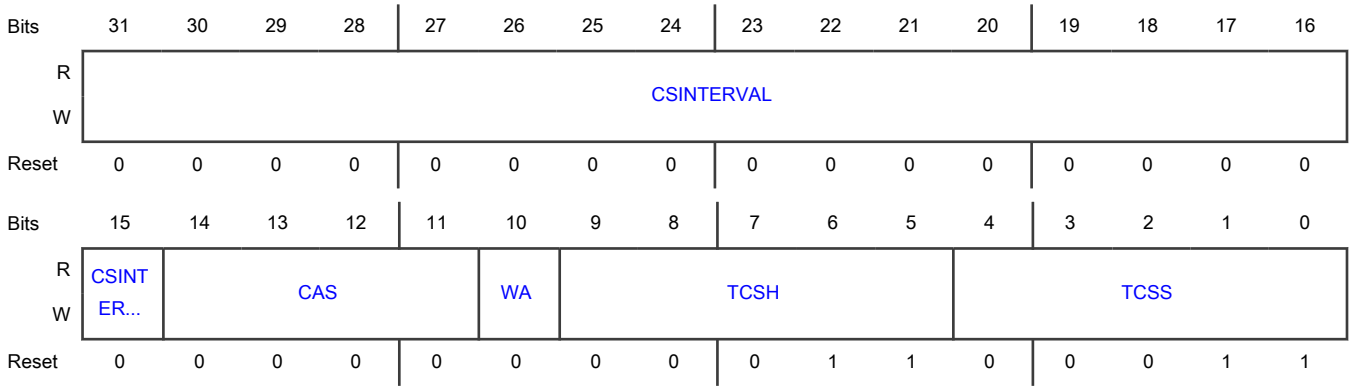
29.8.2.12 Flash Control 1 (FLSHA1CR1 - FLSHB2CR1)

Contains settings for flash device-specific timings and flash internal address space.

Offset

Register	Offset
FLSHA1CR1	70h
FLSHA2CR1	74h
FLSHB1CR1	78h
FLSHB2CR1	7Ch

Diagram



Fields

Field	Description
31-16 CSINTERVAL	Chip Select Interval Configures the minimum interval between flash device chip select deassertion and chip select assertion. If the external flash device has a limitation on the interval between command sequences, configure this field accordingly. If there is no limitation, write 0h to this field. When CSINTERVALUNIT = 0, the chip select invalid interval is: CSINTERVAL × 1 serial clock cycle; When CSINTERVALUNIT = 1, the chip select invalid interval is: CSINTERVAL × 256 serial clock cycles. **NOTE** The minimum chip select interval is 2 cycles, even when the value of CSINTERVAL is less than 2.
15 CSINTERVALUNIT	Chip Select Interval Unit Configures the interval unit for chip select. 0 - 1 serial clock cycle 1 - 256 serial clock cycles
14-11 CAS	Column Address Size When external flash memory has a separate address field for rows and columns, this field configures the flash column address bit width. FlexSPI automatically splits a flash-mapped address into row address and column address according to the values of this field and the WA field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When the external flash memory does not support column address, write 0 to this field. FlexSPI transmits all flash address bits as Row address. For flash address mapping, see Flash address sent to flash memory devices.
10 WA	Word-Addressable Configures whether external flash memory is word-addressable or byte-addressable. If flash memory is word-addressable, it should be accessed in multiples of 16 bits. Currently, FlexSPI does not transmit flash address bit 0 to external flash memory. For flash address mapping, see Flash address sent to flash memory devices. 0 - Byte-addressable 1 - Word-addressable
9-5 TCSH	Serial Flash CS Hold Time Used to meet flash TCSH timing requirement. Serial flash CS Hold time that FlexSPI promises is: (TCSH + 1/2) serial clock cycles for DDR mode, and TCSH serial clock cycles for SDR mode. See Output timing between chip select and SCLK.
4-0 TCSS	Serial Flash CS Setup Time Used to meet flash TCSS timing requirement. Serial flash CS Setup time that FlexSPI promises is: (TCSS + 1/2) serial root clock cycles for SDR and DDR mode. See Output timing between chip select and SCLK.

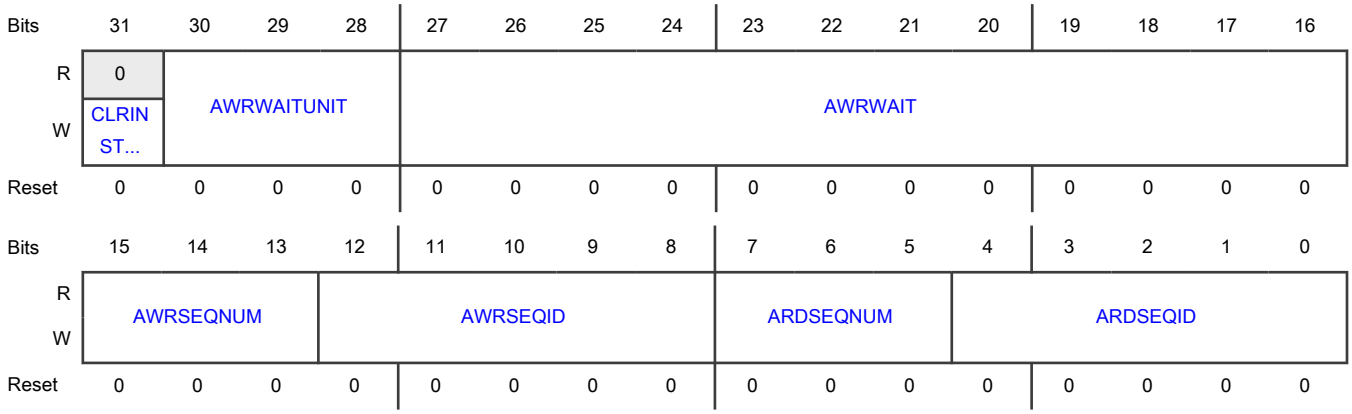
29.8.2.13 Flash Control 2 (FLSHA1CR2 - FLSHB2CR2)

Contains fields to configure AHB bus access. If the four external devices are different types, AHB read and write commands may use different command sequences; AHB bus ready wait time may also differ.

Offset

Register	Offset
FLSHA1CR2	80h
FLSHA2CR2	84h
FLSHB1CR2	88h
FLSHB2CR2	8Ch

Diagram



Fields

Field	Description
31 CLRINSTRPTR	Clear Instruction Pointer Clears the instruction pointer, which is the pointer that JMP_ON_CS saves internally. See Programmable sequence engine. This field is used for AHB read access to external flash memory supporting Execute-In-Place (XIP) mode.
30-28 AWRWAITUNIT	AWRWAIT Unit Configures the unit of AHB write wait time, as the value of AWRWAIT determines, in terms of AHB clock cycles. 000 - 2 001 - 8 010 - 32 011 - 128 100 - 512 101 - 2048 110 - 8192 111 - 32768
27-16 AWRWAIT	AHB Write Wait Configures AHB write wait time, with the AWRWAITUNIT field. Certain devices (such as FPGA) require time to write data into internal memory after the command sequences finished on the FlexSPI interface. If another read command sequence arrives before the current programming finishes internally, the read data may be wrong. This field is used to hold the AHB bus ready for AHB write access, waiting until the programming is finished in the external device. This hold ensures that no AHB read command is triggered before the programming finishes in the external device. The wait cycle between an AHB-triggered command sequence finishing on FlexSPI and the AHB return bus being ready is: AWRWAIT × AWRWAITUNIT.
15-13	Sequence Number for AHB Write-Triggered Command

Table continues on the next page...

Table continued from the previous page...

Field	Description
AWRSEQNUM	Configures the sequence number of an AHB read-triggered command. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash programming access is done via several command sequences. An AHB write command triggers (AWRSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: AWRSEQID + AWRSEQNUM < 32 • Software must ensure that the AWRSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
12-8 AWRSEQID	Sequence Index for AHB Write-Triggered Command
7-5 ARDSEQNUM	Sequence Number for AHB Read-Triggered Command Configures the sequence number of an AHB read-triggered command in the lookup table. For certain flash devices (for example, HyperFlash, HyperRam, and Serial NAND flash), a flash read access is done via several command sequences. An AHB read command triggers (ARDSEQNUM + 1) command sequences to external flash memory each time. FlexSPI executes the sequences in LUT incrementally. **NOTE** • Software should ensure that the last sequence index never exceeds LUT sequence numbers: ARDSEQID + ARDSEQNUM ≤ 32. • Software must ensure that the ARDSEQNUM and LUT fields are configured correctly according to the external device specification. FlexSPI does not check the sequence; it executes the sequences one by one.
4-0 ARDSEQID	Sequence Index for AHB Read-Triggered Command in LUT

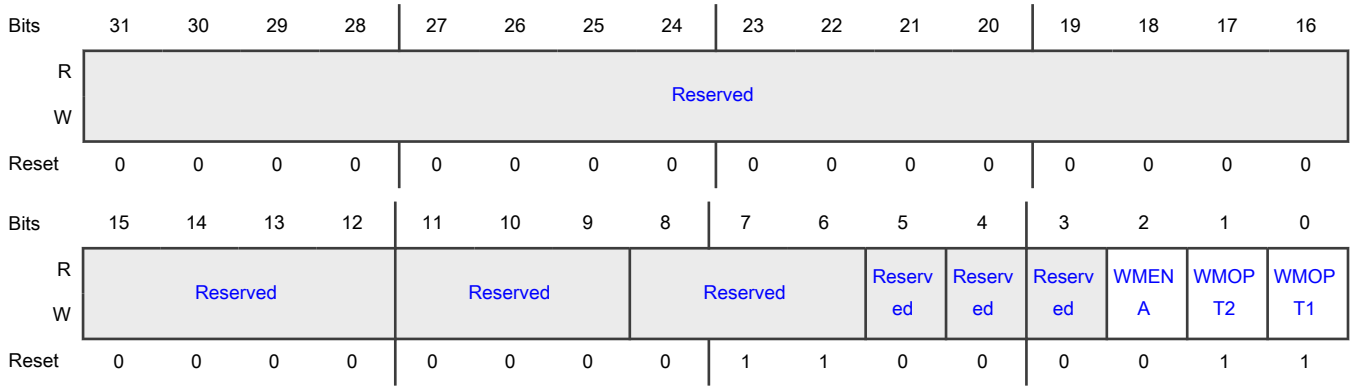
29.8.2.14 Flash Control 4 (FLSHCR4)

Provides configuration for all external devices.

Offset

Register	Offset
FLSHCR4	94h

Diagram



Fields

Field	Description
31-12 —	Reserved
11-9 —	Reserved
8-6 —	Reserved
5 —	Reserved
4 —	Reserved
3 —	Reserved
2 WMENA	Write Mask Enable for Port A Enables write mask for flash device on port A. 0 - Disabled. When writing to external device, DQS(RWDS) pin is not driven. 1 - Enabled. When writing to external device, FlexSPI drives DQS(RWDS) pin as write mask output.
1 WMOPT2	Write Mask Option 2 When using AP memory, used to remove AHB or IP write burst minimum length limitation. When using this field, FLSHCR4[WMOPT1] should be 1. 0 - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is not limited.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst length is limited. The minimum write burst length should be 4.
0 WMOPT1	Write Mask Option 1 Used to remove AHB and IP write burst start address alignment limitation. 0 - When writing to an external device, DQS pin is used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is not limited. 1 - When writing to an external device, DQS pin is not used as write mask. When flash memory is accessed in individual mode, AHB or IP write burst start address alignment is limited.

29.8.2.15 IP Control 0 (IPCR0)

Provides all configuration required for IP commands. Provides the start address for the flash device, instead of the chip address, to be accessed for IP command. FlexSPI determines the chip select automatically according to this start address.

NOTE

- You cannot issue an IP command that crosses flash device boundaries. If you do so, it generates an IPCMDERR interrupt.
- Configure this register before an IP command is triggered.
- Do not change the values in this register while an IP command is in progress.

Offset

Register	Offset
IPCR0	A0h

30-27 —	Reserved
26-24	Sequence Number for IP command: ISEQNUM+1.

Table continues on the next page...

Table continued from the previous page...

Field	Description
ISEQNUM	
23-21 —	Reserved
20-16 ISEQID	Sequence Index in LUT for IP command.
15-0 IDATSZ	Flash Read/Program Data Size (in bytes) for IP command.

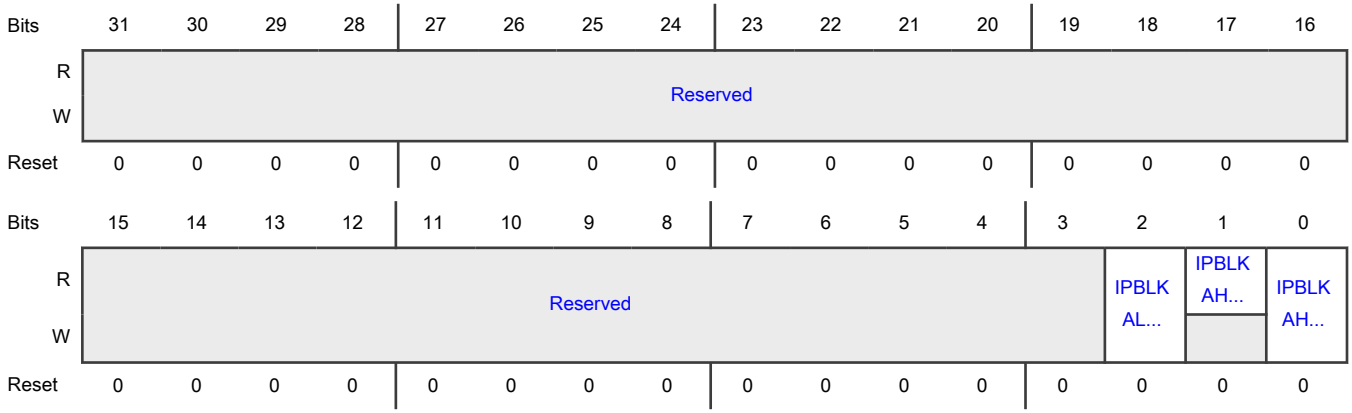
29.8.2.17 IP Control 2 (IPCR2)

Configures whether IP commands can block AHB commands.

Offset

Register	Offset
IPCR2	A8h

Diagram



Fields

Field	Description
31-3 —	Reserved
2	IP Command Blocking All AHB Command Enable 0 - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
IPBLKALLAHB	1 - IP commands block all AHB commands.
1 IPBLKAHBACK	IP Command Blocking AHB Command Acknowledgment Enable 0 - IP commands do not block AHB command acknowledgment. 1 - IP commands block AHB command acknowledgment.
0 IPBLKAHBREQ	IP Command Blocking AHB Command Request Enable 0 - IP commands do not block AHB command requests. 1 - IP commands block AHB command requests.

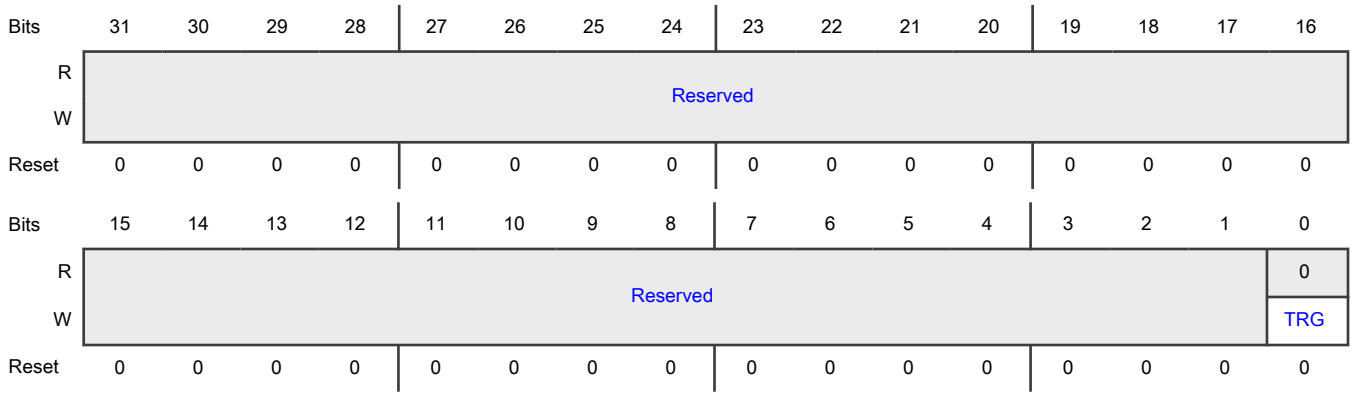
29.8.2.18 IP Command (IPCMD)

Used to trigger an IP command to access external flash device. When the arbitrator grants the IP command, the command is executed on the FlexSPI interface.

Offset

Register	Offset
IPCMD	B0h

Diagram



Fields

Field	Description
31-1 —	Reserved
0 TRG	Command Trigger Triggers an IP command. This field clears automatically after it has been written and always reads as 0.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE You cannot trigger another IP command before the previous IP command finishes on the FlexSPI interface. Software must poll INTR[IPCMDDONE] or wait for this interrupt. 0 - No action 1 - Start the IP command that the IPCR0 and IPCR1 registers define.

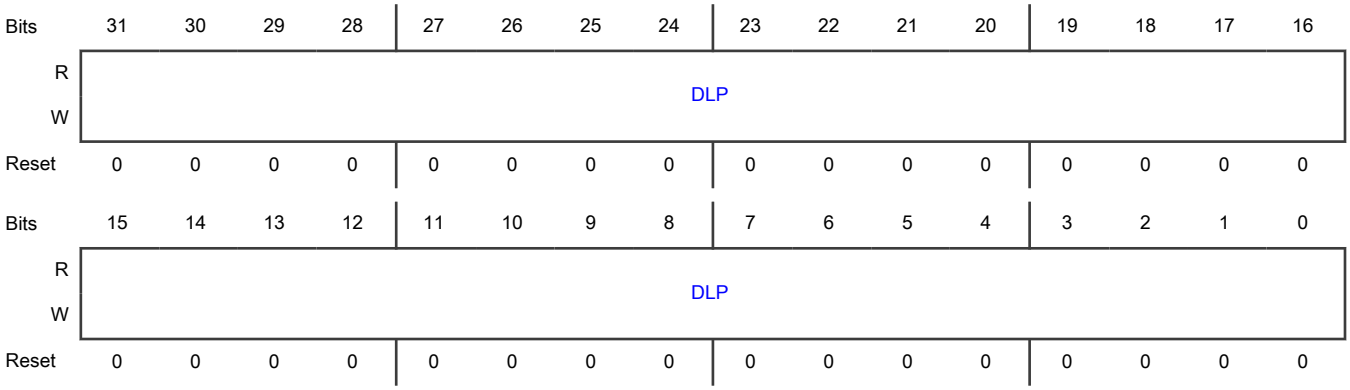
29.8.2.19 Data Learning Pattern (DLPR)

Provides the pattern to be used during Data Learning in FlexSPI.

Offset

Register	Offset
DLPR	B4h

Diagram



Fields

Field	Description
31-0 DLP	Data Learning Pattern The operand in the LEARN_SDR or LEARN_DDR instruction code determines the data learning pattern bit number. This number never exceeds 32 bits. If the operand in the instruction code is greater than 32, a 32-bit pattern is used. See Data learning.

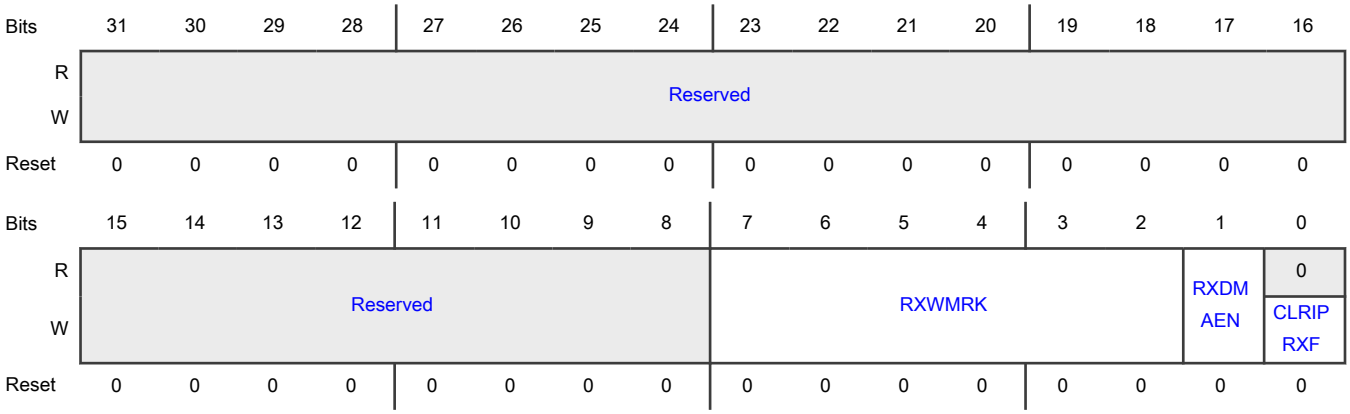
29.8.2.20 IP Receive FIFO Control (IPRXFCR)

Provides the configuration fields for IP receive FIFO management.

Offset

Register	Offset
IPRXFCR	B8h

Diagram



Fields

Field	Description
31-8 —	Reserved
7-2 RXWMRK	IP Receive FIFO Watermark Level Configures the watermark level for the IP receive FIFO. The watermark level is (RXWMRK + 1) × 64 bits. The INTR[IPRXWA] interrupt is set when FlexSPI fills the IP receive FIFO ≥ the watermark level. A DMA request occurs when the fill level is ≥ the watermark level and IPRXFCR[RXDMAEN] = 1. When the fill level is ≥ the watermark level and INTEN[IPRXWAEN] = 1, an INTR[IPRXWA] interrupt is generated. **NOTE** After writing 1 to INTR[IPRXWA] to clear it, the read address should be rolled back to the start address (memory mapped). If the IP bus reads the IP receive FIFO, the read address should roll back to RFDR0. If the AHB bus reads the IP receive FIFO, the read address should roll back to ARDF_BASE.
1 RXDMAEN	IP Receive FIFO Reading by DMA Enable 0 - Disabled. The processor reads the FIFO. 1 - Enabled. DMA reads the FIFO.
0 CLRIPRXF	Clear IP Receive FIFO Clears all valid data entries in IP receive FIFO. Resets the read and write pointers in IP receive FIFO. 0 - No function 1 - A clock cycle pulse clears all valid data entries in IP receive FIFO.

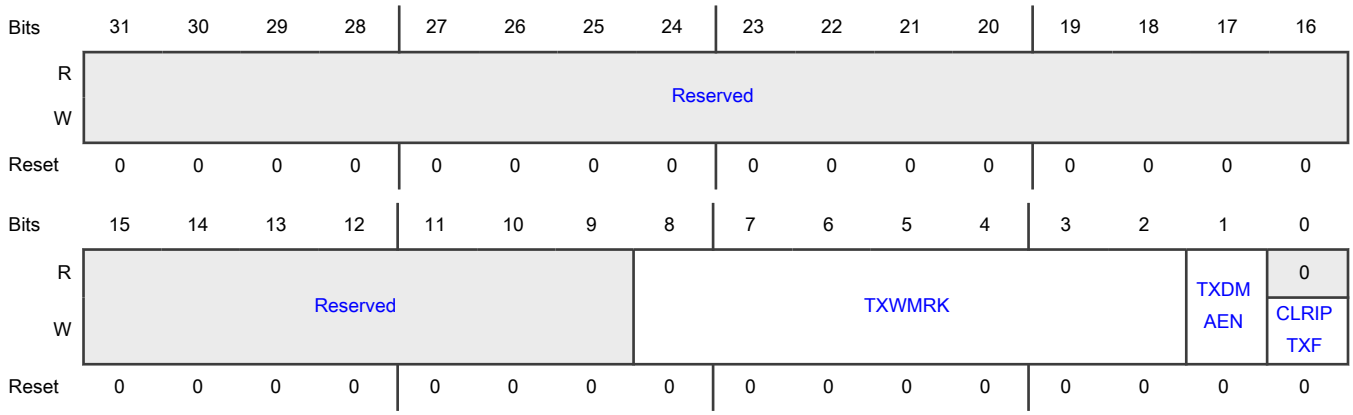
29.8.2.21 IP Transmit FIFO Control (IPTXFCR)

Provides the configuration fields for IP transmit FIFO management.

Offset

Register	Offset
IPTXFCR	BCh

Diagram



Fields

Field	Description
31-9 —	Reserved
8-2 TXWMRK	Transmit Watermark Level Sets the transmit watermark level. The watermark level is (TXWMRK + 1) × 64 bits. INTR[IPTXWE] is set when FlexSPI empties the IP transmit FIFO ≥ the watermark level. When the empty level ≥ the watermark level and IPTXFCR[TXDMAEN] = 1, a DMA request occurs. When the empty level ≥ the watermark level and INTEN[IPTXWEEN] = 1, an INTR[IPTXWE] interrupt is generated. **NOTE** • The watermark level should not be larger than the write window. • The watermark level should not be larger than the IP transmit FIFO size. • The write address to the IP receive FIFO should roll back to the start address of the write window. After pushing the IP transmit fifo, you should write 1 to INTR[IPTXWE] to clear it, which will perform the rollback.
1 TXDMAEN	Transmit FIFO DMA Enable Selects whether DMA or processor fills IP transmit FIFO. 0 - Processor

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - DMA
0 CLRIPTXF	Clear IP Transmit FIFO Clears all valid data entries in IP transmit FIFO. The read and write pointers in IP transmit FIFO are reset. 0 - No function 1 - A clock cycle pulse clears all valid data entries in the IP transmit FIFO.

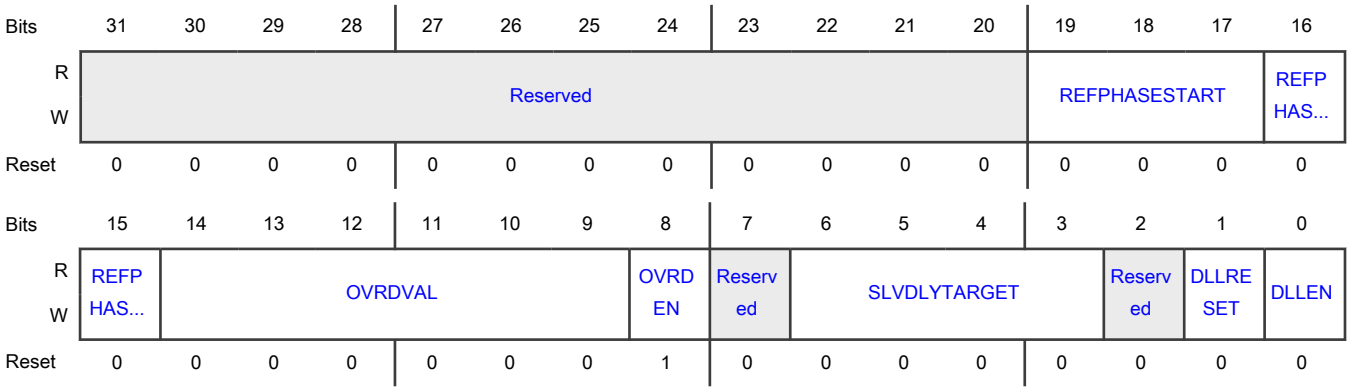
29.8.2.22 DLL Control 0 (DLLACR - DLLBCR)

Configures Flash A and B sample clock DLL.

Offset

Register	Offset
DLLACR	C0h
DLLBCR	C4h

Diagram



Fields

Field	Description
31-20 —	Reserved
19-17 REFPHASEST ART	Reference Clock Delay Line Start Phase If the DLL does not lock well when DLLxCR[DLLEN] is enabled, update the register value of REFPHASESTART. 7h is recommended value. Note that DLLxCR[DLLRESET] is required to be triggered after REFPHASESTART is updated.

Table continues on the next page...

Table continued from the previous page...

Field	Description
16-15 REFPHASEGAP	Reference Clock Delay Line Phase Adjust Gap. REFPHASEGAP setting of 2h is recommended if DLLEN is set.
14-9 OVRDVAL	Target Clock Delay Line Override Value Configures the override value for the target clock line delay cell number. When OVRDEN = 1, the delay cell number in DLL is OVRDVAL + 1. See DLL configuration for sampling.
8 OVRDEN	Target Clock Delay Line Override Value Enable Enables the override value for the target clock line delay cell number. 0 - Disable 1 - Enable
7 —	Reserved
6-3 SLVDLYTARGET	Target Delay Line Configures the target delay line for the target. The delay target for target delay line is: ((SLVDLYTARGET+1) × 1/32 × clock cycle of reference clock (serial root clock). If serial root clock is ≥ 100 MHz, DLLEN is set to 1, OVRDEN is set to 0, then SLVDLYTARGET setting is up to flash parameters used.
2 —	Reserved
1 DLLRESET	DLL reset Forces a DLL reset. The forced reset causes the DLL to lose lock and recalibrate to detect a ref_clock half-period phase shift. The reset action is edge-triggered, so software must write 0 to this field after writing 1 to it (no delay limitation). 0 - No function 1 - Force DLL reset.
0 DLLEN	DLL Calibration Enable Enables DLL calibration. When DLL calibration is disabled, the delay cell number in the target delay line is always 1. When DLLxCR[OVRDEN] = 1, the target delay line is overridden and this field is ignored. 0 - Disable 1 - Enable

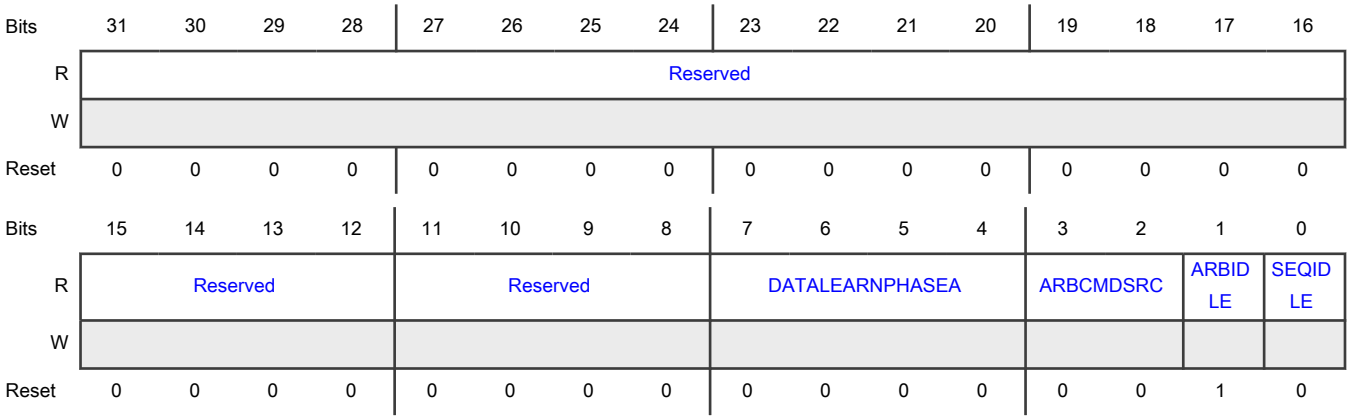
29.8.2.23 Status 0 (STS0)

Indicates the status of the internal state machine.

Offset

Register	Offset
STS0	E0h

Diagram



Fields

Field	Description
31-12 —	Reserved
11-8 —	Reserved
7-4 DATALEARNPHASEA	Data Learning Phase Selection on Port A Indicates the sampling clock phase selection on Port A after data learning. There are 16 clock phases for the sampling clock that the delay cell line generates. When data learning is not enabled, the default clock phase 0 is used to sample flash read data. When data learning is enabled and a LEARN_SDR or LEARN_DDR instruction has executed correctly, FlexSPI determines the correct clock phase to sample read data. See Data learning.
3-2 ARBCMDSRC	ARB Command Source Indicates the trigger source of current command sequence that the arbitrator has granted. When ARB_CTL is not busy (STS0[ARBIDLE] = 1), the value of this field does not matter. 00 - Trigger source is AHB read command. 01 - Trigger source is AHB write command. 10 - Trigger source is IP command (by writing 1 to IPCMD[TRG]). 11 - Trigger source is a suspended command that has resumed.
1	ARB_CTL State Machine Idle

Table continues on the next page...

Table continued from the previous page...

Field	Description
ARBIDLE	Indicates whether the state machine in ARB_CTL is idle, or a command sequence that the arbitrator granted has not finished on the FlexSPI interface. When idle, no transaction is occurring on the FlexSPI interface (STS0[SEQIDLE] = 1). When waiting for the FlexSPI controller to become idle, poll this field instead of STS0[SEQIDLE]. 0 - Not idle 1 - Idle
0 SEQIDLE	SEQ_CTL State Machine Idle Indicates whether the state machine in SEQ_CTL is idle, or a command sequence is executing on the FlexSPI interface. 0 - Not idle 1 - Idle

29.8.2.24 Status 1 (STS1)

Indicates the error code of the AHB or IPS interface error response.

Offset

Register	Offset
STS1	E4h

7-2 ASLVSEL	Flash A Sample Clock Target Delay Line Delay Cell Number Indicates the sample clock target delay line delay cell number for Flash A. There are 0-63 phases. • 000001b - Indicates lock phase 0. • 100000b - Indicates lock phase 63.
1 AREFLOCK	Flash A Sample Clock Reference Delay Line Locked 0 - Not locked 1 - Locked
0 ASLVLOCK	Flash A Sample Target Delay Line Locked 0 - Not locked 1 - Locked

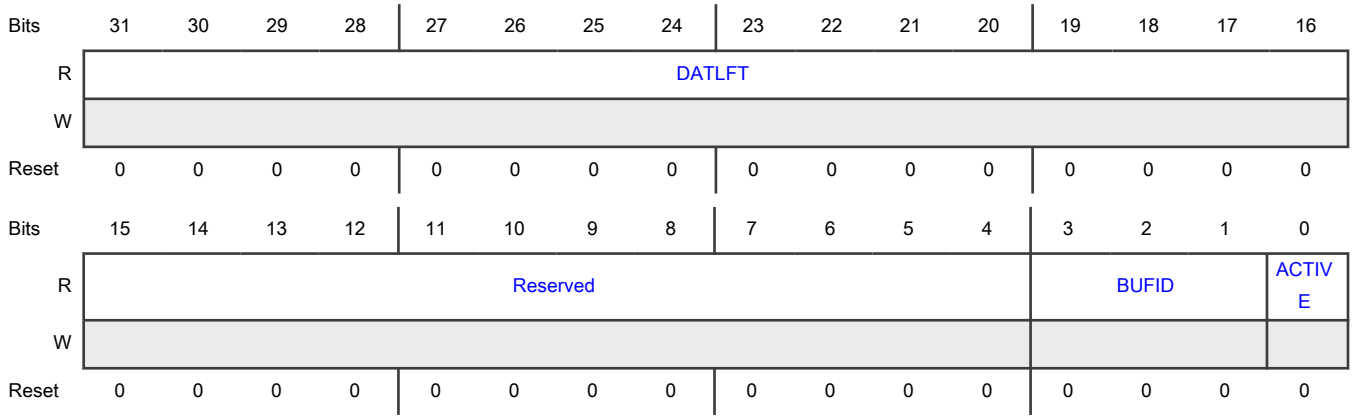
29.8.2.26 AHB Suspend Status (AHBSPNDSTS)

Indicates the status of suspended AHB read prefetch command sequence. When an IP or AHB command is triggered while the arbitrator processes an AHB read sequence (prefetching additional data not for current AHB burst), the prefetch sequence is suspended. When there are no longer transactions on FlexSPI, the prefetch sequence may be resumed. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence already suspended, the previous suspended sequence is removed and never resumed. See Command abort and suspend.

Offset

Register	Offset
AHBSPNDSTS	ECh

Diagram



Fields

Field	Description

Fields

Field	Description
31-0 RXDATA	Receive Data Contains receive data. See Reading data from IP receive FIFO.

29.8.2.30 IP TX FIFO Data a (TFDR0 - TFDR31)

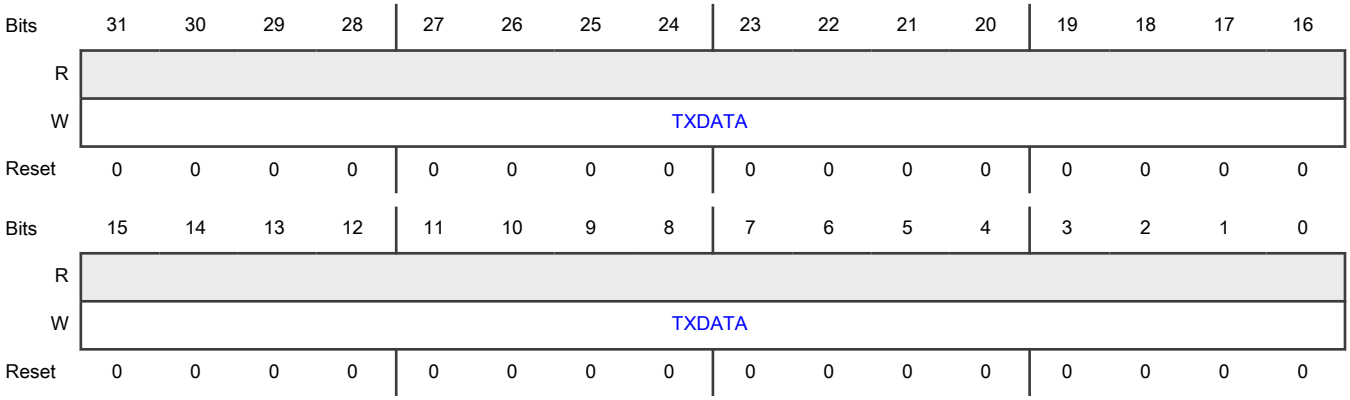
Provides write access to IP transmit FIFO via IPS bus.

Offset

For a = 0 to 31:

Register	Offset
TFDRa	180h + (a × 4h)

Diagram



Fields

Field	Description
31-0 TXDATA	Transmit Data Contains transmit data. See Writing data to IP transmit FIFO.

29.8.2.31 Lookup Table a (LUT0 - LUT127)

Contains a lookup table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI fetches the command sequence from LUT when an IP or AHB command is triggered. There are 32 command sequences in LUT. See Lookup table (LUT) and Programmable sequence engine.

NOTE

LUT is implemented as memory, so the reset value is unknown.

Offset

For a = 0 to 127:

Register	Offset
LUTa	200h + (a × 4h)

11-0 —	Reserved

29.9 AHB memory map definition

This section describes FlexSPI module AHB memory map in detail.

29.9.1 AHB memory map for serial flash memory and RAM access

AHB read and write access for serial flash and RAM memory are mapped to a specific address range. See the system memory map for specific address ranges supported.

AHB bus features supported for serial flash and RAM memory reading:

- Cacheable and non-cacheable access
- Prefetch enable and disable
- Burst size: 8, 16, 32, 64 bits
- All burst types: types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

AHB bus features for Serial RAM writing:

- Bufferable and Non-Bufferable access
- Burst size: 8, 16, 32, 64 bits
- All burst types: SINGLE, INCR, WRAP4, INCR4, WRAP8, INCR8, WRAP16, INCR16

See Flash memory access via AHB command for details about AHB access to serial flash memory and RAM.

29.9.2 AHB Memory Map for IP RX FIFO read access

See chip-specific section for the address range mapped for AHB read access.

AHB Bus feature supported for IP RX FIFO reading:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Reading data from IP receive FIFO for more details about IP RX FIFO reading.

29.9.3 AHB Memory Map for IP TX FIFO write access

See chip-specific section for the address range mapped for AHB write access.

AHB Bus feature supported for IP TX FIFO writing:

- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Writing data to IP transmit FIFO for more details about IP TX FIFO filling.

Chapter 30
Ultra Secured Digital Host Controller (uSDHC)

30.1 Chip-specific USDHC information

Table 201. Reference links to related information

Topic	Related module	Reference
Full description	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing

The chip includes three instances of USDHC that provide simultaneous support for all three of 1x eMMC, 1x SD Card and 1x SDIO (for WIFI connectivity).

NOTE

Write/Read to the Reserved locations will not generate a transfer error.

NOTE

i.MX91 supports mechanical reset to reset eMMC, if uSDHC1 external signal RESET_B is used to reset the eMMC, only 1-bit/4-bit data transfer can be used.

30.2 Overview

uSDHC provides the interface between the host system and the eMMC, SD card, and SDIO as shown in Figure 115. The module acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO by sending commands and performing data accesses to/from the cards. It handles the SD card/SDIO/eMMC protocols at the transmission level.

Table 202. Updated terms

Updated term	Deprecated term
Target	Slave

Initiator	Master (related to AXI bus)
Placeholder	Dummy

30.2.1 Block diagram

The following figure illustrates the block diagram for uSDHC. Dual port SRAM is FIFO for write/read. For more information, see Data buffer.

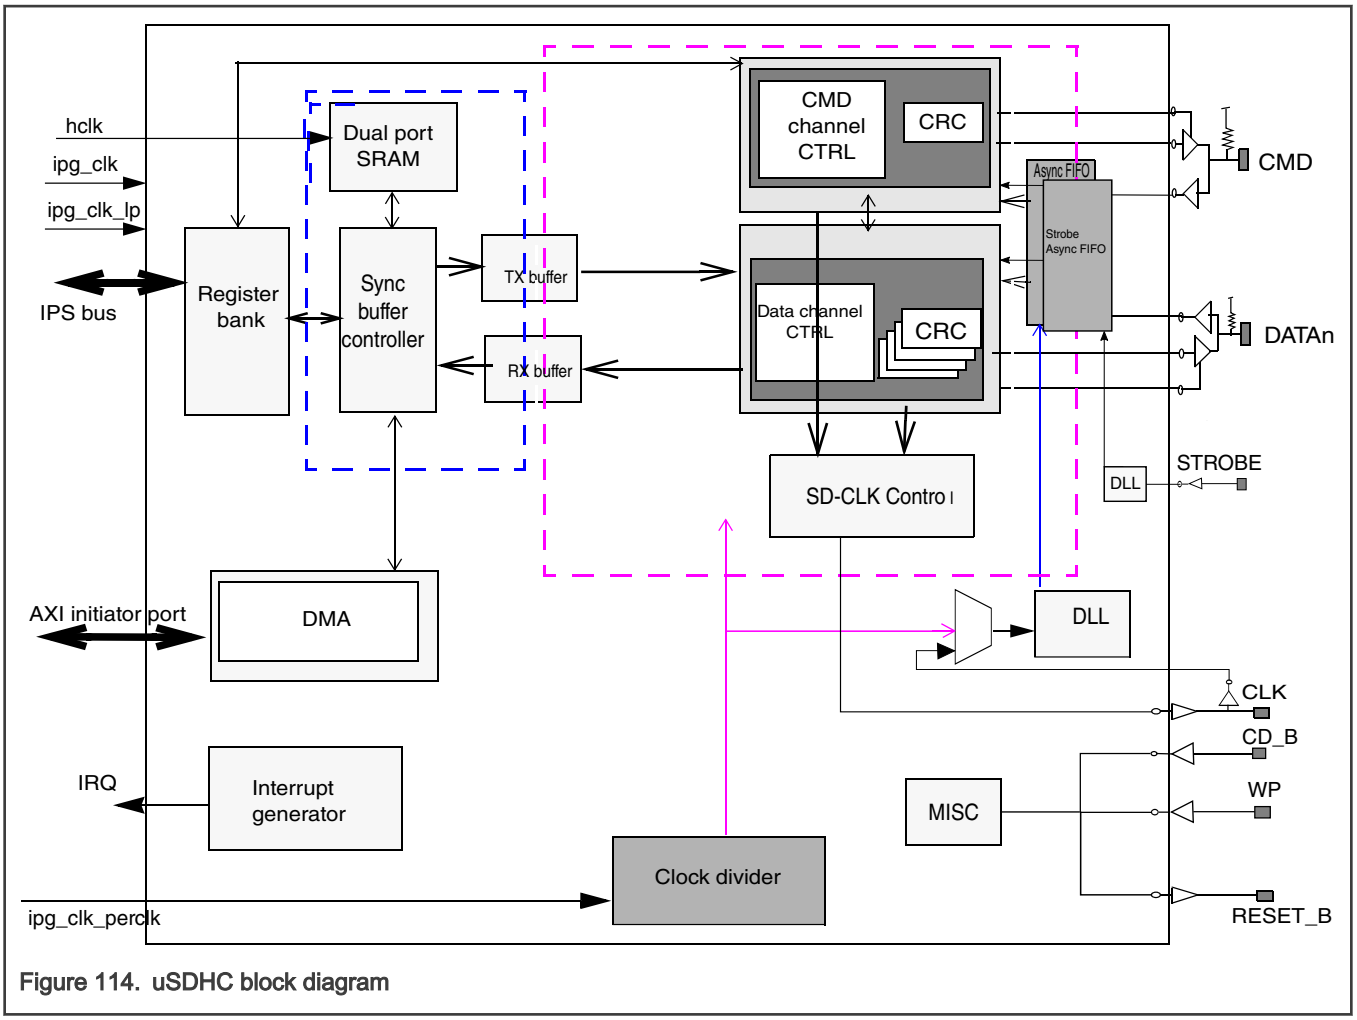

Figure 114. uSDHC block diagram

The figure below shows the System connection of uSDHC:

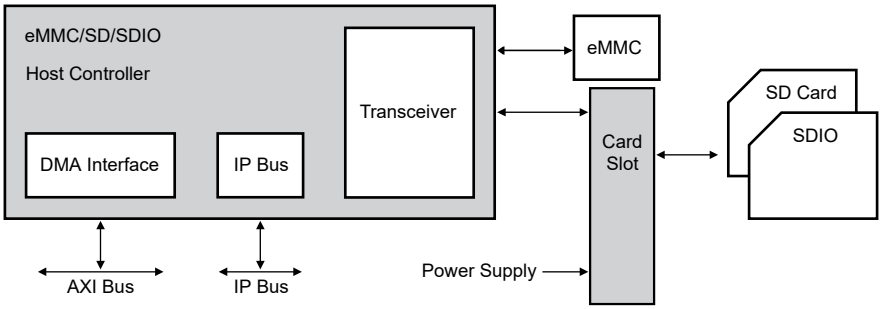

Figure 115. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Embedded MultiMediaCard (eMMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous eMMC were based on a 7-pin serial bus with a single data pin, while the new high speed eMMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.
- The Secure Digital Card (SD) is an evolution of the old eMMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic

devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old eMMC (with some additions).

- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI (Secure Digital Music Initiative) standard. The I/O card, which is also known as SDIO, provides high-speed data I/O with low-power consumption for mobile electronic devices.

30.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, eMMC, MMC plus, and MMC RS cards
- For card bus clock frequency: See the product Data Sheet for the clock frequency of each supported mode.
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit eMMC modes
  - Up to 832 Mbps of data transfer for SDIO using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for eMMC using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for eMMC using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer for memory device
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Supports internal DMA capabilities
- Supports voltage selection by configuring vendor-specific register bit VEND_SPEC[VSELECT]
- Supports Advanced DMA to perform linked memory access
- Supports Command Queue mechanism

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

30.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

30.3.1 Modes and operations

30.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- eMMC 1-bit
- eMMC 4-bit
- eMMC 8-bit
- Identification mode (up to 400 kHz)
- eMMC full-speed mode (up to 26 MHz)
- eMMC high-speed mode (up to 52 MHz)
- eMMC HS200 mode (up to 200 MHz)
- eMMC HS400 mode (200 MHz both edges)
- eMMC DDR mode (52 MHz both edges)
- SD card or SDIO full-speed mode (up to 25 MHz)
- SD card or SDIO high-speed mode (up to 50 MHz)
- SD card or SDIO UHS-I mode (up to 208 or 100 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

30.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the AXI initiator clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme as buffer control and buffer RAM wrapper.

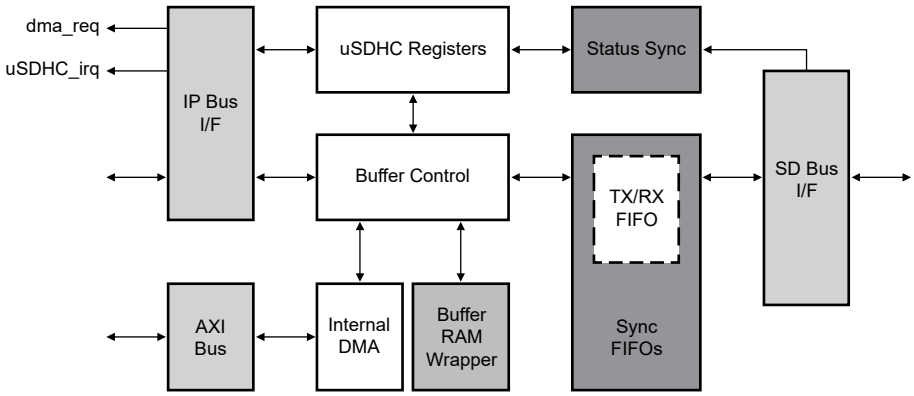

Figure 116. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus.

For a read operation, when there are more words in the buffer than the amount set in WTMK_LVL[RD_WML], the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

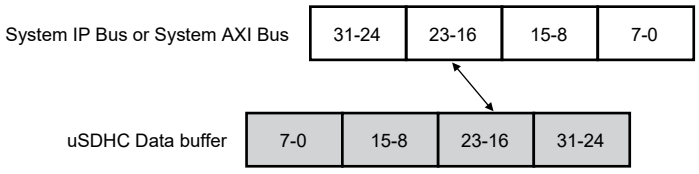

Figure 117. Data swap between system bus and uSDHC data buffer in the byte little endian mode

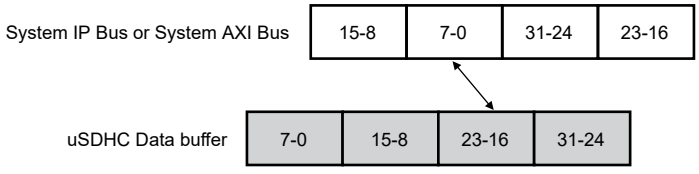

Figure 118. Data swap between system bus and uSDHC data buffer in half word big endian mode

30.3.2.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in WTMK_LVL[WR_WML] and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC stops the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

30.3.2.2 Read operation sequence

There are 2 ways to read data from the buffer when the data is received from the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC stops the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any read transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

30.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes). That means, the largest block size is 512 bytes.

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

30.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add placeholder data in the last block to fill the block size. For option 2, the card must manage the removal of the placeholder data. Only for write, uSDHC sends data to the card.

See Figure 119 for an example showing the division of large data transfers, assuming a kind of WLAN SDIO that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

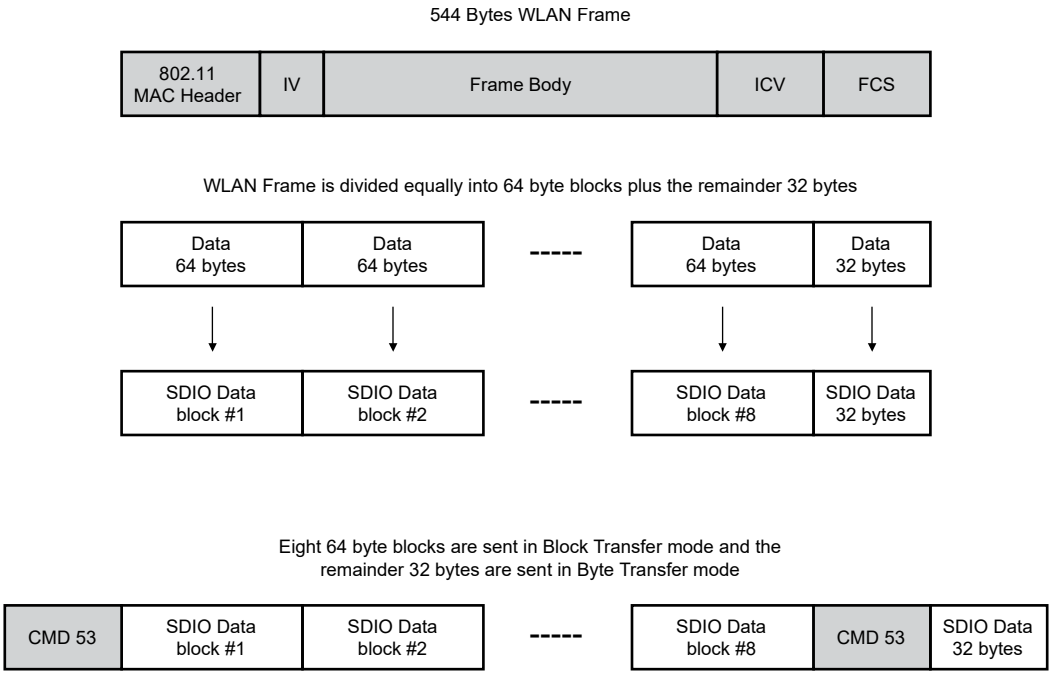

Figure 119. Example for dividing large data transfers

30.3.3 DMA AXI interface

The internal DMA implements a DMA engine and the AXI initiator. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See Figure 120 for an illustration of the DMA AXI interface block.

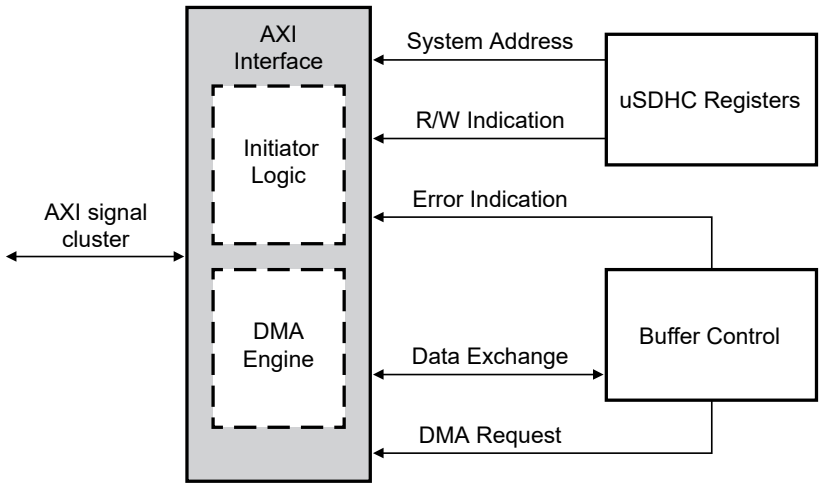

Figure 120. DMA AXI interface block

30.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface.

The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

30.3.3.2 AXI initiator interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

30.3.3.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location (word aligned) and any size (less than 64 KB) can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

30.3.3.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See Figure 121 for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 121. Format of the ADMA1 descriptor table

See Figure 122 for the concept and access method of the descriptor table for ADMA1.

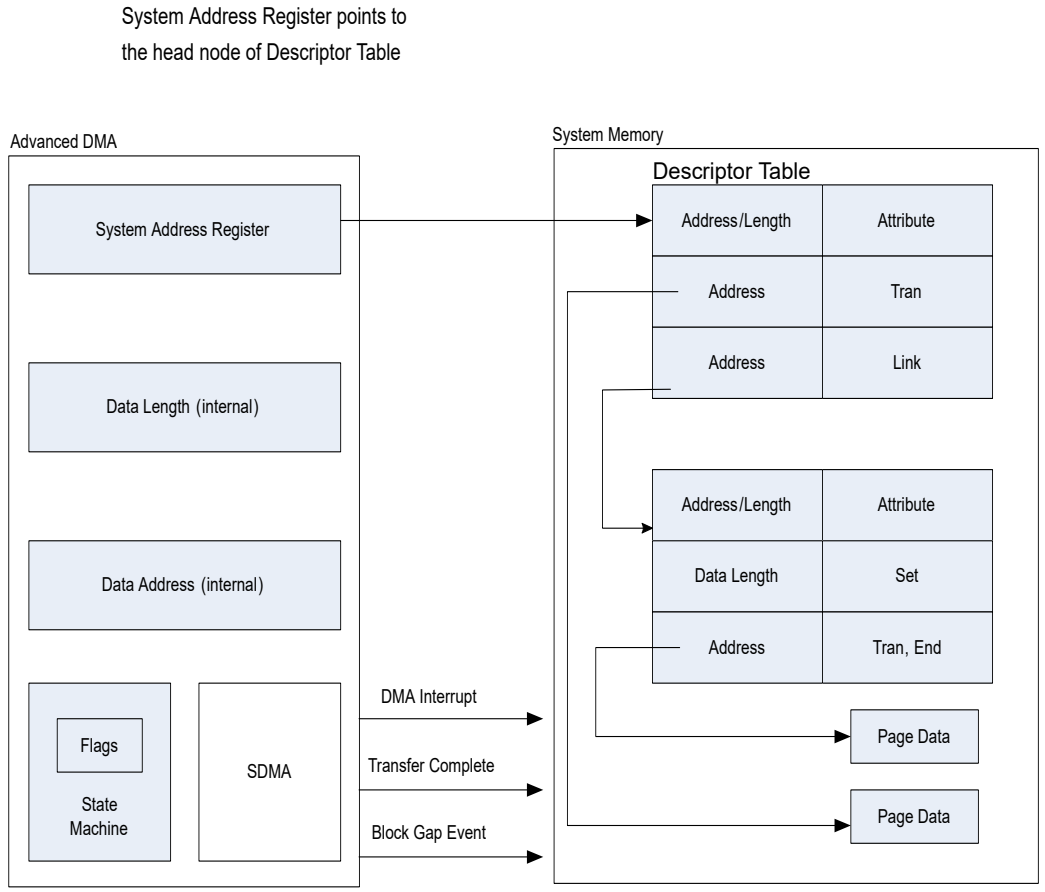

Figure 122. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 123. Format of the ADMA2 descriptor table

See Figure 124 for the concept and access method of the descriptor table for ADMA2.

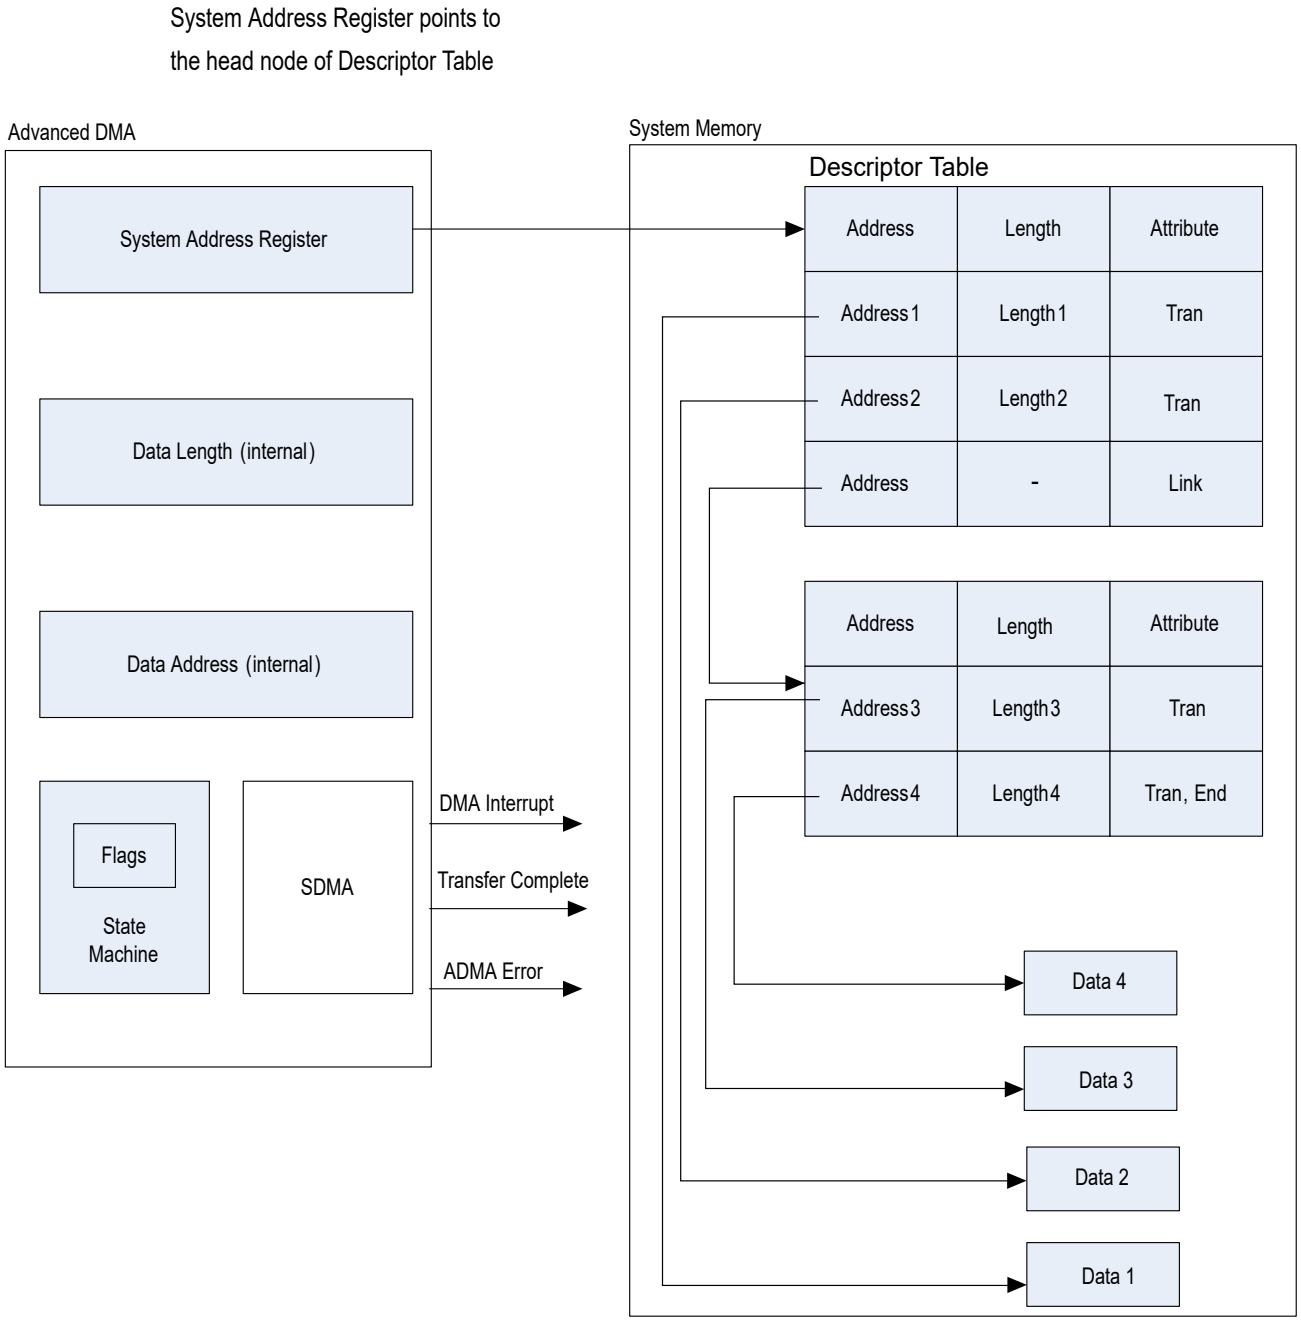

Figure 124. Concept and access method of the ADMA2 descriptor table

30.3.3.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer descriptor is complete, which means the data communication between the host system and uSDHC is finished.
- Link type of descriptor: interrupt is generated when new descriptor address is set.

- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer descriptor is complete, which means the data communication between the host system and uSDHC is finished.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

30.3.3.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

30.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See Figure 125 for the block diagram.

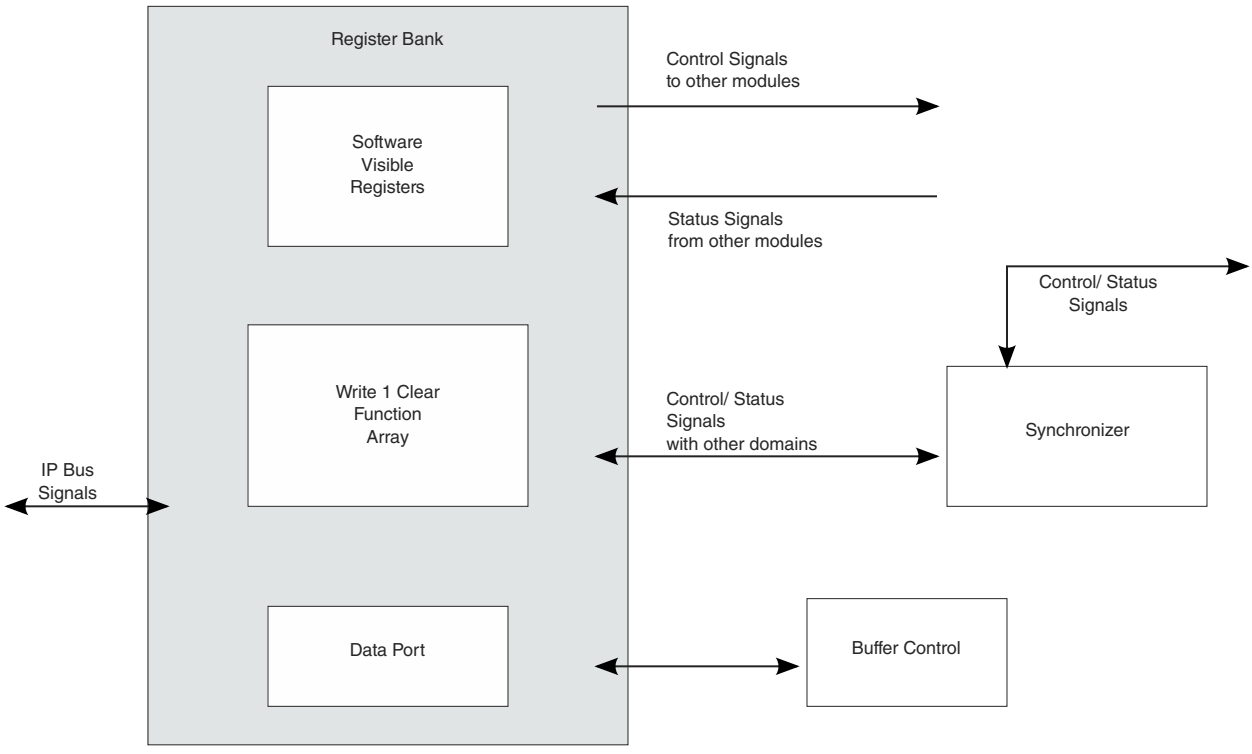

Figure 125. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

30.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from SDIO
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four sub-modules:

- SD control misc
- Command control
- Data control
- Clock control

30.3.4.2 SD control miscellaneous

In the SD control miscellaneous unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is activated as '1', writes to memory and combo cards are ignored by cards. In that case, there is no need to send write command anymore.

30.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

30.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See Figure 126 for an illustration of the structure for the Command CRC shift register.

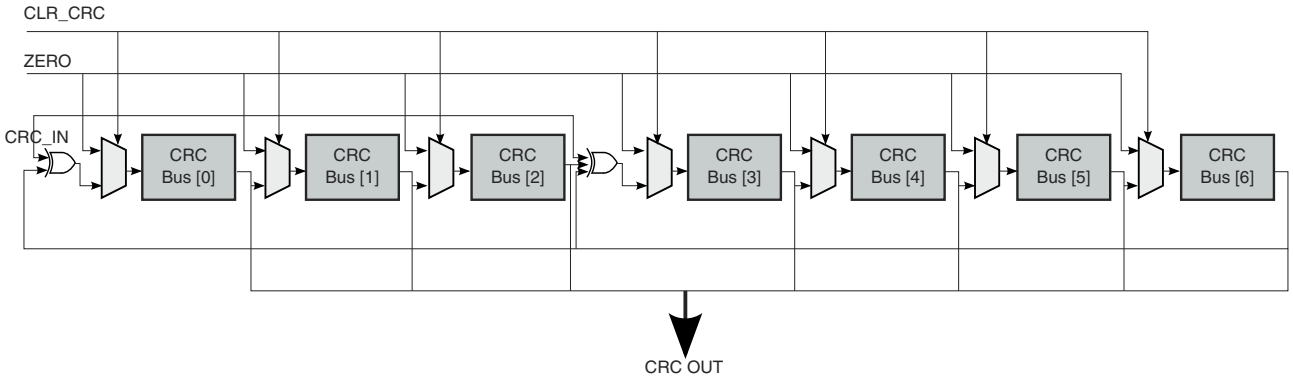

Figure 126. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

30.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

30.3.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. It is controlled by SoC pad or other logic. When there is no card on the eMMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

30.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

30.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

30.3.7 eMMC fast boot

The Embedded MultiMediaCard (eMMC4.3 or later) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 or later specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the uSDHC controller (eMultiMediaCard host) can read boot data from the target (eMMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for target), before issuing CMD1.

NOTE

For the eMMC4.3 setting, please see the eMMC4.3 specification.

30.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the target recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the target starts to send the first boot data to the uSDHC controller on the DATA line(s). The uSDHC controller must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the target has to send acknowledge pattern '010' to the uSDHC controller within 50ms after the CMD line goes low. If boot acknowledge is disabled, the target does not send out acknowledge pattern '010'.

The uSDHC controller can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the uSDHC controller. After the boot operation is executed, the target gets ready for the CMD1 operation and the uSDHC controller needs to start a normal eMMC initialization sequence by sending CMD1.

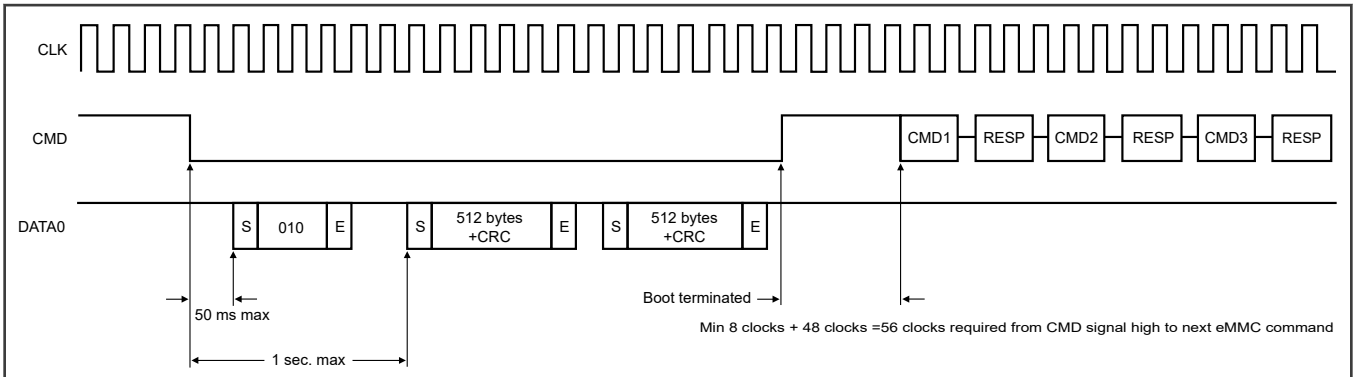

Figure 127. Embedded MultiMediaCard state diagram (normal boot mode)

30.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the target recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the target starts to send the first boot data to the uSDHC controller on the DATA line(s).

If boot acknowledge is enabled, the target must send the acknowledge pattern '010' to the uSDHC controller within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the target does not send out acknowledge pattern '010'.

The uSDHC controller can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the uSDHC controller. After the boot operation is executed, the target gets ready for the CMD1 operation and the uSDHC controller needs to start a normal eMMC initialization sequence by sending CMD1.

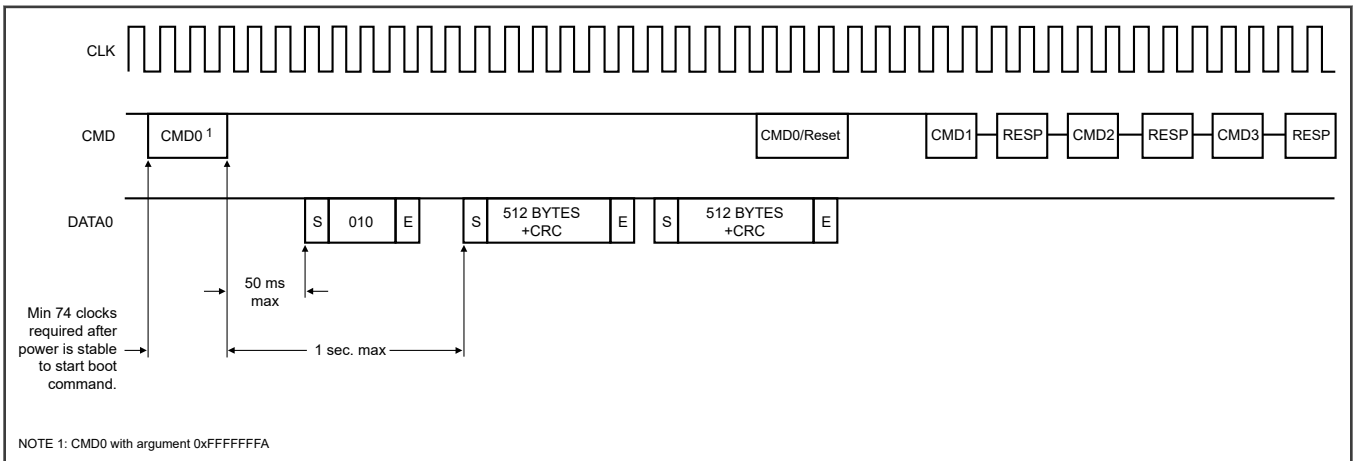

Figure 128. Embedded MultiMediaCard state diagram (alternative boot mode)

30.3.8 Commands for SD card, SDIO, and eMMC

A table containing the list of commands for the eMMC/SD card/SDIO is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the SD card, SDIO, and eMMC:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 203. Commands for eMMC/SD card/SDIO

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all eMMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all eMMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:16] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:16] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.

Table continues on the next page...

Table 203. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The Embedded MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:16] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission. Only supported by memory device.
CMD13	ac	[31:16] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:16] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.

Table continues on the next page...

Table 203. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22	Reserved				
CMD23	ac	[31] reliable write request [30:16] set to 0 [15:0] number of blocks	R1	SET_BLOCK_COUNT	Defines the number of blocks (read/write) and the reliable writer parameter (write) for a block read or write command.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.

Table continues on the next page...

Table 203. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.

Table continues on the next page...

Table 203. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD39	ac	[31:16] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the eMMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				

Table continues on the next page...

Table 203. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers. MMC command defined by CE-ATA Digital Protocol.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer. MMC command defined by CE-ATA Digital Protocol.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.

Table continues on the next page...

Table 203. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for eMMC and SD cards. For eMMC, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed eMMC and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed eMMC. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 204.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 204. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

30.3.9 SDIO interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

30.3.9.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from SDIO, until the interrupt service is finished to clear the interrupt.

30.3.9.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Specification v1.10 for further information about the SDIO interrupt.

30.3.9.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from SDIO does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from SDIO and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See Figure 129 for an illustration of the SDIO interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

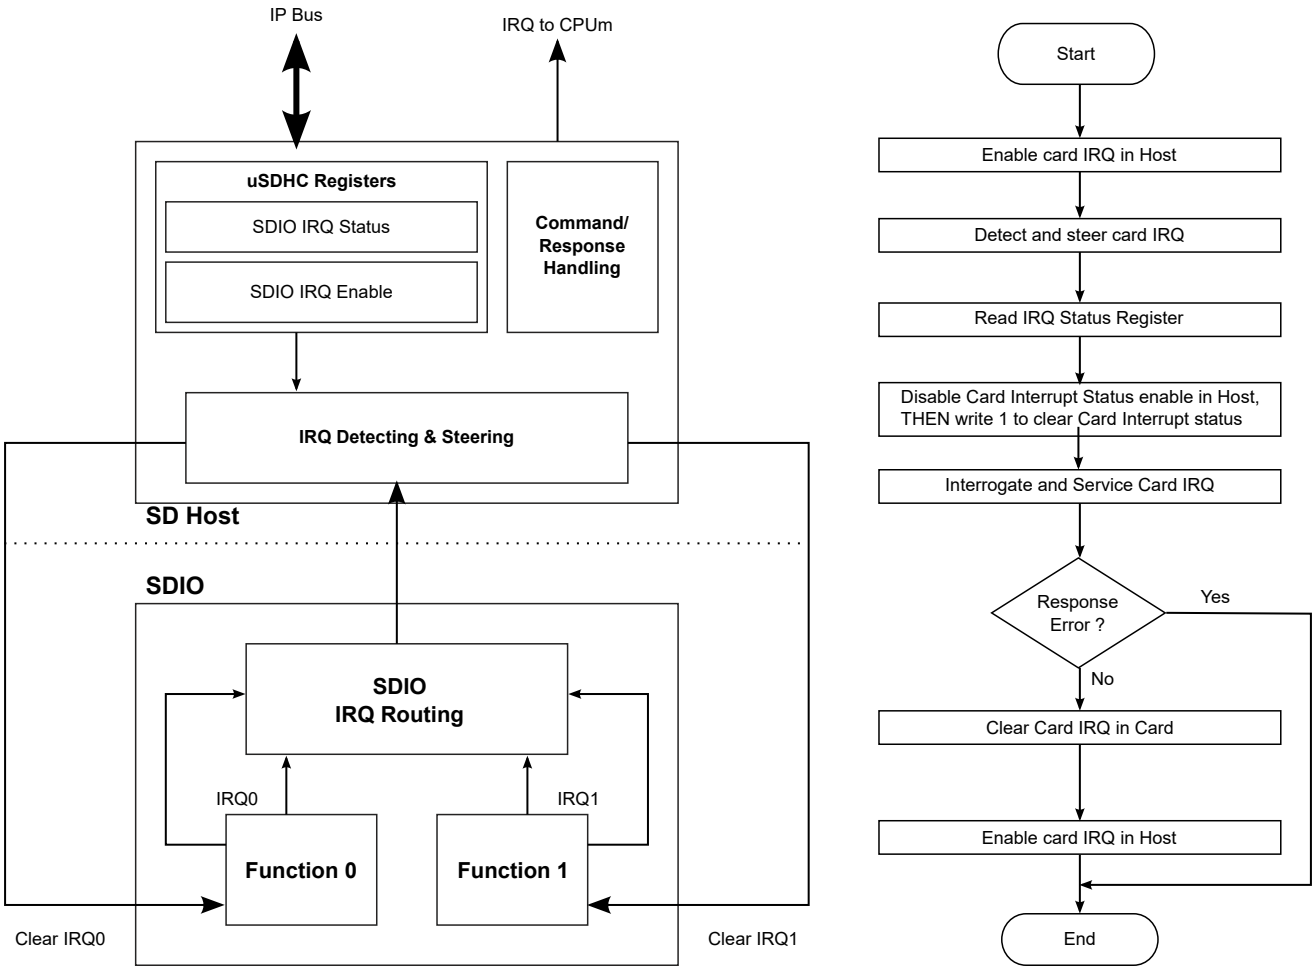

Figure 129. Card interrupt scheme, card interrupt detection, and handling procedure

30.3.10 Speed mode selection

To switch to HS200 or HS400 from High Speed (26 MHz-52 MHz), see the procedure below.

NOTE

While the actual timing change is done, the behavior of any command given (such as CMD13) cannot be guaranteed due to the asynchronous operation. Therefore, you must not use CMD13 to check the busy completion of the timing change indication. In case, CMD13 is used, the host must ignore CRC errors, if appear.

The max frequency for HS200 mode and HS400 mode could be slower than 200 MHz based on the chip implementation, you must set the target frequency for these two speed modes accordingly. Following sections describe the mode selections for HS200 mode and HS400 mode in detail.

30.3.10.1 HS200 mode selection

To switch to HS200, the Driver must perform the following steps:

1. Select the chip (through sending CMD7) and make sure it is unlocked (through CMD42).
2. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate if the chip supports HS200 at the IO voltage appropriate for both host and chip (through CMD8).
3. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip Driver Strengths (through CMD8). The default setting is 50 Ohm. The Host Designer might simulate its specific system, using a device driver models. Host can select the optimal Driver Type that might drive the host system load at the required operating frequency with the minimal noise generated.

   NOTE

   This step can be skipped if changes of Driver strength is not needed.

4. Check the setting of PROT_CTRL[DTW], make sure the data transfer width is set as expected.

   Make sure the I/O pad voltage is 1.8V and corresponding drive strength is set to proper value.

   Set HS200 bit and Driver Strength value in the HS_TIMING [185] field of the Extended CSD register by issuing CMD6. If the host attempts to write an invalid value, the HS_TIMING byte is not changed, the HS200 interface timing is not enabled, the Driver Strength is not changed, and the SWITCH_ERROR field is set. After the chip responds with R1, it might assert Busy signal. Once the busy signal gets de-asserted, the host may send a SEND_STATUS Command (CMD13) using the HS200 timing and after it receives a Trans State indication and No Error it means that the chip is set to HS200 timing and the Driver Strength is set to the selected settings.
5. At this point, the host can set the frequency to ≤ 200 MHz.
6. The host might invoke the HS200 standard tuning procedure, by sending CMD21 to the chip.

NOTE

The host must switch to the required bus width before starting the tuning operation to allow the tuning sequence to be done using the proper bus operating conditions.

30.3.10.2 Standard tuning procedure

By default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using the HS200, HS400, SDR104, or SDR50 modes, the Host Driver executes the tuning procedure at the mode switch sequence.

1. Issue uSDHC SW reset, set SYS_CTRL[RSTT] to 1.
2. Clear VEND_SPEC[FRC_SDCLK_ON] to 0.
3. Clean the history status by following these steps:
   a. Clear AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 0.

b. Read Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS) until AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] reads 0.

c. Write 1 to clear INT_STATUS[BRR].

4. Set TUNING_CTRL to 0x01312880 to enable the standard tuning and disable the CMD line check.
5. Start the tuning procedure by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 1.
6. Issue CMD19(SD) / CMD21(eMMC) with the proper Command Transfer Type (CMD_XFR_TYP) and Mixer Control (MIX_CTRL) settings.
7. Wait for uSDHC BRR (Buffer Read Ready) interrupt signal is 1.
8. Check AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 1, write 1 to clear INT_STATUS[BRR] and then repeat steps 6~7. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 0, standard tuning has completed, or the tuning has not completed within 40 attempts. The Host Driver might abort this loop if the number of loops exceeds 40 or 150 ms timeout occurs. In this case, a fixed sampling clock should be used (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0).
9. Sampling Clock Select (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]) is valid after AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] has changed from 1 to 0.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 1, indicates tuning procedure passed.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0, indicates tuning procedure failed. The tuning result is applied to the delay chain, CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) [30:16], upon the successful tuning procedure completion.
10. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

While the tuning sequence is being performed, the Host Controller does not generate interrupts (including Command Complete), except Buffer Read Ready. CMD19 response errors are not indicated.

Writing AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] to 0 forces the Host Controller to use a fixed sampling clock and resets the tuning circuit of the Host Controller.

NOTE

- There could be slight difference on delay cell delay in each project, and this difference can lead to different loop number needed. TUNING_CTRL[TUNING_STEP] can be used to control how may taps are to be added for each step.
- Manual tuning might be required in cases where standard tuning is not able to close passing window with CMD19/21 transfer fail.

30.3.10.3 Manual tuning procedure

Manual tuning controls more details in the tuning procedure, and some corner cases. Manual tuning provides control to tuning start point, tuning steps, and delay chains. To start manual tuning:

1. Clear TUNING_CTRL[STD_TUNING_EN] to 0.
2. Clear VEND_SPEC[FRC_SDCLK_ON] and MIX_CTRL[FBCLK_SEL] to 0, set MIX_CTRL[SMP_CLK_SEL] and MIX_CTRL[EXE_TUNE] to 1 to start tuning.
3. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
4. Config delay chain, CLK_TUNE_CTRL_STATUS[DLY_CELL_SET_PRE] with the valueA.

NOTE

The valueA must start from 0.

5. Set SYS_CTRL[RST_FIFO] to 1 and wait for self-clear.
6. Send CMD19/21 to card.

7. Poll for CC, CIE, CEBE, CCE and CTOE of Interrupt Status (INT_STATUS) assertion.
8. Poll for TC, DEBE, DCE and DTOE of Interrupt Status (INT_STATUS) assertion.
9. Check TP of Interrupt Status (INT_STATUS); TP = 1 & no command/data error indicates the current CMD19/21 transfer is passed; otherwise, indicates failed.
10. If TP = 0 or command/data error is observed, increase the valueA with the required tuning step(1 to 127) and repeat steps 3~9.
11. If TP = 1 & no command/data error is met after a loop with TP=0 (or command/data error), save the current valueA as value_start. Increase valueA with the required tuning step, and repeat steps 3~9 until TP = 0 (or command/data error) again. Save the current valueA as value_end.
12. Clear MIX_CTRL[EXE_TUNE] to 0.
13. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
14. Set MIX_CTRL[SMP_CLK_SEL] to 1.
15. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with the output of expression {[(((value_start+value_end)/2)< < 8)& 0xffffff00] -0x300 } | 0x33.
16. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the previous step is read.
17. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

The manual tuning procedure defines a passing window, inside which the tuned clock can capture the correct data, and delay chain is to be configured as centered within the passing window.

It is not a fixed flow as the standard tuning. Any step can be changed based on the real case. In cases where passing window is not closed with a tuning fail, the center of the passing region must be applied for the delay chain setting. In cases where two passing windows separated by tuning fail(s) is observed, the center of the first passing window must be applied for the delay chain setting.

NOTE

Both the standard tuning and manual tuning are only for tuning of SD_CLK, cannot be used to tune STROBE clock of HS400 and HS400 enhanced mode.

30.3.10.4 Switch to HS400 mode

The valid IO voltage for HS400 is 1.8 V. The bus width is set to only DDR 8bit in HS400 mode. HS400 supports the same commands as DDR52. To switch to HS400 mode, the host must perform the following steps:

1. Initialize chip with “Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the chip is set as the default "Backward Compatible Timing".
2. Select the chip with CMD7.
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the chip supports HS400 by sending CMD8.
4. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip's Driver Strengths by sending CMD8.

NOTE

You may skip this step if changes of driver strength is not needed.

5. Set the "Selected Driver Strength" parameter in the HS_TIMING [185] field of the Extended CSD register to the appropriate driver strength for HS400 operation and set the "Timing Interface" parameter to 0x2 to switch to HS200 mode with CMD6. Send CMD13 to make sure mode switch to HS200 mode has been successfully done.

6. Perform the tuning procedure (standard or manual) at the HS400 target operating frequency, save the tuning result (CLK_TUNE_CTRL_STATUS[30:16]), clear TUNING_CTRL[STD_TUNING_EN] to 0, set SYS_CTRL[RSTT] to 1 and wait for self-clear.

   NOTE

   Tuning procedure in HS200 mode is required to synchronize the command response on the CMD line to CLK for HS400 operation.

7. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode with CMD6 and then set the clock frequency to a value not greater than 52 MHz.
8. Set BUS_WIDTH[183] to 0x06 to select the dual data rate x8 bus mode. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
9. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6. Set the MIX_CTRL[DDR_EN] and MIX_CTRL[HS400_MODE] to 1 to enable HS400 mode in controller.
10. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with saved tuning result value of 0x68 from standard tuning flow in step 6).
11. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the step 10 is read.
12. Set MIX_CTRL[SMP_CLK_SEL] to 1’b1 to apply the delay on capture clock of CMD channel, then set the clock frequency to ≤ 200 MHz.

    Ensure that uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0.
13. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically tuned to 1/4 cycle of input ipp_strobe to capture data. Ensure that both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

    NOTE

    For speed mode switch like from High Speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

30.3.10.5 Switch to HS400 enhanced mode

This selection flow describes how to initialize the eMMC device in HS400 mode while enabling enhanced strobe without the need for tuning procedure. To switch to HS400 mode with enhanced strobe, the host must perform the following steps:

1. Initialize device with "Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the device is set as the default "Backward Compatible Timing".
2. Select the device with CMD7
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the device supports HS400 with CMD8.
4. Read the STROBE_SUPPORT[184] field of the Extended CSD register to validate whether the device supports enhanced strobe with CMD8.
5. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode by sending CMD6 and then set the clock frequency to a value not greater than 52 MHz.
6. Set BUS_WIDTH[183] to 0x86 to select the dual data rate x8 bus mode and enable enhanced strobe (this is active only after HS400 mode is selected) with CMD6. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
7. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported device Driver Strengths with CMD8.

NOTE

You may skip this step if changes of driver strength is not needed, if needed host may change the device Driver Strength.

8. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6.
9. Set the MIX_CTRL[DDR_EN], MIX_CTRL[HS400_MODE], and MIX_CTRL[EN_HS400_MODE] bits to 1 to enable enhanced HS400 mode in controller.
10. Host may set the clock frequency to a value not greater than 200 MHz. Ensure uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0 .
11. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically delayed 1/4 cycle of input ipp_strobe to capture data. Make sure both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

NOTE

For speed mode switch like from high speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

30.3.11 Software restrictions

30.3.11.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

30.3.11.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

30.3.11.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by SDIO, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is stopped and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

30.3.11.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

30.3.11.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

30.3.11.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

30.3.11.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

30.3.11.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for eMMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

30.3.12 Clocking

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 205. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_perclk	Base clock
ipg_clk_lp	Low power clock

30.3.12.1 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

30.3.12.2 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock (see ipg_clk_perclk in Table 205).

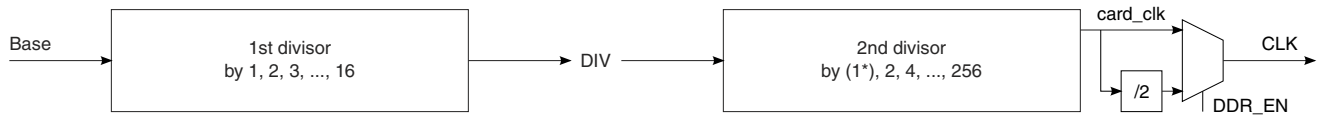

Figure 130. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 116) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times SYS_CTRL[SDCLKFS]}$$

$$f_{CLK} = f_{card_clk}$$

Equation 16. Equation for f_{card_clk} in SDR mode

For HS200 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h01, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card_clk} = \frac{400MHz}{1x(2)} = 200MHz$$

$$f_{CLK} = f_{card_clk} = 200\ MHz$$

- In the DDR mode, CLK is equal to card_clk/2

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times (SYS_CTRL[SDCLKFS]/2)}$$

$$f_{CLK} = \frac{f_{card_clk}}{2}$$

Equation 17. Equation for f_{card_clk} in DDR mode

For HS400 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h00, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card_clk} = \frac{400MHz}{1x(2/2)} = 400MHz$$

$$f_{CLK} = \frac{f_{\text{card_clk}}}{2} = \frac{400MHz}{2} = 200MHz$$

30.3.13 Command Queuing (CQE) operation

To facilitate command queuing in eMMC, the device manages an internal task queue that the host can queue data transfer tasks. Initially, the task queue is empty. Every task is issued by the host and initially queued as pending. The device controller works to prepare the pending tasks for execution. The software flow is described below:

1. Read CMDQ_SUPPORT[308] and CMDQ_DEPTH[307] of the extended CSD register (through CMD8) to verify eMMC chip support of command queue.
2. Set CMDQ_MODE_EN in CMD_MODE_EN[15] field of the extended CSD by issuing CMD6.
3. Send CMD13 to ensure a successful mode switch.
4. Define Task Descriptor List (TDL) comprised of task descriptor and transfer descriptor sets.
    a. 0x0010002b,0x00000000,0x20000023,0x34300000, //Write example
    b. 0x0010102b,0x00000000,0x20000023,0x34500000, //Read example
5. Set PROT_CTRL[DMASEL] to 2 to select ADMA2. CMDQ descriptors are in ADMA2 format.
6. Set CQSSC2[SSC2] to RCA.
7. Set Command Queuing Task Descriptor List Base Address (CQTDLBA) and Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU) to TDL start address.
8. Set CQCFG[CQUE] to 1 to enable the command queuing.
9. Set CQTDBR[TDBR] field(s) to trigger the required task(s).
10. Read CQTCN[TCN] field(s) to confirm the task completion(s).
11. Set CQTCN[TCN] field(s) to 1 to clear status.

30.3.14 Abort transaction

Abort command

There are two types of abort command: CMD12 and I/O abort.

- CMD12 is used for memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).
- I/O abort is used for SDIO card, SDCombo (I/O portion). I/O abort stops an infinite block transfer (block count = 0) by writing the ASx bit in CCCR.

If an exact number of blocks are to be transferred, it is recommended that the uSDHC issues a block command with the correct block count, rather than using an infinite count and aborting the data at the correct time.

Asynchronous and synchronous abort

There are two ways to issue an abort command (CMD12 or I/O abort): asynchronous abort and synchronous abort.

- In an asynchronous abort sequence, uSDHC can issue an abort command (CMD12 or I/O abort) at anytime unless Command Inhibit (PRES_STATE[CIHB]) in the Present State register is set to 1.
- In a synchronous abort sequence, uSDHC shall issue an abort command (CMD12 or I/O abort) after data transfer is stopped by using Stop At Block Gap Request (SABGREQ).

Read wait

This function uses DATA2 to allow uSDHC to signal the SDIO or Combo Card to temporarily halt the sending of read data by a card during the block gap.

30.4 External signals

The following table describes the uSDHC external signals:

Table 206. uSDHC external signals

Signal	Description	Direction
CLK	Is an Internally generated clock used to drive the eMMC, SD card, and SDIO.	O
CMD	Is used to send commands and receive responses to and from the card.	I/O
DAT7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DAT6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DAT5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DAT4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
NOTE If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.		
DAT3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DAT2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DAT1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DAT0	DAT0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection signal directly routed from the socket. Low value (0) indicates there is a card inserted. In the case the pin is not used (for the embedded memory), tie low. Optional for system implementation.	I
WP	Write protection signals directly routed from the socket. Low value (0) indicates it is not write protected. In the case the pin is not used (for the embedded memory), tie low.	I

Table continues on the next page...

Table 206. uSDHC external signals (continued)

Signal	Description	Direction
	Optional for system implementation.	
RESET_B	Is used to reset the eMMC or control Card power. Active Low. • eMMC: connect eMMC RST_n pin. • Card: instead of hardware reset to enable/disable Card power during warm reset.	O
VSELECT	Is used to change the voltage of the external power supplier. Optional for system implementation.	O
STROBE	Input clock for eMMC HS400 mode. **NOTE** If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.	I

30.5 Application information

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, eMMC are in the open-drain mode to avoid bus contention. See Commands for SD card, SDIO, and eMMC for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, for eMMC, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. See Commands for SD card, SDIO, and eMMC for the commands of ac and adtc categories.

30.5.1 Command send and response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)

{

    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner

    wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>

    set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;

    if (internal DMA is used) wCmd |= 0x1;

    if (multi-block transfer) {

        set MSBSEL bit;
```

```
        if (finite block number) {

            set BCEN bit;

            if (auto12 command is to use) set AC12EN bit;

        }

    }

    write_reg(CMDARG, <cmd_arg>); // configure the command argument

    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command

}

wait_for_response(cmd_index)

{

    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set

    read IRQ Status register and check if any error bits about Command are set

    if (any error bits are set) report error;

    write 1 to clear CC bit and all Command Error bits;

}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

30.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for eMMC.

30.5.2.1 Card detect

See Figure 131 for a flow diagram showing the detection of SD card and SDIO using uSDHC.

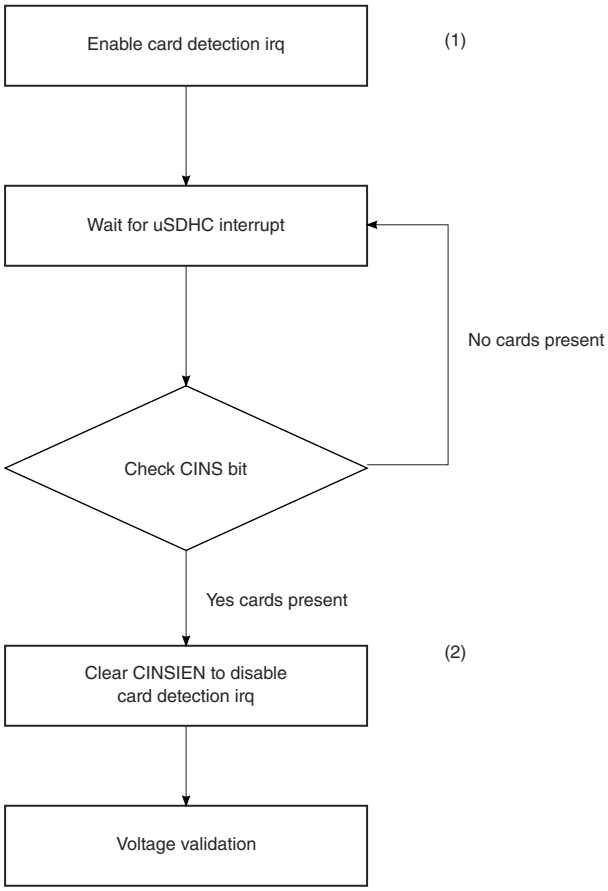

Figure 131. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

30.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of eMMC and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

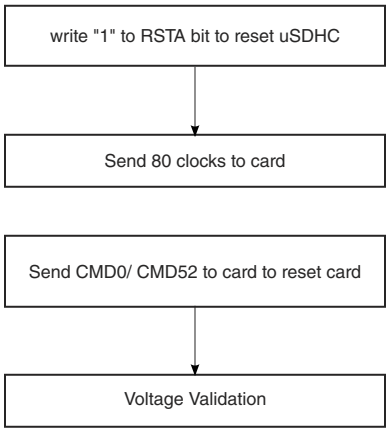

Figure 132. Flow chart for resetting uSDHC and SD card or SDIO

```
software_reset() {
    set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and SDCLKFS fields to get the CLK of
    //frequency around 400kHz
    //configure IO pad to set the power voltage of external card to around 3.0V
    //poll bits CIHB and CDIHB
    //bits of PRSSTAT to wait both fields are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameter>); // reset the card with CMD0 or
    send_command(CMD_IO_RW_DIRECT, <other parameter>);
}
```

30.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for eMMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_argument) {
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation
voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
```

```
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO)
            Label the card as SDCombo; //this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labeled as SDIO)
        return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameter>); // CMD55, Application specific CMD prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range for
memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN)
           label the card as SD;
        return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be eMMC
        if (card is already labeled as SDCombo) { // change label
            re-label the card as SDIO;
            ignore the error or report it;
            return; // card is identified as SDIO
        } // end of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if(RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
            either label the card as UNKNOWN;
            return;
        } // end of if (RESP_TIMEOUT ...
    } // end of else
}
```

30.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the eMMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For eMMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions

(CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using eMMC:

```
card_registry() {
    do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if(RESP_TIMEOUT == wait_for_response(ALL_SEND_CID))
                break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as eMMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; //arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as eMMC...
    } while (response is not time-out);
}
```

30.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

30.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

30.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and stops the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation also stops if the host tries to write over a write-protected area.

For eMMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving, if the device is memory device: such as eMMC, SD Card, SD Combo Card (memory portion).

30.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can only be set to 512 Byte.
2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC, SD card to high-speed mode and use SWITCH (CMD6); or set SDIO to high-speed mode and use IO_RW_DIRECT (CMD52).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH (CMD6); or set SDIO to with 4-bit DDR mode and use IO_RW_DIRECT (CMD52).
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. Set DDR_EN to 1.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).

30.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).

The number of blocks left during the data transfer is accessible by reading the contents of BLK_ATT[BLKCNT]. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt (INT_STATUS[TC]) is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

30.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

30.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo Cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or any other error occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

30.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can only be set to 512 Bytes.
2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC, SD card to high-speed mode and use SWITCH (CMD6); or set SDIO to high-speed mode and use IO_RW_DIRECT (CMD52).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH (CMD6); or set SDIO to with 4-bit DDR mode and use IO_RW_DIRECT (CMD52).
5. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. Set DDR_EN to 1.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

30.5.3.2.3 Read with Pause

The read operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in Control register to pause the transfer between the data blocks.

Only SDIO and SD Combo Card support Read Wait feature while Read with Pause. Read Wait feature means that it uses DATA2 to allow uSDHC to signal the SDIO or SD Combo Card to temporarily halt the sending of read data by a card during the block gap. Before setting SABGREQ to 1, ensure to set the RWCTL bit to 1 after recognizing the read wait capability of SDIO (SRW bit in CCCR register is 1).

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCCR register on SDIO or SD Combo Card (I/O portion) to confirm that the card supports the Read Wait mode.
2. If SDIO or Combo Card (I/O portion) supports Read Wait, set RWCTL to 1.

   If the device is memory device: such as eMMC, SD Card, or SD Combo Card (Memory portion), set RD_DONE_NO_8CLK to 1.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo Cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bitfield in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 4.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or any other error occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer

is resumed. For memory device, if there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. Then uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

30.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the eMMC and SD cards DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are two DLLs, PARTS DLL and STROBE DLL. PARTS DLL controls the SD_CLK loop back delay for which DLL (Delay Line) Control (DLL_CTRL) and DLL Status (DLL_STATUS) are used. STROBE DLL controls the STROBE loop back delay for which Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) are used. For PARTS DLL, below flow can be taken as reference. For STROBE DLL, similar register field with prefix STROBE in Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) must be used.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

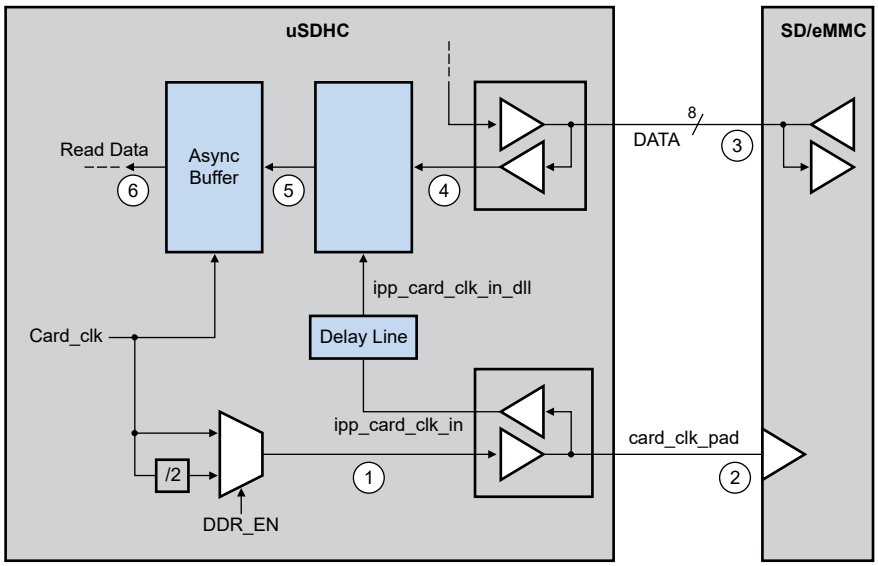

Figure 133. DLL in read path

30.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO and Combo Card, although slightly different than the suggested implementation of Suspend in the SDIO specification. Both Read and Write support Suspend and Resume, however ADMA operation does not support this function.

30.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of SDIO and Combo Card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", i.e., setting the CMDTYP bits to 01. Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Check CCCR[SRW] on SDIO or SD Combo Card (I/O portion) to confirm that the card supports the Read Wait mode. If SDIO or Combo Card (I/O portion) supports Read Wait, set the RWCTL bit to 1.
2. Set the SABGREQ bit to 1 to pause the current data transfer at block gap. Wait for the BGE bit set as 1, and wait for the Transfer Complete interrupt. Save the context registers in the system memory for later use, including the DMA System Address Register DS_ADDR (for internal DMA operation), and the Block Attribute Register BLK_ATT.
3. Send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.

   The following steps show an example of CMD52 function0 suspend with CMDTYP=2'b00:

   a. Set CMD_ARG to 0x88001802

   b. Set MIX_CTRL to 0x80000000

   c. Set CMD_XFR_TYP to 0x341A0000
4. Check the BS bit of the CCCR in the response (CMD_RSP0[0]). If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
5. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended.

The following steps show an example of CMD52 function0 suspend with CMDTYP=2'b01:

a. Set CMD_ARG to 0x00001800

b. Set MIX_CTRL to 0x80000000

c. Set CMD_XFR_TYP to 0x345A0000

6. Clear the BGE bit to 0, and clear the SABGREQ bit to 0. Begin operation for another function on SDIO and Combo Card (I/O portion).

30.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context registers (DS_ADDR and BLK_ATT) with the saved value in the step #2 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bitfields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).

   The following steps show an example of CMD52 function0 resume with CMDTYP=2'b10:

   a. Set CMD_ARG to 0x88001A01

   b. Set MIX_CTRL either to 0x80000023 (Suspend Write, Host to Card) or to 0x80000033 (Suspend Read, Card to Host)

   c. Set CMD_XFR_TYP to 0x34BA0000

3. If the Resume command (INT_STATUS[CC]) has responded, the data transfer is resumed.

30.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are as follows:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.
8. Once the ADMA transfer is complete, clear PROT_CTRL[DMASEL] to 00b.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

30.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

30.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

30.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation stops, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

30.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

30.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it stops the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

30.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For SDIO, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from SDIO must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

30.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the eMMC and SD cards. The eMMC and SD cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO, the high-speed mode /DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For eMMC, the high-speed mode HS200 or HS400 is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of eMMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudo-code examples do not show current capability check, which is recommended in the function switch process.

30.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report SDIO does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of the desired value below 25MHz;
(data transactions like normal peers)
}
```

30.5.4.2 Query, enable, and disable SD high-speed mode/DDR50 /SDR50 /SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
```

```
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
      send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

30.5.4.3 Query, enable, and disable eMMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this eMMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report eMMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

30.5.4.4 Set eMMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

30.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

30.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

30.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
```

```
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

30.5.6 Fast boot operation

30.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure eMMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure eMMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

30.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the eMMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the target (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

30.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during eMMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that

is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.

7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the eMMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

30.6 uSDHC memory map and register definition

30.6.1 USDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

30.6.1.1 USDHC memory map

uSDHC1 base address: 4285_0000h

uSDHC2 base address: 4286_0000h

uSDHC3 base address: 428B_0000h

Offset (hex)	Register	Width (In bits)	Access	Reset value (hex)

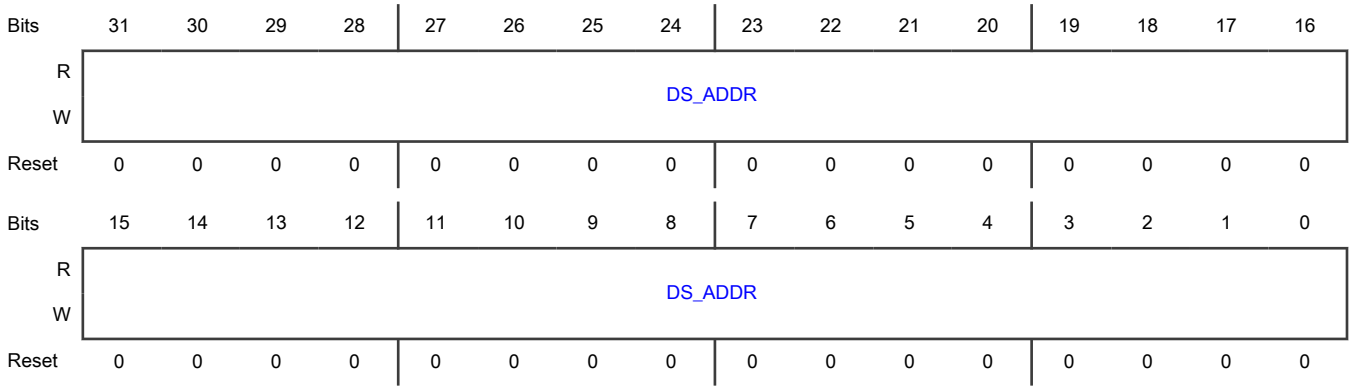
30.6.1.2 DMA System Address (DS_ADDR)

This register contains the physical system memory address used for DMA transfers.

Offset

Register	Offset
DS_ADDR	0h

Diagram



Fields

Field	Description
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both ADMA1 and ADMA2. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

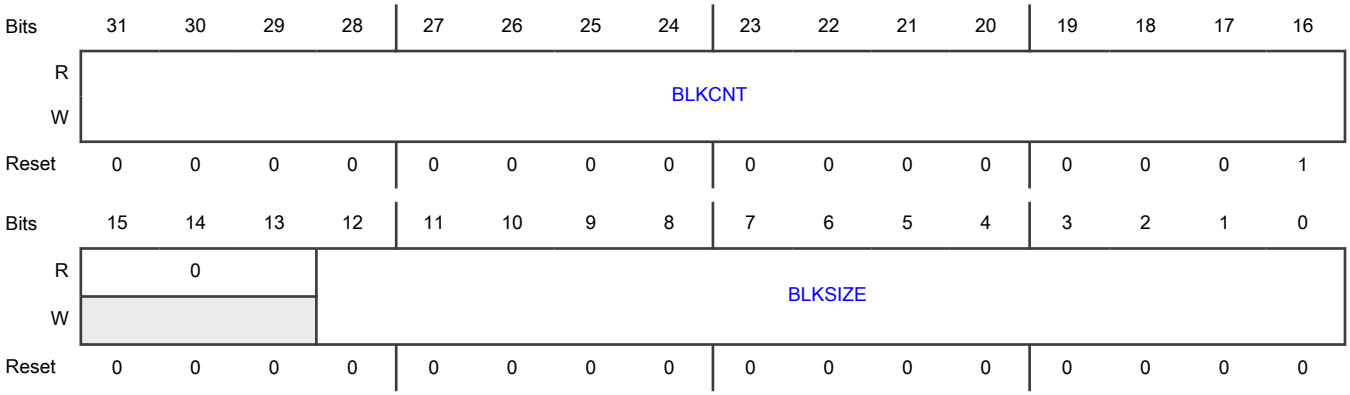
30.6.1.3 Block Attributes (BLK_ATT)

This register is used to configure the number of data blocks and the number of bytes in each block.

Offset

Register	Offset
BLK_ATT	4h

Diagram



Fields

Field	Description
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as stopped and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count. **NOTE** Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000_0000_0000_0000 - Stop count 0000_0000_0000_0001 - 1 block 0000_0000_0000_0010 - 2 blocks

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1111_1111_1111_1111 - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0_0000_0000_0000 - No data transfer 0_0000_0000_0001 - 1 byte 0_0000_0000_0010 - 2 bytes 0_0000_0000_0011 - 3 bytes 0_0000_0000_0100 - 4 bytes 0_0001_1111_1111 - 511 bytes 0_0010_0000_0000 - 512 bytes 0_1000_0000_0000 - 2048 bytes 1_0000_0000_0000 - 4096 bytes

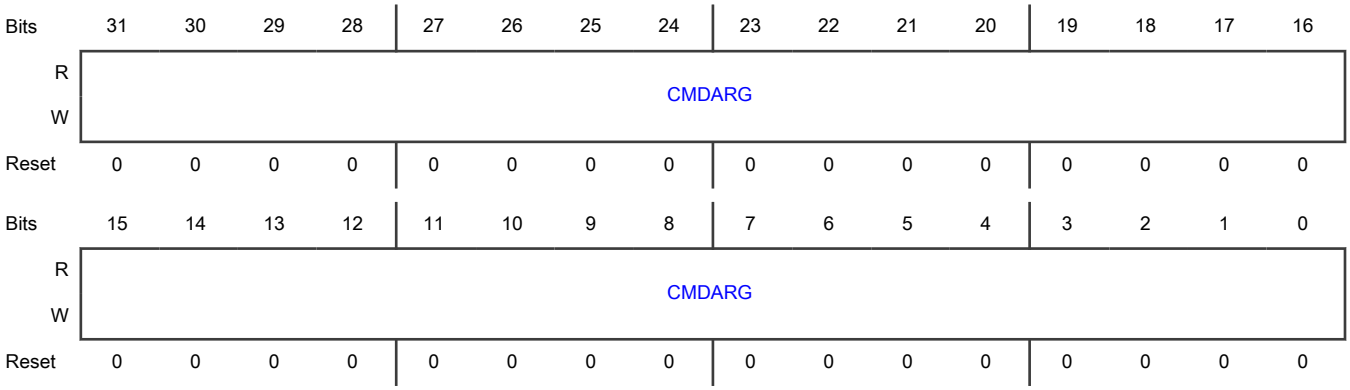
30.6.1.4 Command Argument (CMD_ARG)

This register contains the SD/eMMC command argument.

Offset

Register	Offset
CMD_ARG	8h

Diagram



Fields

Field	Description
31-0 CMDARG	Command argument The SD/eMMC command argument is specified as bits 39-8 of the command format in the SD or eMMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

30.6.1.5 Command Transfer Type (CMD_XFR_TYP)

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, WP is activated as '1', write to memory and combo cards are ignored by cards (in that case, there is no need to send write command anymore).

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and stops the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 207. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 208. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

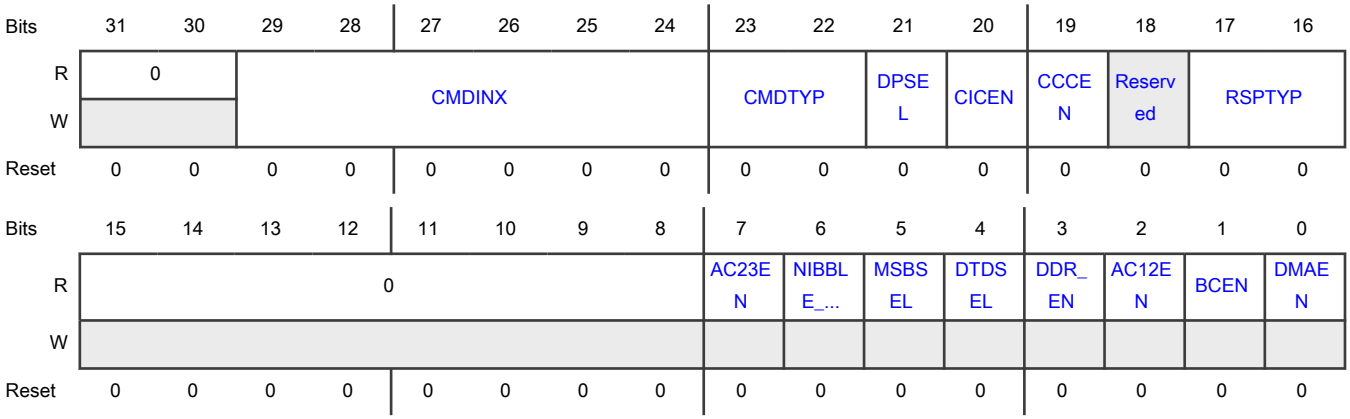
CMD_XFR_TYP	Ch

Diagram



Fields

Field	Description
31-30 —	Reserved
29-24 CMDINX	Command index

Table continues on the next page...

Table continued from the previous page...

Field	Description
	These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00 - Normal other commands 01 - Suspend CMD52 for writing bus suspend in CCCR 10 - Resume CMD52 for writing function select in CCCR 11 - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored. 0 - No data present 1 - Data present
20	Command index check enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
CICEN	If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0 - Disable command index check 1 - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0 - Disables command CRC check 1 - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00 - No response 01 - Response length 136 10 - Response length 48 11 - Response length 48, check busy after response
15-8 —	Reserved
7 AC23EN	AC23EN This field is read when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is tied to '0'. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register. 0 - Disable 1 - Enable
6 NIBBLE_POS	NIBBLE_POS This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'. 0 - Disable 1 - Enable
5	MSBSEL

Table continues on the next page...

Table continued from the previous page...

Field	Description
MSBSEL	This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0 - Disable 1 - Enable
4 DTDSEL	DTDSEL This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0 - Disable 1 - Enable
3 DDR_EN	DDR_EN Dual data rate mode selection. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0 - Disable 1 - Enable
2 AC12EN	AC12EN Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0 - Disable 1 - Enable
1 BCEN	BCEN This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0 - Disable 1 - Enable
0 DMAEN	DMAEN This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register.

Fields

Field	Description
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

30.6.1.9 Command Response3 (CMD_RSP3)

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 209. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Offset

Register	Offset
CMD_RSP3	1Ch

Field	Description
31-0 DATCONT	Data content This field is used to access the internal buffer.

30.6.1.11 Present State (PRES_STATE)

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Offset

Register	Offset
PRES_STATE	24h

Fields

Field	Description
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 0000_0001 - Data 0 line signal level 0000_0010 - Data 1 line signal level 0000_0100 - Data 2 line signal level 0000_1000 - Data 3 line signal level 0001_0000 - Data 4 line signal level 0010_0000 - Data 5 line signal level 0100_0000 - Data 6 line signal level 1000_0000 - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-21 —	Reserved
20 —	Reserved
19 WPSPL	Write protect switch pin level

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0 - Write protected (WP = 1) 1 - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0 - No card present (CD_B = 1) 1 - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0 - Power on reset or no card 1 - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0 - Delay cell select change is not finished. 1 - Delay cell select change is finished.
14-13 —	Reserved
12 RTR	Re-Tuning Request (only for SD3.0 SDR104 mode, and eMMC HS200 mode) Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0 - Fixed or well tuned sampling clock 1 - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0 - Read disable 1 - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0 - Write disable 1 - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer. • When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0 - No valid data

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0 - No valid data 1 - Transferring data
7-4 —	Reserved
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0 - Clock is changing frequency and not stable. 1 - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the read command

Table continues on the next page...

Table continued from the previous page...

Field	Description
	• When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0 - DATA line inactive 1 - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / eMMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0. 0 - Can issue command that uses the DATA line 1 - Cannot issue command that uses the DATA line

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / eMMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0 - Can issue command using only CMD line 1 - Cannot issue command

30.6.1.12 Protocol Control (PROT_CTRL)

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Offset

Fields

Field	Description
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0 - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1 - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0 - Disables wakeup event enable on SD card removal 1 - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0 - Disable wakeup event enable on SD card insertion 1 - Enable wakeup event enable on SD card insertion
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0 - Disables wakeup event enable on card interrupt 1 - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20	Read performed number 8 clock

Table continues on the next page...

Table continued from the previous page...

Field	Description
RD_DONE_NO_8CLK	According to the SD/eMMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of SDIO, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If SDIO cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. 0 - Disables interrupt at block gap 1 - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0 - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1 - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17 CREQ	Continue request This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0 - No effect 1 - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to

Table continues on the next page...

Table continued from the previous page...

Field	Description
	restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that SDIO support read wait. Therefore, the host driver does not set this field during read transfers unless SDIO supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0 - Transfer 1 - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 - No DMA or simple DMA is selected. 01 - ADMA1 is selected. 10 - ADMA2 is selected. 11 - Reserved
7 —	Reserved
6 —	Reserved
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00 - Big endian mode 01 - Half word big endian mode 10 - Little endian mode 11 - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - DATA3 does not monitor card insertion 1 - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00 - 1-bit mode 01 - 4-bit mode 10 - 8-bit mode 11 - Reserved
0 —	Reserved

30.6.1.13 System Control (SYS_CTRL)

This register provides control of the system. See detail in the field description.

Field	Description
—	
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26 RSTD	Software reset for data line Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable — Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0 - No reset 1 - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0 - No reset 1 - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC. **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0 - No reset 1 - Reset
23 IPP_RST_N	Hardware reset This field has alternative function as below: • eMMC: be used to reset eMMC, through pad directly to eMMC RST_n pin. • Card: be used to control SD Card power enable or disable during warm reset, through pad directly to hardware reset on board.
22 RST_FIFO	Reset the async FIFO Reset the async FIFO between card interface and the internal logic. After this field is set, the software waits for self-clear.

Table continued from the previous page...

Field	Description
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000 - SDCLK x 2^{32} 0001 - SDCLK x 2^{33} 0010 - SDCLK x 2^{18} 0011 - SDCLK x 2^{19} 1101 - SDCLK x 2^{29}, recommend to use for supported speed modes except HS200, HS400, SDR104 mode 1110 - SDCLK x 2^{30}, recommend to use for HS200 and SDR104 mode 1111 - SDCLK x 2^{31}, recommend to use for HS400 mode
15-8 SDCLKFS	SDCLK frequency select This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed:

Table continues on the next page...

Table continued from the previous page...

Field	Description
	80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended. For HS400 mode, SDCLKFS must be used so that REF_CLK, generated for STROBE DLL, is at the same frequency as STROBE clock. For HS200 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK. For SDR104 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows:

Field	Description
	0000 - Divide-by-1 0001 - Divide-by-2 1110 - Divide-by-15 1111 - Divide-by-16
3-0 —	Reserved Always write as 1.

30.6.1.14 Interrupt Status (INT_STATUS)

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 210. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 211. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 212. uSDHC status for command CRC error/command timeout error bit combinations

Command CRC error	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error

Fields

Field	Description
31 —	Reserved
30-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0 - No error 1 - Error

Table continues on the next page...

Table continued from the previous page...

Field	Description
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning. This field is relevant in combination with the bus error only and must be cleared prior to all the write and read transactions.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0 - No error 1 - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process. 0 - No error 1 - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0 - No error 1 - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field is not asserted in tuning process. 0 - No error 1 - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0 - No error 1 - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0 - No error 1 - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC stops the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict. This field is not asserted in tuning process. 0 - No error 1 - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is stopped by uSDHC. This field is not asserted in tuning process. 0 - No error 1 - Time out
15	Error Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Description
ERR_INT_STATUS	This bit is set when any of the error status bit DMAE, AC12E, DEBE, DCE, DTOE, CIE, CEBE, CCE and CTOE is set.
14 CQI	Command queuing interrupt This interrupt is asserted when at least one of the bits in CQIS register is set. This interrupt is cleared only by clearing the source interrupt in CQIS register.
13 TP	Tuning pass:(only for SD3.0 SDR104 mode and eMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0 - Re-tuning is not required. 1 - Re-tuning should be performed.
11 —	Reserved
10-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from SDIO and the interrupt to the host system. Writing this field to 1 can clear this field, but as the interrupt source from SDIO does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in SDIO and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0 - No card interrupt 1 - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field

Table continues on the next page...

Table continued from the previous page...

Field	Description
	and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0 - Card state unstable or inserted 1 - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0 - Card state unstable or removed 1 - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0 - Not ready to read buffer 1 - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0 - Not ready to write buffer 1 - Ready to write buffer
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0 - No DMA interrupt 1 - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0 - No block gap event 1 - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0 - Transfer does not complete 1 - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0 - Command not complete 1 - Command complete

30.6.1.15 Interrupt Status Enable (INT_STATUS_EN)

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

30.6.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

Offset

Register	Offset
INT_SIGNAL_EN	38h

30.6.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 213. Relationship between command CRC error and command timeout error for auto CMD12

Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued

- At the end field of an Auto CMD12 response
  - — Check errors correspond to fields 1-4
  - — Set fields 1-4 corresponding to detected errors
  - — Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - — Set field 7 to 1 if there is a command that can't be issued
  - — Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

31-26 —	Reserved
25 —	Reserved
24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0 - Fixed clock is used to sample data 1 - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0 - Tuning procedure is stopped 1 - Start tuning procedure
21-19 —	Reserved
18 —	Reserved
17-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0 - No error 1 - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - No error 1 - Error, the CMD index in response is not CMD12/23
3 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0 - No error 1 - End bit error generated
2 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0 - No CRC error 1 - CRC error met in Auto CMD12/23 response
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0 - No error 1 - Time out
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0 - Executed 1 - Not executed

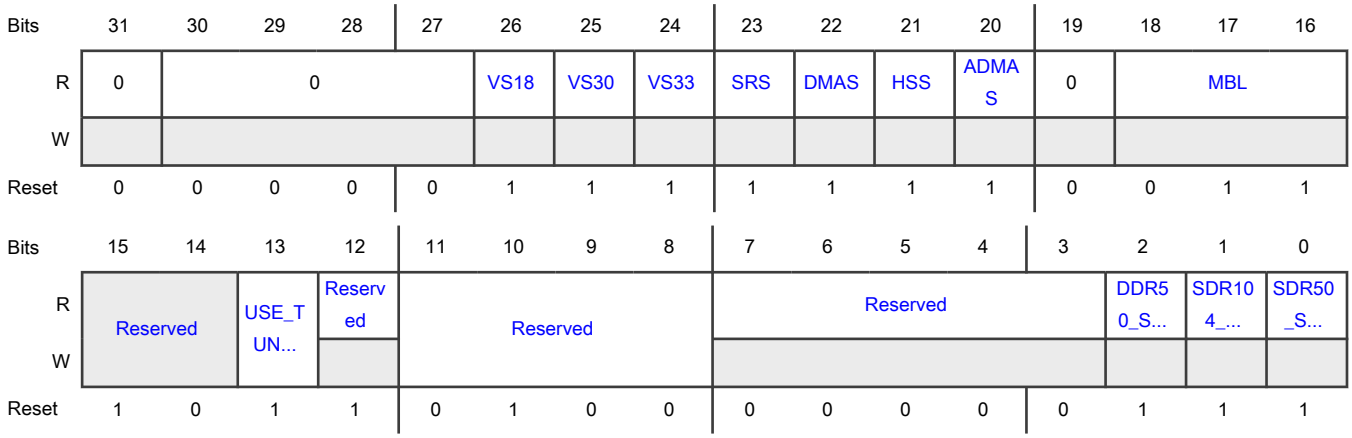
30.6.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

Offset

Register	Offset
HOST_CTRL_CAP	40h

Diagram



Fields

Field	Description
31 —	Reserved
30-27 —	Reserved

1 SDR104_SUPPORT	SDR104 support This field indicates support of SDR104 mode.
0 SDR50_SUPPORT	SDR50 support This field indicates support of SDR50 mode.

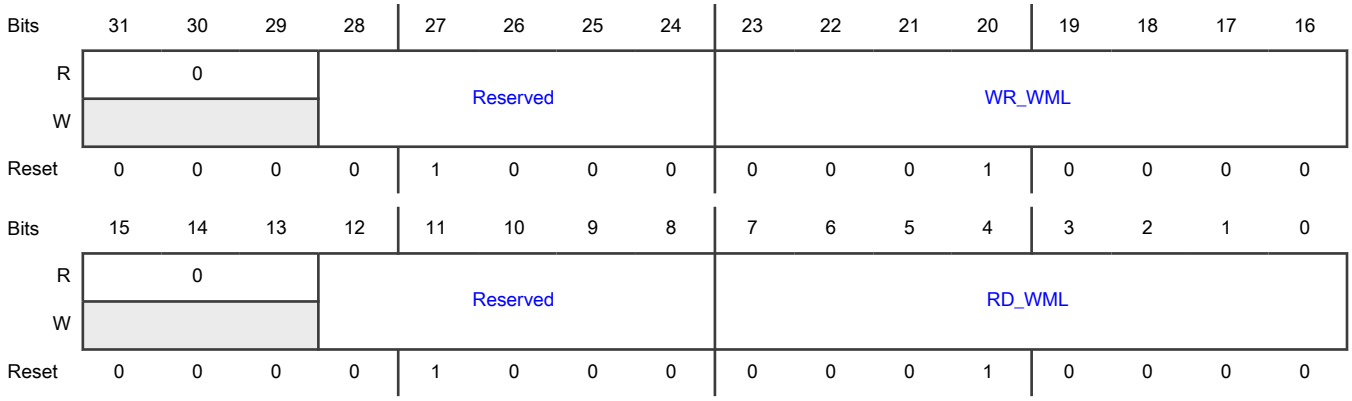
30.6.1.19 Watermark Level (WTMK_LVL)

This register indicates configurability of write and read watermark levels (FIFO threshold). Their value can range from 1 to 128 words.

Offset

Register	Offset
WTMK_LVL	44h

Diagram



Fields

Field	Description
31-29 —	Reserved
28-24 —	Reserved
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

30.6.1.20 Mixer Control (MIX_CTRL)

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 214. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

Offset

29 —	Reserved Always write as 0.
28 —	Reserved
27 EN_HS400_MODE	Enable enhance HS400 mode Enhance HS400 enable
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0 - Feedback clock comes from the loopback CLK 1 - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0 - Disable auto tuning 1 - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and eMMC HS200 mode)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Fixed clock is used to sample data / cmd 1 - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is stopped by writing 0. 0 - Not tuned or tuning completed 1 - Execute tuning
21-8 —	Reserved
7 AC23EN	Auto CMD23 enable This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0 - Single block 1 - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0 - Write (Host to card) 1 - Read (Card to host)
3 DDR_EN	Dual data rate mode selection This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only.
2	Auto CMD12 enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
AC12EN	Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0 - Disable 1 - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0 - Disable 1 - Enable
0 DMAEN	DMA enable This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0 - Disable 1 - Enable

30.6.1.21 Force Event (FORCE_EVENT)

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. Writing 1 to this register sets the corresponding field of Interrupt Status register, while writing 0 to it has no effect. A read from this register always results in 0's. To change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

Offset

Register	Offset
FORCE_EVENT	50h

Fields

Field	Description
31 FEVTCINT	Force event card interrupt Writing 1 to this field generates a short low-level pulse on the internal DATA1 line, as if a self-clearing interrupt was received from the external card. If enabled, the CINT field is set and the interrupt service routine might treat this interrupt as a normal interrupt from the external card.
30-29 —	Reserved
28 FEVTDMAE	Force event DMA error Forces the DMAE field of Interrupt Status register to be set
27 —	Reserved
26 FEVTTNE	Force tuning error Forces the TNE field of Interrupt Status register to be set
25 —	Reserved
24 FEVTAC12E	Force event Auto Command 12 error Forces the AC12E field of Interrupt Status register to be set
23 —	Reserved
22 FEVTDEBE	Force event data end bit error Forces the DEBE field of Interrupt Status register to be set

Table continues on the next page...

Table continued from the previous page...

Field	Description
21 FEVTDCE	Force event data CRC error Forces the DCE field of Interrupt Status register to be set
20 FEVTDTOE	Force event data time out error Force the DTOE field of Interrupt Status register to be set
19 FEVTCIE	Force event command index error Forces the CCE field of Interrupt Status register to be set
18 FEVTCEBE	Force event command end bit error Forces the CEBE field of Interrupt Status register to be set
17 FEVTCCE	Force event command CRC error Forces the CCE field of Interrupt Status register to be set
16 FEVTCTOE	Force event command time out error Forces the CTOE field of Interrupt Status register to be set
15-8 —	Reserved
7 FEVTCNIBAC12E	Force event command not executed by Auto Command 12 error Forces the CNIBAC12E field in the Auto Command12 Error Status register to be set
6-5 —	Reserved
4 FEVTAC12IE	Force event Auto Command 12 index error Forces the AC12IE field in the Auto Command12 Error Status register to be set
3 FEVTAC12EBE	Force event Auto Command 12 end bit error Forces the AC12EBE field in the Auto Command12 Error Status register to be set
2 FEVTAC12CE	Force event auto command 12 CRC error Forces the AC12CE field in the Auto Command12 Error Status register to be set
1 FEVTAC12TOE	Force event auto command 12 time out error Forces the AC12TOE field in the Auto Command12 Error Status register to be set
0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set

30.6.1.22 ADMA Error Status (ADMA_ERR_STATUS)

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.
- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 215. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

Fields

Field	Description
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0 - No error 1 - Error
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0 - No error 1 - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

30.6.1.23 ADMA System Address (ADMA_SYS_ADDR)

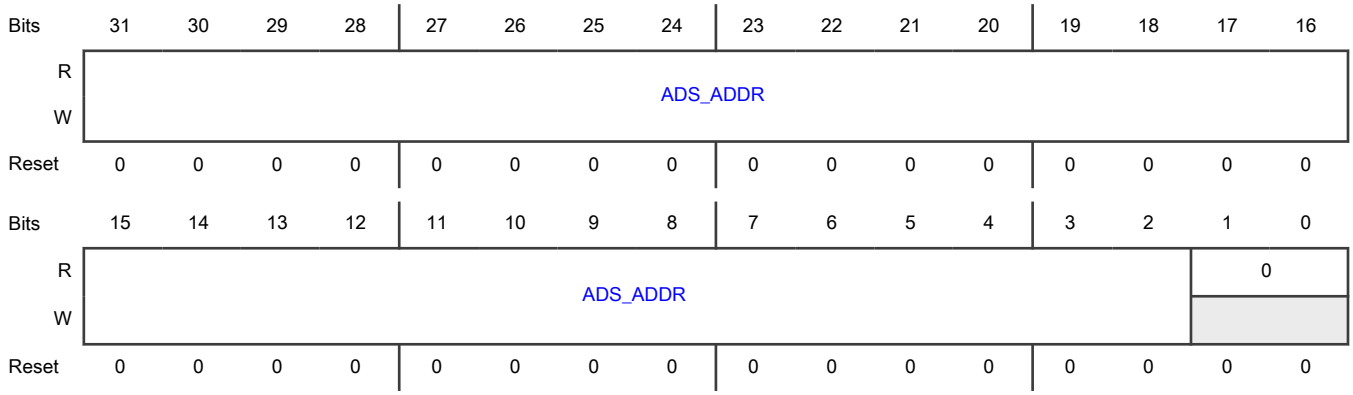
This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Offset

Register	Offset
ADMA_SYS_ADDR	58h

Diagram



Fields

Field	Description
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

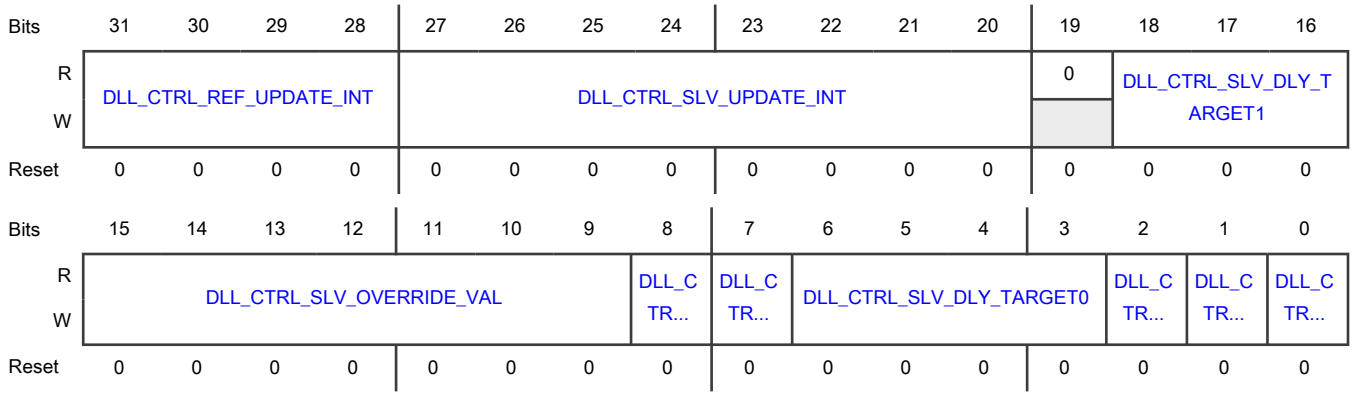
30.6.1.24 DLL (Delay Line) Control (DLL_CTRL)

This register contains control fields for DLL.

Offset

Register	Offset
DLL_CTRL	60h

Diagram



Fields

Field	Description
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 DLL_CTRL_SLV_UPDATE_INT	Target delay line update interval If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the target-delay line using the SLV_FORCE_UPDATE register. Note that the target delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL target delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL target override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL target override Set this field to 1 to Enable manual override for target delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL target delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an REF_CLOCK half-period. The delay is (DLL_CTRL_SLV_DLY_TARGET + 1)* REF_CLOCK_PERIOD[1] / 2) / 16, where DLL_CTRL_SLV_DLY_TARGET is a 7-bit value obtained by concatenating {DLL_CTRL_SLV_DLY_TARGET1, DLL_CTRL_SLV_DLY_TARGET0}. Therefore, the input read-clock can be delayed relative to the input data by (REF_CLOCK_PERIOD / 2) / 16 up to REF_CLOCK_PERIOD * 4.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK_PERIOD/16 and REF_CLOCK_PERIOD*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK_PERIOD*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL target delay line Setting this field to 1, forces the target delay line to update to the DLL calibrated value immediately. The target delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the target-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half-period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the target delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

1. REF_CLOCK_PERIOD is 1/REF_CLOCK.

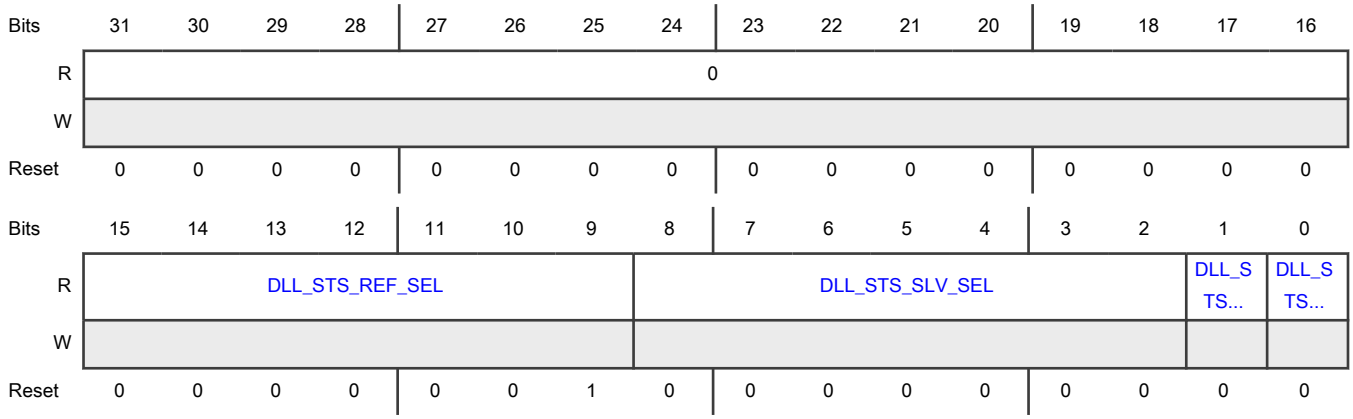
30.6.1.25 DLL Status (DLL_STATUS)

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

Offset

Register	Offset
DLL_STATUS	64h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Target delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to an REF_CLOCK half-period phase shift , allowing the target delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Target delay-line lock status This signifies that a valid calibration has been set to the target-delay line and that the target-delay line is implementing the programmed delay value

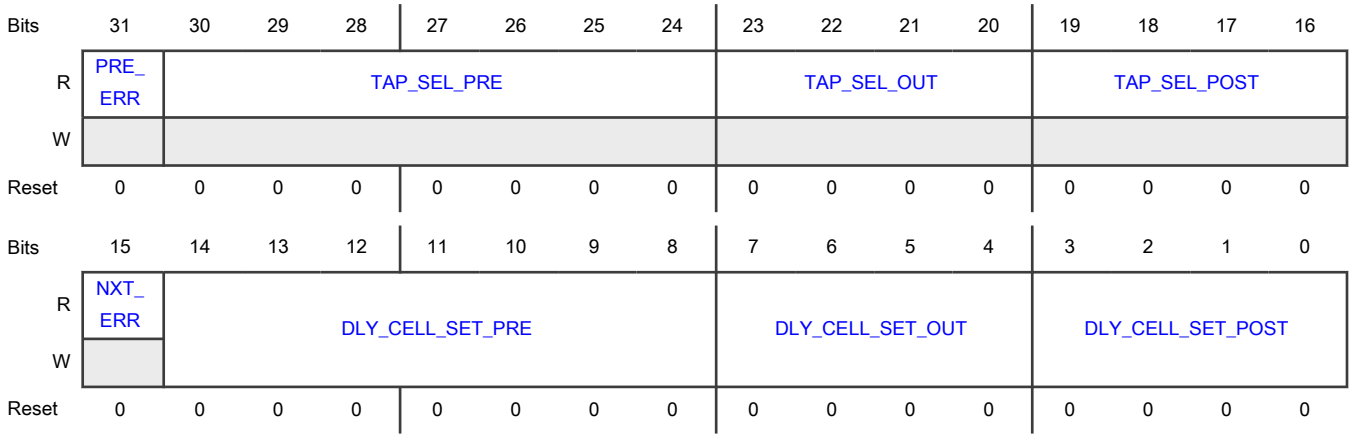
30.6.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

This register contains the Clock Tuning Control status information. This register is added to support SD3.0 UHS-I SDR104 mode and eMMC HS200 mode.

Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Diagram



Fields

Field	Description
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.

Table continues on the next page...

Table continued from the previous page...

Field	Description
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

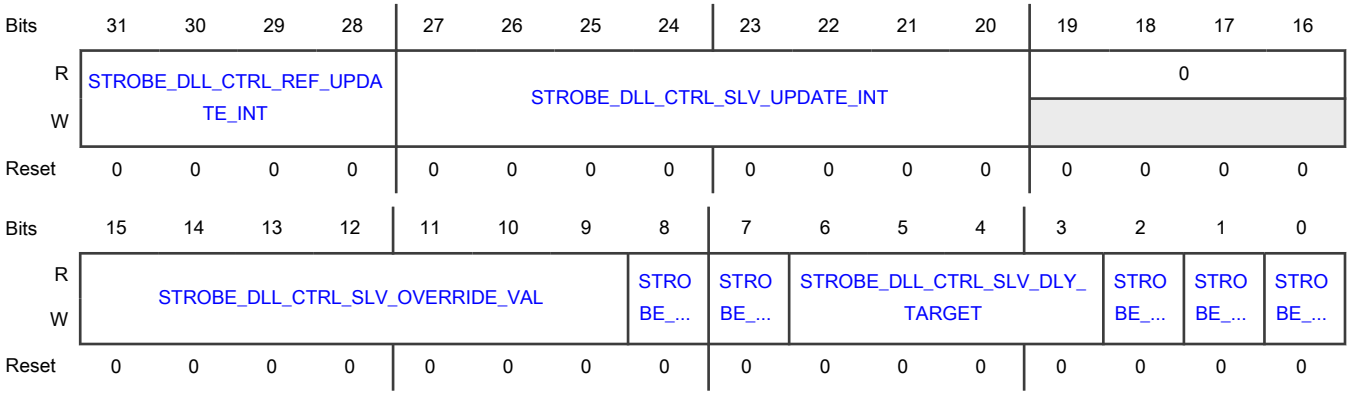
30.6.1.27 Strobe DLL control (STROBE_DLL_CTRL)

This register contains the strobe DLL control information.

Offset

Register	Offset
STROBE_DLL_CTRL	70h

Diagram



Fields

Field	Description
31-28 STROBE_DLL_CTRL_REF_UPDATE_INT	Strobe DLL control reference update interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20 STROBE_DLL_CTRL_SLV_UPDATE_INT	Strobe DLL control target update interval Target delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE software can always cause an update of the target-delay line using the STROBE_SLV_FORCE_UPDATE register. The target delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control target Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control target override Set this field to 1 to Enable manual override for target delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Target Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK_PERIOD[1] / 2) / 16, Therefore, the input read-clock can be delayed relative to the input data by (STROBE_REF_CLOCK_PERIOD / 2) / 16 up to (STROBE_REF_CLOCK_PERIOD *8)/16. **NOTE** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK_PERIOD/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control target force updated Setting this field to 1, forces the target delay line to update to the DLL calibrated value immediately. The target delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the target-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1	Strobe DLL control reset

Table continues on the next page...

Table continued from the previous page...

Field	Description
STROBE_DLL_CTRL_RESET	Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half-period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE** Using the target delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

1. which is 1/STROBE_REF_CLOCK.

30.6.1.28 Strobe DLL status (STROBE_DLL_STATUS)

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

Offset

Register	Offset
STROBE_DLL_STATUS	74h

Field	Description
31-12 —	Reserved
11-8 MAJOR_VN	eMMC major version number Digit left of decimal point, in BCD format
7-4 MINOR_VN	eMMC minor version number Digit right of decimal point, in BCD format
3-0 VERSION_SUFFIX	eMMC version suffix The second digit right of decimal point, in BCD format

30.6.1.34 Command Queuing Capabilities (CQCAP)

This register indicates hardware capabilities.

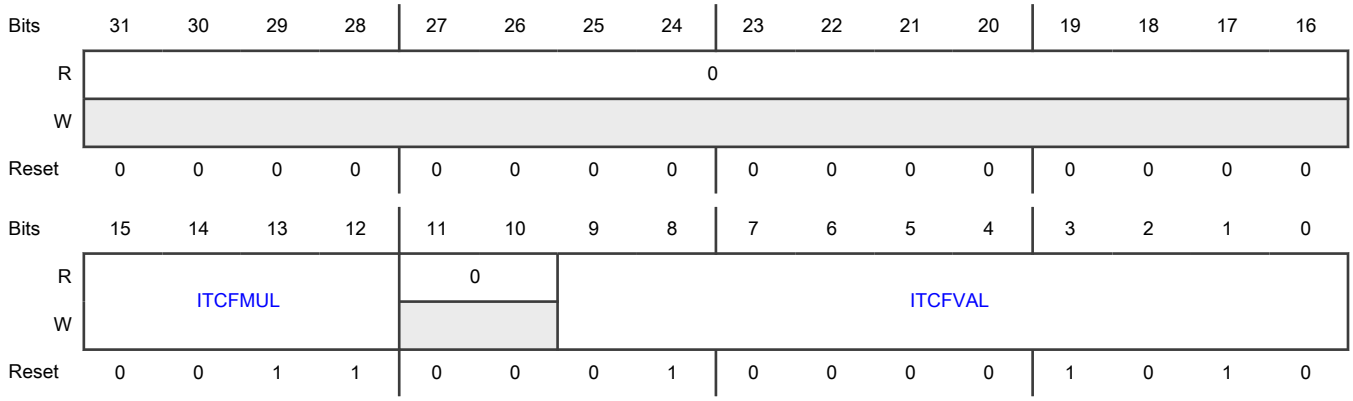
NOTE

This register must not be configured and must be used as a read-only register. Writing to the read-write fields of this register does not affect any functionality. Reset values reflect the correct capability information.

Offset

Register	Offset
CQCAP	104h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-12 ITCFMUL	Internal timer clock frequency multiplier ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See ITCFVAL definition for details. 0001 - 0.001 MHz 0010 - 0.01 MHz 0011 - 0.1 MHz 0100 - 1 MHz 0101 - 10 MHz 0110-1001 - Reserved
11-10 —	Reserved
9-0 ITCFVAL	Internal timer clock frequency value ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the polling period when using periodic SEND_QUEUE_ STATUS (CMD13) polling. The clock frequency is calculated as ITCFVAL* ITCFMUL. For example, to encode 19.2 MHz, ITCFVAL is C0h (= 192 decimal) and ITCFMUL is 3h (0.1 MHz): 192 * 0.1 MHz = 19.2 MHz.

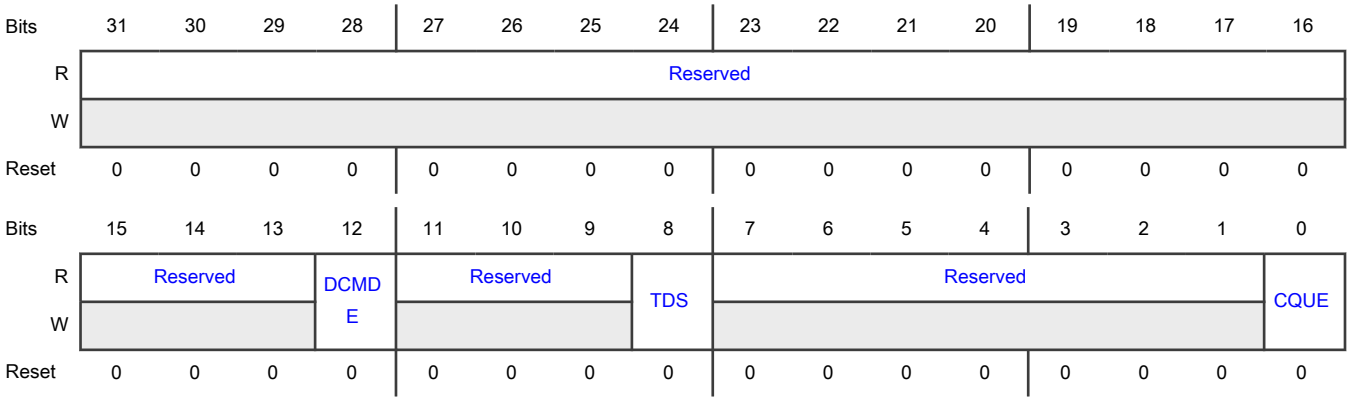
30.6.1.35 Command Queuing Configuration (CQCFG)

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Offset

Register	Offset
CQCFG	108h

Diagram



Fields

Field	Description
31-13 —	Reserved
12 DCMDE	Direct command (DCMD) enable This bit indicates to the hardware whether the Task Descriptor in slot #31 of the TDL is a Data Transfer Task Descriptor, or a Direct Command Task Descriptor. CQE uses this bit when a task is issued in slot #31, to determine how to decode the Task Descriptor. 0 - Task descriptor in slot #31 is a Data Transfer Task Descriptor 1 - Task descriptor in slot #31 is a DCMD Task Descriptor
11-9 —	Reserved
8 TDS	Task descriptor size This bit indicates whether the task descriptor size is 128 bits or 64 bits as detailed in Data Structures section. This bit can only be configured when Command Queuing Enable bit is ‘0’ (command queuing is disabled) 0 - Task descriptor size is 64 bits 1 - Task descriptor size is 128 bits
7-1 —	Reserved
0	Command queuing enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
CQUE	Software shall write '1' this bit when in order to enable command queuing mode (for example, enable CQE). When this bit is 0, CQE is disabled and software controls the eMMC bus using the legacy eMMC host controller. Before software writes '1' to this bit, software shall verify that the eMMC host controller is in idle state and there are no commands or data transfers ongoing. When software wants to exit command queuing mode, it shall clear all previous tasks if such exist before setting this bit to 0.

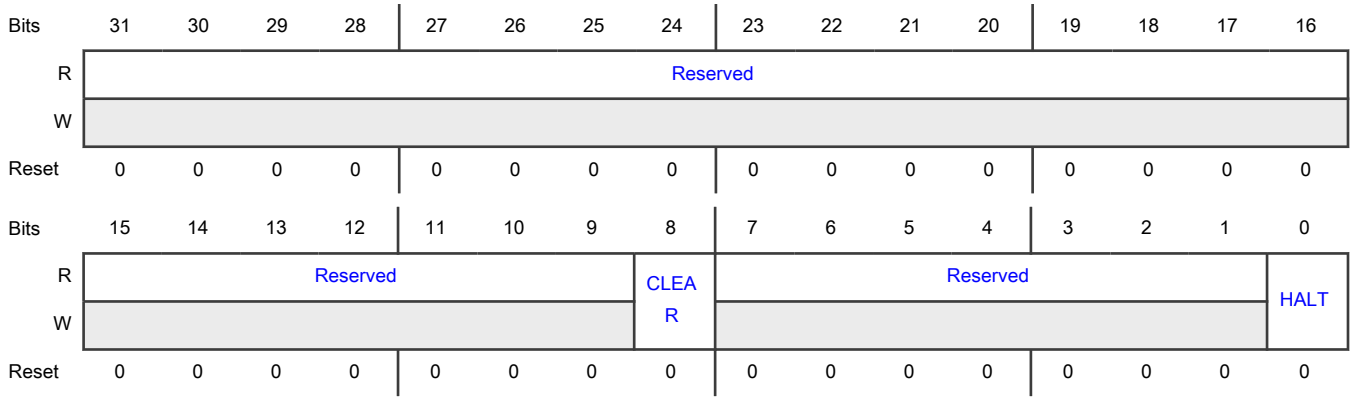
30.6.1.36 Command Queuing Control (CQCTL)

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Offset

Register	Offset
CQCTL	10Ch

Diagram



Fields

Field	Description
31-9 —	Reserved
8 CLEAR	Clear all tasks Software shall write '1' this bit when it wants to clear all the tasks sent to the chip. This bit can only be written when CQE is in halt state (for example, Halt bit is 1).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When software writes 1, the value of the register is updated to '1', and CQE shall reset CQTDBR register and all other context information for all unfinished tasks. Then CQE will clear this bit. Software should poll on this bit until it is set to back 0 and may then resume normal operation, by clearing the Halt bit. CQE does not communicate to the chip that the tasks were cleared. It is software's responsibility to order the chip to discard the tasks in its queue using CMDQ_TASK_MGMT command. Writing '0' to this register shall have no effect.
7-1 —	Reserved
0 HALT	Halt Host software shall write '1' to the bit when it wants to acquire software control over the eMMC bus and disable CQE from issuing commands on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT) When software writes '1', CQE shall complete the ongoing task if such a task is in progress. Once the task is completed and CQE is in idle state, CQE shall not issue new commands and shall indicate so to software by setting this bit to 1. Software may poll on this bit until it is set to 1, and may only then send commands on the eMMC bus. In order to exit halt state (for example, resume CQE activity), software shall clear this bit (write '0'). Writing '0' when the value is already '0' shall have no effect.

30.6.1.37 Command Queuing Interrupt Status (CQIS)

This register indicates pending interrupts that require service. Each bit in this registers is asserted in response a specific event, only if the respective bit is set in CQISTE register.

Offset

Register	Offset
CQIS	110h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W													W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-4 —	Reserved
3 TCL	Task cleared This status bit is asserted (if CQISTE[TCL_STE]=1) when a task clear operation is completed by CQE. The completed task clear operation is either an individual task clear (CQTCLR) or clearing of all tasks (CQCTL).
2 RED	Response error detected interrupt This status bit is asserted (if CQISTE[RED_STE]=1) when a response is received with an error bit set in the device status field. The contents of the device status field are listed in 6.13. Software uses CQRMEM register to configure which device status bit fields may trigger an interrupt, and which are masked.
1 TCC	Task complete interrupt This status bit is asserted (if CQISTE[TCC_STE]=1) when at least one of the following two conditions are met: • A task is completed and the INT bit is set in its Task Descriptor • Interrupt caused by Interrupt Coalescing logic (see 0)
0 HAC	Halt complete interrupt This status bit is asserted (if CQISTE[HAC_STE]=1) when halt bit in CQCTL register transitions from 0 to 1 indicating that host controller has completed its current ongoing task and has entered halt state.

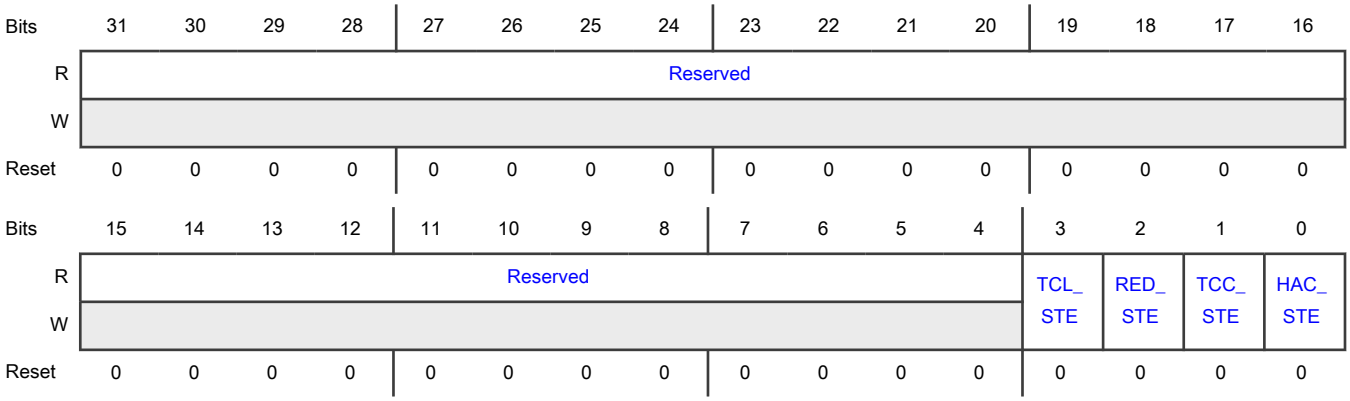
30.6.1.38 Command Queuing Interrupt Status Enable (CQISTE)

This register enables and disables the reporting of the corresponding interrupt to host software in CQIS register. When a bit is set ('1') and the corresponding interrupt condition is active, then the bit is CQIS is asserted. Interrupt sources that are disabled (‘0’) are not indicated in the CQIS register. This register is bit-index matched to CQIS register.

Offset

Register	Offset
CQISTE	114h

Diagram



Fields

Field	Description
31-4 —	Reserved
3 TCL_STE	Task cleared status enable Related to CQIS[TCL] 0 - CQIS[TCL] is disabled 1 - CQIS[TCL] is set when its interrupt condition is active
2 RED_STE	Response error detected status enable Related to CQIS[RED] 0 - CQIS[RED]is disabled 1 - CQIS[RED] is set when its interrupt condition is active
1 TCC_STE	Task complete status enable Related to CQIS[TCC] 0 - CQIS[TCC] is disabled 1 - CQIS[TCC] is set when its interrupt condition is active
0 HAC_STE	Halt complete status enable Related to CQIS[HAC] 0 - CQIS[HAC] is disabled 1 - CQIS[HAC] is set when its interrupt condition is active

30.6.1.39 Command Queuing Interrupt Signal Enable (CQISGE)

This register enables and disables the generation of interrupts to host software. When a bit is set ('1') and the corresponding bit in CQIS is set, then an interrupt is generated. Interrupt sources that are disabled (‘0’) are still indicated in the CQIS register. This register is bit-index matched to CQIS register.

Offset

Register	Offset
CQISGE	118h

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-4 —	Reserved
3 TCL_SGE	Task cleared signal enable When set and CQIS[TCL] is asserted, the CQE generates an interrupt.
2 RED_SGE	Response error detected signal enable When set and CQIS[RED] is asserted, the CQE generates an interrupt.
1 TCC_SGE	Task complete signal enable When set and CQIS[TCC] is asserted, the CQE generates an interrupt.
0 HAC_SGE	Halt complete signal enable When set and CQIS[HAC] is asserted, the CQE generates an interrupt.

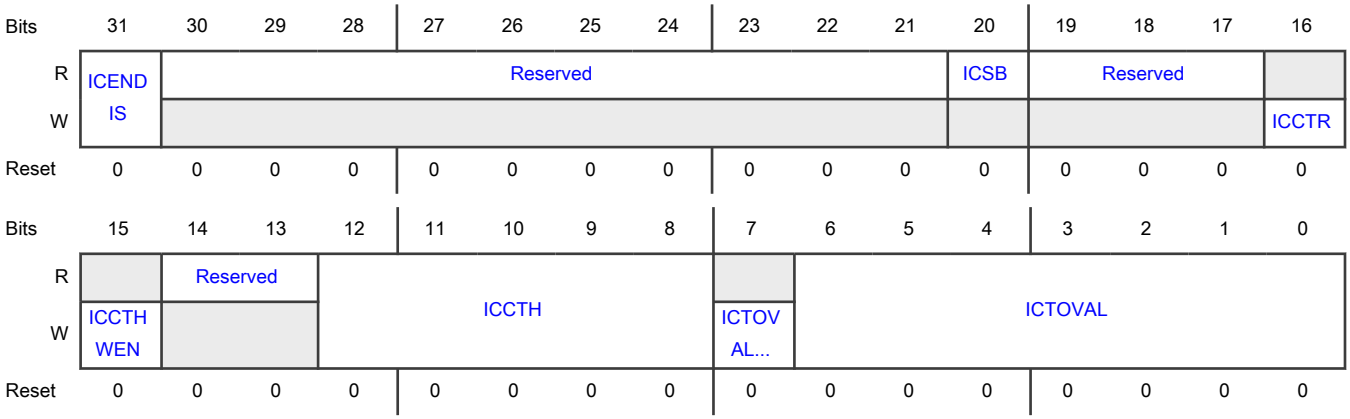
30.6.1.40 Command Queuing Interrupt Coalescing (CQIC)

This register controls the interrupt coalescing feature.

Offset

Register	Offset
CQIC	11Ch

Diagram



Fields

Field	Description
31 ICENDIS	Interrupt coalescing enable/disable When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
30-21 —	Reserved
20 ICSB	Interrupt coalescing status This bit indicates to software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (for example, ICSB is set if and only if IC counter > 0). 0 - No task completions have occurred since last counter reset (IC counter =0) 1 - At least one task completion has been counted (IC counter >0)
19-17 —	Reserved
16 ICCTR	Counter and timer reset When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
15 ICCTHWEN	Interrupt coalescing counter threshold write enable When software writes ‘1’, the value ICCTH is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICCTH is not updated.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE Write operations to ICCTH are only allowed when the task queue is empty.
14-13 —	Reserved
12-8 ICCTH	Interrupt coalescing counter threshold Software uses this field to configure the number of task completions (only tasks with INT=0 in the Task Descriptor) which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in ICCTH. The maximum allowed value is 31. **NOTE** When ICCTH is 0, task completions are not counted, and counting-based interrupts are not generated. In order to write to this field, the ICCTHWEN field must be set at the same write operation.
7 ICTOVALWEN	Interrupt coalescing timeout value write enable When software writes ‘1’, the value ICTOVAL is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICTOVAL is not updated. **NOTE** Write operations to ICTOVAL are only allowed when the task queue is empty.
6-0 ICTOVAL	Interrupt coalescing timeout value Software uses this field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when a data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field it generates an interrupt and stops. The timer’s unit is equal to 1024 clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 01h (1024 clock periods) and the maximum value is 7Fh (127*1024 clock periods). For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in ICTOVAL is 10h, the calculated polling period is 16*1024*52.08 ns= 853.33 us **NOTE** When ICTOVAL is 0, the timer is not running, and timer-based interrupts are not generated. In order to write to this field, the ICTOVALWEN bit must be set at the same write operation.

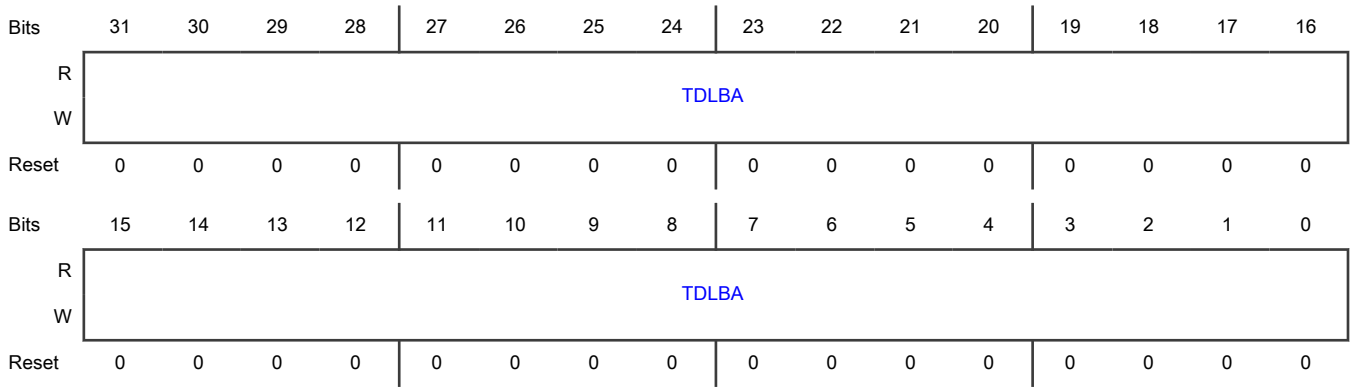
30.6.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)

This register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Offset

Register	Offset
CQTDLBA	120h

Diagram



Fields

Field	Description
31-0 TDLBA	Task descriptor list base address This register stores the LSB bits (bits 31:0) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This address shall be set on 1 KByte boundary: The lower 10 bits of this register shall be set to 0 by software and shall be ignored by CQE.

30.6.1.42 Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU)

This register is used for configuring the upper 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Offset

Register	Offset
CQTDLBAU	124h

Diagram

R W	TDBR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 TDBR	Task doorbell Software configures TDLBA and TDLBAU, and enable CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers CQE to start processing the task encoded in slot n of the TDL. CQE always processes tasks in-order according to the order submitted to the list by CQTDBR write transactions. CQE processes Data Transfer tasks by reading the Task Descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device. CQE processes DCMD tasks (in slot #31, when enabled) by reading the Task Descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to '0' by CQE in one of the following events: 1. When a task execution is completed (with success or error) 2. The task is cleared using CQTCLR register 3. All tasks are cleared using CQCTL register 4. CQE is disabled using CQCFG register Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission: CQE shall process the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution will be based on said processing order. Writing 0 by software shall have no impact on the hardware, and will not change the value of the register bit.

30.6.1.44 Command Queuing Task Completion Notification (CQTCN)

This register is used by CQE to notify software about completed tasks.

Offset

Register	Offset
CQTCN	12Ch

Diagram

R	TCN															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 TCN	Task complete notification CQE shall set bit n of this register (at the same time it clears bit n of CQTDBR) when a task execution is completed (with success or error). When receiving interrupt for task completion, software may read this register to know which tasks have finished. After reading this register, software may clear the relevant bit fields by writing 1 to the corresponding bits.

30.6.1.45 Command Queuing Device Queue Status (CQDQS)

This register stores the most recent value of the device’s queue status.

Offset

Register	Offset
CQDQS	130h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-0 DQS	Device queue status Every time the Host controller receives a queue status register (QSR) from the device, it updates this register with the response of status command (For example, the chip's queue status).

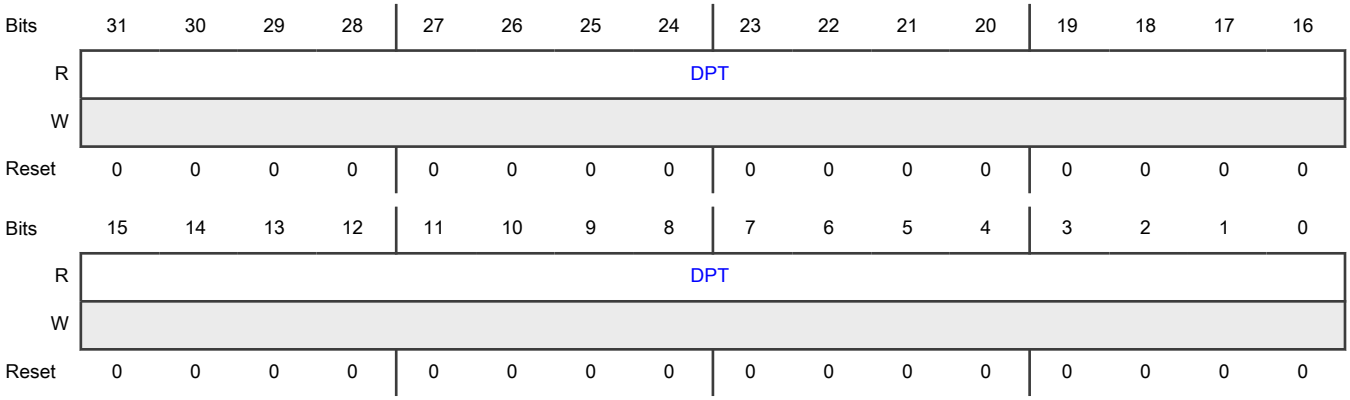
30.6.1.46 Command Queuing Device Pending Tasks (CQDPT)

This register indicates to software which tasks are queued in the device, awaiting execution.

Offset

Register	Offset
CQDPT	134h

Diagram



Fields

Field	Description
31-0 DPT	Device pending tasks Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task hasn't been executed yet. CQE shall set this bit after receiving a successful response for CMD45. CQE shall clear this bit after the task has completed execution. Software needs to read this register in the task-discard procedure, when the controller is halted, to determine if the task is queued in the device. If the task is queued, the driver sends a CMDQ_TASK_MGMT (CMD48) to the device ordering it to discard the task. Then software clears the task in the CQE. Only then the software orders CQE to resume its operation using CQCTL register.

30.6.1.47 Command Queuing Task Clear (CQTCLR)

This register is used for removing an outstanding task in the CQE. The register should be used only when CQE is in Halt state.

Offset

Register	Offset
CQTCLR	138h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	TCLR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 TCLR	Task clear Writing 1 to bit n of this register orders CQE to clear a task which software has previously issued. This bit can only be written when CQE is in Halt state as indicated in CQCFG register Halt bit. When software writes '1' to a bit in this register, CQE updates the value to '1', and starts clearing the data structures related to the task. CQE clears the bit fields (sets a value of 0) in CQTCLR and in CQTDBR once clear operation is complete. Software should poll on the CQTCLR until it is cleared to verify clear operation was complete. Writing to this register only clears the task in the CQE and does not have impact on the device. In order to discard the task in the device, host software shall send CMDQ_TASK _MGMT while CQE is still in Halt state. Host driver is not allowed to use this register to clear multiple tasks at the same time. Clearing multiple tasks can be done using CQCTL register. Writing 0 to a register bit shall have no impact.

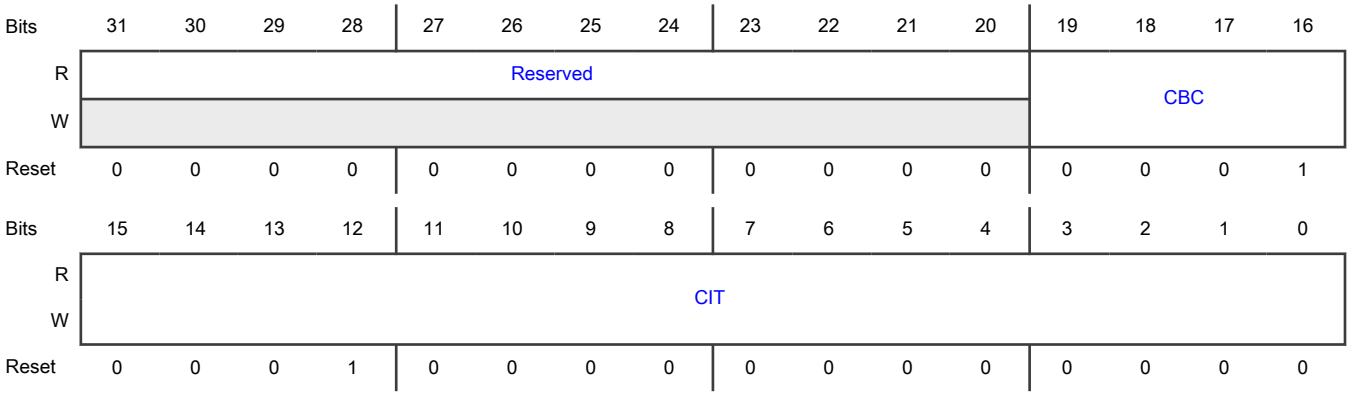
30.6.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)

The register controls the when SEND_QUEUE_STATUS commands are sent.

Offset

Register	Offset
CQSSC1	140h

Diagram



Fields

Field	Description
31-20 —	Reserved
19-16 CBC	Send status command block counter This field indicates to CQE when to send SEND_QUEUE_STATUS (CMD13) command to inquire the status of the device's task queue. A value of *n* means CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. A value of 0 means that SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead it will be sent only when the data lines are idle. A value of 1 means that STATUS command is to be sent during the last block of the transaction.
15-0 CIT	Send status command idle timer This field indicates to CQE the polling period to use when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicating that no task is ready for execution, CQE counts the configured time until it issues the next SEND_QUEUE_STATUS. Timer units are clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). Default interval is: 4096 clock periods. For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in CQSSC1.CIT is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 us

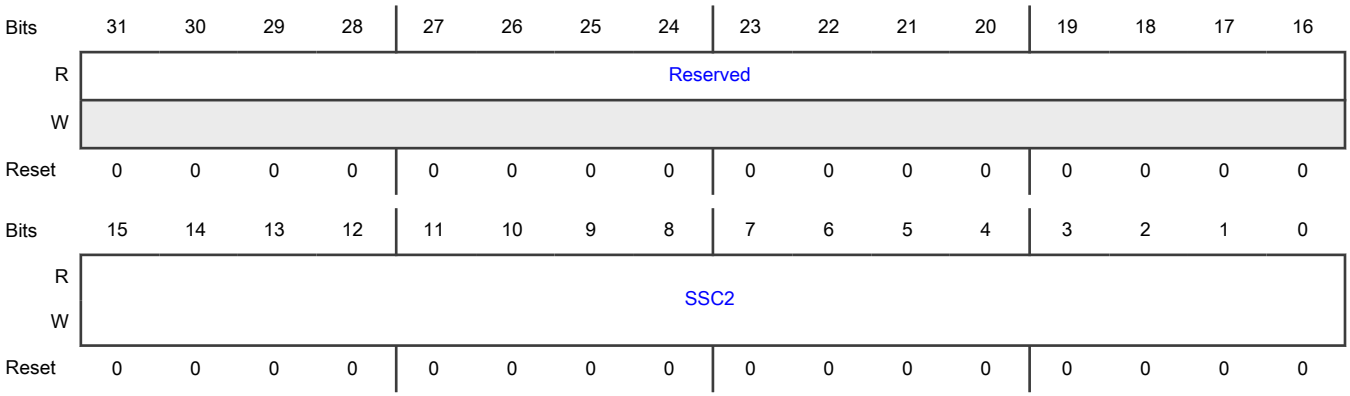
30.6.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)

This register is used for configuring RCA field in SEND_QUEUE_STATUS command argument.

Offset

Register	Offset
CQSSC2	144h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 SSC2	Send queue status RCA This field provides CQE with the contents of the 16-bit RCA field in SEND_QUEUE_ STATUS (CMD13) command argument. CQE copies this field to bits 31:16 of the argument when transmitting SEND_ QUEUE_STATUS (CMD13) command.

30.6.1.50 Command Queuing Command Response for Direct-Command Task (CQCRDCT)

This register is used for passing the response of a DCMD task to software.

Offset

Register	Offset
CQCRDCT	148h

Diagram

Reset	1	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0

Fields

Field	Description
31-0 RMEM	Response mode error mask This bit is used as in interrupt mask on the device status filed which is received in R1/R1b responses. The reset value of this register is set to trigger an interrupt on all “Error” type bits in the device status, as defined in 6.13. **NOTE** Responses to CMD13 (SQS) encode the QSR, so they are ignored by this logic. 0000_0000_0000_0000_0000_0000_0000_0000 - When a R1/R1b response is received, bit i in the device status is ignored 0000_0000_0000_0000_0000_0000_0000_0001 - When a R1/R1b response is received, with bit i in the device status set, a RED interrupt is generated

30.6.1.52 Command Queuing Task Error Information (CQTERRI)

This register is updated by CQE when an error occurs on data or command related to a task activity.

When such error is detected by CQE or indicated by the eMMC controller CQE stores in CQTERRI the task IDs and the command indices of the commands which were executed on the command line and data lines when the error occurred.

Software is expected to use this information in the error recovery procedure. See B.2.8 for more details.

Offset

Register	Offset
CQTERRI	154h

31 DTEFV	Data transfer error fields valid This bit is updated when an error is detected by CQE, or indicated by eMMC controller. If a data transfer is in progress when the error is detected/indicated, the bit is set to 1. If a no data transfer is in progress when the error is detected/indicated, the bit is cleared to 0.
30-29 —	Reserved
28-24 DTETID	Data transfer error task ID This field indicates the ID of the task which was executed on the data lines when an error occurred. The field is updated if a data transfer is in progress when an error is detected by CQE, or indicated by eMMC controller.
23-22 —	Reserved
21-16 DTECI	Data transfer error command index This field indicates the index of the command which was executed on the data lines when an error occurred. The index shall be set to EXECUTE_READ_TASK (CMD46) or EXECUTE_WRITE_TASK (CMD47) according to the data direction. The field is updated if a data transfer is in progress when an error is detected by CQE, or indicated by eMMC controller.
15 RMEFV	Response mode error fields valid This bit is updated when an error is detected by CQE, or indicated by eMMC controller. If a command transaction is in progress when the error is detected/indicated, the bit is set to 1. If a no command transaction is in progress when the error is detected/indicated, the bit is cleared to 0.
14-13 —	Reserved
12-8 RMETID	Response mode error task ID This field indicates the index of the command which was executed on the command line when an error occurred. The field is updated if a command transaction is in progress when an error is detected by CQE, or indicated by eMMC controller.
7-6 —	Reserved
5-0	Response mode error command index

Chapter 31
CAN (FlexCAN)

31.1 Chip-specific FLEXCAN information

Table 216. Reference links to related information

Topic	Related module	Reference
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes two instances of CAN-FD Controllers (CAN-FD1 is in AONMIX and CAN-FD2 is in WAKEUPMIX).

CAN1 features a low-pass filter (=glitch filter) on the CAN RX input. This filter is fed by the can1_root_clk, and enabled by the WAKSRC field in the MCR register. If the filter is enabled and can1_clk_root is gated, then the CAN RX input will not reach the FlexCAN logic. This condition must be avoided either by disabling the glitch filter, or by ensuring can1_clk_root is always running when the CAN functionality is required.

CAN2 features a low-pass filter (=glitch filter) on the CAN RX input. This filter is fed by the WAKEUPMIX 24MHz clock and enabled by the WAKSRC field in the MCR register. If the filter is enabled its clock is gated, then the CAN RX input will not reach the FlexCAN logic. This condition must be avoided either by disabling the glitch filter, or by ensuring its clock is always running when the CAN functionality is required.

NOTE

The FlexCAN clock description mentions an "oscillator domain". This domain is connected either to can_clk_root for the CAN module (CAN_CTRL1[CLKSRC] = 0) or to the WAKEUPMIX bus clock (CAN_CTRL1[CLKSRC]=1). It is not directly connected to any oscillator.

31.2 Overview

FlexCAN is a communication controller implementing the CAN protocol according to the ISO 11898-1:2015 standard and CAN 2.0 Part B protocol specifications.

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific real-time processing and reliable operation requirements in the electromagnetic interference (EMI) environment of a vehicle. FlexCAN is a full implementation of the CAN protocol specification, the CAN with flexible data rate (CAN FD) protocol, and the CAN version 2.0 Part B protocol. It supports both standard and extended message frames and long payloads.

NOTE

Legacy Receive (RX) FIFO cannot be used in CAN Flexible Data (FD) mode. In CAN FD mode, use the Enhanced Receive FIFO feature instead of the Legacy Receive FIFO.

NOTE

FD mode is limited to Message Buffer (MB) mode only, the Enhanced Receive FIFO with DMA is supported.

31.2.1 Block diagram

Figure 134 shows the main submodules implemented in FlexCAN.

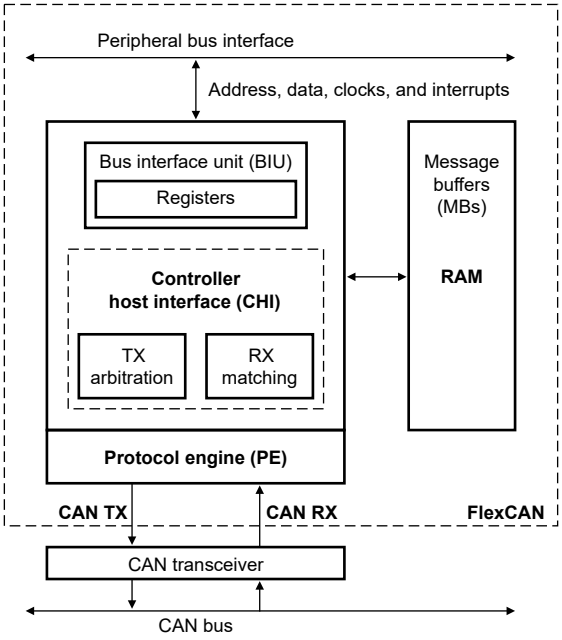

Figure 134. Block diagram

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- RAM access for receiving and transmitting message frames
- Receive message validation
- Error handling
- CAN FD message detection

Controller Host Interface (CHI) manages:

- Message buffer (MB) selection for reception and transmission
- Arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats

Bus Interface Unit (BIU) controls access to and from the internal interface bus to establish connection to the CPU and to other blocks. The BIU manages access to:

- Clocks
- Address and data buses
- Interrupt outputs
- DMA
- Test signals

31.2.2 Features

- Full implementation of *CAN with Flexible data rate (CAN FD) protocol specification* and *CAN Specification Version 2.0, Part B*:
  - Standard data frames
  - Extended data frames
  - Data length of 0–64 bytes
  - Content-related addressing

- Compliance with ISO 11898-1:2015 standard
- Flexible message buffers that can be configured to store a payload of 0, 8, 16, 32, or 64 bytes
  - Increasing the payload size decreases the number of supported message buffers (see FlexCAN memory partition for CAN FD).
  - Message buffers are configurable as receive or transmit, supporting standard and extended messages.
- Individual Receive Mask registers for each message buffer
- Full-featured Legacy RX FIFO with storage capacity for six frames and automatic internal pointer handling with DMA support
- Full-featured Enhanced RX FIFO with storage capacity of 20 CAN FD frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Programmable clock source to CAN Protocol Interface, either peripheral clock or oscillator clock
- Optional general purpose RAM space, using RAM not used by reception or transmission structures
- Listen-Only mode
- Programmable loopback mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Timestamp based on 32-bit free-running timer, with optional external time tick
- Global network time, synchronized by specific message
- Maskable interrupts
- Independence from transmission medium (external transceiver is assumed)
- Short latency time due to arbitration scheme for high-priority messages
- Low-power modes, with programmable wake-up on bus activity
- Transceiver delay compensation when transmitting CAN FD messages at faster data rates
- Management of remote request frames, automatically or by software
- Restriction only to write CAN bit time settings and configuration bits in Freeze mode
- Transmit message buffer status (lowest-priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- ESR1[SYNCH] to indicate module is synchronous with CAN bus
- CRC status for transmitted message
- Legacy RX FIFO Global Mask register
- Selectable priority between message buffers and receive FIFO during matching process
- Powerful legacy RX FIFO ID filtering, capable of matching incoming IDs against either 128 extended IDs, 256 standard IDs, or 512 partial (8-bit) IDs, with 32 individual masking capability
- Powerful enhanced RX FIFO ID filtering, capable of matching incoming IDs against either 64 extended or 128 standard ID filter elements with three filtering schemes: mask plus filter, range, and two filters without mask
- Complete backward compatibility with previous FlexCAN version
- Detection and correction of errors in memory read accesses:
  - Each byte of FlexCAN memory is associated to five parity bits.
  - The error correction mechanism ensures that errors in one bit of this 13-bit word can be corrected (correctable errors).

— Errors in two bits can be detected but not corrected (noncorrectable errors).

31.3 Functional description

FlexCAN is a CAN protocol engine with a flexible message buffer system for transmitting and receiving CAN frames. The system is a set of message buffers (MBs) that stores configuration and control data, timestamp, message ID, and data (see Message buffer structure).

For classical CAN frames, FlexCAN supports simultaneous reception through Legacy FIFO and message buffer. For CAN FD frames, FlexCAN supports reception through message buffer and enhanced receive FIFO.

For message buffer reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the message buffer with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of message buffers to be transmitted based on the message ID (optionally augmented by three local priority bits) or the message buffer ordering.

A message buffer is active at a given time if it can participate in both the matching and arbitration processes. A receive message buffer with a 0b code is inactive (see Table 254). A transmit message buffer with a 1000b or 1001b code is also inactive (see Table 255).

FlexCAN can receive and transmit messages in CAN FD format. The message buffers are sized to store the quantity of data bytes selected by FDCTRL[MBDSRn]. The quantity of FD message buffers available for a given quantity of data bytes is described in the CAN FD Control (FDCTRL) register. See also FlexCAN memory partition for CAN FD.

31.3.1 Modes of operation

FlexCAN has these functional modes:

Table 217. Functional modes

Mode	Description
Normal (User or Supervisor)	In Normal mode, FlexCAN receives and transmits message frames, manages errors normally, and enables all CAN Protocol functions. User and Supervisor modes differ in the access to some restricted control registers.
Freeze	Freeze mode is enabled when MCR[FRZ] = 1. If enabled, FlexCAN enters Freeze mode when MCR[HALT] is 1 or when is requested at chip level and FlexCAN writes 1 to MCR[FRZACK]. In this mode, no transmission or reception of frames is done, and synchronicity to the CAN bus is lost. See Freeze mode.
Loopback	FlexCAN enters this mode when CTRL1[LPB] becomes 1. In this mode, FlexCAN performs an internal loopback that can be used for self-test. The bit stream output of the transmitter is internally fed back to the receiver input. The receiving CAN input pin is ignored and the transmitting CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. To ensure proper reception of its own message, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. Both transmit and receive interrupts are generated.
Listen-Only	FlexCAN enters this mode when CTRL1[LOM] becomes 1. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.
CAN FD Active	In this mode, FlexCAN can transmit and receive all messages formatted according to the CAN FD Standard (2.0) and 2.0B Protocol in an interleaved fashion. The CPU can put FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

Some features available in classical CAN are unavailable in CAN FD mode.

Table 218. Differences between classical CAN and CAN FD

Feature	Classical CAN	CAN FD
Legacy RX FIFO DMA	Yes	No
Legacy RX FIFO	Yes	No
Enhanced RX FIFO DMA	Yes	Yes
Enhanced RX FIFO	Yes	Yes

FlexCAN can operate in these low-power modes:

Table 219. Low-power modes

Mode	Description
Module Disable	FlexCAN enters this mode when the CPU writes 1 to MCR[MDIS] and FlexCAN writes 1 to MCR[LPMACK]. After FlexCAN is disabled, it issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Writing 0 to MCR[MDIS] exits this mode. See Module Disable mode.
Doze	FlexCAN enters this mode when MCR[DOZE] is 1, Doze mode is requested at chip level, and FlexCAN writes 1 to MCR[LPMACK]. When in Doze mode, FlexCAN issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. This mode is exited when: • MCR[DOZE] becomes 0 • The chip is removed from Doze mode • Or activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Doze mode.
Stop	FlexCAN enters this mode when Stop mode is requested at chip level and FlexCAN writes 1 to MCR[LPMACK]. When in Stop mode, FlexCAN puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode occurs when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self-Wake-up mechanism is enabled. See Stop mode.

31.3.1.1 Modes of operation details

FlexCAN has functional modes and low-power modes. See Modes of operation for an introductory description of all the modes of operation. The following subsections contain functional details about Freeze mode and low-power modes.

CAUTION

FlexCAN does not support "Permanent Dominant" failure on the CAN bus line. If a Low-Power request or Freeze mode request occurs during a "Permanent Dominant" condition, the corresponding acknowledgment field can never be 1.

31.3.1.1.1 Freeze mode

This mode is requested either by the CPU writing 1 to MCR[HALT] or when the chip is put into Debug mode. MCR[FRZ] must be 1 and the module must not be in a low-power mode.

When MECR[NCEFAFRZ] becomes 1 and a noncorrectable error is detected in a memory read access performed by FlexCAN internal processes (see Error response), FlexCAN also requests Freeze mode. This request occurs via both MCR[HALT] and MCR[FRZ] automatically becoming 1.

To obtain acknowledgment, FlexCAN writes 1 to MCR[FRZACK]. The CPU must only consider FlexCAN to be in Freeze mode when both request and acknowledgment conditions are satisfied.

When Freeze mode is requested, FlexCAN:

1. Waits to be in either Intermission, Error Passive, Bus Off, or Idle state.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
3. Ignores the receive input pin and drives the transmit pin as recessive.
4. Stops the prescaler, halting all CAN protocol activities.
5. Grants write access to the Error Counters register, which is read-only in other modes.
6. Writes 1 to MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, you must wait for MCR[FRZACK] to become 1 before executing any other action, otherwise FlexCAN may operate unpredictably. In Freeze mode, all memory-mapped registers are accessible, except for CTRL1[CLKSRC], which can be read but cannot be written.

Freeze mode is exited in one of these conditions:

- CPU writes 0 to MCR[FRZ].
- The chip is removed from Debug mode or the MCR[HALT] becomes 0.

MCR[FRZACK] becomes 0 after the protocol engine recognizes the negation of the freeze request. After leaving Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.

31.3.1.1.2 Module Disable mode

This low-power mode is normally used to disable a complete FlexCAN block temporarily, with no power consumption. The CPU requests this mode by writing 1 to MCR[MDIS], and FlexCAN acknowledges the request by writing 1 to MCR[LPMACK]. The CPU must only consider FlexCAN to be in Disable mode when both the request and acknowledgment conditions are satisfied.

If FlexCAN is disabled during Freeze mode, the module requests to disable the clocks to the PE and CHI submodules, writes 1 to MCR[LPMACK] and writes 0 to MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and then checks that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Shuts down the clocks to the PE and CHI submodules.
5. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].

In this mode, the Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except for:

- The Receive Message Buffers Global Mask registers
- The Receive Buffer 14 Mask register
- The Receive Buffer 15 Mask register

When in Disable mode, these items may not be accessible:

- The message buffers
- The Receive Individual Mask registers
- The reserved words within RAM

To exit this mode, the CPU writes 0 to MCR[MDIS], causing FlexCAN to request to resume the clocks and write 0 to MCR[LPMACK]. This write occurs after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

31.3.1.1.3 Doze mode

This is a system low-power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion of MCR[LPMACK] by FlexCAN. The CPU must only consider FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register.

Also, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating MCR [DOZE]
- Self-Wake mechanism

In the Self-Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Doze mode, then after detection of a recessive to dominant transition on the CAN bus, FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK after the CAN protocol engine recognizes the negation of the Doze mode request. It also sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up interrupt to the CPU. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it does not receive the frame that woke it up. The following table details the effect of SLFWAK and WAKMSK after wakeup from Doze mode.

Table 220. Wakeup from Doze mode

SLFWAK	WAKINT	WAKMSK	FlexCAN clocks enabled	Wakeup interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	Yes	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Doze mode. (See MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

31.3.1.1.4 Stop mode

In this low-power mode for the system, all chip clocks can be stopped for maximum power savings. Stop mode is globally requested by the CPU and FlexCAN writes 1 to a Stop Acknowledgment signal to indicate acknowledgment. The CPU must only consider FlexCAN to be in Stop mode when both request and acknowledgment conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it shuts down the clocks globally by:

1. Writing 1 to MCR[LPMACK].
2. Writing 0 to MCR[FRZACK].
3. Sending the Stop Acknowledge signal to the CPU.

If Stop mode is requested during transmission or reception, FlexCAN:

1. Waits to be in either Idle or Bus Off state, or waits for the third bit of Intermission and verifies that it is recessive.
2. Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. FlexCAN does not take a pending move-in into account.
3. Ignores its receive input pin and drives its transmit pin as recessive.
4. Writes 1 to MCR[NOTRDY] and MCR[LPMACK].
5. Sends a Stop Acknowledge signal to the CPU, so that the CPU can shut down the clocks globally.

FlexCAN exits Stop mode when the CPU resumes the clocks and removes the Stop mode request. This exit can occur as a result of the Self-Wake mechanism.

In Self-Wake, if MCR[SLFWAK] = 1 when FlexCAN enters Stop mode, then upon detecting a recessive-to-dominant transition on the CAN bus, FlexCAN writes 1 to ESR1[WAKINT]. If enabled by MCR[WAKMSK], FlexCAN generates a wake-up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up. Table 221 details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Waking from Stop mode only works when both fields are 1.

After the CAN protocol engine recognizes the negation of the Stop mode request, FlexCAN writes 0 to MCR[LPMACK]. FlexCAN then waits for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, FlexCAN does not receive the frame that woke it up.

Table 221. Waking from Stop mode

SLFWAK	WAKINT	WAKMSK	Chip clocks enabled	Wake-up interrupt generated
0	—	—	No	No
0	—	—	No	No
1	0	0	No	No
1	0	1	No	No
1	1	0	No	No
1	1	1	Yes	Yes

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the receive CAN input line when in Stop mode. (See the description in MCR[WAKSRC].) This feature can protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

NOTE

When FlexCAN is in the Bus Off state and Low-Power mode, FlexCAN may take an extra 128 IDLE cycles to leave the Bus Off state after exiting Low-Power mode.

31.3.2 Transmission process

NOTE

Instances of MB_CS in this topic refer to items in message buffers. See Message buffer structure for details.

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt flag is set, and clear it if necessary.
2. If the message buffer is active (transmission pending), request an abort of the transmission. Write the ABORT code (1001b) to the CODE field of the Control and Status word.
3. Poll the IFLAG register until the corresponding IFLAG flag is set, or wait for the interrupt request (if enabled by the respective IMASK field).
4. Read the CODE field to identify whether the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIOEN]).
7. Write payload data bytes.
8. Configure the Control and Status word as needed.
    a. Set ID type via MB_CS[IDE].
    b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
    c. If MCR[FDEN] = 1, configure MB_CS[EDL] and MB_CS[BRS]. For details about the relationship between the written value and transmitted value of MB_CS[ESI], see Table 231.[2]
    d. Configure Data Length Code in bytes via MB_CS[DLC]. See Table 258 for detailed information.
    e. To transmit the CAN frame, activate the message buffer by writing Ch to MB_CS[CODE].

NOTE

To maximize software performance, configure all the fields in the MB_CS word in a single 32-bit write operation. If the fields are configured in separate writes, MB_CS[CODE] must be the last write in the Control and Status word.

When the MB is activated, it participates in the arbitration process and its contents are eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission exceeds the MB payload size, FlexCAN completes the expected DLC by adding a constant CCh pattern.

After a successful transmission:

1. The value of the free-running timer is written into the timestamp field.
2. The CODE field in the Control and Status word is updated.
3. Both Cyclic Redundancy Check (CRCR) and CAN FD CRC (FDCRC) are updated.
4. A status flag is set in the Interrupt Flag register.
5. If allowed by the corresponding Interrupt Mask Register field, an interrupt is generated.

[2] There is no need to write the ESI field; it is automatically transmitted as dominant by error active nodes and as recessive by error passive nodes. If FlexCAN is operating as a network gateway, however, the CPU writes MB_CS[ESI] according to the error status of the node that sent the message.

After transmission, the new CODE field depends on the code used to activate the message buffer (see Table 254 and Table 255 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is 1), after the Interrupt flag is set for an MB configured as transmit buffer, the message buffer is blocked. The CPU cannot update the message buffer until the Interrupt Flag is cleared by the CPU. The CPU must clear the corresponding IFLAG flag before preparing this MB for a new transmission or reception.

NOTE

For backward compatibility (MCR[AEN] is 0), write the INACTIVE code (1000b) to the CODE field to deactivate the MB. In this case, the pending frame may be transmitted without notification (see Message buffer inactivation).

31.3.3 Arbitration process

The arbitration process scans the message buffers, searching for the transmission MB that holds the message to be sent at the next opportunity. This MB is called the arbitration winner. The scan starts from the lowest number MB and continues to the higher ones.

The arbitration process is triggered when at least one of the following occur:

- CRC field of the CAN frame arrives. The starting point depends on the value of CTRL2[TASD].
- Error Delimiter field of a CAN frame is in progress.
- Overload Delimiter field of a CAN frame is in progress.
- The winner of the arbitration is deactivated, and the CAN bus has not reached the first bit of the Intermission field.
- CPU writes to the Control and Status word of a winner MB, and the CAN bus has not reached the first bit of the Intermission field.
- CHI is in the Idle state and the CPU writes to the Control and Status word of any message buffer.
- FlexCAN exits Bus Off state.
- FlexCAN leaves Freeze mode or a low-power mode.

If the arbitration process does not evaluate all message buffers before the CAN bus reaches the first bit of the Intermission field, the temporary arbitration winner is invalidated. FlexCAN will not compete for the CAN bus at the next opportunity.

The arbitration process selects the winner among the active transmission message buffers at the end of the scan according to the values of CTRL1[LBUF] and MCR[LPRIOEN].

See Arbitration process (continued) for more information about this process.

31.3.3.1 Lowest-number message buffer first

If CTRL1[LBUF] is 1, the first (lowest number) active transmission message buffer found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is 1.

31.3.3.2 Highest-priority message buffer first

If CTRL1[LBUF] is 0, the arbitration process searches for the active transmission message buffer with the highest priority. The frame of this message buffer has a higher probability of winning the arbitration on the CAN bus when multiple external nodes compete for the bus simultaneously.

The sequence of bits considered for this arbitration is called the arbitration value of the message buffer. The transmission message buffer with the lowest arbitration value among all transmission message buffers has the highest priority.

If two or more message buffers have equivalent arbitration values, the message buffer with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN].

31.3.3.2.1 Local priority disabled

If MCR[LPRIOEN] = 0, the arbitration value is built using the exact sequence of bits that would be transmitted in a CAN frame where local priority is disabled.

Table 222. Composition of the arbitration value when local priority is disabled

Format	Message buffer arbitration value (32 bits)				
Standard (IDE = 0)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

31.3.3.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be 1. In this case, the message buffer PRIO field (see Message buffer structure) is included at the very left of the arbitration value.

Table 223. Composition of the arbitration value when local priority is enabled

Format	Message buffer arbitration value (35 bits)					
Standard (IDE = 0)	PRIO (3 bits)	Standard ID (11 bits)	RTR (1 bit)	IDE (1 bit)	— (18 bits)	— (1 bit)
Extended (IDE = 1)	PRIO (3 bits)	Extended ID[28:18] (11 bits)	SRR (1 bit)	IDE (1 bit)	Extended ID[17:0] (18 bits)	RTR (1 bit)

Because the PRIO field is the most significant part of the arbitration value, message buffers with low PRIO values have higher priority than message buffers with high PRIO values. This priority is maintained regardless of the rest of their arbitration values.

The PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

31.3.3.3 Arbitration process (continued)

After the arbitration winner is found (see Arbitration process), its content is copied to a hidden auxiliary message buffer called a transmit serial message buffer (TX SMB). The TX SMB has the same structure as a normal message buffer, but is not user-accessible. This copy operation is called move-out. After it is done, write access to the Control and Status word of the corresponding MB is blocked (if MCR[AEN] = 1). Write access is restored in one of the following events:

- The CPU clears the corresponding IFLAG flag after the message buffer is transmitted.
- FlexCAN enters Freeze mode or Bus Off state.
- FlexCAN loses the bus arbitration, or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the TX SMB is transmitted according to the CAN protocol rules.

The arbitration process can be triggered under the following conditions:

- During RX and TX frames from CAN CRC field to end of frame. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT = 124 to 128. The value of CTRL2[TASD] may be changed to optimize the arbitration start point.
- During Control and Status write by CPU in Bus Idle. The first Control and Status write starts the arbitration process, and a second Control and Status write during this same arbitration restarts the process. If other Control and Status writes are performed, the transmission arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle

state starts, then an arbitration process is triggered. In this case, the first and second Control and Status writes in Bus Idle do not restart the arbitration process. If there is not enough time to finish arbitration in the Wait for Bus Idle state and the next state is Idle, the scan is not interrupted. That scan is completed during Bus Idle state. During this arbitration, a Control and Status write does not cause an arbitration restart.

- Deactivation of an arbitration winner during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait for Bus Idle state). If a resynchronization occurs during the Wait for Bus Idle state, the arbitration process is restarted.

The arbitration process stops when:

- All message buffers are scanned.
- A transmission message buffer is found (if lowest buffer feature is enabled).
- An arbitration winner deactivates or aborts during any arbitration process.
- There is not enough time to finish the transmission arbitration process (for instance, when a deactivation is performed near the end of frame). In this case, the arbitration process is pending.
- An error or overload flag occurs in the bus.
- A low-power or Freeze mode request occurs in Idle state.

Arbitration is considered pending when:

- It is not possible to finish arbitration process in time.
- A Control and Status write occurs during arbitration, when that write is performed in an MB whose number is lower than the transmission arbitration pointer.
- Any Control and Status write occurs when there is no transmission arbitration process in progress.
- RX Match has updated an RX code to TX code.
- FlexCAN enters the Bus Off state.

If a Control and Status write is performed in the arbitration winner, a new process is restarted immediately.

If a Control and Status write is performed in an MB whose number is higher than the transmission arbitration pointer, the ongoing arbitration process scans this MB as normal.

31.3.4 Receive process

To be able to receive CAN frames into a message buffer, the CPU must prepare it for reception by executing the following steps:

1. If the message buffer is active (either TX or RX), deactivate it (see Message buffer inactivation), preferably with a safe deactivation (see Transmission abort mechanism).
2. Write the ID word into the message buffer.
3. To activate the message buffer, write the EMPTY code (0100b) to the CODE field of the Control and Status word. No setup is required for EDL, BRS, and ESI fields. The respective fields in the received message overwrite these fields.

After the MB is activated, it can receive frames that match the programmed filter. At the end of a successful reception, the move-in process updates the message buffer (see Move-in) as follows:

1. The received data field (up to eight bytes for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the free-running timer when the second bit of the Identifier field of the frame is written into the Timestamp field of the MB.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.

5. The CODE field in the Control and Status word is updated (see Table 254 and Table 255 in Section Message buffer structure).
6. If allowed by the corresponding Interrupt Mask field, a status flag is set in the Interrupt Flag register and an interrupt is generated.

The recommended way for the CPU to service (read) the frame received in a message buffer is:

1. Read the Control and Status word of that message buffer.
2. Verify that the BUSY bit is 0, indicating that the message buffer is locked. If it is not 0, repeat step 1 until it becomes 0. See Message buffer lock mechanism.
3. Read the contents of the message buffer. After the message buffer is locked, FlexCAN move-in processes do not modify its contents. See Move-in.
4. Acknowledge the proper flag in the IFLAG registers.
5. Unlock the message buffer by reading the free-running timer.

To verify frame reception, the CPU should poll the status flag bit for that specific message buffer in one of the IFLAG registers, not the CODE field of that message buffer. Polling the CODE field does not work in this case. After a frame is received and the CPU services the message buffer (by reading the Control and Status word and unlocking the message buffer), the CODE field does not return to EMPTY. It remains FULL, as explained in Table 254. If the CPU tries to work around this behavior by writing to the Control and Status word to force an EMPTY code after reading the message buffer without a prior safe deactivation, a newly received frame matching the filter of that message buffer may be lost.

CAUTION

In summary: never poll by reading the Control and Status word of the message buffers directly. Instead, read the IFLAG registers.

The Identifier field of the received frame is always stored in the matching message buffer. If the match was due to masking, the contents of the ID field in a message buffer may change. When MCR[SRXDIS] becomes 1, FlexCAN does not store frames transmitted by itself in any MB, even if it contains a matching receive MB. Also, no interrupt flag or interrupt signal is generated. Otherwise, when MCR[SRXDIS] becomes 0, if a matching receive MB exists, FlexCAN can receive frames transmitted by itself.

When MCR[DMA]) becomes 1, upon receiving a frame in the Legacy FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Legacy RX FIFO in DMA operation). The IMASK1 fields in the Legacy RX FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 80h address, optional).
2. Read the ID field (read 84h address, optional).
3. Read all data bytes (start read at 88h address, optional).

31.3.5 Matching process

The matching process scans the message buffer memory for RX MBs programmed with the same ID as the one received from the CAN bus. The matching starts from the lowest number message buffer and continues toward the higher-numbered ones.

For enhanced RX FIFO, see Enhanced RX FIFO.

For legacy RX FIFO, see Legacy RX FIFO.

As the frame is received, it is stored in a hidden auxiliary MB called Receive Serial Message Buffer (RX SMB).

The starting point of the matching process depends on the following conditions:

- If the received frame is a remote frame, the starting point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the starting point is the CRC field of the frame.

- If the received frame is a data frame and the DLC field has a nonzero value, the starting point is the DATA field of the frame.

If a matching ID is found in one of the message buffers, the move-in process transfers the contents of the RX SMB to the matched MB. If any CAN protocol error is detected, no match results are transferred to the matched MB at the end of reception.

The matching process scans all matching elements of the active receive MBs (CODE is EMPTY, FULL, OVERRUN, or RANSWER). The process searches for a successful comparison to the matching elements of the RX SMB that is receiving the frame on the CAN bus. The RX SMB has the same structure as a message buffer. The reception structures (message buffers) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures. The matching winner depends on conditions described in Table 224.

Table 224. Matching architecture

Structure	SMB[RTR]	CTRL2[RRS]	CTRL2[EACEN]	MB[IDE]	MB[RTR]	MB[ID[1]]	MB[CODE]
Message buffer	0	—	0	cmp[2]	no_cmp[3]	cmp_msk[4]	EMPTY, FULL, or OVERRUN
Message buffer	0	—	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	0	—	cmp	no_cmp	cmp	RANSWER
Message buffer	1	1	0	cmp	no_cmp	cmp_msk	EMPTY, FULL, or OVERRUN
Message buffer	1	1	1	cmp_msk	cmp_msk	cmp_msk	EMPTY, FULL, or OVERRUN

1. For message buffer structure, if SMB[IDE] is 1, the ID is 29 bits (ID Standard plus ID Extended). If SMB[IDE] is 0, the ID is 11 bits (ID Standard). For Legacy RX FIFO structure, the ID depends on IDAM.
2. cmp: Compares the RX SMB contents to the MB contents regardless of masks.
3. no_cmp: The RX SMB contents are not compared to the MB contents.
4. cmp_msk: Compares the RX SMB contents to MB contents, accounting for masks.

NOTE

For Enhanced RX FIFO, see Enhanced RX FIFO matching process.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the message buffer is EMPTY.
- The CODE field of the message buffer is either FULL or OVERRUN, and it has already been serviced (the CPU has read the Control and Status word and unlocked it as described in Message buffer lock mechanism).
- The CODE field of the message buffer is either FULL or OVERRUN and an inactivation (see Message buffer inactivation) is performed.

The scan order for message buffers is from the matching element with the lowest number to the higher ones.

31.3.5.1 Matching priority

MCR[IRMQ] affects the matching winner search for MBs. If the field is 0, the matching winner is the first matched MB whether it is free-to-receive or not. If it is 1, the matching winner is selected according to this priority:

1. The first free-to-receive matched message buffer
2. The last non-free-to-receive matched message buffer

31.3.5.2 Special cases

If a non-safe MB inactivation (see Message buffer inactivation) occurs during the matching process and the inactivated MB is the temporary matching winner, the temporary matching winner is invalidated. The matching elements scan is not stopped and not restarted; it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist. In this case, a message may be lost.

Consider an example where:

- MCR[IRMQ] is 1.
- There are two message buffers with the same ID: the second and fifth MBs in the array.
- FlexCAN starts receiving messages with that ID.

When the first message arrives, the matching algorithm finds the first match in message buffer number 2. The code of this message buffer is EMPTY, so the message is stored in that MB. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive." It continues looking, finds MB number 5, and stores the message in that MB. If yet another message with the same ID arrives, the matching algorithm finds no matching free-to-receive MBs, so it overwrites the last matched message buffer (MB number 5). In doing so, it updates the CODE field of the message buffer to OVERRUN.

The ability to match the same ID in more than one MB can be used to implement a reception queue to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the message buffers. The CPU can examine the Timestamp field of the message buffers to determine the order in which the messages arrived.

Matching a range of IDs is possible via ID acceptance masks. FlexCAN supports individual masking per message buffer (see Receive Individual Mask (RXIMR0 - RXIMR95)). During the matching algorithm, if a mask field is 1, the corresponding ID bit is compared. If the mask field is 0, the corresponding ID bit is a "don't care". Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, the module blocks them.

FlexCAN also supports an alternate masking scheme with only RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), and Receive 15 Mask (RX15MASK) for backward compatibility with legacy applications. This alternate masking scheme is enabled when the MCR[IRMQ] = 0.

31.3.6 Move process

There are two types of move process: move-in and move-out.

31.3.6.1 Move-in

The move-in process is the copying of a message received by an RX SMB to an RX message buffer that has matched it. Each RX SMB has its own move-in process, but only one is performed at a given time. The move-in starts only when the message held by the RX SMB has a corresponding match (see Matching process) and all of the following conditions are true:

- The CAN bus has reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the RX SMB.
  - The first bit of an overload frame next to the frame that carried the message in the RX SMB.
- There is no ongoing matching process.
- The CPU is not locking the destination message buffer.
- No move-in process from another RX SMB is ongoing. If more than one move-in process is to be started at the same time, both are performed and the newest process substitutes for the oldest.

The term "pending move-in" is used throughout the documentation and stands for a move-to-be that does not satisfy all of the above conditions.

If any of the following conditions is satisfied, the move-in is canceled and the RX SMB is able to receive another message:

- The destination message buffer is inactivated after the CAN bus has reached the first bit of the Intermission field next to the frame that carried the message. Also, its matching process has finished.
- There is a previous pending move-in to the same destination message buffer.
- The RX SMB is receiving a frame transmitted by FlexCAN itself and self-reception is disabled (MCR[SRXDIS] = 1).
- Any CAN protocol error is detected.

If the module enters Freeze or Low-Power mode, the pending move-in is not canceled. It remains on hold, waiting for Freeze and Low-Power mode to be exited and for the module to be unlocked. If a message buffer is unlocked during Freeze mode, the move-in occurs immediately.

The move-in process is FlexCAN executing the following steps:

1. Read all data words from the RX SMB in accordance with the selected payload size for the RX storage element.
2. Write all data words to the RX message buffer according to the selected payload size for the RX storage element. If the data size of the storage element is smaller than the original payload size described in the DLC field of the message, the payload is truncated. The high-order bytes that do not fit the destination size are lost.
3. Read the Control and Status and ID words from the RX SMB.
4. Write the Control and Status and ID words to the RX message buffer, and update the CODE field.

The move-in process is not atomic; the inactivation of the destination message buffer immediately cancels it (see Message buffer inactivation). In this case, the message buffer may remain partially updated, and therefore incoherent.

To alert the CPU that the message buffer content is temporarily incoherent, the BUSY Bit (least significant bit of the CODE field) of the destination message buffer becomes 1 during move-in.

31.3.6.2 Move-out

The move-out process is the copying of content from a TX message buffer to the TX SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- In the first bit of the Intermission field
- During the Bus Off state, when the TX error counter is in the 124 to 128 range
- During the Bus Idle state
- During the Wait for Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently outside the Bus Idle state. In Bus Idle, the move-out has the lowest priority of the concurrent memory accesses.

31.3.7 Data coherence

In order to maintain data coherency and proper FlexCAN operation, the CPU must obey the rules described in Transmission process and Receive process.

31.3.7.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU whether the transmission was aborted or the frame could not be aborted and was transmitted instead.

These primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be 1.
- The first CPU action must be the writing of abort code (1001b) into the CODE field of the Control and Status word.

Active message buffers configured for transmission must be aborted before they can be updated. The write operation is blocked and the transmission is not disturbed when the abort code is written to:

- A message buffer currently being transmitted.
- A message buffer that was already loaded into the TX SMB for transmission.

In this case, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters the Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

1. The message buffer is transmitted correctly.
2. The interrupt flag is set in the proper IFLAG register.
3. If enabled, an interrupt to the CPU is generated.

The abort request is automatically cleared when the interrupt flag is set. If only one of the above conditions is reached, the frame is not transmitted. In this case:

1. The abort code is written into the CODE field.
2. The interrupt flag is set in the proper IFLAG register.
3. Optionally, an interrupt is generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, the write operation is not blocked. The MB is updated and the interrupt flag is set. In this way, the CPU only needs to read the abort code to verify that the active MB was safely inactivated. In this case, although MCR[AEN] = 1 and the CPU wrote the abort code, the MB is inactivated and not aborted, because the transmission did not start yet. A message buffer is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

31.3.7.2 Message buffer inactivation

Inactivation protects the message buffer against updates by FlexCAN internal processes. It allows the CPU to rely on message buffer data coherence after having updated it, even in Normal mode.

Inactivation of transmission message buffers must be performed only when MCR[AEN] = 0.

If a message buffer is inactivated, it does not participate in the arbitration process or the matching process until it is reactivated. See Transmission process and Receive process for detailed instructions on how to inactivate and reactivate a message buffer.

To inactivate a message buffer, the CPU must update its CODE field to INACTIVE (either 0b or 1000b).

Because you cannot synchronize the CODE field update with FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of an inactivated RX message buffer may be lost without notice. This loss can occur even if there are other message buffers with the same filter.
- A frame containing the message within an inactivated TX message buffer may be transmitted without setting the respective IFLAG flag.

To perform a safe inactivation and avoid the above consequences for TX message buffers, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the message buffer (see Message buffer lock mechanism).

31.3.7.3 Message buffer lock mechanism

In addition to message buffer inactivation, FlexCAN uses a message buffer lock mechanism to maintain data coherence for the receive process. When the CPU reads the Control and Status word of an RX message buffer with codes FULL or OVERRUN, FlexCAN is configured to allow the CPU to read the whole message buffer in an atomic operation. FlexCAN sets an internal lock flag for that message buffer.

The lock is released in any of the following events:

- The CPU reads the free-running timer (global unlock operation).
- The CPU reads the Control and Status word of another message buffer, regardless of its code.
- The CPU writes into the Control and Status word. This procedure is not recommended for normal unlocking, because it cancels a pending move and may lose a received message.

The message buffer lock prevents a new frame from being written into the message buffer when the CPU is reading it.

NOTE

The locking mechanism applies only to RX message buffers that have a code other than INACTIVE (0b) or EMPTY[1] (0100b). TX message buffers cannot be locked.

Consider an example where:

- The second and the fifth message buffers of the array are programmed with the same ID.
- FlexCAN has already received and stored messages into these two message buffers.
- The CPU reads message buffer number 5 while another message with the same ID is arriving.

When the CPU reads the Control and Status word of message buffer number 5, this message buffer is locked. The new message arrives and the matching algorithm finds no free-to-receive message buffers, so it overrides message buffer number 5. This message buffer is locked, so the new message cannot be written to it. The message remains in the RX SMB until the message buffer is unlocked, and only then is it written to the message buffer.

If the message buffer remains locked and another new message with the same ID arrives, the new message overwrites the one in the RX SMB. There is no indication of lost messages in the CODE field of the message buffer or in Error and Status 1 (ESR1).

When the message is moved from the RX SMB to the message buffer, the BUSY bit on the CODE field becomes 1. If the CPU reads the Control and Status word and identifies that the BUSY bit is 1, it must wait until the BUSY bit becomes 0 to access the MB.

NOTE

If the BUSY bit is 1 or the message buffer is empty, reading the Control and Status word does not lock the message buffer.

Inactivation takes precedence over locking. If the CPU inactivates a locked receive message buffer, then its lock status is negated and the message buffer is marked as invalid for the current matching round. Any pending message on the RX SMB is not transferred to the message buffer. A message buffer is unlocked when the CPU reads Free-Running Timer (TIMER) or the Control and Status word of another message buffer.

The lock and unlock mechanisms have the same functionality in Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. If unlocking occurs during a low-power mode, however, the move-in is postponed (see Modes of operation). Move-in takes place only when the module returns to Normal or Freeze mode.

31.3.8 Enhanced RX FIFO

FlexCAN supports an enhanced RX FIFO engine which can store up to 20 CAN FD messages. The region 2000h–204Fh contains the output of the FIFO, which the CPU should read. To enable the enhanced RX FIFO, write 1 to ERFCR[ERFEN]. FlexCAN has

[1] In previous FlexCAN versions, reading the Control and Status word locked the message buffer even when CODE indicates it is EMPTY. This behavior is maintained when the IRMQ bit is 0.

two FIFO options, Legacy RX FIFO and Enhanced RX FIFO, but both options cannot be enabled at the same time. See Legacy RX FIFO for additional information.

To configure the enhanced RX FIFO watermark, write a value to ERFCR[ERFWM]. If ERFCR[ERFWM] is configured, the CPU is notified only if a minimum number of messages is stored in the FIFO. When the number of stored messages is greater than the value in ERFCR[ERFWM], the module sets ERFSR[ERFWMI]. Optionally, if MCR[DMA] or ERFIER[ERFWMIIE] are enabled, a DMA transfer or an interrupt can be triggered, respectively.

For the enhanced RX FIFO to receive, the CPU must execute the configuration procedure below. If the CPU must change any configurations of the Enhanced RX FIFO, the same procedure must be followed.

Prerequisites

MCR[RFEN] must be 0.

Procedure

Step	Purpose	Programming	Notes
1	Enter Freeze mode.	See Freeze mode.	—
2	If enhanced RX FIFO is not already enabled, enable it.	Write 1 to ERFCR[ERFEN].	—
3	Reset enhanced RX FIFO engine.	Write 1 to ERFSR[ERFCLR].	—
4	If the enhanced RX FIFO error flags are set, clear them.	Write 1 to these flags: • ERFSR[ERFUFW] • ERFSR[ERFOVF] • ERFSR[ERFWMI] • ERFSR[ERFDA]	—
5	Specify the total number of enhanced RX FIFO filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NFE].	—
6	Specify the number of extended ID and standard ID filter elements to be used in Enhanced RX FIFO reception.	Write the number to ERFCR[NEXIF].	ERFCR[NEXIF] ≤ ERFCR[NFE] + 1.
7	If you are using DMA, enable DMA.	Write 1 to MCR[DMA].	—
8	If you are using DMA, specify the number of words to transfer for each Enhanced RX FIFO data element.	Write the number to ERFCR[DMALW].	—
9	Specify the Enhanced RX FIFO watermark.	Write the number to ERFCR[ERFWM].	If MCR[DMA] = 1, ERFCR[ERFWM] should be 0h.
10	If you are using interrupts, enable the interrupts.	Write 1 to the interrupt enables in Enhanced RX FIFO Interrupt Enable (ERFIER).	—
11	Configure the filter elements.	Write to the ERFFEL*n* registers.	ERFFEL*n* registers are implemented in RAM; you must explicitly initialize them before prior any reception.
12	Exit Freeze mode.	See Freeze mode.	—

There are two types of enhanced RX FIFO filter elements that can be stored in ERFFEL*n* registers: extended-ID filter elements and standard-ID filter elements. Each extended-ID filter element is stored in two ERFFEL*n* registers, and each standard-ID filter element is stored in one ERFFEL*n* register. ERFCR[NFE] defines the total number of Enhanced RX FIFO filter elements.

In addition, the filter memory space can be split into two regions: one for extended-ID filter elements and another for standard-ID filter elements, according to ERFCR[NEXIF]. Figure 135 shows how the enhanced RX filter elements are defined. See Enhanced RX FIFO matching process for information about the Enhanced RX FIFO matching process and filter element formats.

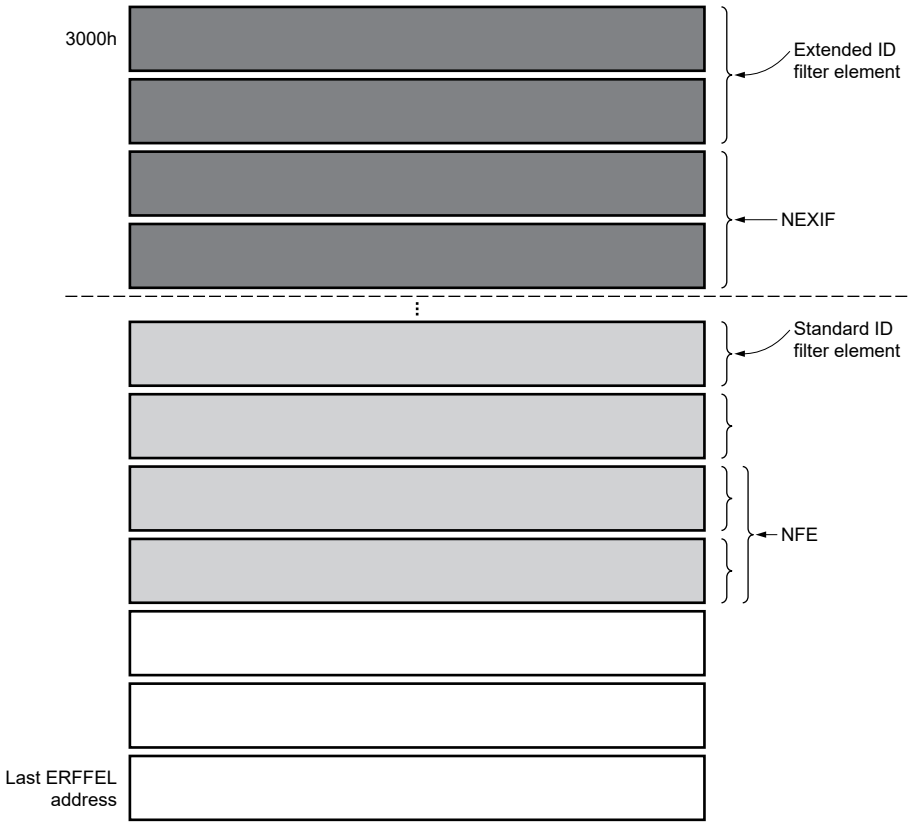

Figure 135. Number of enhanced RX FIFO filter elements

31.3.8.1 Enhanced RX FIFO matching process

When ERFCR[ERFEN] = 1, FlexCAN scans the ERFFEL*n* memory region. If at least one filter element satisfies the matching criteria, the CAN message content is transferred to the enhanced RX FIFO memory. If multiple filters match the incoming message ID, the first matching filter found by the matching process must be indicated in IDHIT.

Each ERFFEL*n* register can store one standard filter element. ERFFEL*n*[FEL][31:30], also called FSCH, determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base-frame format (IDE = 0).
  2. (ID[*n*] = STD ID filter [*n*]) or (STD ID Mask[*n*] = 0) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

In this explanation, RTR and ID are the Remote Transmit Request field and the ID from a CAN message, respectively.

If FSCH = b00, the filters and masks are defined as shown in Table 225.

Table 225. Standard ID filter element with filter and mask scheme (FSCH = b00)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b00		Reserved		RTR Filter	STD ID Filter		Reserved		RTR MASK	STD ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. ID ≥ STD ID Filter1.
  3. ID ≤ STD ID Filter2.
  4. (RTR = RTR filter) or (RTR MASK = 0).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b01, the filters and mask are defined as shown in Table 226.

Table 226. Standard ID filter element with range scheme (FSCH = b01)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b01		Reserved		RTR Filter	STD ID Filter2		Reserved		RTR MASK	STD ID Filter1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches a standard ID filter element only if these criteria are reached:
  1. CAN message is base frame format (IDE = 0).
  2. (ID[*n*] = STD ID Filter1[*n*]) or (ID[*n*] = STD ID Filter2[*n*]) for each bit *n* from 0 to 10.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

RTR and ID are the Remote Transmit Request bit and ID from a CAN message, respectively. If FSCH = b10, the filters are defined as shown in Table 227.

Table 227. Standard ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	27	26	16	15	12	11	10	0
FSCH = b10		Reserved		RTR Filter 2	STD ID Filter2		Reserved		RTR Filter 1	STD ID Filter1	

Each pair of ERFFEL*n* registers can store one extended filter element. ERFFEL*n*[FSCH] determines the matching criteria in this way:

- If FSCH = b00, the filter scheme is based on mask and filter. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID filter [*n*]) or (EXT ID Mask[*n*] = 0) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b00, the filters and masks are defined as shown in Table 228.

Table 228. Extended ID filter element with filter + mask scheme (FSCH = b00)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter	
Reserved		RTR MASK	EXT ID MASK	

- If FSCH = b01, the filter scheme is based on range. A CAN message matches an extended ID filter element only if the following criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. ID ≥ EXT ID Filter1.
  3. ID ≤ EXT ID Filter2.
  4. (RTR = RTR Filter) or (RTR MASK = 0).

If FSCH = b01, the filters and masks are defined as shown in Table 229.

Table 229. Extended ID filter element with range scheme (FSCH = b01)

31	30	29	28	0
FSCH		RTR Filter	EXT ID Filter2	
Reserved		RTR MASK	EXT ID Filter 1	

- If FSCH = b10, the filter scheme is based on two filters without masks. A CAN message matches an extended ID filter element only if these criteria are reached:
  1. CAN message is extended frame format (IDE = 1).
  2. (ID[*n*] = EXT ID Filter1[*n*]) or (ID[*n*] = EXT ID Filter2[*n*]) for each bit *n* from 0 to 28.
  3. (RTR = RTR Filter1) or (RTR = RTR Filter2).

If FSCH = b10, the filters are defined as shown in Table 230.

Table 230. Extended ID filter element with two-filter scheme (FSCH = b10)

31	30	29	28	0
FSCH		RTR Filter2	EXT ID Filter2	
Reserved		RTR Filter1	EXT ID Filter 1	

31.3.8.2 Enhanced RX FIFO under DMA operation

You can enable the DMA feature by writing 1 to both ERFCR[ERFEN] and MCR[DMA]. The DMA controller can read the received message by reading a message buffer structure at the enhanced FIFO output port at the address range defined in Enhanced RX FIFO structure.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

For proper FIFO engine operation, the CPU should not access the Enhanced FIFO output port address range during DMA operation. Before writing 1 to MCR[DMA], the CPU must service Enhanced RX FIFO status bits. Otherwise, these bits may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must first clear the ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFWMI], and ERFSR[ERFDA] flags. It must then clear the enhanced RX FIFO engine by writing one to ERFSR[ERFCLR].

When there is one frame available to be read from the Enhanced RX FIFO, FlexCAN sets ERFSR[ERFDA]. Upon receiving the request, the DMA controller can read the message in the Enhanced RX FIFO output. Each message reading process must end by the address defined in ERFCR[DMALW].

Follow these rules for Enhanced RX FIFO DMA operation:

- Because a DMA transfer cannot be changed dynamically, program ERFCR[DMALW] so the enhanced RX FIFO element can store the largest CAN message present on the CAN bus.
- Data bytes are valid according to the DLC field. See Table 258.

Each time the DMA controller reads one message from the FIFO, FlexCAN clears ERFSR[ERFDA]. If there is at least one message stored in the FIFO, FlexCAN sets it again.

Consider an example where the maximum number of bytes in the data field of a CAN frame for a certain application is eight, and high-resolution timestamp is enabled. In that case, the last enhanced RX FIFO address offset can be found in Table 268 and Table 269. Using this address offset, ERFCR[DMALW] can be determined in this way:

- Maximum number of data bytes = 8
- HR_TIME_STAMP enabled
- Last address offset = TS_OFF = 2014h
- DMALW = 5

31.3.8.3 Enhanced RX FIFO clear operation

When ERFCR[ERFEN] is 1, the CPU can clear the Enhanced RX FIFO by writing 1 to ERFSR[ERFCLR]. The clear operation resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. This operation can only be performed in Freeze mode; the module blocks the operation in other modes. This operation does not clear ERFSR[ERFUFW], ERFSR[ERFOVF], ERFSR[ERFDA], or ERFSR[ERFWMI]. The CPU must service all these fields before executing the clear FIFO operation.

31.3.9 Legacy RX FIFO

The Legacy RX FIFO is receive-only. To enable it, write 1 to MCR[RFEN]. To maintain software backward compatibility with previous versions of FlexCAN that did not have the Legacy FIFO feature, the reset value of this field is zero.

CAUTION

Do not enable Legacy RX FIFO when the CAN FD feature is enabled.

The Legacy FIFO is six messages deep. The memory region the Legacy FIFO structure occupies (both message buffers and Legacy FIFO engine) is described in Legacy RX FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the Legacy FIFO.

IFLAG1[BUF5I] (Frames Available in Legacy RX FIFO) is set when at least one frame is available to be read from the Legacy FIFO. If the corresponding mask bit enables it, an interrupt is generated. Upon receiving the interrupt, the CPU can read the message (accessing the output of the Legacy FIFO as a message buffer) and Legacy RX FIFO Information (RXFIR), then clear the interrupt. If there are more messages in the Legacy FIFO, clearing the interrupt:

1. Updates the output of the Legacy FIFO with the next message.
2. Updates RXFIR with the attributes of that message.
3. Reissues the interrupt to the CPU.

Otherwise, the flag remains cleared. The output of the Legacy FIFO is valid only when IFLAG1[BUF5I] is set.

IFLAG1[BUF6I] (Legacy RX FIFO Warning) is set when the Legacy RX FIFO receives a new message that increases the number of unread messages from four to five. This change means that the Legacy RX FIFO is almost full. The flag remains set until the CPU clears it.

IFLAG1[BUF7I] (Legacy RX FIFO Overflow) is set when an incoming message is lost because the Legacy RX FIFO is full. The flag is not set when the Legacy RX FIFO is full and a message buffer captures the message. The flag remains set until the CPU clears it.

Clearing one of the three flags above does not affect the state of the other two.

If an IFLAG flag is set and the corresponding mask bit is 1, an interrupt is generated.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria are specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN]. This table can be configured to one of the following formats (see also Legacy RX FIFO structure):

- Format A: 128 Identifier Acceptance Filters (IDAFs) — extended or standard IDs including IDE and RTR
- Format B: 256 IDAFs — standard IDs or extended 14-bit ID slices including IDE and RTR
- Format C: 512 IDAFs — standard or extended 8-bit ID slices

NOTE

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the Legacy RX FIFO has a corresponding Identifier Acceptance Filter Hit Indicator (IDHIT). The IDHIT can be read in the IDHIT field in the Control and Status word, as shown in the Legacy RX FIFO Structure description. The CPU can also obtain this information by accessing Legacy RX FIFO Information (RXFIR). RXFIR[IDHIT] refers to the message at the output of the Legacy FIFO, and is valid when IFLAG1[BUF5I] is set. RXFIR must be read only before clearing the flag, guaranteeing that the information refers to the correct frame within the Legacy FIFO.

The Individual Mask Registers (RXIMR*n*) individually affect up to 32 elements of the filter table, according to the value of CTRL2[RFFN]. This configuration allows very powerful filtering criteria to be defined. If MCR[IRMQ] is 0, the Legacy RX FIFO filter table is affected by Legacy RX FIFO Global Mask (RXFGMASK).

NOTE

See Table 218 for information about the difference between FD and non-FD regarding this feature.

31.3.9.1 Legacy RX FIFO in DMA operation

The receive-only Legacy FIFO can support DMA. To enable this feature, write 1 to both MCR[RFEN] and MCR[DMA]. To maintain backward compatibility with previous versions of the module that did not have the DMA feature, the reset value of MCR[DMA] is zero.

The DMA controller can read the received message by reading a message buffer structure at the Legacy FIFO output port in the 80h–8Ch address range.

NOTE

FlexCAN supports 32-bit access only for DMA transfers.

When MCR[DMA] = 1, the CPU must not access the Legacy FIFO output port address range. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. Otherwise, these flags may indicate that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before writing 0 to MCR[DMA], the CPU must perform a clear Legacy FIFO operation.

When at least one frame available to be read from the FIFO, IFLAG1[BUF5I] (Frames available in Legacy RX FIFO) is set. A DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the Legacy FIFO as a message buffer). The DMA reading process must end by reading address 8Ch. This read operation:

- Clears IFLAG1[BUF5I].
- Updates the FIFO output with the next message (if the FIFO is not empty).
- Updates Legacy RX FIFO Information (RXFIR) with the attributes of the new message.

If there are more messages stored in the FIFO, IFLAG1[BUF5I] is reasserted and another DMA request is issued. Otherwise, the flag remains cleared.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Legacy RX FIFO interruption and must not clear the related IFLAG flags. The related IMASK bits are not used to mask the generation of DMA requests.

NOTE

See Table 218 for information about the difference between FD and non-FD regarding this feature.

31.3.9.2 Clear legacy FIFO

When MCR[RFEN] = 1, you can use the clear Legacy FIFO operation to empty Legacy FIFO contents. When the CPU writes 1 to IFLAG1[BUF0I], the clear FIFO operation occurs. This operation can only be performed in Freeze mode; FlexCAN blocks it in other modes. This operation does not clear the FIFO IFLAG flags; the CPU must service all FIFO IFLAG flags before executing the clear FIFO operation.

When Legacy RX FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I], and the DMA request is canceled.

CAUTION

The clear Legacy FIFO operation does not clear IFLAG flags, except when MCR[DMA] = 1; in this case, only IFLAG1[BUF5I] is cleared.

31.3.10 Fault reaction

This situation is catastrophic, and in response to the fault reaction, FlexCAN goes into a safe state (Freeze) and drives a safe value (recessive bit) on the bus. Either CTRL2[FLT_RXN] or an input "fault reaction" signal from another module can trigger a fault reaction. FlexCAN remains in a safe state as long as CTRL2[FLT_RXN] = 1 or the "fault reaction" signal is asserted and MCR[FRZ] = 1.

A fault can occur at any time, including during frame transmission, reception, and BUS IDLE. If a fault occurs during frame transmission, FlexCAN stops the frame transmission and goes into a safe state.

If a fault occurs during frame reception, FlexCAN stops receiving the frame and goes into a safe state. If FlexCAN is in loopback or self-reception mode, the effect of the fault reaction is the same as described above.

When the fault condition is removed, FlexCAN remains in Freeze mode until the CPU writes 0 to MCR[FRZ].

31.3.11 Retransmission

If a message transmission is unsuccessful due to a reason other than a loss of arbitration or being aborted by the host, FlexCAN attempts to retransmit the message a number of times determined by the value of CTRL2[RETRY].

When a message transmission is unsuccessful, a counter is decremented. When that counter reaches zero, FlexCAN aborts the message. FlexCAN sets the IFLAG for the aborted message and an interrupt is generated (if enabled). FlexCAN sets the IFLAG and updates the CODE field of the control and status word by abort code. The host can read the IFLAG flag and CODE field to identify which message FlexCAN aborted due to retransmission attempts greater than the value of CTRL2[RETRY].

31.3.12 CAN protocol-related features

31.3.12.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure-detection capability that was in the original CAN FD protocol. This original protocol is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-ISO CAN FD protocol. FlexCAN still supports non-ISO CAN FD, so it can be used during an intermediate phase, for evaluation and development purposes.

It is recommended that you configure FlexCAN with the ISO CAN FD protocol by writing 1 to CTRL2[ISOCANFDEN].

31.3.12.2 CAN FD frames

ISO 11898-1:2015 specifies the Classical Frame format compliant to ISO 11898-1:2003 (2003) and introduces the CAN Flexible Data Rate Frame format (CAN FD). The Classical Frame format allows bit rates up to one Mbit/s and payloads up to eight bytes per frame. The Flexible Data Rate Frame format allows bit rates faster than one Mbit/s and payloads longer than eight bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are additional control bits in the CAN FD frame:

- The Extended Data Length (EDL) bit enables a longer data payload with different data length coding.
- The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame.
- The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes.

There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in Classical CAN format. When an FD frame is received and matches a message buffer, the RTR bit in the receiving message buffer becomes 0. The RTR bit must be considered in classical frames only.

31.3.12.2.1 CAN FD messages

CAN FD messages may be formatted as long frames where the data field exceeds eight bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching. In this case, the control field, data field, and CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and end of the frame. Messages in the classical CAN format are limited to transport a maximum payload of eight bytes at nominal rate. Figure 136 illustrates the message formats for classical and FD frames with either standard or extended ID.

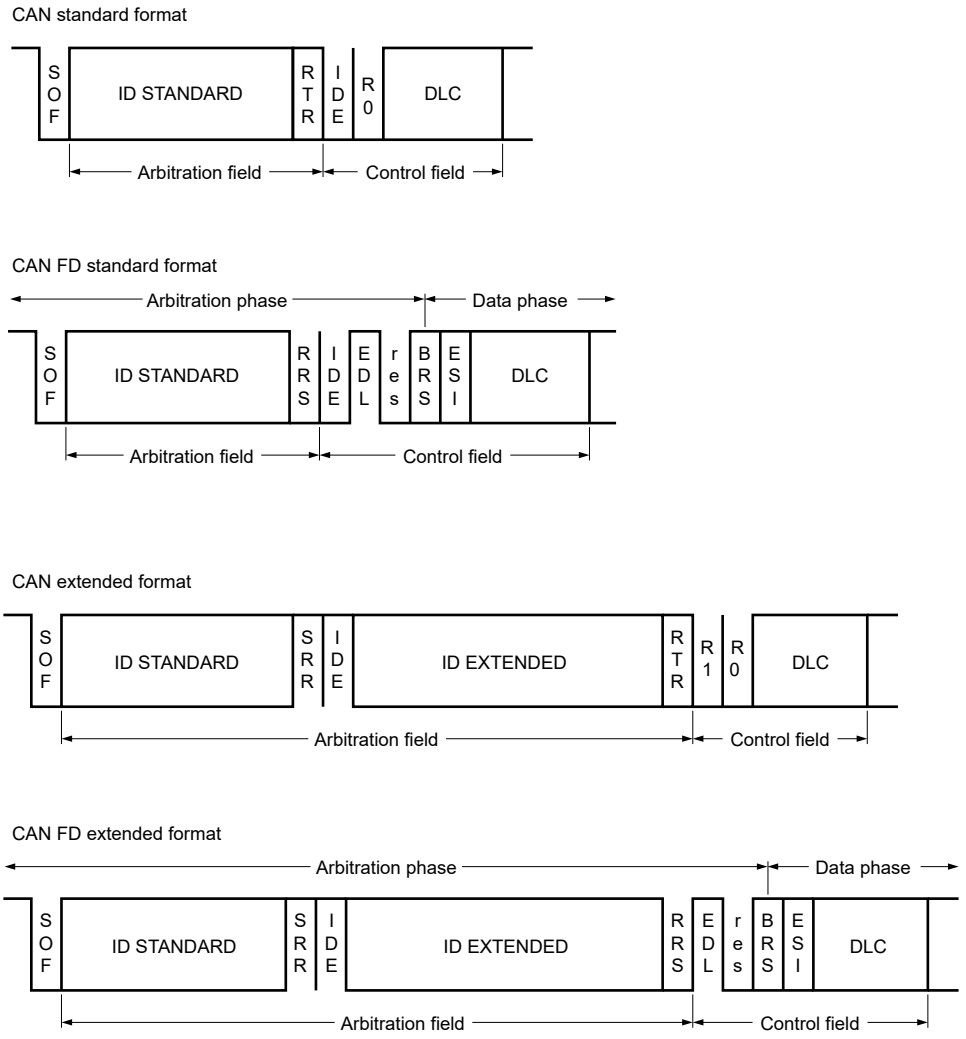

Figure 136. CAN message formats

MCR[FDEN] enables the ability to receive and transmit CAN FD messages. A recessive R0 bit in CAN frames with 11-bit identifiers, or a recessive R1 bit in CAN frames with 29-bit identifiers, is decoded as an EDL bit (not a reserved one). A recessive EDL bit identifies a CAN FD frame, and a dominant EDL bit identifies a Classical CAN frame. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded according to the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start of Frame (SOF) bit until the Bit Rate Switch (BRS) bit is called the arbitration phase. This part is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, is called the data phase. When this second part is transmitted, a second set of CAN data bit timing configuration values determines the data bit rate. Finally, from the CRC delimiter until the Intermission bits, the transmission returns to nominal bit rate.

31.3.12.2.2 BRS in CAN FD

In CAN FD frames with bit rate switching, the bit timing changes inside the frame at the sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by CAN Bit Timing (CBT). (Control 1 (CTRL1) also defines this timing for backward compatibility.) Upon detecting a recessive BRS bit, the CAN data bit timing is used as defined by CAN FD Bit Timing (FDCBT).

NOTE

If the time quantum length in nominal bit timing and in the data bit timing are not identical, a quantization error of up to one time quantum of the arbitration phase may be present as a phase error. This situation can occur after the switch from arbitration to data phase, and it lasts until the next synchronization event. The length of the time quantum should be the same in nominal and data bit timing. This configuration minimizes the chance of error frames on the CAN bus, and optimizes the clock tolerance in networks that use FD frames.

If BRS = 1 in the selected TX MB, FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching. If FDCTRL[FDRATE] = 0, the transmission is performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be written at any time but takes effect only for the next message transmitted or received.

Nominal bit timing is resumed at the sample point of the CRC Delimiter bit or when an error is detected, whichever occurs first. Figure 137 describes the mechanism for entering and leaving the data phase when the BRS bit is recessive.

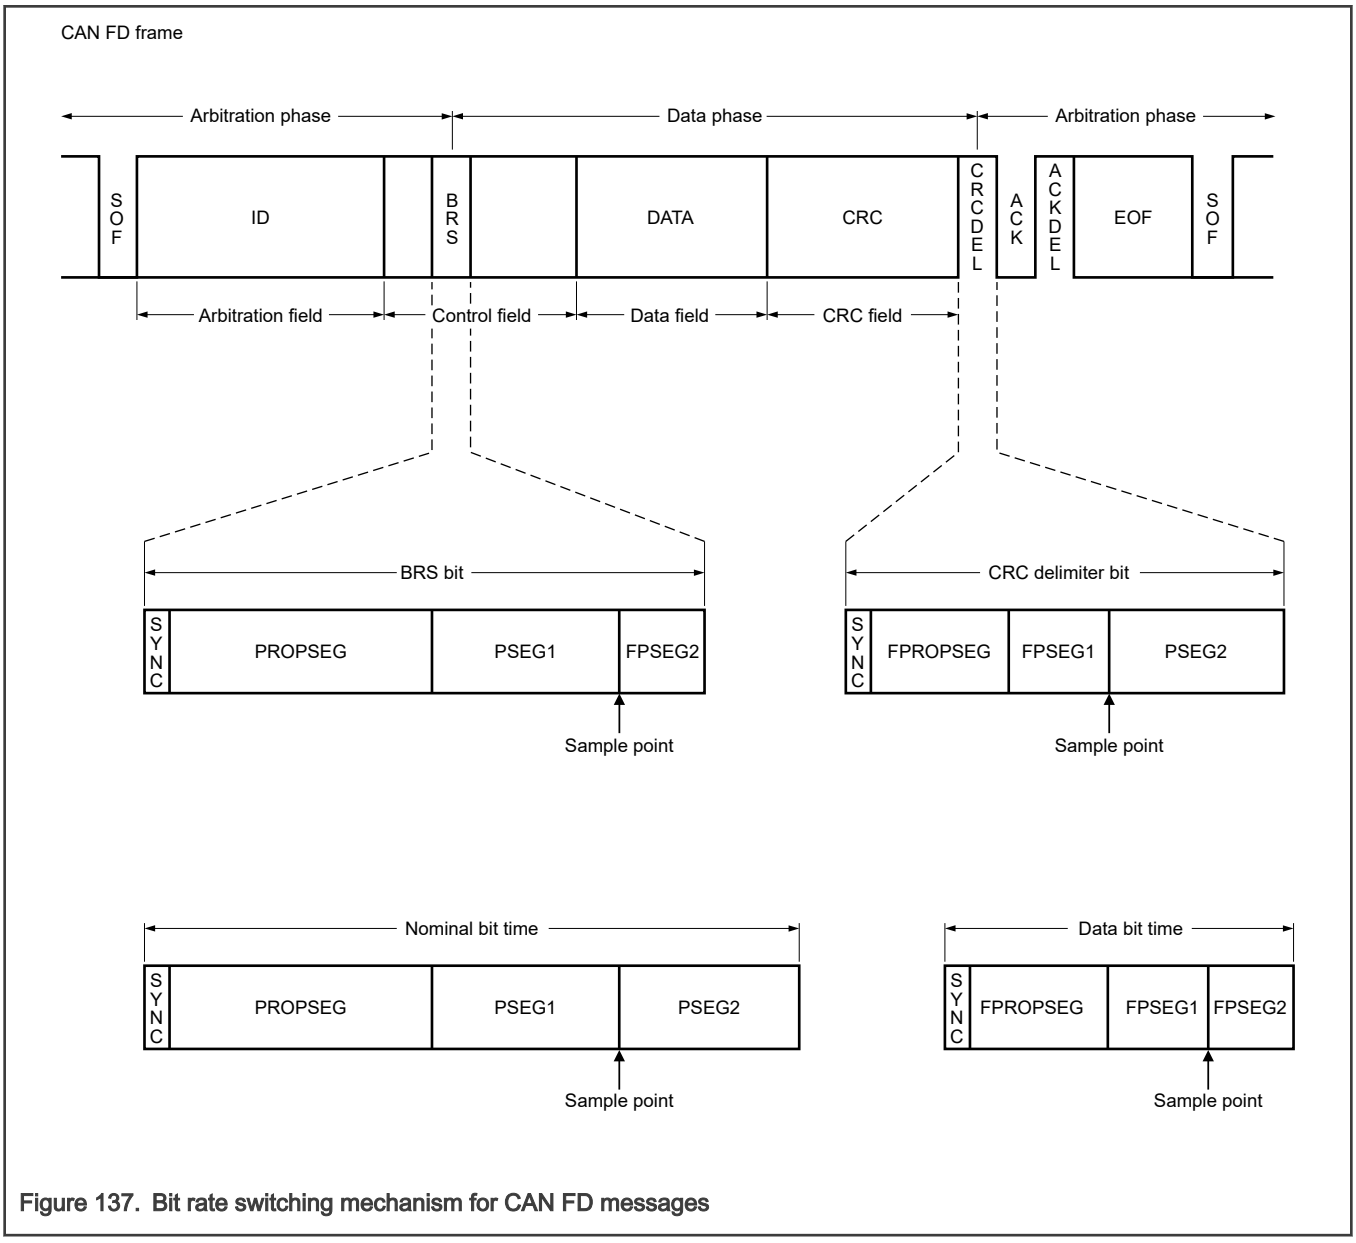

Figure 137. Bit rate switching mechanism for CAN FD messages

NOTE

In Classical CAN frames, the CRC delimiter is one recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter. It accepts two recessive bits before the recessive-to-dominant edge that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.

The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of the CAN_PE subblock. For example, for a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.

NOTE

The frequency used in this example may not be supported on this chip. It is shown only to demonstrate how the maximum configurable bit rate is calculated.

31.3.12.2.3 ESI in CAN FD

The value of the ESI field is determined by either of the following:

- The error state of the transmitter at the start of the transmission, if the frame is originated in the FlexCAN node
- The original transmitting node when FlexCAN is acting as a gateway for the message

If the transmitter is error-passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in Table 231.

Table 231. Written versus transmitted values of the ESI field

FlexCAN fault confinement status at start of frame	ESI field of TX MB	Transmitted ESI
Error active	0	0 (Error Active)
Error passive	0	1 (Error Passive)
Error active	1	1 (Error Passive)
Error passive	1	1 (Error Passive)

31.3.12.2.4 CRC calculations in CAN FD

Different CAN frame formats have different CRC polynomials. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to 16 bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than 16 bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The values of the EDL bit and the DLC field select the CRC sequence to be transmitted. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, CAN FD CRC (FDCRC) stores the calculated CRC for the transmitted message. This storage is performed with adequate length for the type of message, for CAN FD and non-FD messages. Cyclic Redundancy Check (CRCR) reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method changes for the CRC sequence, so the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence. This insertion occurs even if the last bits of the preceding field do not fulfill the CAN stuff condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN receives a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

31.3.12.2.5 CAN FD errors

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters ECR[RXERRCNT] and ECR[TXERRCNT] accumulate the counts of RX and TX errors, respectively, for both FD and non-FD frames indiscriminately. Two extra error counters, ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST], accumulate RX and TX errors occurring in the data phase of CAN FD frames with BRS = 1 only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see Error Counter (ECR)).

These error flags report errors in both CAN FD and non-FD frames:

- ESR1[BIT1ERR]
- ESR1[BIT0ERR]
- ESR1[ACKERR]
- ESR1[CRCERR]
- ESR1[FRMERR]
- ESR1[STFERR]

If CTRL1[ERRMSK] = 1, they also generate the ERRINT interrupt.

These additional error flags indicate the occurrence of errors in the data phase of CAN FD frames with BRS = 1:

- ESR1[BIT1ERR_FAST]
- ESR1[BIT0ERR_FAST]
- ESR1[CRCERR_FAST]
- ESR1[FRMERR_FAST]
- ESR1[STFERR_FAST]

No ACKERR is detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on ECR[RXERRCNT] and ECR[TXERRCNT] only. Information in ECR[RXERRCNT_FAST] and ECR[TXERRCNT_FAST] may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN detects an error while transmitting or receiving a CAN FD message in the data phase, it immediately switches:

- Back to the arbitration phase, and
- Back to the nominal rate to start an error flag.

31.3.12.2.6 CAN FD synchronization

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. A hard synchronization is also performed at the recessive-to-dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize when transmitting in the CAN FD data phase.

31.3.12.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase, when BRS = 1 in the message. This feature enables the use of rates up to 8 Mbit/s.

During the data phase of a CAN FD frame, if the transmitter cannot receive its own latest transmitted bit at the sample point of that bit, it detects a bit error. When bit rate switching is enabled (BRS = 1), the CAN bit time in the data phase can become shorter than the loop delay of the transceiver. This condition impedes the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

The transceiver delay compensation (TDC) process defines a secondary sample point where the transmitted bit is correctly compared to the received bit to check for bit errors.

You can enable the TDC mechanism via FDCTRL[TDCEN] or ETDC[ETDCEN]. The TDC mechanism is effective only during the data phase of FD frames with BRS = 1. It has no effect on either non-FD frames or FD frames transmitted at the normal bit rate. When the transmitted message has BRS = 1, TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit. When TDC is active, the real received bit is compared to the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

NOTE

The transmitters using TDC disregard the value of the CRC delimiter bit. A global error at the end of the CRC field causes the receivers to send error frames that the transmitter detects during Acknowledge or End of Frame.

For every transmitted FD frame with BRS = 1, the transition from the recessive EDL bit to the dominant R0 bit triggers the delay measurement (as shown in Figure 138). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The measured loop delay time added to an offset value specified in FDCTRL[TDCOFF] or ETDC[ETDCOFF] determines the position of the secondary sample point. FDCTRL[TDCVAL] or ETDC[ETDCVAL] stores the result of this calculation. The TDCVAL and ETDCVAL value saturates at its maximum value of 63 CANCLK and 255 CANCLK when the delay measurement is too long.

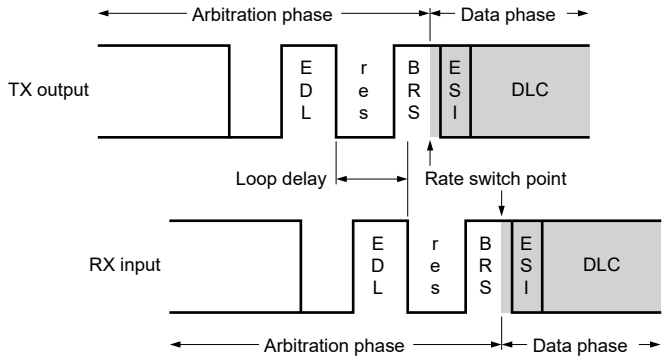

Figure 138. Transceiver loop delay measurement

The measured loop delay is not enough to define the secondary sample point, because it relates to the CAN bit edges. The transceiver delay compensation offset FDCTRL[TDCOFF] or ETDC[ETDCOFF] is used to shift the secondary sample point to an intermediate point inside the bit time, far away from its edges. The value of FDCTRL[TDCOFF] or ETDC[ETDCOFF] cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset must use optimal settings. To ensure that bit sampling is performed in the best region, configure the TDC offset as shown in this equation:

$$Offset = (FPSEG1 + FPROPSEG + 2) \times (FPRESDIV + 1)$$
or
$$Offset = (DTSEG1 + 2) \times (EDPRESDIV + 1), \textit{ if ETDCEN}$$

Equation 18. TDC offset calculation

Figure 139 shows the SSP position when these settings are used.

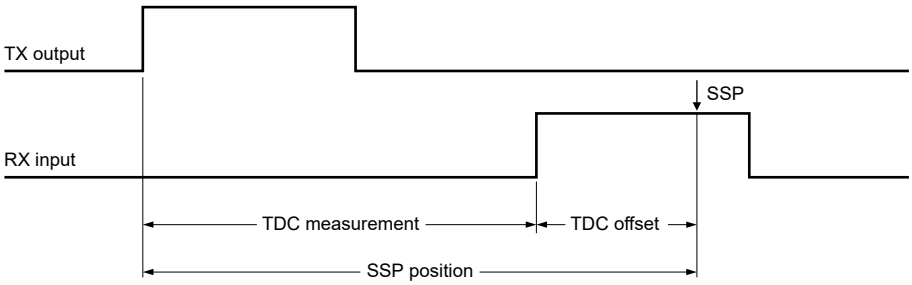

Figure 139. SSP position with optimal values

Alternatively, if CTRL2[BTE] and ETDC[ETDCEN] are 1, you can write 1 to ETDC[TDMDIS] to disable the transceiver delay measurement. In this case, only ETDC[ETDCOFF] defines the SSP position. Figure 140 shows the secondary sample point position when the transceiver delay measurement is disabled.

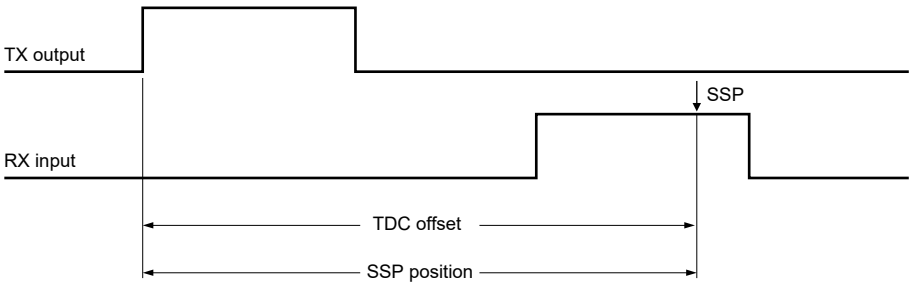

Figure 140. SSP position with TDC measurement disabled by ETDCEN and TDMDIS

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every TX CAN bit:

- The transmitted TX bit value is temporarily stored in a buffer.
- A time countdown based on FDCTRL[TDCVAL] or ETDC[ETDCVAL] is started. This countdown ends with the comparison of the received RX bit (delayed by the external loop delay plus the specified offset) to the stored TX bit.

If a bit error is detected at the secondary sample point, FlexCAN issues an error flag to the CAN bus at the next sample point.

During the arbitration phase, delay compensation is always disabled. During the data phase, the TDC mechanism of FlexCAN can compensate a maximum delay of 3 CAN bit times − 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] or ETDC[ETDCFAIL] flag is set. The flag indicates when the TDC mechanism is out of range and is unable to compensate the transceiver loop delay.

31.3.12.4 Remote frames

A remote frame is a special type of frame. You can program a message buffer to be a remote request frame by configuring the message buffer as Transmit with the RTR = 1. After the remote request frame is transmitted successfully, the message buffer becomes a receive message buffer, with the same ID as before.

When FlexCAN receives a remote request frame, the frame can be treated in different ways, depending on remote request storing (CTRL2[RRS]) and RX FIFO Enable (MCR[RFEN]):

- If RRS = 0, the ID of the frame is compared to the IDs of the transmit message buffers with the CODE field 1010b. If a matching ID exists, this message buffer frame is transmitted. If the matching message buffer has the RTR = 1, FlexCAN transmits a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response.

  The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. If a remote request frame is received and matches a message buffer, this message buffer immediately enters the internal arbitration process. However, it is considered a normal TX message buffer, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If CTRL2[RRS] = 1, the ID of the frame is compared to the IDs of the receive message buffers with the CODE field 0100b, 0010b, or 0110b. If a matching ID exists, this message buffer stores the remote frame in the same fashion as a data frame. No automatic remote response frame is generated. The mask registers are used in the matching process.
- If MCR[RFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Legacy FIFO filtering criteria. If the remote frame matches one of the target IDs, it is stored in the Legacy FIFO and presented to the CPU.

  For filtering formats A and B (see Legacy RX FIFO structure), it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted if they match the ID. Remote request frames are considered as normal frames. They generate a Legacy FIFO overflow when a successful reception occurs and the Legacy FIFO is already full.
- If ERFCR[ERFEN] = 1, FlexCAN does not generate an automatic response for remote request frames that match the Enhanced RX FIFO filtering criteria. Remote Request Frames are considered normal frames. They generate an Enhanced RX FIFO overflow when a successful reception occurs and the enhanced RX FIFO is already full.

NOTE

There is no remote frame in the CAN FD format. A fixed dominant RRS bit replaces the RTR bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

31.3.12.5 Overload frames

When a dominant bit is detected on the CAN bus in these locations, FlexCAN transmits overload frames:

- The first or second bit of Intermission.
- The seventh bit (last) of End of Frame field (RX frames).
- The eighth bit (last) of Error Frame Delimiter or Overload Frame Delimiter.

31.3.12.6 Message buffer timestamp

The value of the free-running timer is sampled at the beginning of the Identifier field on the CAN bus. This value is stored at the end of move-in in the TIME_STAMP field of a message buffer, providing network behavior regarding time.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously clocks the free-running timer.

When CTRL2[TIMER_SRC] = 0, the FlexCAN bit clock clocks the free-running timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free-running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See CTRL1[TSYN].

Alternatively, by configuring CTRL2[MBTSBASE], the timestamp of the message buffer can capture the lower or higher 16 bits of the high-resolution dedicated counter. See the chip-specific FlexCAN timestamp implementation.

31.3.12.7 High-resolution timestamp

The high-resolution timestamp (HR_TIME_STAMP) uses a dedicated timer with a 32-bit counter operating in free-running mode. CTRL2[TSTAMPCAP] enables the high-resolution timestamp. When this field is not zero, the dedicated 32-bit counter value is captured during a valid CAN frame and stored in an HR_TIME_STAMP*n* register.

Each HR_TIME_STAMP*n* corresponds to a specific message buffer. For example, HR_TIME_STAMP0 stores the 32-bit timestamp associated with message buffer 0. HR_TIME_STAMP1 stores the 32-bit timestamp associated with message buffer 1, and so on.

The counter value is captured according to CTRL2[TSTAMPCAP]. For classical CAN frames, the capture points can be the start of frame bit or the point in time a CAN frame is considered valid. This valid point is the seventh bit of end of frame for transmission and the sixth bit of end of frame for reception.

For CAN FD frames, the capture points can be:

- The start of frame

- The point in time a CAN FD frame is considered valid
- The res bit of a CAN FD frame

The 16-bit timestamp of the message buffer can be configured to capture the lower or higher 16 bits of the high-resolution timer. This configuration is made by CTRL2[MBTSBASE]. See the chip-specific FlexCAN timestamp implementation.

31.3.12.8 Protocol timing

Figure 141 shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source field CTRL1[CLKSRC] defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock. To guarantee reliable operation, select the clock source when the module is in Disable mode (MCR[MDIS] = 1).

NOTE

To identify the proper clock source, see the clock distribution chapter (module clocks table).

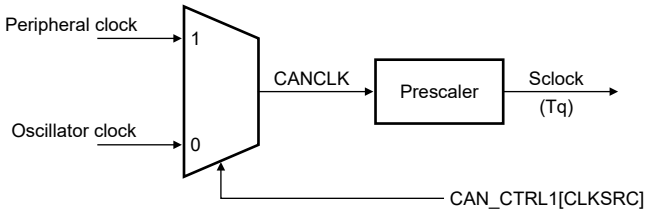

Figure 141. CAN engine clocking scheme

Select the oscillator clock whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

31.3.12.8.1 Bit timing configuration

FlexCAN supports various means to configure bit timing parameters required by the CAN protocol. Control 1 (CTRL1) has various fields to control bit timing parameters:

- CTRL1[PRESDIV]
- CTRL1[PROPSEG]
- CTRL1[PSEG1]
- CTRL1[PSEG2]
- CTRL1[RJW]

CAN Bit Timing (CBT) extends the range of the CAN bit timing variables in CTRL1. Enhanced Data Phase CAN Bit Timing (EDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) = 1.

Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in CBT. Enhanced Nominal CAN Bit Timing (ENCBT) extends the range of CAN bit timing variables in FDCBT. When using ENCBT and EDCBT, you must program the nominal bit timing and data phase serial clock (Sclock) dividers in Enhanced CAN Bit Timing Prescalers (EPRS).

NOTE

When the CAN FD feature is enabled, always write 1 to CBT[BTF] or CTRL2[BTE] and specify the CAN bit timing variables in CBT or ENCBT. See CAN Bit Timing (CBT) or Enhanced Nominal CAN Bit Timing (ENCBT).

CTRL1[PRESDIV], and its extended range CBT[EPRESDIV] (or EPRS[ENPRESDIV]) and FDCBT[FPRESDIV] (or EPRS[EDPRESDIV]) for the data phase bits of CAN FD messages, defines the prescaler value that generates the serial

clock (Sclock). (See Equation 19.) The period of Sclock defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine. It is the smallest time unit for all configuration values.

$$Tq = \frac{(PRESDIV + 1)}{f_{CANCLK}}$$

Equation 19. Time quantum

The bit rate, which defines the rate the CAN message is received or transmitted, is calculated with the formula:

$$CAN\ bit\ time = (Number\ of\ time\ quanta\ in\ 1\ bit\ time) \times Tq$$

$$Bit\ rate = \frac{1}{CAN\ bit\ time}$$

Equation 20. CAN bit time and baud rate

31.3.12.8.2 Bit time segments

A bit time is subdivided into three segments as shown in Figure 142. See also Figure 143 , Figure 144, and Table 232.

NOTE

For further explanation of the underlying concepts, see ISO 11898-1:2015. See also *CAN Specification Version 2.0, Part A and Part B* for bit timing.

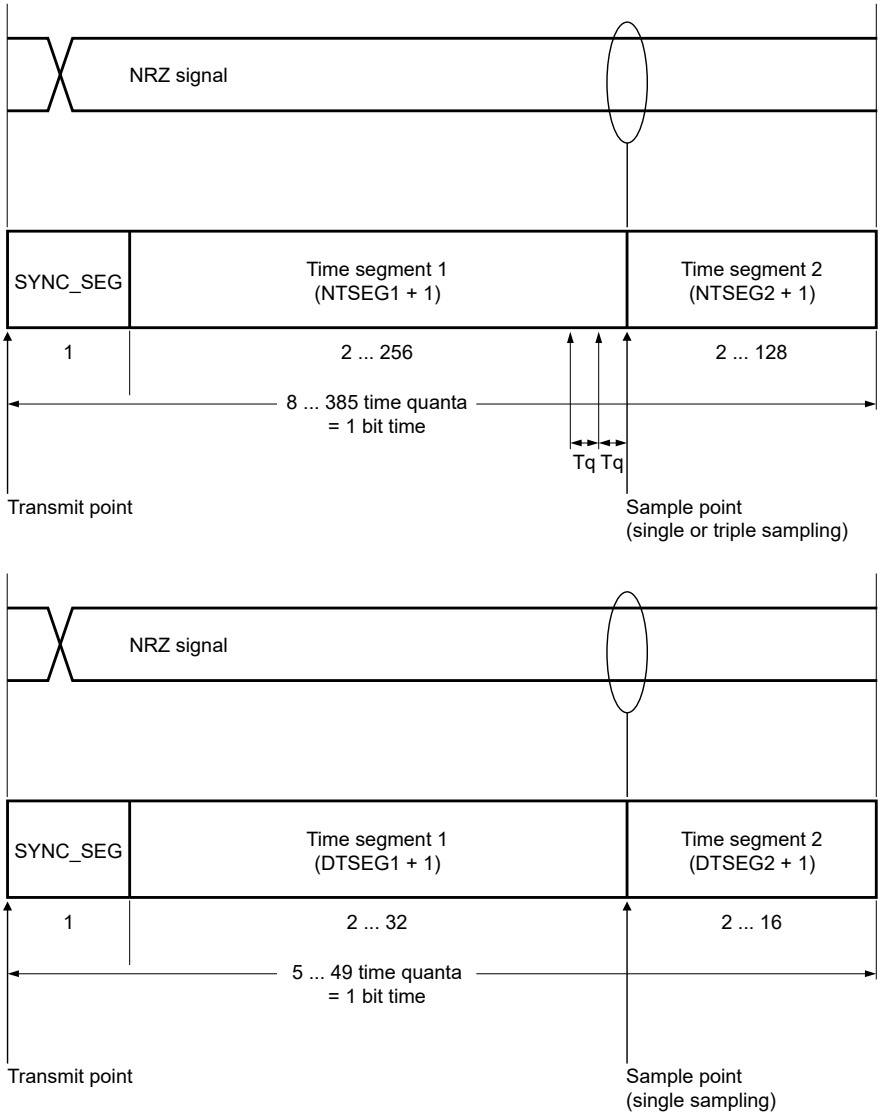

Figure 142. Segments within the bit timing (example using ENCBT and EDCBT bit timing variables)

The three bit time segments are:

- SYNC_SEG—this segment has a fixed length of one time quantum. Signal edges are expected to occur within this section.
- Time Segment 1—this segment includes the propagation segment and the phase segment 1 of the CAN standard.

  It can be programmed by configuring CTRL1[PROPSEG] and CTRL1[PSEG1] so that the sum (plus 2) is 2–16 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPROPSEG] and CBT[EPSEG1] so that the sum (plus 2) is 2–96 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses FDCBT[FPROPSEG] and FDCBT[FPSEG1] so that the sum (plus 1) is 2–39 time quanta.

  If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG1] to configure time segment 1 to 2–256 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG1] must be used for configuring time segment 1 to 2–32 time quanta.
- Time Segment 2—this segment represents the phase segment 2 of the CAN standard.

  It can be programmed by configuring CTRL1[PSEG2] (plus 1) to be 2–8 time quanta. When CBT[BTF] = 1, FlexCAN uses CBT[EPSEG2] so that its value (plus 1) is 2–32 time quanta. For messages in CAN FD format with the BRS = 1, FlexCAN uses

FDCBT[FPSEG2] instead, so that its value (plus 1) is 2–8 time quanta. Time segment 2 cannot be smaller than the Information Processing Time (IPT), which is 2 time quanta in FlexCAN.

If CTRL2[BTE] = 1, FlexCAN uses ENCBT[NTSEG2] to configure time segment 2 to 2–128 time quanta. For the data phase in CAN FD messages with BRS = 1, EDCBT[DTSEG2] must configure time segment 2 to 2–16 time quanta.

NOTE

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

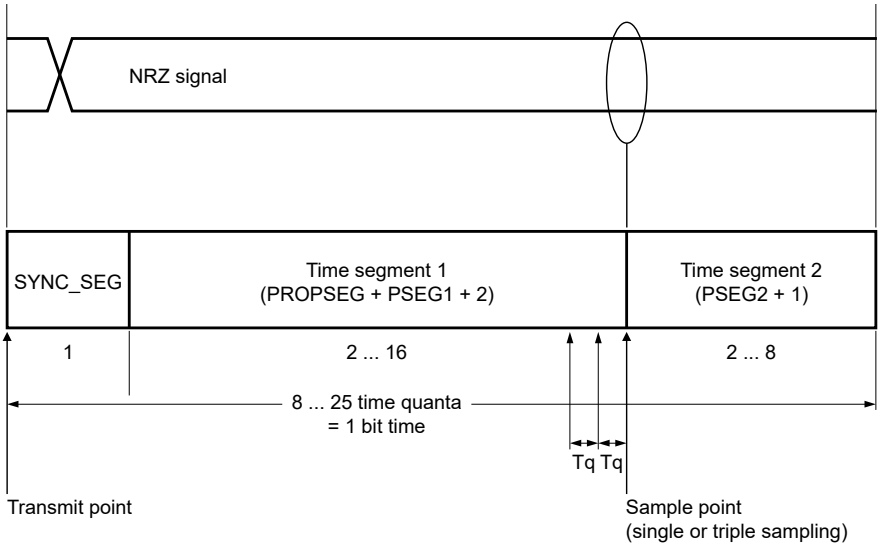

Figure 143. Segments within the bit time (example using CTRL1 bit timing variables for Classical CAN format)

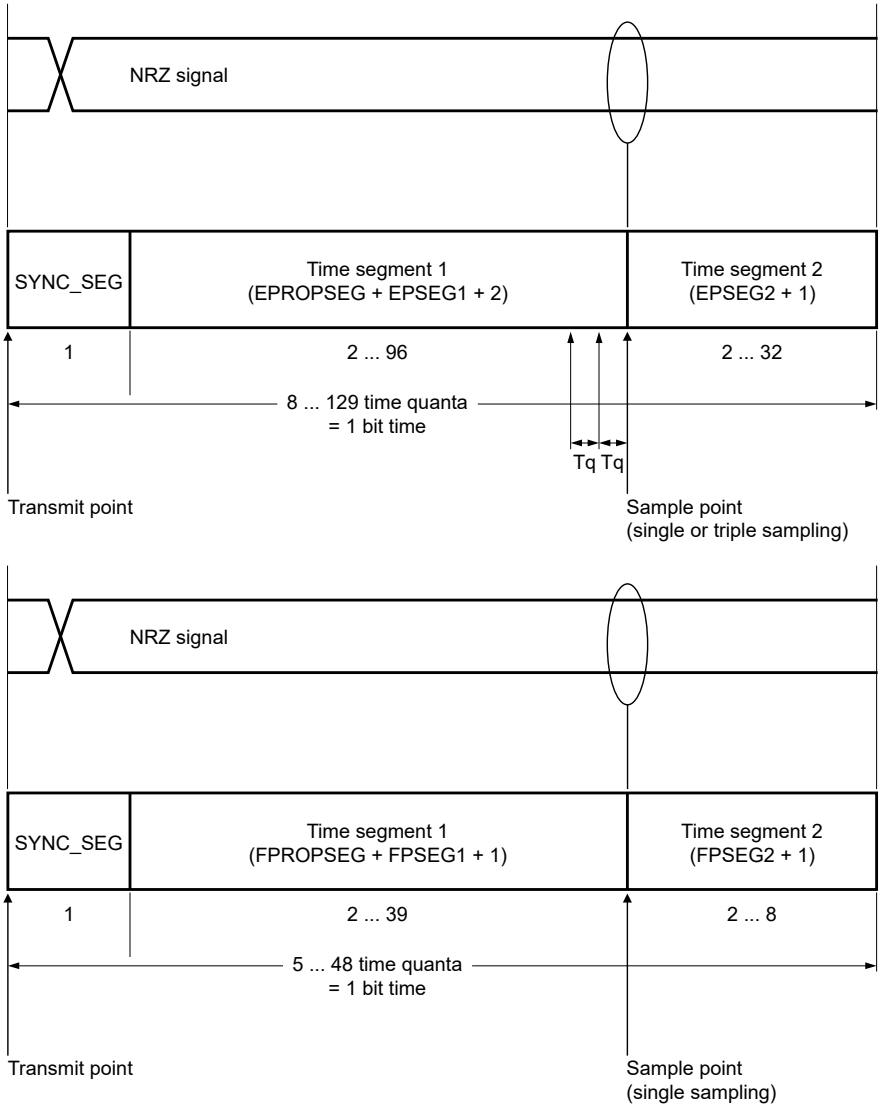

Figure 144. Segments within the bit time (example using CBT and FDCBT bit timing variables for CAN FD format)

Table 232. Time segment syntax

Syntax	Description
SYNC_SEG	Period during which the system expects transitions to occur on the bus
TSEG1	Period corresponding to the sum of PROPSEG and PSEG1
TSEG2	Period corresponding to the PSEG2 value
Transmit point	Point at which a node in Transmit mode transfers a new value to the CAN bus
Sample point	Point at which a node samples the bus. If the option of three samples per bit is selected, this point marks the position of the third sample.

Table 233 gives some examples of the CAN-compliant segment settings for Classical CAN format (Bosch CAN 2.0B) (non-FD) messages.

Table 233. Bosch CAN 2.0B standard compliant bit time segment settings

Time segment 1	Time segment 2	Resynchronization jump width
5 to 10	2	1 to 2
4 to 11	3	1 to 3
5 to 12	4	1 to 4
6 to 13	5	1 to 4
7 to 14	6	1 to 4
8 to 15	7	1 to 4
9 to 16	8	1 to 4

NOTE

You must ensure the bit time settings comply with the CAN Protocol standard (ISO 11898-1:2015).

31.3.12.8.3 Calculating peripheral clocks

A CAN bit can be used as a measure of duration (for example, estimating the occurrence of a CAN bit event in a message). When a CAN bit is used in this way, the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

Equation 21. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 0

Or, if CTRL2[BTE] = 1:

$$NumClkBit = \frac{f_{SYS}}{f_{CANCLK}} \times (ENPRESDIV + 1) \times (NTSEG1 + NTSEG2 + 3)$$

Equation 22. Number of peripheral clocks per CAN bit when CTRL2[BTE] = 1

Where:

- NumClkBit is the number of peripheral clocks in one CAN bit.
- f_{CANCLK} is the Protocol Engine (PE) Clock (see Figure 141), in Hz.
- f_{SYS} is the frequency of operation of the system (CHI) clock, in Hz.
- PSEG1 is the value of CTRL1[PSEG1].
- PSEG2 is the value of CTRL1[PSEG2].
- PROPSEG is the value of CTRL1[PROPSEG].
- PRESDIV is the value in CTRL1[PRESDIV].
- ENPRESDIV is the value of EPRS[ENPRESDIV].
- NTSEG1 is the value of ENCBT[NTSEG1].
- NTSEG2 is the value of ENCBT[NTSEG2].

The formula above is also applicable to the alternative CAN bit timing variables described in:

- CAN Bit Timing (CBT)

- Enhanced Nominal CAN Bit Timing (ENCBT)
- CAN FD Bit Timing (FDCBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

For example, 180 CAN bits = (180 × NumClkBit) peripheral clock periods.

31.3.12.9 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame. These windows are shown in the following figures.

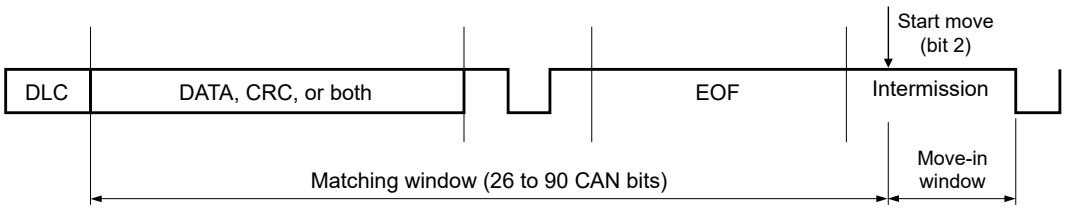

Figure 145. Matching and move-in time windows

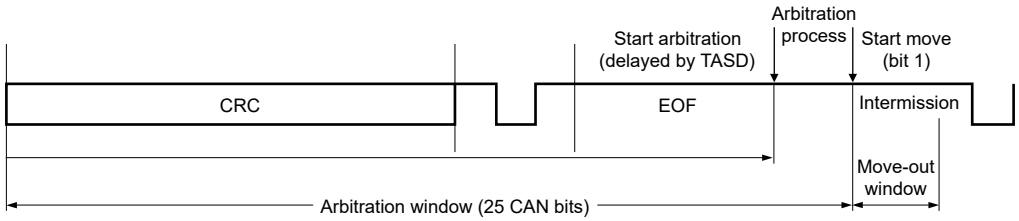

Figure 146. Arbitration and move-out time windows

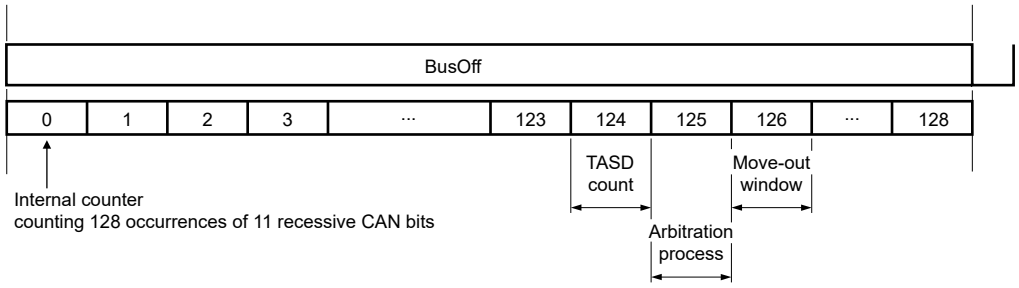

Figure 147. Arbitration at the end of bus off and move-out time windows

NOTE

In these figures, the matching and arbitration timing do not consider delays caused by concurrent memory access due to the CPU or other internal FlexCAN subblocks.

31.3.12.10 TX arbitration start delay

TX Arbitration Start Delay (CTRL2[TASD]) indicates the number of CAN bits that FlexCAN uses to delay the TX arbitration process starting point from the first bit of the CRC field of the current frame. This variable can be written only in Freeze mode; FlexCAN blocks it in other modes.

The ability of the CPU to reconfigure message buffers for transmission after the end of the internal arbitration process impacts transmission performance. In the arbitration process, FlexCAN finds the winner MB for transmission (see Arbitration process). If

the arbitration ends too early (before the first bit of the Intermission field) the CPU may reconfigure some TX message buffers. It is possible that the winning message buffer is no longer the best candidate to be transmitted.

TASD can optimize the transmission performance by defining the arbitration start point, as shown in Figure 148, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers in use by the matching and arbitration processes

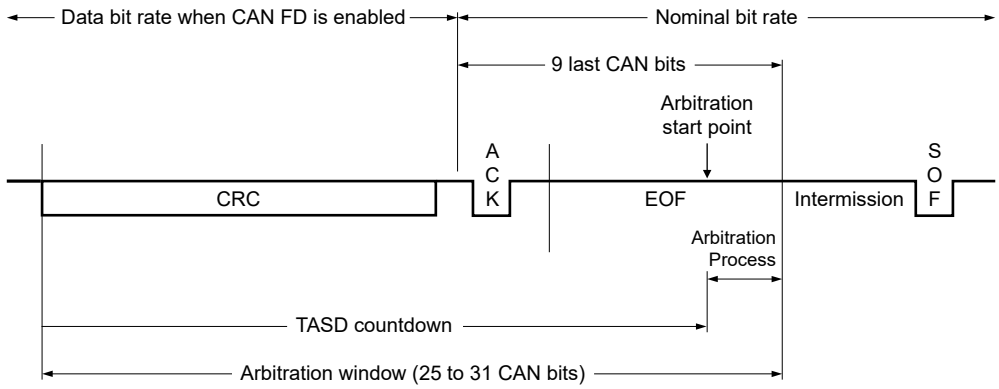

Figure 148. Optimal TX arbitration start point

The duration of an arbitration process, in terms of CAN bits, is:

- Directly proportional to the number of available message buffers
- Directly proportional to the CAN bit rate
- Inversely proportional to the peripheral clock frequency

The optimal arbitration timing occurs when the last message buffer is scanned immediately before the first bit of the Intermission field of a CAN frame. For instance, if the following are true:

- There are few message buffers.
- The peripheral-to-oscillator clock ratio is high.
- The CAN baud rate is low.

Then the arbitration can be placed closer to the end of the frame, adding more delay to its starting point, and vice versa.

If CTRL2[TASD] = 0, the arbitration start is not delayed, and more time is reserved for arbitration. Alternatively, if CTRL2[TASD] is close to 24, the CPU can configure a TX message buffer later, and less time is reserved for arbitration. If too little time is reserved for arbitration, FlexCAN may not be able to find a winner MB in time. The transmitted arbitration winner may not have the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:

For CAN FD frames and (MAXMB + 1) ≤ NMB_{END}

$$TASD = 31 - \frac{2 * (MAXMB + 1) + 4}{CPCB_N}$$

For CAN FD frames and (MAXMB + 1) > NMB_{END}

$$TASD = 22 - \frac{2 * (MAXMB + 1) - NMB_{END}}{CPCB_F}$$

For non-FD frames

$$TASD = 25 - \frac{2 * (MAXMB + 1) + 4}{CPCB}$$

Equation 23. Optimal value for TASD

Where:

$$NMB_{END} = \frac{(9 \times CPCB_N) - 4}{2}$$

$$BITRATE_N = \left(\frac{f_{CANCLK}}{[1 + (EPSEG1 + 1) + (EPSEG2 + 1) + (EPROPSEG + 1)] \times (EPRESDIV + 1)} \right)$$

$$BITRATE_F = \left(\frac{f_{CANCLK}}{[1 + (FPSEG1 + 1) + (FPSEG2 + 1) + FPROPSEG] \times (FPRESDIV + 1)} \right)$$

$$CPCB_N = \frac{f_{SYS}}{BITRATE_N}$$

$$CPCB_F = \frac{f_{SYS}}{BITRATE_F}$$

$$CPCB = CPCB_N$$

Equation 24. Variables used in TASD calculation

- MAXMB is the value in MCR[MAXMB].
- NMB_{END} is the number of message buffers that the arbitration process can scan during the last nine CAN bits at the end of a frame. (See Equation 24.)
- $BITRATE_N$ is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- $BITRATE_F$ is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- $CPCB_N$ is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- $CPCB_F$ is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- f_{CANCLK} is the oscillator clock, in Hz.
- f_{SYS} is the peripheral clock, in Hz.
- EPSEG1 is the value in CBT[EPSEG1] (CTRL1[PSEG1] can also be used).
- EPSEG2 is the value in CBT[EPSEG2] (CTRL1[PSEG2] can also be used).
- EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
- EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
- FPSEG1 is the value in FDCBT[FPSEG1].

- FPSEG2 is the value in FDCBT[FPSEG2].
- FPROPSEG is the value in FDCBT[FPROPSEG].
- FPRESDIV is the value in FDCBT[FPRESDIV].
- NTSEG1 is the value in ENCBT[NTSEG1].
- NTSEG2 is the value in ENCBT[NTSEG2].
- ENPRESDIV is the value in EPRS[ENPRESDIV].
- DTSEG1 is the value in EDCBT[DTSEG1].
- DTSEG2 is the value in EDCBT[DTSEG2].
- EDPRESDIV is the value in EPRS[EDPRESDIV].

If CTRL2[BTE] = 1, then:

$$BITRATE_N = \frac{f_{CANCLK}}{[1 + (NTSEG1 + 1) + (NTSEG2 + 1)] \times (ENPRESDIV + 1)}$$

Equation 25. Nominal baud rate when CTRL2[BTE] = 1

$$BITRATE_F = \frac{f_{CANCLK}}{[1 + (DTSEG1 + 1) + (DTSEG2 + 1)] \times (EDPRESDIV + 1)}$$

Equation 26. Fast baud rate when CTRL2[BTE] = 1

See also Protocol timing for more details.

31.3.12.10.1 TASD configuration examples

The following tables show the TASD value calculated for some configuration cases.

Case 1:

- Clock ratio = 2:1 (for example, peripheral clock 80 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 234. TASD values in Case 1

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	24	8.0
64	23	8.0
96	22	8.0

Case 2:

- Clock ratio = 1:1 (for example, peripheral clock 40 MHz and oscillator clock 40 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 235. TASD values in Case 2

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid

Table continues on the next page...

Table 235. TASD values in Case 2 (continued)

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
32	23	6.67
54	22	5.0
64	21	3.33
96	20	1.6

Case 3:

- Clock ratio = 2:1 (for example, peripheral clock 40 MHz and oscillator clock 20 MHz)
- Bit rate in arbitration phase = 1 Mbaud

Table 236. TASD values in Case 3

Number of message buffers	TASD value	Maximum bit rate in data phase (MBd)
16	24	Invalid
32	23	4.0
54	22	4.0
64	21	3.33
96	20	1.54

31.3.13 Clocks

The following table describes the clock sources for FlexCAN. See the Clock Controller Module (CCM) for clock setting, configuration, and gating information.

Table 237. FlexCAN clocks

Clock name	Description
MODULE_CLK (system_clk)	Peripheral clock
MODULE_CLK_CHI (host_clock)	Control Host Interface (CHI) clock
MODULE_CLK_PE (protocol_engine_clock)	Protocol Engine (PE) clock
MODULE_CLK_PE_NOGATE (protocol_engine_clock_nogate)	Protocol Engine clock (no gating)
MODULE_CLK_S (system_clock_nogate)	Peripheral access clock

31.3.13.1 Clock domains and restrictions

FlexCAN has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule.

When CTRL1[CLKSRC] = 1, synchronous operation occurs because both domains are connected to the peripheral clock. This setting creates a 1:1 ratio between the peripheral and oscillator clocks.

When the two domains are connected to clocks with different frequencies or phases, the frequency relationship between the two clock domains is restricted. In asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When performing matching and arbitration, FlexCAN must scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. To provide sufficient time for the scan, observe the following requirements:

- The peripheral clock frequency cannot be less than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in Table 238.

Table 238. Minimum number of peripheral clocks per CAN bit for Classical CAN format

Number of message buffers	Value of MCR[RFEN]	Value of ERFCR[ERFEN]	Minimum number of peripheral clocks per CAN bit
16	0	0	16
32	0	0	16
64	0	0	25
96	0	0	37
16	1	0	16
32	1	0	17
64	1	0	30
96	1	0	42
16	0	1	16
32	0	1	19
64	0	1	31
96	0	1	42

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in Table 238 determines the minimum peripheral clock frequency for a given number of message buffers and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit. This number can be defined by adjusting one or more of the bit timing values contained in:

- Control 1 (CTRL1)
- CAN Bit Timing (CBT)
- Enhanced Nominal CAN Bit Timing (ENCBT)

The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be eight, so the oscillator clock frequency should be at least eight times the CAN bit rate.

31.3.13.1.1 Clock restrictions for CAN FD

For CAN FD frame format, some constraints must be satisfied. The equation below calculates the number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit).

$$NumClkNomBit = \frac{f_{SYS}}{f_{CANCLK}} \times (PRESDIV + 1) \times (PROPSEG + PSEG1 + PSEG2 + 4)$$

$$= \frac{f_{SYS}}{NomBitRate}$$

Equation 27. Number of peripheral clocks per nominal CAN bit

Where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in Control 1 (CTRL1). Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CAN Bit Timing (CBT) or the values of EPRS[ENPRESDIV], ENCBT[NTSEG1], and ENCBT[NTSEG2] can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with BRS = 1 (fast CAN bits) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in Table 239. Having fewer data bytes means having fewer fast CAN bits. It also means that less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.

Table 239. Number of fast CAN bits in a CAN FD frame

Minimum number of data bytes	DLC field	NumOfFastBits
0	0h	21
1	1h	29
2	2h	37
3	3h	45
4	4h	53
5	5h	61
6	6h	69
7	7h	77
8	8h	85
12	9h	117
16	Ah	149
20	Bh	186
24	Ch	218
32	Dh	282
48	Eh	410
64	Fh	538

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

$$MinNumClkFastBit_A = \frac{(8.5 \times MaxNumOfMb) + [ERFEN \times (2 \times NFE + 4)] + 64 - (9 \times NumClkNomBit)}{NumOfFastBits}$$

Equation 28. Minimum number of peripheral clocks per fast CAN bit for FlexCAN scan process

Where MaxNumOfMb is the maximum number of available message buffers defined in MCR[MAXMB]. NFE and ERFEN are the fields defined in Enhanced RX FIFO Control (ERFCR).

The clock-domain-crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit. This minimum is required for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{f_{SYS}}{f_{CANCLK}}\right)$$

Equation 29. Minimum number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

Therefore, the larger of the two values calculated above determines the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit).

$$MinNumClkFastBit = Maximum\ (MinNumClkFastBitA, MinNumClkFastBitB)$$

Equation 30. Minimum number of peripheral clocks per fast CAN bit

Then, the maximum CAN bit rate in the data phase of CAN FD frames (DataBitRateMAX) can be calculated as below.

$$DataBitrate_{MAX} = \frac{f_{CANCLK}}{ROUNDUP\left(\frac{MinNumClkFastBit \times f_{CANCLK}}{f_{SYS}}\right)}$$

Equation 31. Maximum achievable baud rate for data phase

These factors affect the maximum data bit rate attainable by FlexCAN in CAN FD mode:

- The peripheral and oscillator clock frequencies
- The maximum number of message buffers
- The expected nominal bit rate

Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the configuration of FlexCAN variables affects the CAN FD bit rate, consider this application example:

- The peripheral clock frequency is set to 50 MHz
- The oscillator clock frequency is set to 40 MHz

1. Considering the nominal bit rate as 1 Mbit/s, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

   $$NumClkNomBit = \frac{50 \times 10^6}{1 \times 10^6} = 50$$

   Equation 32. Calculation example for number of peripheral clocks per nominal CAN bit

2. The number of fast CAN bits (NumOfFastBits) is determined in Table 239. For example, if the minimum payload in FD frames is 8 bytes, there are 85 CAN bits in the data phase.
3. Assuming the maximum number of message buffers is 96, and Enhanced RX FIFO is disabled, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated.

$$MinNumClkFastBit_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06$$

Equation 33. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN scan process

$$MinNumClkFastBit_B = 3 \times \left(1 + \frac{50}{40}\right) = 6.75$$

Equation 34. Calculation example for number of peripheral clocks per fast CAN bit for FlexCAN clock domain interface

$$MinNumClkFastBit = Maximum\ (\ 5.06, 6.75\ ) = 6.75$$

Equation 35. Calculation example for number of peripheral clocks per fast CAN bit

4. The maximum CAN bit rate in the data phase can finally be found.

$$DataBitRate_{MAX} = \frac{40 \times 10^6}{ROUNDUP\left(\frac{6.75 \times 40 \times 10^6}{50 \times 10^6}\right)} = 6.667\ Mbps$$

Equation 36. Calculation example for maximum achievable baud rate

Even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbit/s in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbit/s. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

Table 240 shows the maximum data rate for CAN FD with Enhanced RX FIFO disabled according to clock frequencies, payload size, and number of available message buffers. For some cases, if the number of available message buffers is reduced, FlexCAN can then achieve a data rate up to 8 Mbit/s.

Table 240. Maximum CAN bit rate in data phase on CAN FD frames with Enhanced RX FIFO disabled

Peripheral clock frequency (MHz)	Payload size	Number of available message buffers	Maximum data rate (Mbit/s)
40	8	94	6.667
40	8	114	>5.0
40	12	>117	6.667
40	12	128	5.714
50	12–64	128	6.667
60	8	126	8.0
60	12	128	8.0
67	6	128	8.0
80	3	128	8.0
100	0	128	8.0

31.3.14 Reset

You can reset FlexCAN in the following ways:

- Chip-level hard reset, which resets all memory-mapped registers asynchronously.
- Soft reset:
  - MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. To see which registers soft reset affects, see Table 243.
  - The chip level soft reset input is not supported, use the MCR[SOFTRST] to trigger a soft reset.

Soft reset is synchronous and must follow an internal request-and-acknowledge procedure across clock domains. Therefore, it may take some time to propagate its effects fully. MCR[SOFTRST] remains 1 when soft reset is pending, so software can poll this field to identify when the reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected when the module is in Disable mode (see CTRL1[CLKSRC]). After the clock source is selected and the module is enabled (MCR[MDIS] becomes 0), FlexCAN automatically enters Freeze mode. In Freeze mode:

1. FlexCAN is unsynchronized to the CAN bus.
2. MCR[HALT] and MCR[FRZ] become 1.
3. The internal state machines are disabled.
4. MCR[FRZACK] and MCR[NOTRDY] become 1.

The TX pin is in the recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Reset does not affect the message buffers and the RX Individual Mask registers, so they are not automatically initialized.

31.3.15 Interrupts

FlexCAN has many interrupt sources:

- Interrupts due to message buffers
- Interrupts due to interrupts combined via an OR operator from:
  - Message buffers
  - Bus Off
  - Bus Off Done
  - Error
  - Error Fast (errors detected in the data phase of CAN FD format messages with BRS = 1)
  - Wake Up
  - TX Warning
  - RX Warning

If its corresponding IMASK bit is 1, each message buffer can be an interrupt source. There is no distinction between TX and RX interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each buffer has an assigned flag bit in the IFLAG registers. When the corresponding buffer completes a successful transfer, the flag is set. When the CPU writes 1 to it, the flag is cleared (unless another interrupt is generated at the same time).

NOTE

The CPU must clear only the bit causing the current interrupt. For this reason, do not use bit manipulation instructions (BSET) to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt handler.

If the Legacy RX FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to message buffers 0–7 have different meanings.

- Bit 7 of Interrupt Flags 1 (IFLAG1) becomes the Legacy FIFO Overflow flag
- Bit 6 becomes the Legacy FIFO Warning flag

- Bit 5 becomes the Frames Available in Legacy FIFO flag
- Bits 4–0 are unused.

See Interrupt Flags 1 (IFLAG1) for more information.

If both Legacy RX FIFO and DMA are enabled (MCR[RFEN] = 1 and MCR[DMA] = 1), FlexCAN does not generate any Legacy FIFO interrupt. Bit 5 of IFLAG1 still indicates Frames Available in Legacy FIFO and generates a DMA request. Bits 7, 6, and 4–0 are unused.

CAUTION

Legacy FIFO cannot be enabled when CAN FD is enabled.

When multiple message buffer interrupt sources are combined via an OR operator into a single interrupt, the interrupt is generated when any associated message buffer (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which message buffer or FIFO source caused the interrupt.

These interrupt sources generate interrupts like the message buffer interrupt sources, and can be read from Error and Status 1 (ESR1):

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up
- TX Warning
- RX Warning

The Bus Off, Error, TX Warning, and RX Warning interrupt masks are located in Control 1 (CTRL1); the wake-up interrupt mask is located in Module Configuration (MCR).

31.3.16 Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers results in an access error. In Table 243, supervisor registers are registers identified with an S, and registers that are identified with S/U that are in Supervisor Mode
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only, no access error is issued. Write permission to specific positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM-located positions during Low-Power mode results in an access error.
- The RXIMR memory region can be considered as general-purpose memory and available for access via these methods:
  - If you write 0 to MCR[IRMQ], the individual masks (RXIMR) are disabled. In this case, the RXIMR memory region is considered general-purpose memory.
  - If MCR[MAXMB] is programmed with a value smaller than the available number of message buffers, the unused memory space can be used as general-purpose RAM space. Reserved words within RAM cannot be used. For example, suppose the RAM in FlexCAN can support up to 16 message buffers, CTRL2[RFFN] = 0h, and MCR[MAXMB] = 0.
    - In this case, the maximum number of message buffers becomes one.
    - The RAM starts at 0080h, and the space 0080h–008Fh is used by the one message buffer.

- The memory space 0090h–017Fh is available.
- The space 0180h–087Fh is reserved.
- The space 0880h–0883h is used by the one individual mask and the available memory in the mask register space is 0884h–08BFh.
- In the space from 08C0h–09DFh, there are reserved words for internal use which cannot be used as general-purpose RAM.

As a rule, free memory space for general purpose depends only on MCR[MAXMB].

— If MCR[FDEN] = 1, general-purpose memory can be used only outside Freeze mode.

1. Access in low power is only possible if RAM_clk and MODULE_CLK are enabled.
2. If MCR[RFEN] = 1, see Legacy FIFO access rules in the rows below.
3. Write operation has no effect.
4. If MCR[RFEN] = 1, do not access Enhanced RX FIFO.

31.3.17 Detection and correction of memory errors

To update the parity bits in memory properly, all FlexCAN memory must be initialized before starting its operation. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize these registers:

- RX Message Buffers Global Mask (RXMGMASK)
- Receive 14 Mask (RX14MASK)
- Receive 15 Mask (RX15MASK)
- Legacy RX FIFO Global Mask (RXFGMASK)

MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated with five parity bits that ensure a Hamming distance of 4. The error correction mechanism ensures that in this 13-bit word, errors in one bit can be corrected (correctable errors). Errors in two bits can be detected but not corrected (uncorrectable errors). Errors in more than two bits may not be detected. For uncorrectable errors, the error correction logic does not change the corrupted data. When a read access is performed, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

When an all-zeroes or an all-ones read occurs, FlexCAN detects an uncorrectable error. See Error Report Syndrome (RERRSYNR).

Memory errors are indicated to the host via status register (Error Status (ERRSR)) and bus transfer errors. Memory errors are reported via these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

MECR[ECCDIS] determines whether the error detection and correction mechanism can be activated. When disabled, updates on indications and reporting registers are stopped. To ensure that memory has consistent parity bits associated with the data, the parity bits are still calculated and written with data in memory write operations.

To avoid accidentally changing the critical error correction configuration, follow this protocol to enable the update of Memory Error Control (MECR):

1. Write 1 to CTRL2[ECRWRE]. (By default, CTRL2[ECRWRE] is 0 and MECR[ECRWRDIS] is 1.)
2. Write 0 to MECR[ECRWRDIS].
3. All writes to Memory Error Control (MECR) must keep MECR[ECRWRDIS] = 0.
4. After configuration is done, lock MECR by writing 1 to MECR[ECRWRDIS] or writing 0 to CTRL2[ECRWRE].

31.3.17.1 Sources of memory access

These major sources (or requestors) can access FlexCAN memory:

- Host (CPU). The largest word accessed is 32-bit.
- FlexCAN internal processes:
  - RX matching
  - TX arbitration
  - Move-in on reception
  - Move-out on transmission

  The largest word accessed is 64-bit.

The source of access determines the way that uncorrectable errors are indicated and reported.

31.3.17.2 Error indication

These flags indicate memory errors:

- ERRSR[HANCEIF]
- ERRSR[FANCEIF]
- ERRSR[CEIF]

Uncorrectable errors detected in memory reads requested by the host are indicated separately from the errors detected in requests by FlexCAN internal processes. When correctable errors are detected, FlexCAN makes no distinction of the source of the access. There are three independent flags for these three cases, and each flag raises an interrupt unless a mask in Memory Error Control (MECR) masks it. If both uncorrectable and correctable errors are found in different bytes in the same read operation, both flags are set.

An uncorrectable error detected in host access is also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If ERRSR[HANCEIF] is not masked, the same uncorrectable error raises a bus transfer error and an interrupt request.

Each indication flag has one overrun flag in Error Status (ERRSR). The overrun flags do not request interrupts. Overrun flags for uncorrectable errors indicate that other errors of the same nature were detected after the current error being treated. Overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated.

The recommended handling sequence for error indication is:

1. Get error report information from report registers.
2. Use this information to take proper measures in the application.
3. Clear the ERRSR[HANCEIF], ERRSR[FANCEIF], and ERRSR[CEIF] flags.
4. If the overrun flag is active:
    a. Alert the application that at least one error could not be managed.
    b. Clear the overrun flag.

FlexCAN internal processes can access memory in transactions larger than 32 bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in two or more 32-bit words, the interrupt and overrun flags are set simultaneously.

31.3.17.3 Error reporting

The error report registers provide detailed information about the address read, raw data, and syndrome read with error. The flags described in Error indication indicate these report registers:

- Error Report Address (RERRAR)
- Error Report Data (RERRDR)
- Error Report Syndrome (RERRSYNR)

The address, data, and syndrome registers are updated simultaneously with the error flags, according to these rules:

1. If either of the uncorrectable error flags is set, the report registers are not updated. The previous uncorrectable error reporting is preserved.
2. Otherwise, either no error flag is set or only the correctable error flag is set. The report registers are updated according to the new error, or according to the most severe new error, if uncorrectable and correctable errors are simultaneously detected.

Reporting of errors detected in accesses larger than 32 bits follows the rules described in Error indication and in the description of Error Report Address (RERRAR).

The addresses reported in RERRAR and defined in ERRIAR are not the same as the addresses listed in the module memory map. The relation between the reported addresses and the respective ones in the module memory map is shown in the description of Error Injection Address (ERRIAR).

Addresses reported when reading memory portions organized as FIFOs refer to the address of the specific entry accessed in the FIFO, not to the FIFO base address. Such memory portions include:

- Legacy RX FIFO Structure
- Enhanced RX FIFO Structure
- Legacy RX FIFO Information (RXFIR)

To ensure coherence of error report registers, disable the report update by writing 1 to MECR[RERRDIS] before reading the report registers.

31.3.17.4 Error response

Correctable errors have no consequence to FlexCAN operation because the host or FlexCAN internal processes corrects affected data before its use.

For host-initiated reads, an uncorrectable error may affect the host, but does not affect FlexCAN operation.

Uncorrectable errors detected on memory read operations requested by FlexCAN internal processes may result in incorrect operation depending on the state of MECR[NCEFAFRZ], as follows:

- During reception (either matching or move-in process), when an uncorrectable error occurs:
  - An incorrect destination may be selected to store the incoming frame.
  - A corrupted frame may be stored in the correct destination.
  - Both of these events may occur.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode to prevent corrupted data from being treated as valid by FlexCAN internal processes. If MECR[NCEFAFRZ] = 0, FlexCAN continues working, and a corrupted frame is received.
- During arbitration, when an uncorrectable error occurs:
  - A non-highest-priority TX message buffer may be mistakenly selected for transmission.
  - Its data may be corrupted.

  If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the move-out. If MECR[NCEFAFRZ] = 0, FlexCAN proceeds to move-out with a corrupted frame that will be transmitted on the CAN bus.
- During move-out, when an uncorrectable error occurs, a corrupted frame is copied from the selected TX MB that won the arbitration to the TX SMB for transmission. If MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode before starting the transmission. When MECR[NCEFAFRZ] = 0, the corrupted frame is transferred from the TX SMB to the Protocol Engine (PE) subblock and is transmitted on the CAN bus.
- An uncorrectable error can also be detected beyond move-out, when TX data is read from TX SMB (buffer located in RAM) to be transferred to the PE subblock for transmission. In this case, a frame with corrupted ID or data is transmitted on the CAN bus.

  To prevent the external nodes from successfully receiving the frame, FlexCAN inverts all bits in the CRC field (CRC sequence plus CRC delimiter). Also, it transmits an error flag just after CRC delimiter due to self-detecting a Bit1 error and a form error due to the CRC field inversion. When MECR[NCEFAFRZ] = 1, FlexCAN stops operation automatically and enters Freeze mode just after the error frame. When MECR[NCEFAFRZ] = 0, FlexCAN may attempt to retransmit the same frame, as long as no other higher-priority TX MB is configured for transmission after.

  If the uncorrectable error persists, FlexCAN eventually reaches the Bus Off state due to consecutive error detections. ECR[TXERRCNT] is updated every time FlexCAN inverts the CRC field, causing errors as described above.

When MECR[NCEFAFRZ] = 1 and FlexCAN enters Freeze mode, only the CPU can cause FlexCAN to exit Freeze mode and resume Normal mode. MECR[NCEFAFRZ] becoming 1 is the only way to prevent corrupted frames from being transmitted on the CAN bus to the move-out internal process.

The error report registers can provide information to the application for customized management of these situations.

31.3.17.5 Error injection

These error injection registers are used to inject errors in memory reads to force errors and update the indication and reporting registers:

- Error Injection Address (ERRIAR)
- Error Injection Data Pattern (ERRIDPR)
- Error Injection Parity Pattern (ERRIPPR)

The relation between the error injection addresses and the corresponding addresses in the module memory map is shown in Error Injection Address (ERRIAR).

The injection is done by flipping the data and parity bits corresponding to the bits set to 1 in ERRIDPR and ERRIPPR. You can select injection specifically for memory accesses requested by the host or by FlexCAN internal processes.

For accesses larger than 32 bits, MECR[EXTERRIE] extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

NOTE

It is possible, but very unlikely, for error injection to correct a bit with error. This correction does not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, you must clear MECR[HAERRIE] and MECR[FAERRIE] when configuring the memory injection registers.

31.4 External signal descriptions

FlexCAN has two I/O signals connected to the external chip pins. These signals are summarized in Table 242 and described in the following subsections.

Table 242. FlexCAN signal descriptions

Signal	Description	I/O
CAN RX	CAN receive pin	Input
CAN TX	CAN transmit pin	Output

31.4.1 CAN RX

This pin is the receive pin from the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

31.4.2 CAN TX

This pin is the transmit pin to the CAN bus transceiver. Logic level 0 represents its dominant state. Logic level 1 represents its recessive state.

31.5 Initialization and application information

31.5.1 FlexCAN initialization sequence

For any configuration change or initialization, you must put FlexCAN into Freeze mode (see Freeze mode). The module must be initialized after every reset. FlexCAN memory must be initialized before switching to functional mode.

The following is a generic initialization sequence applicable to FlexCAN:

1. Initialize Module Configuration (MCR).
    a. Enable the individual filtering per message buffer and reception queue features by writing 1 to MCR[IRMQ].
    b. Enable the warning interrupts by writing 1 to MCR[WRNEN].
    c. If required, disable frame self-reception by writing 1 to MCR[SRXDIS].
    d. Enable the Legacy RX FIFO by writing 1 to MCR[RFEN] or enable the Enhanced RX FIFO by writing 1 to ERFCR[ERFEN].
    e. If Legacy RX FIFO or Enhanced RX FIFO is enabled and DMA is required, write 1 to MCR[DMA].
    f. Enable the abort mechanism by writing 1 to MCR[AEN].

g. Enable the local priority feature by writing 1 to MCR[LPRIOEN].

2. Initialize Control 1 (CTRL1) and CAN FD Bit Timing (FDCBT). Optionally initialize CAN Bit Timing (CBT).
   a. Determine the bit timing parameters: CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW].
   b. Optionally determine the bit timing parameters: CBT[EPROPSEG], CBT[EPSEG1], CBT[EPSEG2], and CBT[ERJW].
   c. Determine the CAN FD bit timing parameters: FDCBT[FPROPSEG], FDCBT[FPSEG1], FDCBT[FPSEG2], and FDCBT[FRJW].
   d. Determine the bit rate by programming CTRL1[PRESDIV] and optionally programming CBT[EPRESDIV].
   e. Determine the CAN FD bit rate by programming FDCBT[FPRESDIV].
   f. Determine the internal arbitration mode by programming CTRL1[LBUF].
3. If Error Code Correction (ECC) is enabled, you must initialize all FlexCAN memory. See Detection and correction of memory errors.
4. Initialize the message buffers. (See Message buffer structure for message buffer details.)
   a. The control and status word of all message buffers must be initialized.
   b. If RX FIFO is enabled, the ID filter table must be initialized.
   c. Other entries in each message buffer should be initialized as required.
5. Initialize Receive Individual Mask (RXIMR0 - RXIMR95).
6. Write 1 to required interrupt mask bits in:
   - IMASK registers (for all message buffer interrupts)
   - Module Configuration (MCR) (for wake-up interrupt)
   - Control 1 (CTRL1) and Control 2 (CTRL2) (for Bus Off and Error interrupts)
7. Write 0 to MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

31.6 Memory map and register definition

This section describes the registers and data structures in FlexCAN. The base address of the module depends on the particular memory map of the chip.

31.6.1 FlexCAN memory mapping

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0080h.

Each individual register is identified by its complete name and corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 243.

NOTE

An invalid register access results in a bus error. Invalid accesses include reading a write-only register, writing a read-only register, and accessing an invalid address.

NOTE

To update the parity bits in memory properly, all FlexCAN memory must be initialized before reading registers which are implemented in memory. CTRL2[WRMFRZ] grants write access to all memory positions that require initialization, from 080h–ADFh and from C20h–31FFh. You must also initialize RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK) and Legacy RX FIFO Global Mask (RXFGMASK). MCR[RFEN] and ERFCR[ERFEN] must not be 1 during memory initialization.

Table 243. Register access and reset information

Register	Access type	Affected by hard reset	Affected by soft reset
Module Configuration (MCR)	S	Yes	Yes
Control 1 (CTRL1)	S/U	Yes	No
Free-Running Timer (TIMER)	S/U	Yes	Yes

FlexCAN can store CAN messages for transmission and reception using message buffers and RX FIFO structures.

31.6.2 FlexCAN register descriptions

The table below shows the FlexCAN memory map.

The address range from offset 80h–67Fh allocates the ninety-six 128-bit message buffers. The memory maps for the message buffers are in FlexCAN message buffer memory map.

The address range from offset 2000h–204Ch allocates the Enhanced RX FIFO output, and the address range from offset 2050h–263Ch allocates the rest of Enhanced RX FIFO 19 elements. The memory map for the Enhanced RX FIFO is in Enhanced RX FIFO structure.

31.6.2.1 FlexCAN memory map

CAN_FD1 base address: 443A_0000h

CAN_FD2 base address: 425B_0000h

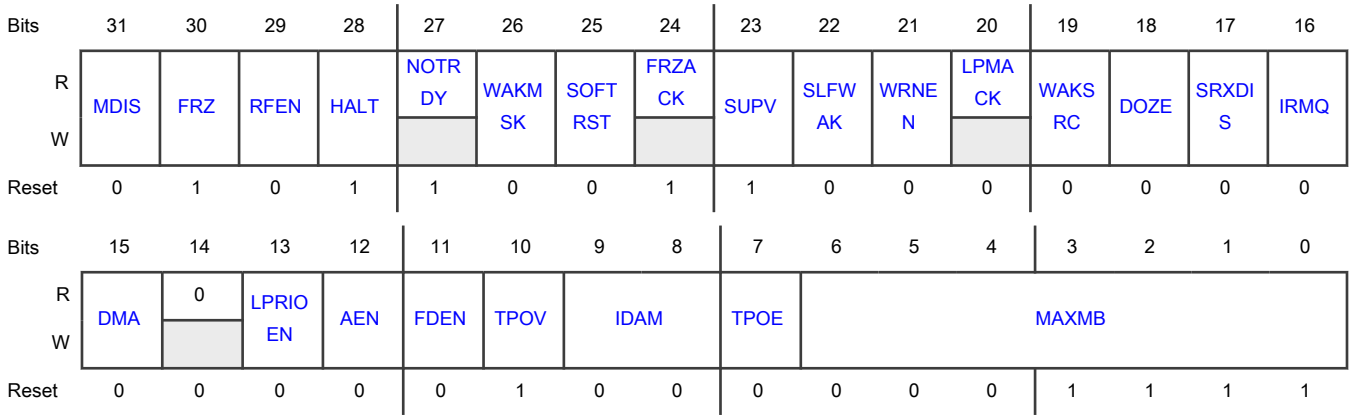
31.6.2.2 Module Configuration (MCR)

Defines global system configurations, including the module operation modes and the maximum message buffer configuration.

Offset

Register	Offset
MCR	0h

Diagram



Fields

Field	Description
31 MDIS	Module Disable Disables FlexCAN. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Soft reset does not affect this field. 0 - Enable 1 - Disable
30 FRZ	Freeze Enable Specifies FlexCAN behavior when MCR[HALT] = 1 or when Debug mode is requested at chip level. When this field becomes 1, FlexCAN can enter Freeze mode. Writing 0 to this field causes FlexCAN to exit from Freeze mode. The chip writes 1 to this field when a noncorrectable error is detected (MECR[NCEFAFRZ] becomes 1). 0 - Disable 1 - Enable
29 RFEN	Legacy RX FIFO Enable Enables the Legacy RX FIFO feature. When this field is 1, message buffers 0–5 cannot be used for normal reception and transmission. The corresponding memory region (80h–DCh) is used by the FIFO engine and additional message buffers (up to 32, depending on CTRL2[RFFN]). These message buffers are used as Legacy RX FIFO ID filter table elements. This field also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 238. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** When CAN FD operation is enabled (see MCR[FDEN]), you cannot write 1 to this field. **NOTE** This field must not be 1 if ERFCR[ERFEN] = 1. 0 - Disable 1 - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
28 HALT	Halt FlexCAN Puts FlexCAN into Freeze mode. The CPU should write 0 to this field after initializing the message buffers and Control 1 (CTRL1) and Control 2 (CTRL2). FlexCAN performs no reception or transmission before this field becomes 0. Freeze mode cannot be entered when FlexCAN is in a low-power mode. The module writes 1 to this field when a noncorrectable error is detected and MECR[NCEFAFRZ] = 1. 0 - No request 1 - Enter Freeze mode, if MCR[FRZ] = 1.
27 NOTRDY	FlexCAN Not Ready Indicates whether FlexCAN is in Disable mode, Doze mode, Stop mode or Freeze mode. When FlexCAN has exited these modes, this field becomes 0. Soft reset does not affect this field. 0 - FlexCAN is in Normal mode, Listen-Only mode, or Loopback mode. 1 - FlexCAN is in Disable mode, Doze mode, Stop mode, or Freeze mode.
26 WAKMSK	Wake-up Interrupt Mask Enables the wake-up interrupt generation under the Self Wake-Up mechanism. 0 - Disabled 1 - Enabled
25 SOFTRST	Soft Reset Resets internal state machines of FlexCAN and some memory-mapped registers. The CPU can write 1 to this field directly. This field also becomes 1 when global soft reset is requested at the chip level. Because soft reset is synchronous and must follow a request-and-acknowledge procedure across clock domains, it may take some time to propagate its effect fully. When reset is pending, this field remains 1; it automatically becomes 0 when reset completes. You can poll this field to know when the soft reset has completed. Soft reset cannot be applied when clocks are shut down in a low-power mode. Transfer the module out of the low-power mode before applying soft reset. Soft reset does not affect this field. **NOTE** This field becomes 0 within 2 CAN bits after assertion of this bit. 0 - No reset 1 - Soft reset affects reset registers
24 FRZACK	Freeze Mode Acknowledge Indicates whether FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished. Therefore, you can poll this field to know when FlexCAN has entered Freeze mode. If the Freeze mode request is negated, this field becomes 0 after the FlexCAN prescaler is running again. If Freeze mode is requested when FlexCAN is in a low-power mode, this field becomes 1 only when the low-power mode is exited. See Freeze mode. Soft reset does not affect this field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the Freeze mode request removal (see Protocol timing). 0 - Not in Freeze mode, prescaler running. 1 - In Freeze mode, prescaler stopped.
23 SUPV	Supervisor Mode Configures FlexCAN to be either in Supervisor or User mode. The registers that this field affects are marked as S/U in the Access type column of Table 243. The affected registers start with Supervisor access allowance only. In User mode, affected registers allow both Supervisor and Unrestricted accesses. In Supervisor mode, affected registers allow only Supervisor access. Unrestricted access behaves as though the access is performed on an unimplemented register location. This field can be written only in Freeze mode; the module blocks it in other modes. 0 - User mode 1 - Supervisor mode
22 SLFWAK	Self-Wake-Up Feature Enables the self-wake-up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for a wake-up event (that is, a recessive-to-dominant transition). If a wake-up event is detected during Doze mode, FlexCAN requests to resume its clocks. If enabled to do so, it also generates a wake-up interrupt to the CPU. If a wake-up event is detected during Stop mode, FlexCAN generates, if enabled to do so, a wake-up interrupt to the CPU. The CPU can exit Stop mode globally and FlexCAN can request to resume the clocks. When FlexCAN is in a low-power mode other than Disable mode, this field cannot be written, as the module blocks it. 0 - Disable 1 - Enable
21 WRNEN	Warning Interrupt Enable Enables the generation of the flags ESR1[TWRNINT] and ESR1[RWRNINT]. When this field is 1, TWRNINT and RWRNINT flags are set when the respective error counter transitions from less than 96 to greater than or equal to 96. When this field is 0, the TWRNINT and RWRNINT flags are always zero, independent of the values of the error counters. No warning interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Disable 1 - Enable
20	Low-Power Mode Acknowledge

Table continues on the next page...

Table continued from the previous page...

Field	Description
LPMACK	Indicates whether FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission and reception processes have finished. The CPU can poll this field to know when FlexCAN has entered low-power mode. Soft reset does not affect this field. **NOTE** This field becomes 1 within 180 CAN bits if current transmission or reception is ongoing for classical frames and 730 CAN bits if current transmission or reception is ongoing for FD frames after the low-power mode requested by CPU. This field becomes 0 within 2 CAN bits after the low-power mode request removal (see Protocol timing). 0 - Not in a low-power mode 1 - In a low-power mode
19 WAKSRC	Wake-Up Source Determines whether the integrated low-pass filter is applied to the RX input that FlexCAN uses to detect recessive-to-dominant edges on the CAN bus. This filter can protect the RX CAN input from spurious wake-up. This field can be written only in Freeze mode. The module blocks it in other modes. 0 - No filter applied 1 - Filter applied
18 DOZE	Doze Mode Enable Determines whether FlexCAN can enter low-power mode when Doze mode is requested at chip level. This field is automatically reset when FlexCAN wakes from Doze mode upon detecting activity on the CAN bus (self wake-up enabled). 0 - Disable 1 - Enable
17 SRXDIS	Self-Reception Disable Determines whether FlexCAN can receive frames transmitted by itself. If 1, frames transmitted by the module are not stored in any MB, regardless of whether the MB is programmed with an ID that matches the transmitted frame. No interrupt flag or interrupt signal is generated due to the frame reception. This field can be written only in Freeze mode; the module blocks it in other modes. 0 - Enable 1 - Disable
16 IRMQ	Individual RX Masking and Queue Enable Indicates whether RX matching process is based on individual masking and queue, or based on a masking scheme with RX Message Buffers Global Mask (RXMGMASK), Receive 14 Mask (RX14MASK), Receive 15 Mask (RX15MASK), and Legacy RX FIFO Global Mask (RXFGMASK). When this field is disabled, for backward compatibility with legacy applications, reading the Control and Status word locks the MB even if it is empty. This field can be written in Freeze mode only. The module blocks it in other modes. 0 - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable
15 DMA	DMA Enable Enables DMA. The DMA feature can only be used in Legacy RX FIFO or Enhanced RX FIFO, so MCR[RFEN] or ERFCR[ERFEN] must be 1. When DMA and RFEN are 1, IFLAG1[BUF5I] generates the DMA request, and no RX FIFO interrupt is generated. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Disable 1 - Enable
14 —	Reserved
13 LPRIOEN	Local Priority Enable Enables the local priority feature. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word. However, the actual transmitted ID is 11 bits for standard frames and 29 bits for extended frames. This field can be written only in Freeze mode; the module blocks it in other modes. This bit is provided for backward compatibility with legacy applications. 0 - Disable 1 - Enable
12 AEN	Abort Enable Enables the TX abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** When this field is 1, only use the abort mechanism (see Transmission abort mechanism) to update message buffers configured for transmission. **CAUTION** Writing the abort code into RX message buffers can cause unpredictable results when this field is 1. 0 - Disabled 1 - Enabled
11 FDEN	CAN FD Operation Enable Enables the CAN with flexible data rate (CAN FD) operation. This field can be written in Freeze mode only. FlexCAN can receive and transmit messages in CAN 2.0 format. If this field is enabled, FlexCAN can also receive and transmit messages in CAN FD format. FlexCAN can transmit FD frame format according to ISO 11898-1:2015.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE If the value of this field is 1, the Legacy RX FIFO Enable (MCR[RFEN]) field cannot be 1. 0 - Disable 1 - Enable
10 TPOV	TX Pin Override Value Indicates forced value on the TX pin. This bit is affected by soft reset. 0 - TX pin is forced to be dominant 1 - TX pin is forced to be recessive
9-8 IDAM	ID Acceptance Mode Identifies the format of the Legacy RX FIFO ID filter table elements. This field configures all elements of the table at the same time; they are all the same format. See Legacy RX FIFO structure. This field can be written only in Freeze mode; the module blocks it in other modes. 00 - Format A: One full ID (standard and extended) per ID filter table element. 01 - Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element. 10 - Format C: Four partial 8-bit standard IDs per ID filter table element. 11 - Format D: All frames rejected.
7 TPOE	TX Pin Override Enable Enables forcing of the TX pin to recessive or dominant. This bit is affected by soft reset. **NOTE** This bit must not be enabled during the functional mode. 0 - TX pin forcing is disabled 1 - TX pin forcing is enabled
6-0 MAXMB	Number of the Last Message Buffer Defines the number of the last message buffer that takes part in the matching and arbitration processes. The reset value (0Fh) is equivalent to a 16-MB configuration. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** You must write a value smaller than or equal to the number of available message buffers to this field, as described in FlexCAN memory partition for CAN FD. Additionally, the MAXMB value must consider the region of message buffers occupied by Legacy RX FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit, as described in Table 238.

31.6.2.3 Control 1 (CTRL1)

Contains specific FlexCAN control features related to the CAN bus. These features include bit rate, programmable sampling point within an RX bit, Loopback mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.

The CAN bit timing variables (CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW]) can also be configured in CAN Bit Timing (CBT), which extends the range of all these variables. If CBT[BTF] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] become read-only.

If CTRL2[BTE] = 1, CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are not used by the module. Instead, these fields are read as zero, and a write operation to them has no effect.

NOTE

When the CAN FD feature is enabled, do not use CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] for CAN bit timing. Instead use CBT[EPRESDIV], CBT[ERJW], CBT[EPSEG1], CBT[EPSEG2], and CBT[EPROPSEG].

The CAN bit variables in CTRL1 and in CBT are stored in the same internal register.

Soft reset does not affect the contents of this register.

Offset

Register	Offset
CTRL1	4h

Fields

Field	Description
31-24 PRESDIV	Prescaler Division Factor Determines the ratio between the PE clock frequency and the serial clock (Sclock) frequency. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency. The maximum value of this field is FFh, which gives a minimum Sclock frequency equal to the PE clock frequency divided by 256. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Sclock frequency = PE clock frequency ÷ (PRESDIV + 1).
23-22 RJW	Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time. One time quantum is equal to one Sclock period. The valid programmable values are 0–3. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = RJW + 1.
21-19 PSEG1	Phase Segment 1 Defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time Quanta.
18-16 PSEG2	Phase Segment 2 Defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. See Protocol timing for more information. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time Quanta.
15 BOFFMSK	Bus Off Interrupt Mask Provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0 - Interrupt disabled 1 - Interrupt enabled
14 ERRMSK	Error Interrupt Mask Provides a mask for the Error interrupt ESR1[ERRINT]. 0 - Interrupt disabled 1 - Interrupt enabled
13 CLKSRC	CAN Engine Clock Source Selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. When the oscillator clock is selected, the oscillator clock frequency must be lower than the bus clock. The selected clock is fed to the prescaler to generate the serial clock (Sclock). To guarantee reliable operation, this field can be written only in Disable mode. The module blocks it in other modes. See Protocol timing. Ensure the protocol engine clock tolerance according to the CAN Protocol standard (ISO 11898-1:2015). To identify the proper clock source, see the clock distribution chapter (module clocks table). If this field is 0, you can further select the peripheral clock source according to the Clock Root section of CCM chapter. 0 - Peripheral clock

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Bus clock
12 LPB	Loopback Mode Configures FlexCAN to operate in Loopback mode. In this mode, FlexCAN performs an internal loopback that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The RX CAN input pin is ignored and the TX CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field. It generates an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This field can be written only in Freeze mode; the module blocks it in other modes. **NOTE** In this mode, MCR[SRXDIS] cannot become 1, because it would impede the self-reception of a transmitted message. **NOTE** FDCTRL[TDCEN] and MCR[ETDCEN] must be 0 when this field is 1. 0 - Disabled 1 - Enabled
11 TWRNMSK	TX Warning Interrupt Mask Provides a mask for the TX Warning interrupt associated with the ESR1[TWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0 - Disabled 1 - Enabled
10 RWRNMSK	RX Warning Interrupt Mask Provides a mask for the RX Warning interrupt associated with the ESR1[RWRNINT] flag. When MCR[WRNEN] = 0, this field is read as 0. This field can be written only if MCR[WRNEN] = 1. 0 - Disabled 1 - Enabled
9 —	Reserved
8 ROM	Restricted Operation Mode Enables restricted operation mode. In restricted operation mode, FlexCAN is able to receive and acknowledge CAN messages, but it cannot send error frames and overload frames. If an error or overload condition is detected, FlexCAN treats it as a protocol exception and enters an integrating state. In restricted operation mode, FlexCAN does not increment or decrement the error counters. Besides,

Table continues on the next page...

Table continued from the previous page...

Field	Description
	FlexCAN is able to transmit time reference messages of potential time controllers in a network, but other types of frames must not be configured to be transmitted. **NOTE** This field can be written in freeze mode only. 0 - Restricted operation is disabled 1 - Restricted operation is enabled
7 SMP	CAN Bit Sampling Determines the sampling mode of CAN bits at the RX input. This field can be written in Freeze mode only; the module blocks it in other modes. **NOTE** For proper operation, to write 1 to this field, you must guarantee a minimum value of two time quanta in CTRL1[PSEG1] (or CBT[EPSEG1]).This bit cannot become 1 when CAN FD is enabled (MCR[FDEN] = 1). 0 - One sample is used to determine the bit value. 1 - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples. A majority rule is used.
6 BOFFREC	Bus Off Recovery Determines how FlexCAN recovers from Bus Off state. If 0, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If 1, automatic recovering from Bus Off is disabled. The module remains in Bus Off state until you write 1 to this field. If this field becomes 0 before 128 sequences of 11 recessive bits are detected on the CAN bus, Bus Off recovery happens as if this field had never become 1. If this field becomes 0 after 128 sequences of 11 recessive bits occurred, FlexCAN resynchronizes to the bus. It waits for 11 recessive bits before joining the bus. After this field becomes 0, it can become 1 again during Bus Off, but it will only be effective the next time the module enters Bus Off. If this field becomes 0 when the module is in Bus Off, writing 1 to this field is not effective for the current Bus Off recovery. **NOTE** See Bus Off in the CAN Protocol standard (ISO 11898-1:2015) for details. 0 - Enabled 1 - Disabled
5 TSYN	Timer Sync Enables a mechanism that resets the free-running timer each time a message is received in message buffer 0. This feature provides the means to synchronize multiple FlexCAN stations with a special "SYNC" message (that is, global network time). If MCR[RFEN] = 1 (Legacy RX FIFO enabled), the first available message buffer, according to CTRL2[RFFN], is used for timer synchronization instead of MB0. This field can be written in Freeze mode only; the module blocks it in other modes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Disable 1 - Enable
4 LBUF	Lowest Buffer Transmitted First Determines the ordering mechanism for message buffer transmission. When 1, MCR[LPRIOEN] does not affect the priority arbitration. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Buffer with highest priority is transmitted first. 1 - Lowest number buffer is transmitted first.
3 LOM	Listen-Only Mode Configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters described in Error Counter (ECR) are frozen, and the module operates in CAN Error Passive mode. Only messages acknowledged by another CAN station are received. If FlexCAN detects an unacknowledged message, it flags a BIT0 error without changing the receive error counter (ECR[RXERRCNT]), as if it is trying to acknowledge the message. FlexCAN acknowledges Listen-Only mode when ESR1[FLTCONF] = 1, indicating the Error Passive state. There can be some delay between the Listen-Only mode request and its acknowledgment. This field can be written in Freeze mode only; the module blocks it in other modes. 0 - Listen-Only mode is deactivated. 1 - FlexCAN module operates in Listen-Only mode.
2-0 PROPSEG	Propagation Segment Defines the length of the propagation segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation segment time = (PROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.

31.6.2.4 Free-Running Timer (TIMER)

Represents a 16-bit free-running counter that the CPU can read and write. The timer starts from 0h after reset, counts linearly to FFFFh, and wraps around.

When CTRL2[TIMER_SRC] = 1, an external time tick continuously increments the timer. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.

When CTRL2[TIMER_SRC] = 0, the CAN bit clock increments the timer, which defines the baud rate on the CAN bus. During a message transmission or reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the timestamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] = 1, the timer is reset whenever a message is received in the first available message buffer, according to CTRL2[RFFN].

The CPU can write to this register anytime. However, if the write occurs simultaneously with the timer being reset by a reception in the first message buffer, the write value is discarded.

Reading this register affects the message buffer unlocking procedure (see Message buffer lock mechanism).

15-0 TIMER	Timer Value Contains the free-running counter value.

31.6.2.5 RX Message Buffers Global Mask (RXMGMASK)

Masks the filter bits of all RX message buffers, excluding MB14 and MB15, which have individual mask registers.

This register is located in RAM.

RXMGMASK is provided for legacy application support.

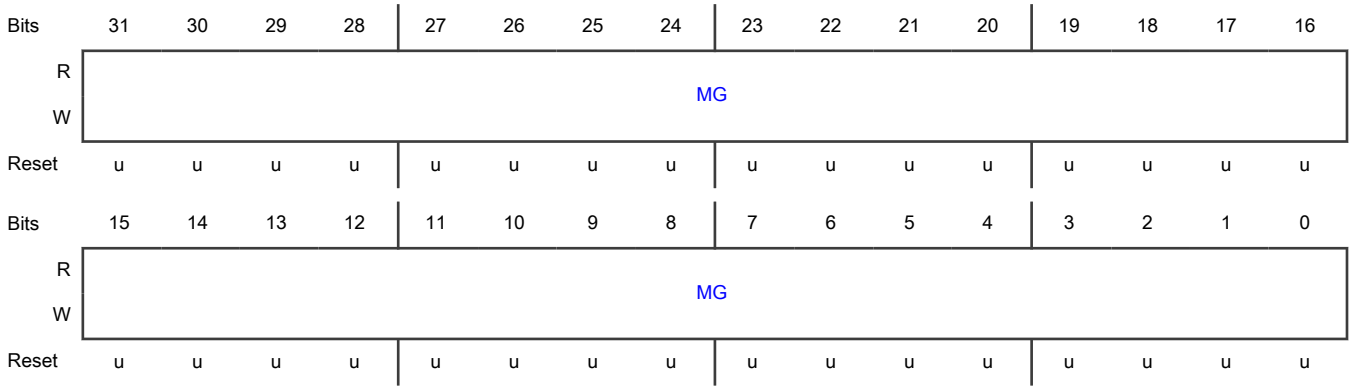
- When MCR[IRMQ] is 0, RXMGMASK is always in effect. The bits in RXMGMASK[MG] mask the MB filter bits.
- When MCR[IRMQ] is 1, RXMGMASK has no effect. The bits in RXMGMASK[MG] do not mask the MB filter bits.

This register can only be written in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
RXMGMASK	10h

Diagram



Fields

Field	Description
31-0 MG	Global Mask for RX Message Buffers Masks the message buffer filter bits. The alignment with the ID word of the message buffer is imperfect. The two most significant MG bits affect the fields RTR and IDE, which are located in the Control and Status word of the MB. The following table shows which MG bits mask each MB filter field.

SMB[RTR] [1]	CTRL2[RRS]	CTRL2[EACEN]	Message buffer filter fields			
			MB[RTR]	MB[IDE]	MB[ID]	Reserved
0	-	0	Note [2]	Note [3]	MG[28:0]	MG[31:29]
0	-	1	MG[31]	MG[30]	MG[28:0]	MG[29]
1	0	-	-	-	-	MG[31:0]
1	1	0	-	-	MG[28:0]	MG[31:29]
1	1	1	MG[31]	MG[30]	MG[28:0]	MG[29]

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called RX serial message buffer (RX SMB).
2. If CTRL2[EACEN] is 0, the RTR bit of MB is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is 0, the IDE bit of MB is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."

1b - The corresponding bit in the filter is checked.

31.6.2.6 Receive 14 Mask (RX14MASK)

Masks the filter fields of MB14.

This register is located in RAM.

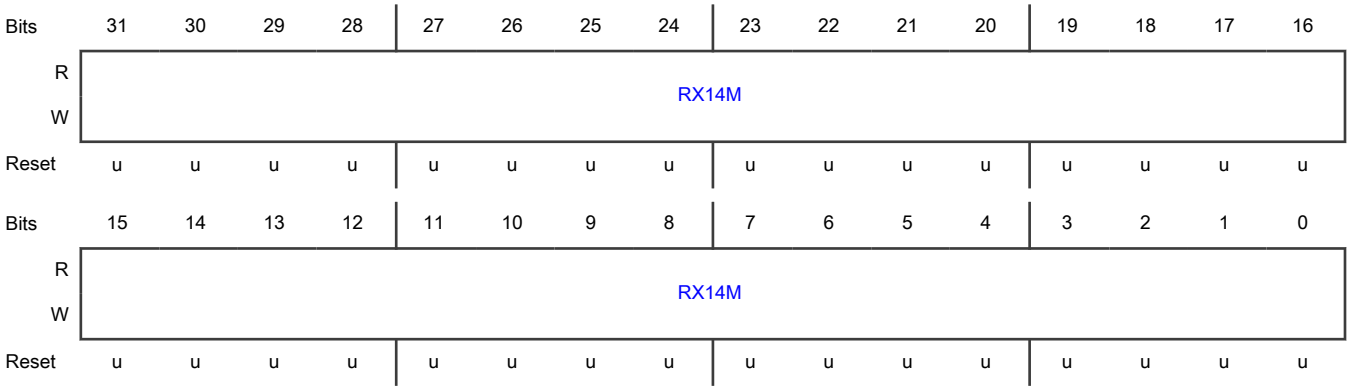
RX14MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX14MASK has no effect.

This register can only be programmed when the module is in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
RX14MASK	14h

Diagram



Fields

Field	Description
31-0 RX14M	RX Buffer 14 Mask Bits Masks the corresponding MB14 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of the other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

31.6.2.7 Receive 15 Mask (RX15MASK)

Masks the filter fields of MB15.

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] = 1, RX15MASK has no effect.

This register can be programmed only when the module is in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
RX15MASK	18h

Fields

Field	Description
31-0 RX15M	RX Buffer 15 Mask Bits Masks the corresponding MB15 filter field in the same way that RX Message Buffers Global Mask (RXMGMASK) masks the filters of other message buffers. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

31.6.2.8 Error Counter (ECR)

Contains error counters for received and transmitted messages.

TXERRCNT and RXERRCNT consider all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST count only the errors that occur in the data phase of CAN FD frames that have BRS = 1.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. The rules for increasing and decreasing these counters are described in the CAN protocol and are entirely implemented in FlexCAN.

The basic rules for FlexCAN bus state transitions are:

- If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
- If the state of FlexCAN is Error Passive, and TXERRCNT or RXERRCNT decrements to a value less than 128 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
- If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in Bus Off, TXERRCNT is cascaded with another internal counter to count the occurrences of 11 consecutive recessive bits on the bus. TXERRCNT is reset to zero. It counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to Error Active, and both error counters are reset to zero. Upon any instance of a dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
- If only one node is operating during system startup, its TXERRCNT increases upon each attempted message transmission, as a result of acknowledge errors (indicated by ESR1[ACKERR]). After the transition to Error Passive state, TXERRCNT no longer increments upon acknowledge errors. The chip never goes into the Bus Off state.

- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to the Error Active state.
- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames that have BRS = 1. These counters follow the same increment and decrement rules as TXERRCNT and RXERRCNT. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in the Bus Off state. They are reset when FlexCAN leaves the Bus Off state and resume counting after FlexCAN returns to the Error Active state.

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Description
31-24 RXERRCNT_FAST	Receive Error Counter for Fast Bits Counts errors detected in the data phase of received CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
23-16 TXERRCNT_FAST	Transmit Error Counter for Fast Bits Counts errors detected in the data phase of transmitted CAN FD messages that have BRS = 1. This field is read-only except in Freeze mode, when the CPU can write an 8-bit zero value only.
15-8 RXERRCNT	Receive Error Counter Counts all errors detected in received messages. This field is read-only except in Freeze mode, when the CPU can write to it.
7-0	Transmit Error Counter

Table continues on the next page...

Table continued from the previous page...

Field	Description
TXERRCNT	Counts all errors detected in transmitted messages. This field is read-only except in Freeze mode, when the CPU can write to it.

31.6.2.9 Error and Status 1 (ESR1)

Reports various error conditions detected in the reception and transmission of a CAN frame. This register provides status information about the chip, and is the source of some interrupts to the CPU. The reported error conditions are:

NOTE

Reading host can clear these fields.

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

One or more error flags may report an error detected in a single CAN frame. To account for more error events occurring in subsequent frames when the CPU does not attempt to read this register, error reporting is cumulative.

Status flags:

- TXWRN
- RXWRN
- IDLE
- TX
- FLTCONF
- RX
- SYNCH

Interrupt flags:

- BOFFINT
- BOFFDONEINT
- ERRINT
- ERRINT_FAST

- WAKINT
- TWRNINT
- RWRNINT

The CPU should follow this procedure when servicing interrupt requests generated by these flags:

1. Read this register to capture all error condition and status flags. This action clears the respective flags that were set since the last read access.
2. Write 1 to clear the interrupt flag that triggered the interrupt request.
3. Write 1 to clear the ERROVR flag, if it is set.

Starting from all error flags cleared, a first error event sets either ERRINT or ERRINT_FAST (provided the corresponding mask bit is 1). If other error events in subsequent frames occur before the CPU serves the interrupt request, the ERROVR flag is set to indicate that errors from different frames have accumulated.

Table 244. CAN bus status

SYNCH	IDLE	TX	RX	FlexCAN state
0	0	0	0	Not synchronized to CAN bus
1	1	X	X	Idle
1	0	1	0	Transmitting
1	0	0	1	Receiving

NOTE

See Fault confinement in the CAN Protocol standard (ISO 11898-1:2015) for details.

Fields

Field	Description
31 BIT1ERR_FAST	Fast Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit transmitted as recessive is received as dominant.
30 BIT0ERR_FAST	Fast Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit transmitted as dominant is received as recessive.
29 —	Reserved
28 CRCERR_FAST	Fast Cyclic Redundancy Check Error Flag Indicates that the receiver node has detected a CRC error in the CRC field of CAN FD frames that have BRS = 1. This error means that the calculated CRC is different from the received CRC. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A CRC error occurred since last read of this register.
27 FRMERR_FAST	Fast Form Error Flag Indicates whether the receiver node has detected a form error in the data phase of CAN FD frames that have BRS = 1. This error means that a fixed-form bit field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A form error occurred since last read of this register.
26 STFERR_FAST	Fast Stuffing Error Flag Indicates that a stuffing error has been detected in the data phase of CAN FD frames that have BRS = 1. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - A stuffing error occurred since last read of this register.
25-24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
23 PTA	Passive to Active State If this field is 1, controller is transitioned from passive to active error state. If this field is 0, controller is not transitioned from passive to active error state. Interrupt signals are asserted if enabled from FLTCONF_IE when the controller is transitioned from passive to active error state. 0 - Does not transition 1 - Transitions
22 ATP	Active to Passive State If this field is 1, controller is transitioned from active to passive error state. If this field is 0, controller is not transitioned from active to passive error state. Interrupt signals are asserted if enabled from FLTCONF_IE when the controller is transitioned from active to passive error state. 0 - Does not transition 1 - Transitions
21 ERROVR	Error Overrun Flag Indicates that an error condition occurred when any error flag is already set. 0 - No overrun 1 - Overrun
20 ERRINT_FAST	Fast Error Interrupt Flag Indicates that at least one error flag detected in the data phase of CAN FD frames that have BRS = 1 (BIT1ERR_FAST, BIT0ERR_FAST, CRCERR_FAST, FRMERR_FAST, or STFERR_FAST) is set. If CTRL2[ERRMSK_FAST] = 1, an interrupt is generated to the CPU. 0 - No such occurrence. 1 - Error flag set in the data phase of CAN FD frames that have BRS = 1.
19 BOFFDONEINT	Bus Off Done Interrupt Flag Indicates whether ECR[TXERRCNT] has finished counting 128 occurrences of 11 consecutive recessive bits on the CAN bus and is ready to leave Bus Off. If CTRL2[BOFFDONEMSK] = 1, an interrupt is generated to the CPU. 0 - No such occurrence 1 - FlexCAN module has completed Bus Off process.
18 SYNCH	CAN Synchronization Status Flag Indicates whether FlexCAN is synchronized to the CAN bus and able to participate in the communication process. FlexCAN sets and clears this flag. See the table in Error and Status 1 (ESR1). 0 - Not synchronized 1 - Synchronized
17	TX Warning Interrupt Flag

Table continues on the next page...

Table continued from the previous page...

Field	Description
TWRNINT	Indicates whether TX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the TXWRN flag transitions from 0 to 1, meaning that the TX error counters reached 96. If CTRL1[TWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not generated when in the Bus Off state. This flag is not updated during Freeze mode. 0 - No such occurrence 1 - TX error counter changed from less than 96 to greater than or equal to 96.
16 RWRNINT	RX Warning Interrupt Flag Indicates whether the RX error counter changed from less than 96 to greater than or equal to 96. If MCR[WRNEN] = 1, this flag is set when the RXWRN flag transitions from 0 to 1, meaning that the RX error counters reached 96. If CTRL1[RWRNMSK] = 1, an interrupt is sent to the CPU. When MCR[WRNEN] = 0, this flag is masked. The CPU must clear this flag before writing 0 to MCR[WRNEN]. Otherwise, this flag is set when MCR[WRNEN] = 1 again. Writing 0 has no effect. This flag is not updated during Freeze mode. 0 - No such occurrence 1 - RX error counter changed from less than 96 to greater than or equal to 96.
15 BIT1ERR	Bit1 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. **NOTE** A transmitter does not set this flag for an arbitration field or ACK slot. It is not set for a node sending an error passive flag that detects dominant bits. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as recessive is received as dominant.
14 BIT0ERR	Bit0 Error Flag Indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - At least one bit sent as dominant is received as recessive.
13 ACKERR	Acknowledge Error Flag Indicates whether the transmitter node has detected an acknowledge error. This error means that a dominant bit has not been detected during the ACK SLOT.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
12 CRCERR	Cyclic Redundancy Check Error Flag Indicates whether the receiver node has detected a cyclic redundancy check (CRC) error either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format. This error means that the calculated CRC is different from the received. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
11 FRMERR	Form Error Flag Indicates whether a form error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. This error means that a fixed-form field contains at least one illegal bit. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
10 STFERR	Stuffing Error Flag Indicates that a stuffing error has been detected in a non-FD message or in the arbitration or data phase of an FD message by the receiver node. After a read operation, the field's value clears to 0. 0 - No error 1 - Error occurred since last read of this register.
9 TXWRN	TX Error Warning Flag Indicates when repetitive errors occur during message transmission. Only the value of ECR[TXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - TXERRCNT is 96 or greater.
8 RXWRN	RX Error Warning Flag Indicates when repetitive errors occur during message reception. Only the value of ECR[RXERRCNT] affects this flag. This flag is not updated during Freeze mode. After a read operation, the field's value clears to 0. 0 - No such occurrence. 1 - RXERRCNT is greater than or equal to 96.

Table continues on the next page...

Table continued from the previous page...

Field	Description
7 IDLE	Idle Indicates whether CAN bus is in IDLE state. See Table 244. 0 - Not IDLE 1 - IDLE
6 TX	FlexCAN In Transmission Indicates whether FlexCAN is transmitting a message. See Table 244. 0 - Not transmitting 1 - Transmitting
5-4 FLTCONF	Fault Confinement State Indicates the confinement state of FlexCAN. If CTRL1[LOM] = 1, after a delay that depends on the CAN bit timing, this field indicates Error Passive. The same delay affects the way that this field reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time for coherence to be restored. Soft reset affects this field, but if CTRL1[LOM] = 1, its reset value lasts for only one CAN bit. After that time, this field reports Error Passive. 00 - Error Active 01 - Error Passive 1x - Bus Off
3 RX	FlexCAN in Reception Flag Indicates whether FlexCAN is receiving a message. See the table in Error and Status 1 (ESR1). 0 - Not receiving 1 - Receiving
2 BOFFINT	Bus Off Interrupt Flag Indicates whether FlexCAN has entered Bus Off state. If CTRL1[BOFFMSK]) = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0 - No such occurrence. 1 - FlexCAN module entered Bus Off state.
1 ERRINT	Error Interrupt Flag Indicates that at least one of the error flags (ESR1[BIT1ERR], ESR1[BIT0ERR], ESR1[ACKERR], ESR1[CRCERR], ESR1[FRMERR], or ESR1[STFERR]) is set. If the corresponding mask CTRL1[ERRMSK] = 1, an interrupt is generated to the CPU. Writing 0 to this field has no effect. 0 - No such occurrence. 1 - Indicates setting of any error flag in the Error and Status register.

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 WAKINT	Wake-up Interrupt Flag Generates an interrupt to the CPU when a recessive-to-dominant transition is detected on the CAN bus and MCR[WAKMSK] = 1. This field applies when FlexCAN is in low-power mode during Self Wake-up: • Doze mode • Stop mode When MCR[SLFWAK] = 0, this flag is masked. The CPU must clear this flag before disabling the field. Otherwise, it is set when MCR[SLFWAK] becomes 1 again. Writing 0 has no effect. 0 - No such occurrence. 1 - Indicates that a recessive-to-dominant transition was received on the CAN bus.

31.6.2.10 Interrupt Masks 2 (IMASK2)

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB63–MB32. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 2 (IFLAG2) flag is set.

Fields

Field	Description
31-0	Buffer MBi Mask Masks the corresponding FlexCAN message buffer interrupt for MB63–MB32.

Table continues on the next page...

Field	Description
BUF63TO32M	**NOTE** If the corresponding Interrupt Flags 2 (IFLAG2) flag is set, writing 1 or 0 to a field in IMASK2 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

31.6.2.11 Interrupt Masks 1 (IMASK1)

Masks interrupt flags. This register allows any of the 32 message buffer interrupts to be enabled or disabled for MB31–MB0. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding Interrupt Flags 1 (IFLAG1) flag is set.

Offset

Register	Offset
IMASK1	28h

Fields

Field	Description
31-0 BUF31TO0M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB31–MB0. **NOTE** If the corresponding Interrupt Flags 1 (IFLAG1) flag is set, writing 1 or 0 to a field in IMASK1 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

31.6.2.12 Interrupt Flags 2 (IFLAG2)

Contains the flags for the 32 message buffer interrupts for MB63–MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective flag in this register. If the corresponding Interrupt Masks 2 (IMASK2) bit is set, an interrupt is generated.

Before updating MCR[MAXMB], the CPU must service the IFLAG2 flags whose MB value is greater than the MAXMB to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

R	BUF63TO32I															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-0 BUF63TO32I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB63–MB32. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

31.6.2.13 Interrupt Flags 1 (IFLAG1)

Contains the flags for the 32 message buffer interrupts for MB31–MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding Interrupt Masks 1 (IMASK1) bit is set, an interrupt is generated. There is an exception when DMA for Legacy RX FIFO is enabled, as described below.

The BUF7I–BUF5I flags also represent Legacy FIFO interrupts when the Legacy RX FIFO is enabled. When MCR[RFEN] is 1 and MCR[DMA] is 0, the function of the eight least significant interrupt flags changes:

- BUF7I, BUF6I, and BUF5I indicate operating conditions of the Legacy FIFO.
- BUF4I–BUF1I fields are reserved.
- BUF0I empties the Legacy FIFO.

Before writing 1 to MCR[RFEN], the CPU must service the IFLAG flags set in the Legacy RX FIFO region; see Legacy RX FIFO. Otherwise, these IFLAG flags mistakenly show the related message buffers now belonging to Legacy FIFO as having contents to be serviced. When MCR[RFEN] is 0, the Legacy FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Legacy RX FIFO filters beyond MB7. For example, when RFFN is 8h, Legacy RX FIFO filters occupy the MB23–MB0 range, and related IFLAG flags must be cleared.

When MCR[RFEN] and MCR[DMA] are 1 (DMA feature for Legacy RX FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) changes to support DMA operation. BUF7I, BUF6I, and BUF4I–BUF1I are not used.

BUF5I indicates the operating condition of the Legacy FIFO, and BUF0I empties the Legacy FIFO. Moreover, BUF5I does not generate a CPU interrupt, but it does generate a DMA request. IMASK1 bits in the Legacy RX FIFO region are not considered when bit MCR[DMA] = 1. In addition, the CPU must not clear the BUF5I flag when DMA is enabled. Before writing 1 to MCR[DMA], the CPU must service the IFLAG flags set in the Legacy RX FIFO region. When MCR[DMA] is 0, the Legacy FIFO must be empty. Legacy FIFO must be disabled when MCR[FDEN] = 1.

Before updating MCR[MAXMB], the CPU must service the IFLAG1 flags whose MB value is greater than the MCR[MAXMB] to be updated. Otherwise, those flags remain set and are inconsistent with the number of message buffers available.

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-8 BUF31TO8I	Buffer MBi Interrupt Flags the corresponding FlexCAN message buffer interrupt for MB31–MB8. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
7 BUF7I	Buffer MB7 Interrupt or Legacy RX FIFO Overflow Flags the interrupt for MB7 when MCR[RFEN] = 0 (Legacy RX FIFO disabled).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO overflow. In this case, the flag indicates that a message was lost because the Legacy RX FIFO is full. When the Legacy RX FIFO is full and a message buffer captures the message, this flag is not set. 0 - No occurrence of MB7 completing transmission or reception, or no FIFO overflow. 1 - MB7 completed transmission or reception, or FIFO overflow.
6 BUF6I	Buffer MB6 Interrupt or Legacy RX FIFO Warning Flags the interrupt for MB6 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, this flag represents a Legacy RX FIFO warning. In this case, the flag indicates when the number of unread messages within the Legacy RX FIFO is increased to five from four due to the reception of a new message. In other words, the Legacy RX FIFO is almost full. If this flag is cleared when there are more than four unread messages, it does not set again until the number of unread messages in the Legacy RX FIFO decreases to four or fewer. 0 - No occurrence of MB6 completing transmission or reception, or FIFO not almost full. 1 - MB6 completed transmission or reception, or FIFO almost full.
5 BUF5I	Buffer MB5 Interrupt or Frames available in Legacy RX FIFO Flags the interrupt for MB5 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears this flag. When MCR[RFEN] = 1, the BUF5I flag represents frames available in Legacy RX FIFO. In this case, the flag indicates that at least one frame is available to be read from the Legacy RX FIFO. When MCR[DMA] = 1, this flag generates a DMA request. The CPU must not clear this field by writing 1 to BUF5I. 0 - No occurrence of completed transmission or reception, or no frames available 1 - MB5 completed transmission or reception, or frames available
4-1 BUF4TO1I	Buffer MBi Interrupt or Reserved Flags the interrupts for MB4–MB1 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). **NOTE** When a CPU write changes the value of MCR[RFEN], FlexCAN clears these flags. When MCR[RFEN] = 1, the BUF4TO1I flags are reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.
0 BUF0I	Buffer MB0 Interrupt or Clear Legacy FIFO bit Flags the interrupt for MB0 when MCR[RFEN] = 0 (Legacy RX FIFO disabled). If MCR[RFEN] = 1, this field is used to trigger the clear Legacy FIFO operation. This operation empties the Legacy FIFO contents. Before performing this operation, the CPU must service all Legacy FIFO-related IFLAG flags. When MCR[DMA] = 1, this operation also clears the BUF5I flag, aborting the DMA request. The clear Legacy FIFO operation occurs when the CPU writes 1 to BUF0I. This operation is only allowed in Freeze mode; the module blocks it in other conditions. 0 - MB0 has no occurrence of successfully completed transmission or reception. 1 - MB0 has successfully completed transmission or reception.

31.6.2.14 Control 2 (CTRL2)

Complements Control 1 (CTRL1), providing control bits for memory write-access in Freeze mode. This register extends Legacy FIFO filter quantity, and adjusts the operation of internal FlexCAN processes such as matching and arbitration.

Soft reset does not affect the contents of this register.

Table 245 shows how the value of CTRL2[RFFN] determines the Legacy RX FIFO filter structure.

Table 245. Possible Legacy RX FIFO filter structures

RFFN[3:0]	Number of Legacy RX FIFO filter elements	Message buffers occupied by Legacy RX FIFO and ID filter table	Remaining available message buffers	Legacy RX FIFO ID filter table elements affected by RX individual masks	Legacy RX FIFO ID filter table elements affected by Legacy RX FIFO global mask

Fields

Field	Description
31 ERRMSK_FAST	Error Interrupt Mask for Errors Detected in the Data Phase of Fast CAN FD Frames Enables the ESR1[ERRINT_FAST] interrupt. 0 - Disable 1 - Enable
30 BOFFDONEMSK	Bus Off Done Interrupt Mask Enables the Bus Off Done interrupt, ESR1[BOFFDONEINT]. 0 - Disable 1 - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Description
29 ECRWRE	Error Correction Configuration Register Write Enable Enables updates for Memory Error Control (MECR). If the protocol described in Detection and correction of memory errors is not followed, this field is automatically 0. 0 - Disable 1 - Enable
28 WRMFRZ	Write Access to Memory in Freeze Mode Enables unrestricted write access to FlexCAN memory in Freeze mode. When this field is 0, write access restrictions are maintained. This field can only be written in Freeze mode, and has no effect out of Freeze mode. **NOTE** Do not write 1 to MCR[RFEN] during FlexCAN memory initialization. 0 - Disable 1 - Enable
27-24 RFFN	Number of Legacy Receive FIFO Filters Defines the number of Receive Legacy FIFO filters, as shown in Table 245. The chip determines the maximum selectable number of filters. Do not program this field with values that cause the number of message buffers occupied by Legacy RX FIFO and Legacy RX FIFO ID Filter to exceed MCR[MAXMB]. MCR[MAXMB] defines the number of message buffers present. This field can only be written in Freeze mode; the module blocks it in other modes. Each group of eight filters occupies a memory space equivalent to two message buffers. The more filters are implemented, the fewer message buffers are available. The Legacy RX FIFO occupies the memory space originally reserved for MB5–MB0. This field should be programmed with a value corresponding to a number of filters less than the number of available memory words. The number of available words can be calculated as follows: (SETUP_MB - 6) × 4 Where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[MAXMB]. The number of remaining message buffers available is: (SETUP_MB - 8) - (RFFN × 2) If the number of Legacy RX FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), the exceeding ones are not functional. **NOTE** • The number of the last remaining available message buffers is the smaller of (NUMBER_OF_MB - 1) and MCR[MAXMB]. • If RX Individual Mask registers are not enabled, the Legacy RX FIFO Global Mask affects all Legacy RX FIFO filters.
23-19	Transmission Arbitration Start Delay

Table continues on the next page...

Table continued from the previous page...

Field	Description
TASD	Indicates by how many CAN bits the transmission arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See TX arbitration start delay for details. This field can be written only in Freeze mode; the module blocks it in other modes.
18 MRP	Message Buffers Reception Priority Sets the priority for the matching process. This field can be written only in Freeze mode; the module blocks it in other modes. 0 - Matching starts from Legacy RX FIFO or Enhanced RX FIFO and continues on message buffers. 1 - Matching starts from message buffers and continues on Legacy RX FIFO or Enhanced RX FIFO.
17 RRS	Remote Request Storing Determines what the module does with a remote request. The remote request frame is submitted to a matching process. If this field is 1, the frame is stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame is generated. If this field is 0, an automatic remote response frame is generated if a message buffer with CODE = 1010b is found with the same ID. You can only write to this field in Freeze mode. The module blocks it in other modes. 0 - Generated 1 - Stored
16 EACEN	Entire Frame Arbitration Field Comparison Enable for RX Message Buffers Controls the comparison of IDE and RTR fields within RX message buffer filters with their corresponding bits in the incoming frame by the matching process. If enabled, the IDE and RTR fields of the RX message buffer are compared to their corresponding bits within the incoming frame (mask bits apply). If disabled, the IDE field of the RX message buffer filter is always compared and RTR is never compared despite mask bits. This field does not affect matching for Legacy RX FIFO or Enhanced RX FIFO. You can only write to this field in Freeze mode; the module blocks it in other modes. 0 - Disable 1 - Enable
15 TIMER_SRC	Timer Source Selects the time tick source used for incrementing the free-running timer counter. If CAN bit clock is selected, it defines the baud rate on the CAN bus. If External time tick is selected, the period can be adjusted to match the baud rate on the CAN bus. It can also be adjusted to a different value as required. See the chip-specific section for details about the external time tick. You can only write to this field in Freeze mode. 0 - CAN bit clock

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - External time tick
14 PREXCEN	Protocol Exception Enable Enables the protocol exception feature. You can only write to this field in Freeze mode. **NOTE** See Protocol exception event in the CAN Protocol standard (ISO 11898-1:2015) for details. 0 - Disabled 1 - Enabled
13 BTE	Bit Timing Expansion Enable Enables the use of Enhanced CAN Bit Timing Prescalers (EPRS), Enhanced Data Phase CAN Bit Timing (EDCBT), and Enhanced Nominal CAN Bit Timing (ENCBT) to configure the CAN bit timing segments, instead of using the bit timing fields of CAN Bit Timing (CBT), CAN FD Bit Timing (FDCBT), and Control 1 (CTRL1). If this field is 1: • CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] are read as zero. A write operation to these fields has no effect. • CBT[EPRESDIV], CBT[ERJW], CBT[EPROPSEG], CBT[EPSEG1], and CBT[EPSEG2], and the corresponding fields in CAN FD Bit Timing (FDCBT), are read as zero. A write operation to these fields has no effect. • ETDC[ETDCOFF], ETDC[ETDCEN], ETDC[ETDCFAIL], and ETDC[ETDCVAL] are used by FlexCAN instead of FDCTRL[TDCOFF], FDCTRL[TDCEN], FDCTRL[TDCFAIL], and FDCTRL[TDCVAL]. These fields are read as zero, and a write operation to them has no effect. • ETDC[TDMDIS] can be used to disable transceiver delay measurement. 0 - Disable 1 - Enable
12 ISOCANFDEN	ISO CAN FD Enable Enables the CAN FD protocol according to ISO specification (ISO 11898-1:2015) (see CAN FD ISO compliance). When disabled, FlexCAN operates using the non-ISO CAN FD protocol. You can only write to this field in Freeze mode. **NOTE** FlexCAN is able to transmit FD frame format according to CAN Protocol standard (ISO 11898-1:2015). 0 - Disable 1 - Enable
11	Edge Filter Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
EDFLTDIS	Disables the edge filter used during the Bus Integration state. When the Edge Filter is enabled, two consecutive nominal time quanta with dominant bus states are required to detect an edge that causes synchronization. When synchronization occurs, the counting of the sequence of 11 consecutive recessive bits is restarted. The edge filter prevents dominant pulses that are shorter than a nominal bit time (present during the data phase of an FD frame) from being mistaken for an idle condition. You can only write to this field in Freeze mode. **NOTE** See Bus Integration state in the CAN Protocol standard (ISO 11898-1:2015) for details. 0 - Enabled 1 - Disabled
10 FLT_RXN	Fault reaction Indicates fault reaction during the functional mode. Setting this bit makes the TX pin to recessive state. 0 - Fault reaction is disabled 1 - Fault reaction is enabled
9-8 MBTSBASE	Message Buffer Timestamp Base Selects the timebase used for capturing the 16-bit TIME_STAMP field of the message buffer register. This field can be written in Freeze Mode only. 00 - TIMER 01 - Lower 16 bits of high-resolution timer 10 - Upper 16 bits of high-resolution timer 11 - Reserved
7-6 TSTAMPCAP	Timestamp Capture Point Configures the point in time when a 32-bit timebase is captured during a CAN frame. This base is stored in the high-resolution timestamp register (HR_TIME_STAMP). For classical CAN frames, capture points can be the start-of-frame bit or the point when CAN frame is considered valid. This point is the seventh bit of the end-of-frame for transmission and the sixth bit of the end-of-frame for reception. For CAN FD frames, the high-resolution timestamp can be captured at the start of frame, when a CAN FD frame is considered valid, or the res bit. You can only write to this field in Freeze mode. 00 - Disabled 01 - End of the CAN frame 10 - Start of the CAN frame 11 - Start of frame for classical CAN frames; res bit for CAN FD frames
5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
4-2 RETRY	Number of Retransmission Requests The message is discarded in case of a re-transmission counter exhausted. **NOTE** You can only write to this field in Freeze mode. 000 - No retransmission 001 - Count of re-transmission attempts 010 - Count of re-transmission attempts 011 - Count of re-transmission attempts 100 - Count of re-transmission attempts 101 - Count of re-transmission attempts 110 - Count of re-transmission attempts 111 - Unlimited number of retransmission
1-0 —	Reserved

31.6.2.15 Error and Status 2 (ESR2)

Reports general status information.

Offset

Register	Offset
ESR2	38h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0	VPS	IMB	RX_PIN_...	0											
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-23 —	Reserved
22-16 LPTM	Lowest Priority TX Message Buffer Indicates the lowest number inactive message buffer when ESR2[VPS] = 1 (see ESR2[IMB]). If no message buffer is inactive, the message buffer indicated depends on the value of CTRL1[LBUF]. If CTRL1[LBUF] = 0, the message buffer indicated is the one with the greatest arbitration value (see Highest-priority message buffer first). If CTRL1[LBUF] = 1, the message buffer indicated is the active TX message buffer with the highest number. If a TX message buffer is being transmitted, it is not considered in the LPTM calculation. If ESR2[IMB] is not 0 and a frame is transmitted successfully, the value of LPTM is updated with its message buffer number.
15 —	Reserved
14 VPS	Valid Priority Status Indicates whether the contents of ESR2[IMB] and ESR2[LPTM] are valid. It becomes 1 upon every complete TX arbitration process, unless the CPU writes to the Control and Status word of a message buffer already scanned. In other words, it is behind the TX Arbitration Pointer, during the TX arbitration process. If there is no inactive message buffer and only one TX message buffer that is being transmitted, this field remains 0. This field becomes 0 upon the start of every TX arbitration process or upon a write to the Control and Status word of any message buffer. **NOTE** No CPU write to the Control and Status of a message buffer that the abort mechanism blocks affects this field. When MCR[AEN] = 1, the abort code write to the Control and Status of an MB being transmitted (pending abort) is blocked. Any write attempt to a TX MB with its IFLAG flag set is also blocked. 0 - Invalid 1 - Valid
13 IMB	Inactive Message Buffer Indicates whether any message buffer is inactive (CODE field is either 1000b or 0b) when ESR2[VPS] = 1. This field becomes 1 when: • A lowest-priority TX message buffer (ESR2[LPTM]) is found and it is inactive during arbitration. • This field is not 1, and a frame is transmitted successfully. This field always becomes 0 at the start of arbitration (see Arbitration process). If a message buffer is successfully transmitted and this field is 0 (no inactive message buffer), ESR2[VPS] and this field both become 1. The index related to the MB transmitted is loaded into ESR2[LPTM]. In this case, the value of ESR2[LPTM] is the number of the first inactive message buffer. 0 - Message buffer indicated by ESR2[LPTM] is not inactive. 1 - At least one message buffer is inactive.

Table continues on the next page...

Table continued from the previous page...

Field	Description
12 RX_PIN_ST	RX Pin Status Indicates the current state of the RX pin. This bit is affected by soft reset. **NOTE** IP takes a few clock cycles to propagate the value of RX pin to this status bit. 0 - RX pin is in the dominant state 1 - RX pin is in a recessive state
11-0 —	Reserved

31.6.2.16 Cyclic Redundancy Check (CRCR)

Provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low-order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, you must use the CAN FD CRC (FDCRC). This register is updated at the same time that the TX interrupt flag is set.

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Offset

Register	Offset
CRCR	44h

Fields

Field	Description
31-23 —	Reserved
22-16 MBCRC	CRC Message Buffer Indicates the number of the message buffer corresponding to the value in CRCR[TXCRC].
15 —	Reserved
14-0 TXCRC	Transmitted CRC value Indicates the CRC value of the last transmitted message for non-FD frames. For FD frames, CRC value is reported in CAN FD CRC (FDCRC).

31.6.2.17 Legacy RX FIFO Global Mask (RXFGMASK)

Masks the Legacy RX FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN], when Legacy RX FIFO is enabled.

This register is located in RAM.

You can only write to this register in Freeze mode; the module blocks it in other modes.

The following table shows how the FGM bits correspond to each IDAF field.

Table 246. Correspondence of Legacy RX FIFO global mask bits to IDF fields

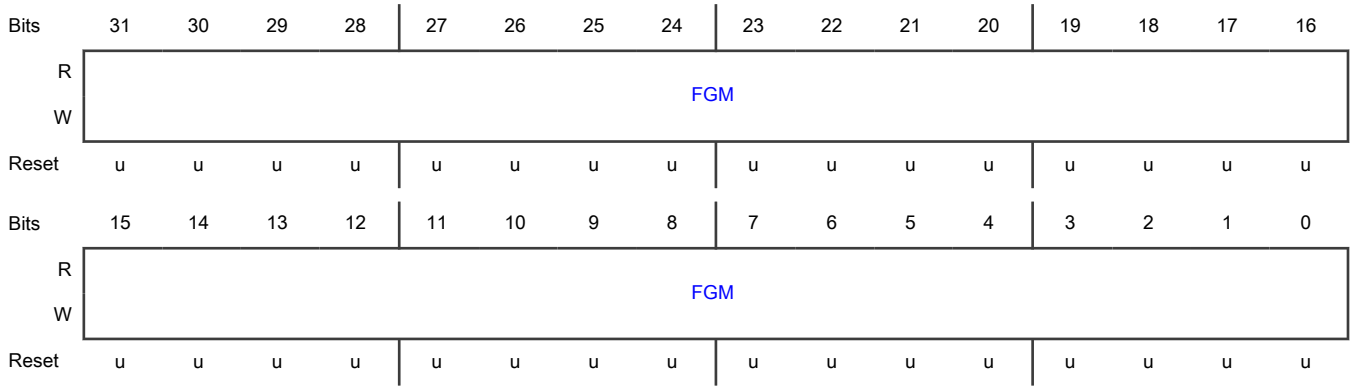
Legacy RX FIFO ID filter table elements format (MCR[IDAM])	Identifier acceptance filter fields					
	RTR	IDE	RXIDA	RXIDB [1]	RXIDC [2]	Reserved
A	FGM[31]	FGM[30]	FGM[29:1]	—	—	FGM[0]
B	FGM[31], FGM[15]	FGM[30], FGM[14]	—	FGM[29:16], FGM[13:0]		—
C	—	—		—	FGM[31:24], FGM[23:16], FGM[15:8], FGM[7:0]	

1. If MCR[IDAM] is equivalent to format B, only the 14 most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Legacy RX FIFO filter.

Offset

Register	Offset
RXFGMASK	48h

Diagram



Fields

Field	Description
31-0 FGM	Legacy RX FIFO Global Mask Bits Masks the ID filter table elements bits in a perfect alignment. 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

31.6.2.18 Legacy RX FIFO Information (RXFIR)

Provides information about Legacy RX FIFO.

This register is the port through which the CPU accesses the output of the Legacy RXFIR FIFO located in RAM. FlexCAN writes to the Legacy RXFIR FIFO when a new message is moved into the Legacy RX FIFO. Also, its output is updated whenever the output of the Legacy RX FIFO is updated with the next message. See Legacy RX FIFO for instructions on reading this register.

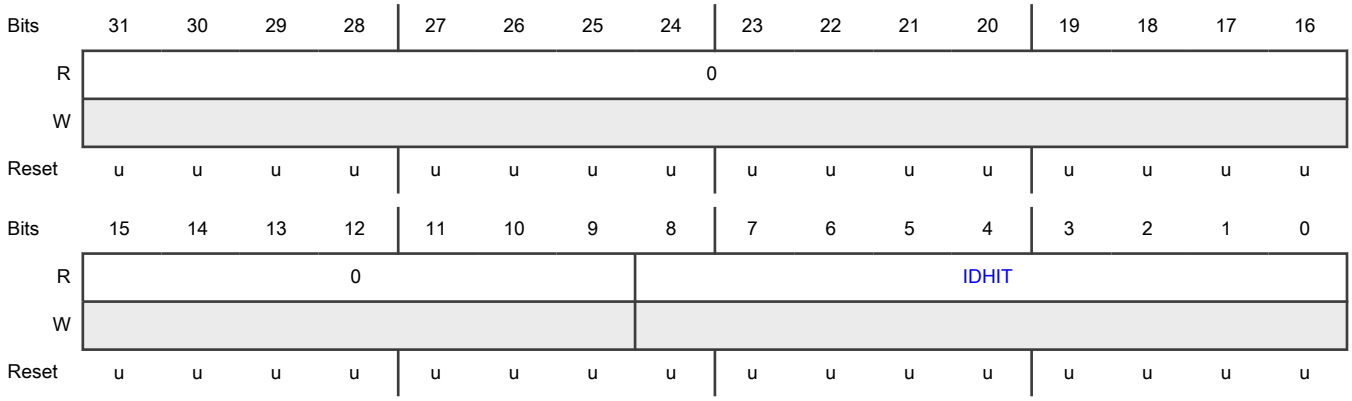
NOTE

RXFIR can be written only during memory initialization, due to the error code correction (ECC) feature. In every other case, this register is read-only.

Offset

Register	Offset
RXFIR	4Ch

Diagram



Fields

Field	Description
31-9 —	Reserved
8-0 IDHIT	Identifier Acceptance Filter Hit Indicator Indicates which Identifier Acceptance filter that the received message hit in the output of the Legacy RX FIFO. If multiple filters match the incoming message ID, the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only when IFLAG1[BUF5I] is set.

31.6.2.19 CAN Bit Timing (CBT)

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1). EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of CTRL1[PRESDIV], CTRL1[PROPSEG], CTRL1[PSEG1], CTRL1[PSEG2], and CTRL1[RJW] respectively.

NOTE

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

CBT[BTF] selects the use of the timing variables defined in this register.

When the CAN FD feature is enabled (MCR[FDEN] = 1), always write 1 to CBT[BTF].

Soft reset does not affect the contents of this register.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

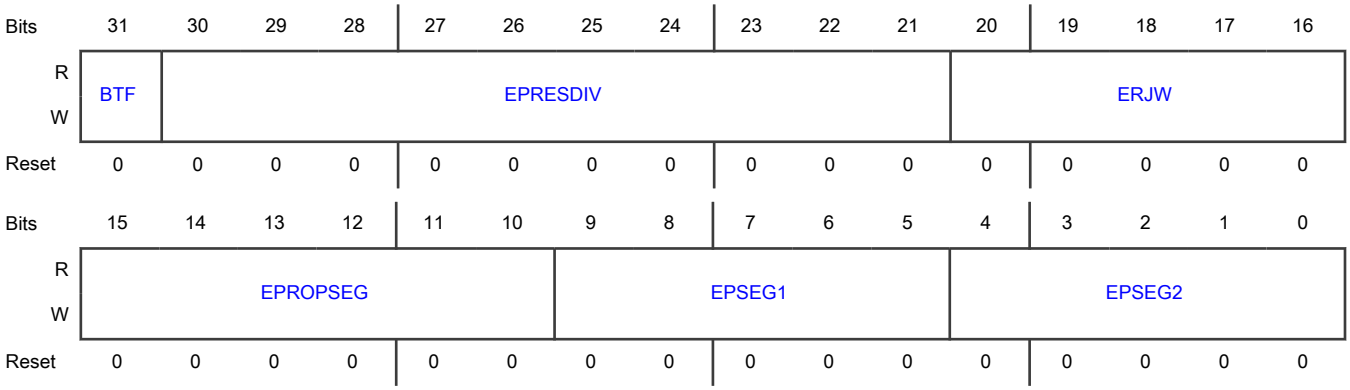
NOTE

If CTRL2[BTE] = 1, EPRESDIV, ERJW, EPROPSEG, EPSEG1, and EPSEG2 are read as zero. A write operation to them has no effect.

Offset

Register	Offset
CBT	50h

Diagram



Fields

Field	Description
31 BTF	Bit Timing Format Enable Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW. These fields replace the CAN bit timing variables defined in Control 1 (CTRL1). This field can be written in Freeze mode only. 0 - Disable 1 - Enable
30-21 EPRESDIV	Extended Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range. The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (EPRESDIV + 1)
20-16 ERJW	Extended Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time when CBT[BTF] = 1. Otherwise, it has no effect. It extends the CTRL1[RJW] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = ERJW + 1. One Time Quantum = one Sclock period.
15-10	Extended Propagation Segment

Table continues on the next page...

Table continued from the previous page...

Field	Description
EPROPSEG	Defines the length of the propagation segment in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = (EPROPSEG + 1) × Time Quanta. One Time Quantum = one Sclock period.
9-5 EPSEG1	Extended Phase Segment 1 Defines the length of phase segment 1 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-0 EPSEG2	Extended Phase Segment 2 Defines the length of phase segment 2 in the bit time when CBT[BTF] = 1, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Buffer Segment 1 = (EPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

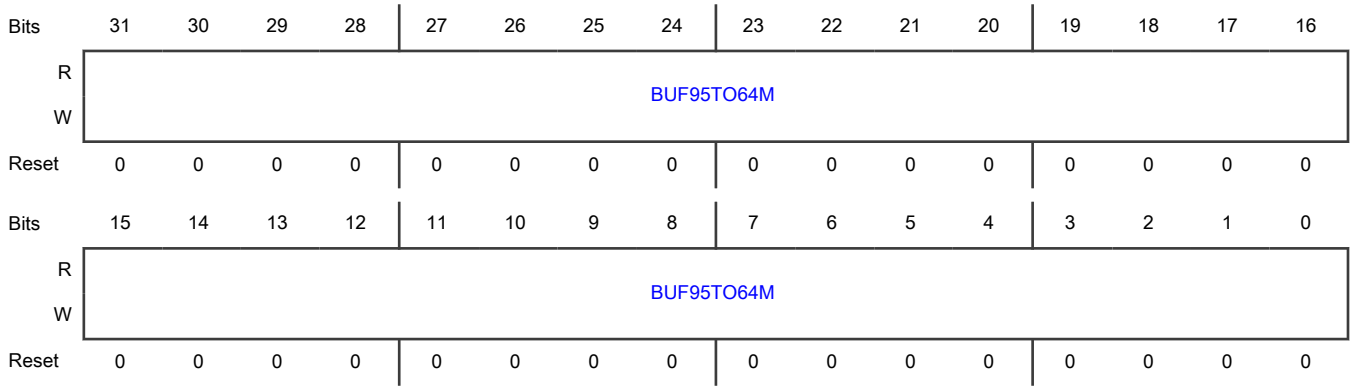
31.6.2.20 Interrupt Masks 3 (IMASK3)

Enables or disables any number of the 32 message buffer interrupts for MB95–MB64. It contains one interrupt mask bit per buffer. This configuration allows the CPU to determine which buffer generates an interrupt after a successful transmission or reception when the corresponding IFLAG3 flag is set.

Offset

Register	Offset
IMASK3	6Ch

Diagram



Fields

Field	Description
31-0 BUF95TO64M	Buffer MBi Mask Enables or disables the corresponding FlexCAN message buffer interrupt for MB95–MB64. When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. **NOTE** If the corresponding IFLAG3 flag is set, writing 1 or 0 to a field in IMASK3 can set or clear an interrupt request. 0b - The corresponding buffer interrupt is disabled. 1b - The corresponding buffer interrupt is enabled.

31.6.2.21 Interrupt Flags 3 (IFLAG3)

Defines the flags for the 32 message buffer interrupts for MB95–MB64. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG3 flag. If the corresponding IMASK3 bit is 1, an interrupt is generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], the CPU must service the IFLAG3 flags whose MB value is greater than the MAXMB to be updated. Otherwise, they remain set and are inconsistent with the number of message buffers available.

Offset

Register	Offset

Fields

Field	Description
31-0	Buffer MBi Interrupt

Table continues on the next page...

Field	Description
BUF95TO64	Flags the corresponding FlexCAN message buffer interrupt for MB95–MB64.When CAN FD is enabled, the MB range is defined in accordance with FDCTRL[MBDSRn]. 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception. 1b - The corresponding buffer has successfully completed transmission or reception.

31.6.2.22 External Timer (ET)

This register captures the value of external timer.

Offset

Register	Offset
ET	78h

Diagram

Fields

Field	Description
31-0 TIMER	Timer Indicates the current value of the external timer. This field is affected by soft reset.

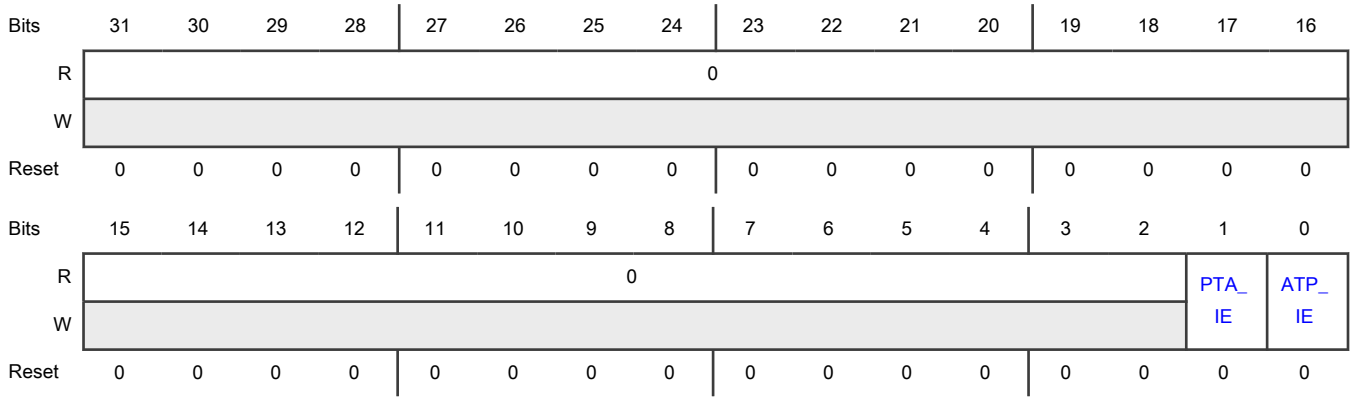
31.6.2.23 Fault Confinement Interrupt Enable (FLTCONF_IE)

Interrupt enables for active to passive and passive to active state transitions.

Offset

Register	Offset
FLTCONF_IE	7Ch

Diagram



Fields

Field	Description
31-2 —	Reserved
1 PTA_IE	Passive to Active Interrupt Enable Enables passive to active error state interrupt. When this field is 1, passive to active error state interrupt is enabled. When this field is 0, passive to active error state interrupt is not enabled. 0 - Disable 1 - Enable
0 ATP_IE	Active to Passive Interrupt Enable Enables active to passive error state interrupt. When this field is 1, active to passive error state interrupt is enabled. When this field is 0, active to passive error state interrupt is not enabled. 0 - Disable 1 - Enable

31.6.2.24 Receive Individual Mask (RXIMR0 - RXIMR95)

Stores the acceptance masks for ID filtering in RX message buffers and the Legacy RX FIFO.

When the Legacy RX FIFO is disabled (MCR[RFEN] = 0), an individual mask is provided for each available RX message buffer on a one-to-one correspondence. When the Legacy RX FIFO is enabled (MCR[RFEN] = 1), an individual mask is provided for each Legacy RX FIFO ID filter table element on a one-to-one correspondence. This correspondence depends on the setting of CTRL2[RFFN] (see Legacy RX FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0. RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

The CPU can only access the RXIMR registers when the module is in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

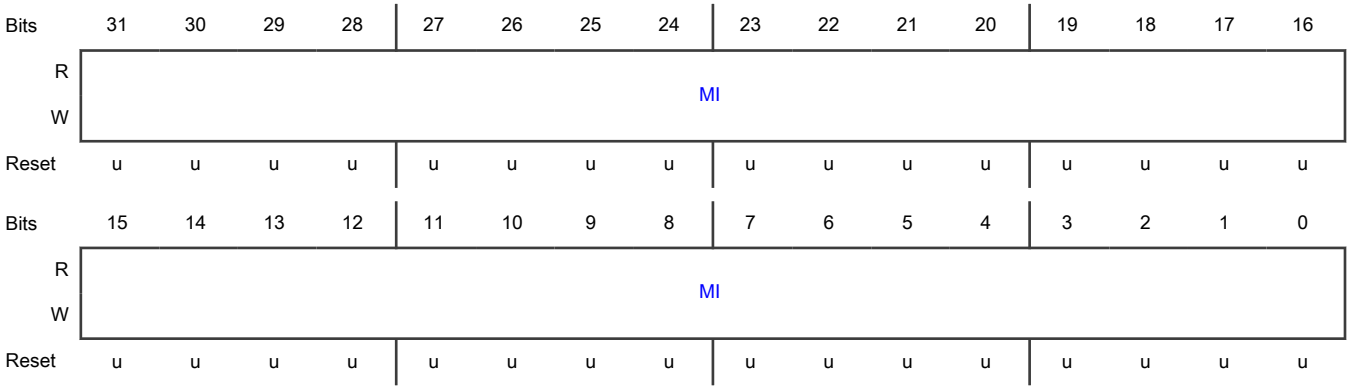
It is possible for the RXIMR memory region to be accessed as general-purpose memory. See Bus interface for more information.

Offset

For n = 0 to 95:

Register	Offset
RXIMRn	880h + (n × 4h)

Diagram



Fields

Field	Description
31-0 MI	Individual Mask Bits Masks the corresponding bit in both the message buffer filter and Legacy RX FIFO ID filter table element in distinct ways. For message buffer filters, see RX Message Buffers Global Mask (RXMGMASK). For Legacy RX FIFO ID filter table elements, see Legacy RX FIFO Global Mask (RXFGMASK). 0b - The corresponding bit in the filter is "don't care." 1b - The corresponding bit in the filter is checked.

31.6.2.25 Memory Error Control (MECR)

Contains control bits for memory error detection and correction (ECC).

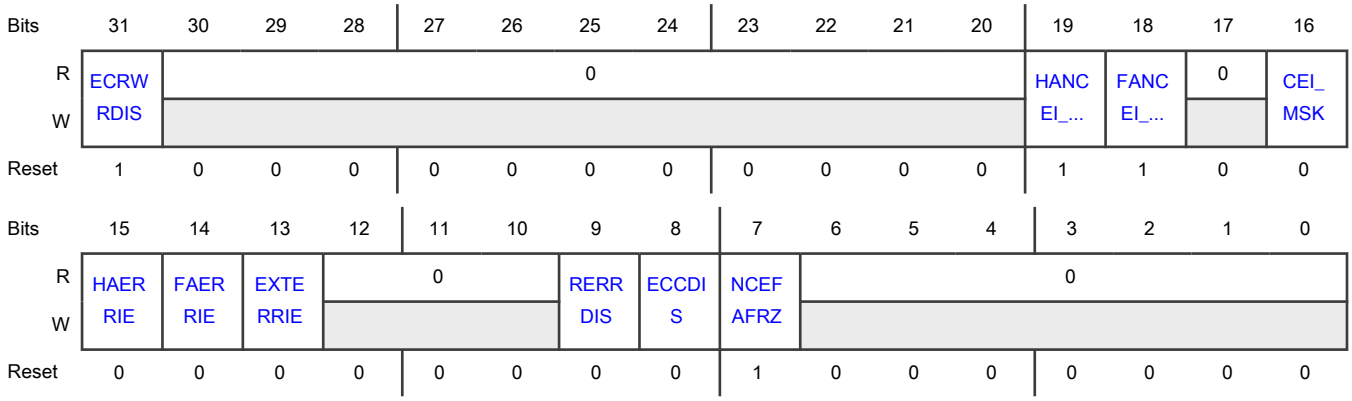
NOTE

When CTRL2[ECRWRE] = 0, writes to this register are blocked, except for MECR[ECRWRDIS].

Offset

Register	Offset
MECR	AE0h

Diagram



Fields

Field	Description
31 ECRWRDIS	Error Configuration Register Write Disable Disables writes on this register. This field automatically becomes 1 (disabled) when CTRL2[ECRWRE] is 1. The protocol described in Detection and correction of memory errors must be followed. 0 - Enable 1 - Disable
30-20 —	Reserved
19 HANCEI_MSK	Host Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by the host (CPU). 0 - Disable 1 - Enable
18 FANCEI_MSK	FlexCAN Access with Noncorrectable Errors Interrupt Mask Enables the interrupt for noncorrectable errors detected in memory reads issued by FlexCAN internal processes. 0 - Disable 1 - Enable
17 —	Reserved
16 CEI_MSK	Correctable Errors Interrupt Mask Enables the interrupt for correctable errors detected in memory reads issued by the host or FlexCAN internal processes. 0 - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Enable
15 HAERRIE	Host Access Error Injection Enable Enables the injection of errors only in memory reads issued by the host (CPU). 0 - Disable 1 - Enable
14 FAERRIE	FlexCAN Access Error Injection Enable Enables the injection of errors only in memory reads issued by FlexCAN internal processes. 0 - Disable 1 - Enable
13 EXTERRIE	Extended Error Injection Enable Extends the error injection on 32-bit memory accesses to the complementary 32-bit word. This feature uses the same 32-bit error injection data and parity words used for 64-bit memory accesses performed by internal FlexCAN processes. See Error Injection Data Pattern (ERRIDPR) and Error Injection Parity Pattern (ERRIPPR). 0 - Disable. Apply error injection only to the 32-bit word. 1 - Enable. Apply error injection to the 64-bit word.
12-10 —	Reserved
9 RERRDIS	Error Report Disable Disables the update of the error report registers. The update of error-related flags and the generation of bus transfer errors are still active. **NOTE** When reading the report registers, this field must be 1 to ensure coherence on the consecutive register reads. 0 - Enable 1 - Disable
8 ECCDIS	Error Correction Disable Completely disables the memory detection and correction mechanism. Besides disabling the error report mechanism, it also stops the update of the error-related flags and the generation of bus transfer errors. The parity bits continue to be calculated and written into memory on write transactions. 0 - Enable 1 - Disable
7	Noncorrectable Errors in FlexCAN Access Put Chip in Freeze Mode

Table continues on the next page...

Table continued from the previous page...

Field	Description
NCEFAFRZ	Determines whether to put FlexCAN into Freeze mode when a noncorrectable error is detected in a memory read performed by FlexCAN internal processes. In this case, entering Freeze mode prevents FlexCAN internal processes from treating corrupted data as valid. See Freeze mode for more information. 0 - Normal operation 1 - Freeze mode
6-0 —	Reserved

31.6.2.26 Error Injection Address (ERRIAR)

Contains the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM. Where pairs of values are provided, the first is the address for MCR[FDEN] = 0, the second is for MCR[FDEN] = 1.

Table 247. Error injection address for classical CAN format

RAM contents	Injection address	Memory map
FlexCAN registers	Not mapped	—
Message buffers	0000h	0080h
RXIMRs	600h	0880h
RXFIR_0	780h	0A80h
RXFIR_1	784h	0A84h
RXFIR_2	788h	0A88h
RXFIR_3	78Ch	0A8Ch
RXFIR_4	790h	0A90h
RXFIR_5	794h	0A94h
Reserved	—	0A98h
RXMGMASK	7A0h	0AA0h
RXFGMASK	7A4h	0AA4h
RX14MASK	7A8h	0AA8h
RX15MASK	7ACh	0AACh
Tx_SMB	7B0h	0AB0h / 0F28h
Rx_SMB0	7C0h / 7F8h	0AC0h / 0F70h
Rx_SMB1	7D0h / 840h	0AD0h / 0FB8h
Rx_SMB0_TIME_STAMP	888h	0C20h
Rx_SMB1_TIME_STAMP	88Ch	0C24h

Table continues on the next page...

Table 247. Error injection address for classical CAN format (continued)

RAM contents	Injection address	Memory map
HR_TIME_STAMP	890h	0C30h
Enhanced RX FIFO	A10h	2000h
ERFFEL	1050h	3000h

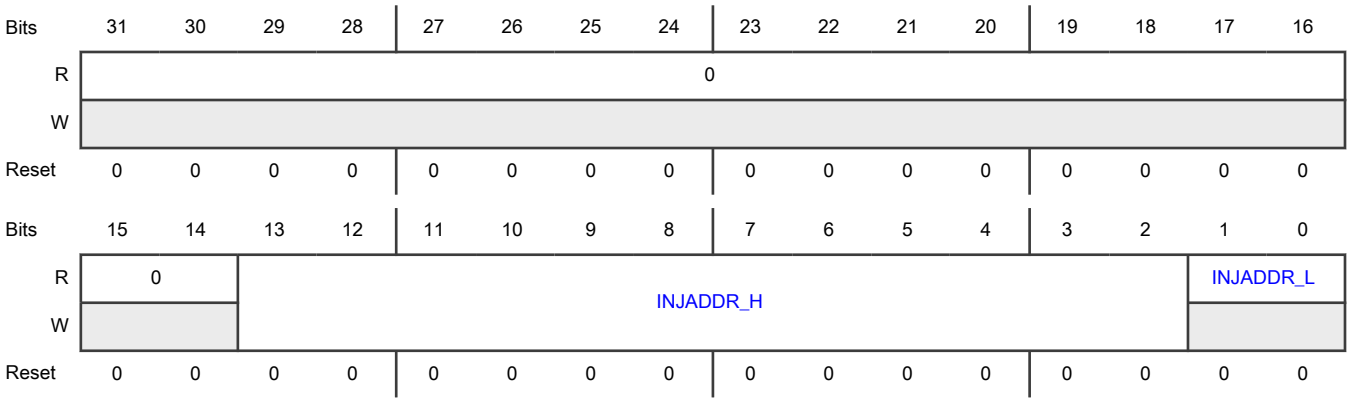
NOTE

For RXFIR, Enhanced RX FIFO, and HR_TIME_STAMP addresses, you must inject ECC errors in host access only.

Offset

Register	Offset
ERRIAR	AE4h

Diagram



Fields

Field	Description
31-14 —	Reserved
13-2 INJADDR_H	Error Injection Address High Defines the 12 most significant bits of the physical RAM address where error is to be injected (see table above).
1-0 INJADDR_L	Error Injection Address Low Defines the two least significant bits of the physical RAM address where error is to be injected. These bits ensure that the address is on a 32-bit boundary.

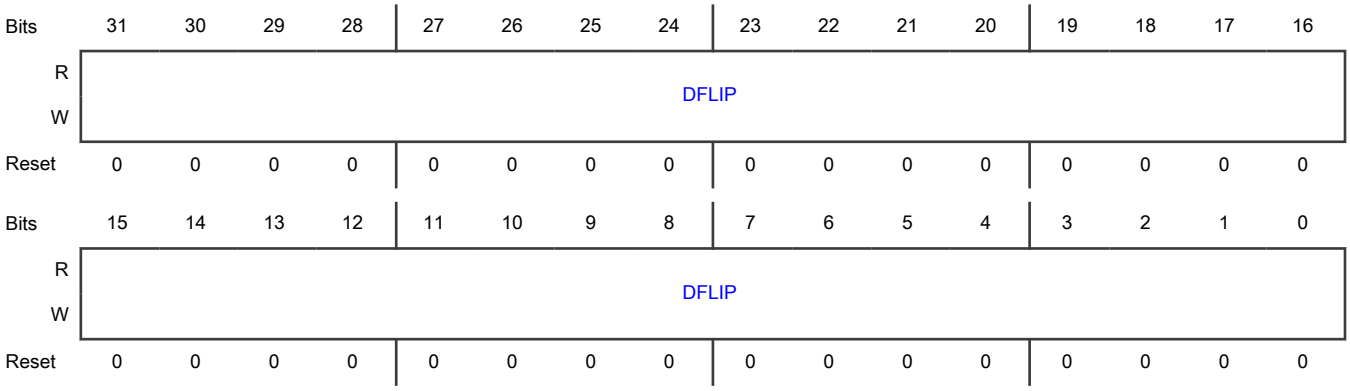
31.6.2.27 Error Injection Data Pattern (ERRIDPR)

Contains the error pattern to be injected in the data word read from memory.

Offset

Register	Offset
ERRIDPR	AE8h

Diagram



Fields

Field	Description
31-0 DFLIP	Data Flip Pattern Contains the flip pattern. Bits set to 1 in the flip pattern cause the corresponding data bit in the word read from memory to invert.

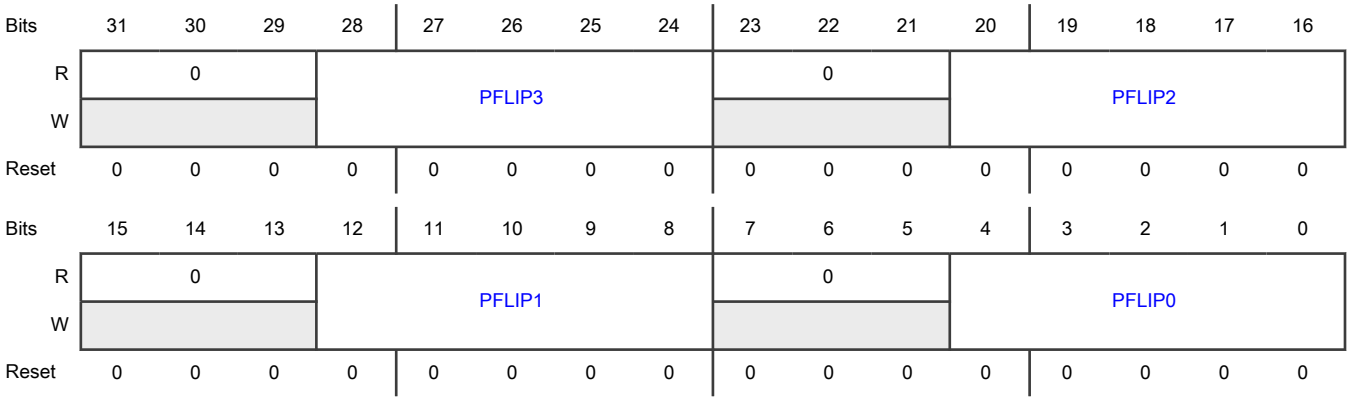
31.6.2.28 Error Injection Parity Pattern (ERRIPPR)

Contains the error pattern to be injected in parity bits read from memory with the data word. Bits set to 1 in the flip pattern cause the corresponding parity bit in the word read from memory to invert.

Offset

Register	Offset
ERRIPPR	AECh

Diagram



Fields

Field	Description
31-29 —	Reserved
28-24 PFLIP3	Parity Flip Pattern for Byte 3 (Most Significant) Contains the error injection pattern for Byte 3.
23-21 —	Reserved
20-16 PFLIP2	Parity Flip Pattern for Byte 2 Contains the error injection pattern for Byte 2.
15-13 —	Reserved
12-8 PFLIP1	Parity Flip Pattern for Byte 1 Contains the error injection pattern for Byte 1.
7-5 —	Reserved
4-0 PFLIP0	Parity Flip Pattern for Byte 0 (Least Significant) Contains the error injection pattern for Byte 0.

31.6.2.29 Error Report Address (RERRAR)

Reports the address used for an access operation in which an error (correctable or noncorrectable) was detected. Also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] nonzero) are reported with the address aligned, and data is reported in Error Report Data (RERRDR) shifted accordingly. When errors are detected in accesses

larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word where the error was detected is reported. For errors detected in more than one 32-bit word, only the least significant address is reported.

Table 248. Source of memory access

SAID[2:0]	Error during...
0	Move-out FlexCAN access
1	Move-in
2	TX arbitration
3	RX matching
4	Move-out host access

24 NCE	Noncorrectable Error Indicates that the report is due to a noncorrectable error. 0 - Reporting a correctable error 1 - Reporting a noncorrectable error
23-19	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
18-16 SAID	SAID SAID[2] — Identification of the requester of the memory read request: • 0 = Requested by FlexCAN internal processes • 1 = Requested by host (CPU) SAID[1] — Details of FlexCAN operation: • 0 = Move • 1 = Scanning SAID[0] — Operation that requested the memory read: • 0 = Transmission • 1 = Reception For more information, see Table 248.
15-14 —	Reserved
13-0 ERRADDR	Address Where Error Detected See description of Error Injection Address (ERRIAR).

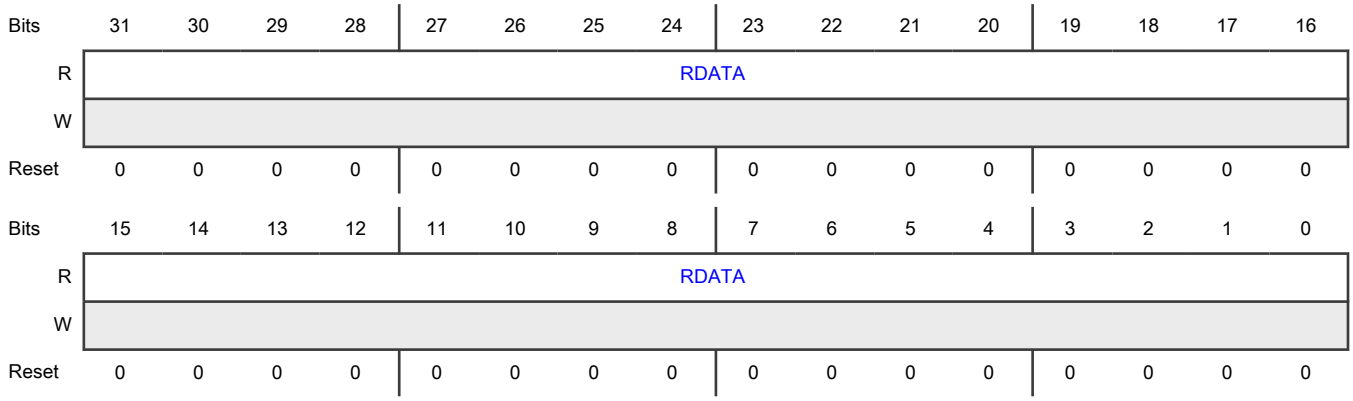
31.6.2.30 Error Report Data (RERRDR)

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see Table 254) when reading a message buffer.

Offset

Register	Offset
RERRDR	AF4h

Diagram



Fields

Field	Description
31-0 RDATA	Raw Data Word Read from Memory with Error

31.6.2.31 Error Report Syndrome (RERRSYNR)

Contains the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYND*n* field indicates the type of error and which bit in byte (*n*) the error affects. SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.

Table 249. Syndrome definition

SYND*n* (hex)	Type	Bit affected
00	—	None (no error)
01	Code	0
02	Code	1
04	Code	2
07	Data	5
08	Code	3
0E	Data	7
10	Code	4
13	Data	2
15	Data	6
16	Data	1
19	Data	3
1A	Data	4

Table continues on the next page...

Table 249. Syndrome definition (continued)

SYND*n* (hex)	Type	Bit affected
1C	Data	0
06	—	All-zeroes noncorrectable error
1F	—	All-ones noncorrectable error
All others	—	Noncorrectable error

Each BE*n* field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, including the non-read ones. Errors detected in non-read bytes are indicated (see Error indication) and reported (see Error reporting).

Offset

Fields

Field	Description
31-20 —	Reserved
19 HANCEIF	Host Access with Noncorrectable Error Interrupt Flag Indicates that a noncorrectable error was detected in a memory read initiated by host. A bus transfer error is asserted for that access. If MECR[HANCEI_MSK] = 1, the interrupt is 1. 0 - No errors detected 1 - Error detected
18 FANCEIF	FlexCAN Access with Noncorrectable Error Interrupt Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes. If MECR[FANCEI_MSK] = 1, the interrupt is 1. 0 - No errors detected 1 - Error detected
17 —	Reserved
16 CEIF	Correctable Error Interrupt Flag Indicates that a correctable error was detected in a memory read. If MECR[CEI_MSK] = 1, the interrupt is 1. 0 - No errors detected 1 - Error detected
15-4 —	Reserved
3	Host Access with Noncorrectable Error Interrupt Overrun Flag

Table continues on the next page...

Table continued from the previous page...

Field	Description
HANCEIOF	Indicates that a noncorrectable error was detected in a memory read initiated by host when ERRSR[HANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0 - No errors detected 1 - Error detected
2 FANCEIOF	FlexCAN Access with Noncorrectable Error Interrupt Overrun Flag Indicates that a noncorrectable error was detected in a memory read initiated by FlexCAN internal processes when ERRSR[FANCEIF] was set. No interrupt is associated with this flag. See Error indication. 0 - No errors detected 1 - Error detected
1 —	Reserved
0 CEIOF	Correctable Error Interrupt Overrun Flag Indicates that a correctable error was detected in a memory read when ERRSR[CEIF] was set. No interrupt is associated with this flag. See Error indication. 0 - No errors detected 1 - Error detected

31.6.2.33 Enhanced CAN Bit Timing Prescalers (EPRS)

Defines the CAN bit timing prescalers for the nominal phase and data phase when CTRL2[BTE] = 1.

Used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

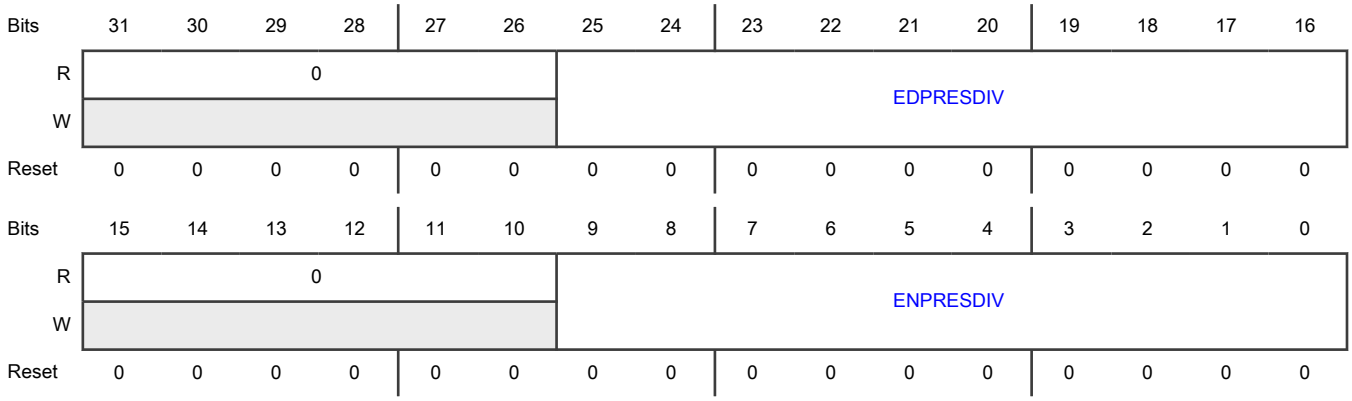
This register can be written only in Freeze mode; the module blocks it in other modes.

Soft reset does not affect the contents of this register.

Offset

Register	Offset
EPRS	BF0h

Diagram



Fields

Field	Description
31-26 —	Reserved
25-16 EDPRESDIV	Extended Data Phase Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency in the data phase of a CAN FD message when CTRL2[BTE] = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. Sclock frequency = PE clock frequency ÷ (EDPRESDIV + 1) **NOTE** To minimize errors when processing FD frames, use the same value for this field and for EPRS[ENPRESDIV]. See the first note in CAN FD frames for details.
15-10 —	Reserved
9-0 ENPRESDIV	Extended Nominal Prescaler Division Factor Defines the ratio between the PE clock frequency and the Sclock frequency when CTRL2[BTE] = 1. Otherwise, it reads as 0 and a write operation has no effect. The Sclock period defines the time quantum of the CAN protocol in the nominal phase. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). Sclock frequency = PE clock frequency ÷ (ENPRESDIV + 1)

31.6.2.34 Enhanced Nominal CAN Bit Timing (ENCBT)

Provides an alternative way to store the CAN bit timing variables described in Control 1 (CTRL1) and CAN Bit Timing (CBT), to get higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

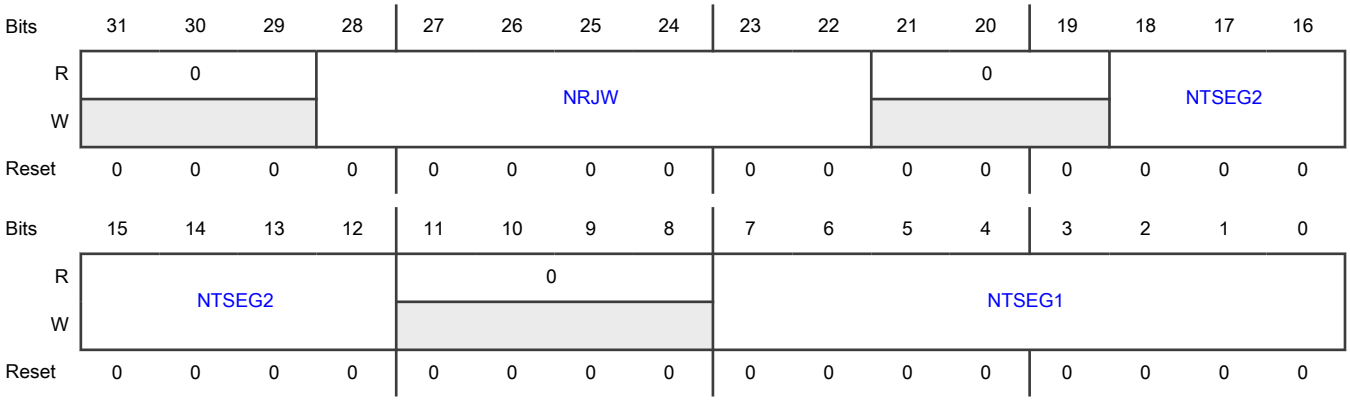
Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

Offset

Register	Offset
ENCBT	BF4h

Diagram



Fields

Field	Description
31-29 —	Reserved
28-22 NRJW	Nominal Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. One time quantum = one Sclock period Nominal Resync Jump Width = NRJW + 1
21-19 —	Reserved
18-12 NTSEG2	Nominal Time Segment 2 Defines the length of Time Segment 2 in the nominal bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 2 = (NTSEG2 + 1) × Time Quanta One time quantum = one Sclock period
11-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
7-0 NTSEG1	Nominal Time Segment 1 Defines the length of Time Segment 1 in the bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Nominal Time Segment 1 = (NTSEG1 + 1) × Time Quanta One time quantum = one Sclock period

31.6.2.35 Enhanced Data Phase CAN Bit Timing (EDCBT)

Provides an alternative way to store the data phase CAN bit timing variables described in CAN FD Bit Timing (FDCBT) to achieve higher CAN bit timing resolution.

This register is used by the module only if CTRL2[BTE] = 1; otherwise, a write operation has no effect and all fields are read as zero.

Soft reset does not affect the contents of this register.

This register can be written only in Freeze mode; the module blocks it in other modes.

NOTE

Ensure that bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

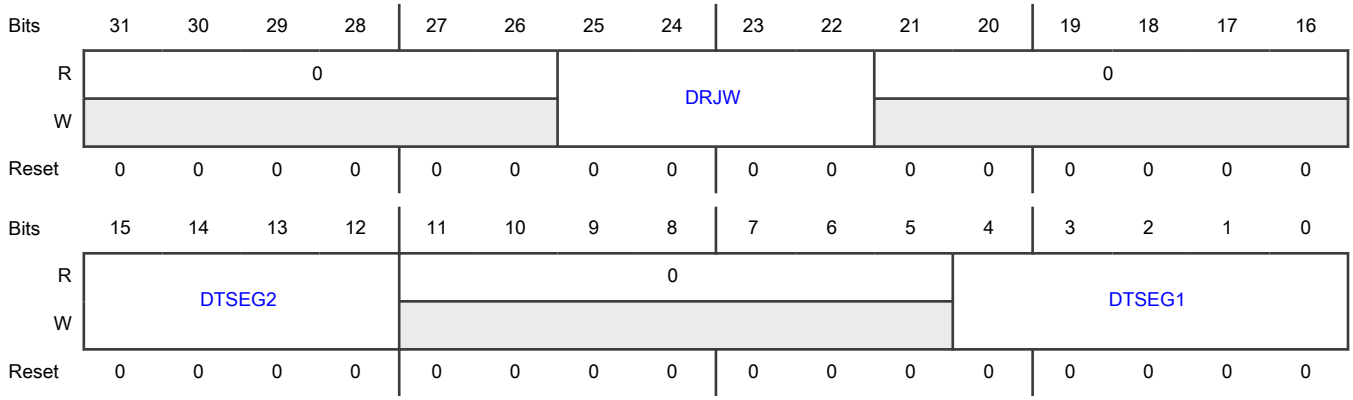
NOTE

DTSEG1 must be at least two time quanta.

Offset

Register	Offset
EDCBT	BF8h

Diagram



Fields

Field	Description
31-26 —	Reserved
25-22 DRJW	Data Phase Resynchronization Jump Width Defines the maximum number of time quanta that one resynchronization can change a data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Resync Jump Width = DRJW + 1.
21-16 —	Reserved
15-12 DTSEG2	Data Phase Time Segment 2 Defines the length of time segment 2 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 2 = (DTSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.
11-5 —	Reserved
4-0 DTSEG1	Data Phase Segment 1 Defines the length of time segment 1 in the data phase bit time when CTRL2[BTE] = 1. Otherwise, it has no effect. Data Phase Time Segment 1 = (NTSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.

31.6.2.36 Enhanced Transceiver Delay Compensation (ETDC)

Contains extended versions of FDCTRL[TDCOFF] and FDCTRL[TDCVAL]. This register is used by the module only if CTRL2[BTE] = 1. Otherwise, a write operation has no effect and all fields are read as zero.

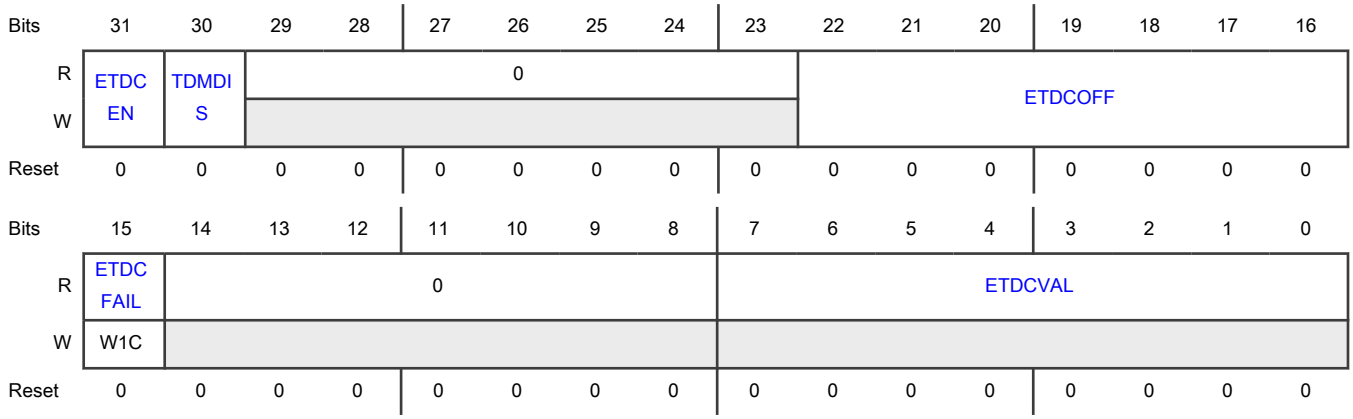
NOTE

See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details.

Offset

Register	Offset
ETDC	BFCh

Diagram



Fields

Field	Description
31 ETDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. **NOTE** See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. **NOTE** TDC must be disabled when the Loop Back Mode is enabled. See CTRL1[LPB]. 0 - Disable 1 - Enable
30 TDMDIS	Transceiver Delay Measurement Disable Disables the transceiver delay measurement. When the TDC measurement is disabled, only ETDC[ETDCOFF] determines the secondary sample point position. If TCD measurement is enabled, the sum of the transceiver delay measurement plus the enhanced TDC offset determines the secondary sample point position. Soft reset does not affect this field. **NOTE** This bit can be enabled only if CTRL2[BTE] = 1. 0 - Enable 1 - Disable
29-23 —	Reserved
22-16	Enhanced Transceiver Delay Compensation Offset

Table continues on the next page...

Table continued from the previous page...

Field	Description
ETDCOFF	Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details on how the loop delay measurement is performed. This field can be written in Freeze mode only. Its value can be defined in protocol engine (PE) clock periods (CANCLK, see Protocol timing for more details). It must be smaller than the CAN bit duration in the data bit rate for proper operation. Do not write 0 to this field. **NOTE** If CTRL2[BTE] becomes 1 after a chip-level hard reset, this field is read as 1h.
15 ETDCFAIL	Transceiver Delay Compensation Fail Indicates whether the transceiver delay compensation (TDC) mechanism is out of range. In this case, it is unable to compensate the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones. (See Transceiver delay compensation.) This field becomes 0 the first time FlexCAN detects the out of range condition. 0 - In range 1 - Out of range
14-8 —	Reserved
7-0 ETDCVAL	Enhanced Transceiver Delay Compensation Value Contains ETDC[ETDCOFF] added to the measured value of the transceiver loop delay in the latest transmitted CAN FD frame, with BRS = 1. The module only updates this field when ETDC[ETDCEN] = 1. Soft reset affects this field. **NOTE** If ETDC[TDMDIS] = 1, this field stores ETDC[ETDCOFF] only.

31.6.2.37 CAN FD Control (FDCTRL)

Contains control bits for CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in Table 250.

When an 8-byte payload is selected:

- Block R0 allocates MB0–MB31.
- Block R1 allocates MB32–MB63.
- Block R2 allocates MB64–MB95.

When a payload larger than eight bytes is selected, the maximum number of message buffers in a block is limited as described below.

Table 250. Number of message buffers

Payload size	Maximum number of message buffers per RAM block
8 bytes	32
16 bytes	21
32 bytes	12
64 bytes	7

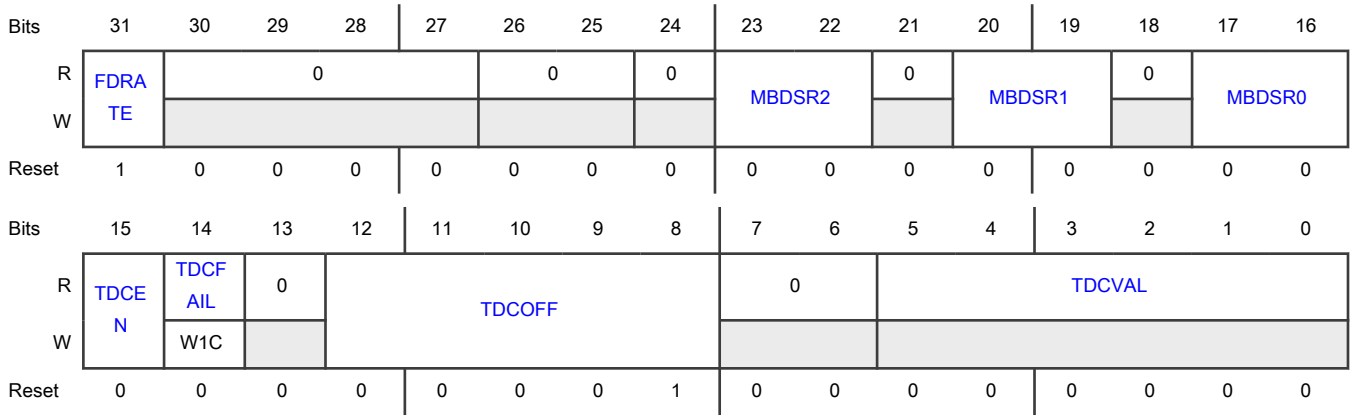
One memory block fits exactly 32 message buffers with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last message buffer in a block and the beginning of the next block. This empty memory corresponds to less than one message buffer, and must not be used.

Soft reset does not affect the contents of this register.

Offset

Register	Offset
FDCTRL	C00h

Diagram



Fields

Field	Description
31 FDRATE	Bit Rate Switch Enable Enables the effect of the Bit Rate Switch (BRS bit) during the data phase of TX messages. When 1, if BRS = 1 in the TX message buffer, frames are transmitted with bit rate switching. When 0, frames are transmitted at a nominal rate, and the BRS bit in the TX MB has no effect. The CPU can write to this field at any time. However, its effect becomes active only under one of these conditions: • The CAN bus is in the Wait for Bus Idle state. • The CAN bus is in the Bus Idle state.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	• The CAN bus is in the Bus Off state. • The current frame under reception or transmission reaches the interframe space. By writing 0 to FDCTRL[FDRATE], the CPU can force all bits in CAN FD messages to be transmitted at nominal bit rate. This transmission occurs regardless of the value in the BRS bit of the TX message buffers. 0 - Disable 1 - Enable
30-27 —	Reserved
26-25 —	Reserved
24 —	Reserved
23-22 MBDSR2	Message Buffer Data Size for Region 2 Selects the data size per message buffer for region R2 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00 - 8 bytes 01 - 16 bytes 10 - 32 bytes 11 - 64 bytes
21 —	Reserved
20-19 MBDSR1	Message Buffer Data Size for Region 1 Selects the data size per message buffer for region R1 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00 - 8 bytes 01 - 16 bytes 10 - 32 bytes 11 - 64 bytes
18 —	Reserved
17-16	Message Buffer Data Size for Region 0

Table continues on the next page...

Table continued from the previous page...

Field	Description
MBDSR0	Selects the data size per message buffer for region R0 of message buffers allocated in RAM. This field can be written in Freeze mode only. 00 - 8 bytes 01 - 16 bytes 10 - 32 bytes 11 - 64 bytes
15 TDCEN	Transceiver Delay Compensation Enable Enables the TDC feature. It can be written in Freeze mode only. See Transmitter delay compensation in the CAN Protocol standard (ISO 11898-1:2015) for details. TDC must be disabled when Loopback mode is enabled (see CTRL1[LPB]). **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0 - Disable 1 - Enable
14 TDCFAIL	Transceiver Delay Compensation Fail Indicates whether the Transceiver Delay Compensation (TDC) mechanism is out of range. In this case, the mechanism cannot compensate for the loop delay of the transceiver and successfully compare the delayed received bits to the transmitted ones (see Transceiver delay compensation). The first time that FlexCAN detects the out-of-range condition, this field becomes 1. **NOTE** If CTRL2[BTE] = 1, this field is read as 0 and a write operation has no effect. 0 - In range 1 - Out of range
13 —	Reserved
12-8 TDCOFF	Transceiver Delay Compensation Offset Contains the offset value to be added to the loop delay of the measured transceiver. This value defines the position of the delayed comparison point when bit rate switching is active. See Transceiver delay compensation for details about loop delay measurement. This field can be written in Freeze mode only. Its value can be defined in Protocol Engine Clock periods (CANCLK, see Protocol timing for more details). The value must be smaller than the CAN bit duration in the data bit rate for proper operation. **NOTE** If CTRL2[BTE] = 1, TDCOFF is read as 0 and a write operation has no effect.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Do not write 0 to this field.
7-6 —	Reserved
5-0 TDCVAL	Transceiver Delay Compensation Value Contains the value of the transceiver loop delay measured from the transmitted EDL-to-R0 transition edge to the respective received one added to FDCTRL[TDCOFF]. This value is an integer multiple of the Protocol Engine Clock period (CANCLK). If CTRL2[BTE] = 1, this field is read as 0. See Protocol timing for details on the loop delay measurement.

31.6.2.38 CAN FD Bit Timing (FDCBT)

Stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] = 1, compatible with the CAN FD specification. Fields in this register define:

- The time quantum duration
- The number of time quanta per CAN bit
- The sample point position for the data bit rate portion of a CAN FD message with BRS = 1

Soft reset does not affect the contents of this register.

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

Ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1:2015).

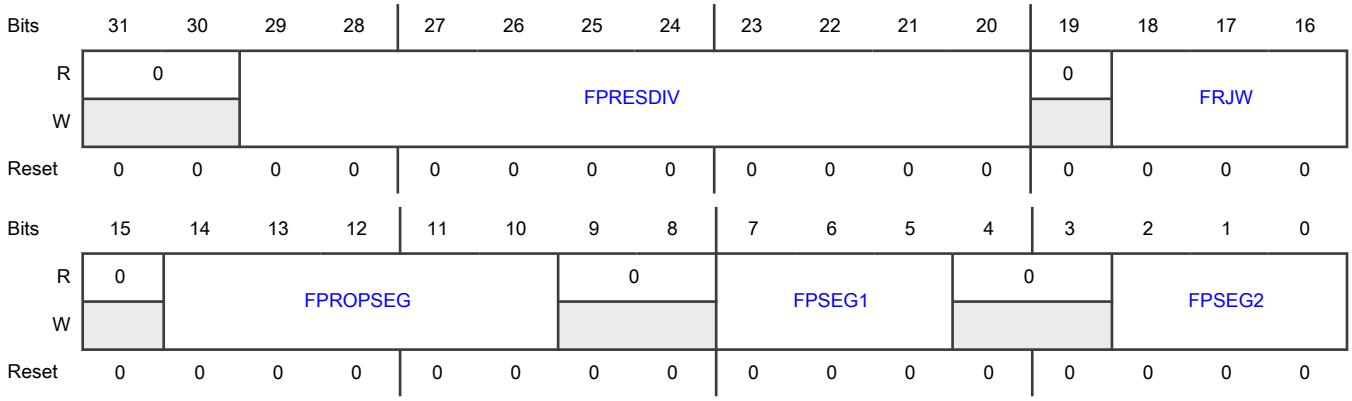
NOTE

If CTRL2[BTE] = 1, this register is read as zero and a write operation has no effect.

Offset

Register	Offset
FDCBT	C04h

Diagram



Fields

Field	Description
31-30 —	Reserved
29-20 FPRESDIV	Fast Prescaler Division Factor Defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency in the data bit rate portion of a CAN FD message with BRS = 1. The Sclock period defines the time quantum of the CAN FD protocol for the data bit rate. This field can be written only in Freeze mode; the module blocks it in other modes. Sclock frequency = PE clock frequency ÷ (FPRESDIV + 1). **NOTE** To minimize errors when processing FD frames, use the same value for this field and for CTRL1[PRESDIV] or CBT[EPRESDIV]. See the first note in CAN FD frames for details.
19 —	Reserved
18-16 FRJW	Fast Resync Jump Width Defines the maximum number of time quanta that one resynchronization can change a bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Resync Jump Width = FSJW + 1. One Time Quantum = one Sclock period.
15 —	Reserved
14-10 FPROPSEG	Fast Propagation Segment

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Defines the length of the propagation segment in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Propagation Segment Time = FPROPSEG × Time Quanta. One Time Quantum = one Sclock period.
9-8 —	Reserved
7-5 FPSEG1	Fast Phase Segment 1 Defines the length of phase segment 1 in the bit time in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 1 = (FPSEG1 + 1) × Time Quanta. One Time Quantum = one Sclock period.
4-3 —	Reserved
2-0 FPSEG2	Fast Phase Segment 2 Defines the length of phase segment 2 in the data bit rate portion of a CAN FD message with BRS = 1. This field can be written only in Freeze mode; the module blocks it in other modes. Phase Segment 2 = (FPSEG2 + 1) × Time Quanta. One Time Quantum = one Sclock period.

31.6.2.39 CAN FD CRC (FDCRC)

Provides information about the cyclic redundancy check (CRC) of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats.

- The CRC_15 polynomial is used for all frames in CAN format.
- The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to 16 bytes.
- The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than 16 bytes.

Each polynomial shown below results in a Hamming distance of 6. This register is updated at the same time that the TX Interrupt flag is set.

$$\text{CRC_15} = \text{C599h}: \ (x^{15} + x^{14} + x^{10} + x^{8} + x^{7} + x^{4} + x^{3} + 1)$$

$$\text{CRC_17} = \text{3685Bh}: \ (x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^{6} + x^{4} + x^{3} + x^{1} + 1)$$

$$\text{CRC_21} = \text{302899h}: \ (x^{21} + x^{20} + x^{13} + x^{11} + x^{7} + x^{4} + x^{3} + 1)$$

Equation 37. CRC polynomial used on CAN frame

NOTE

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1:2015) for details.

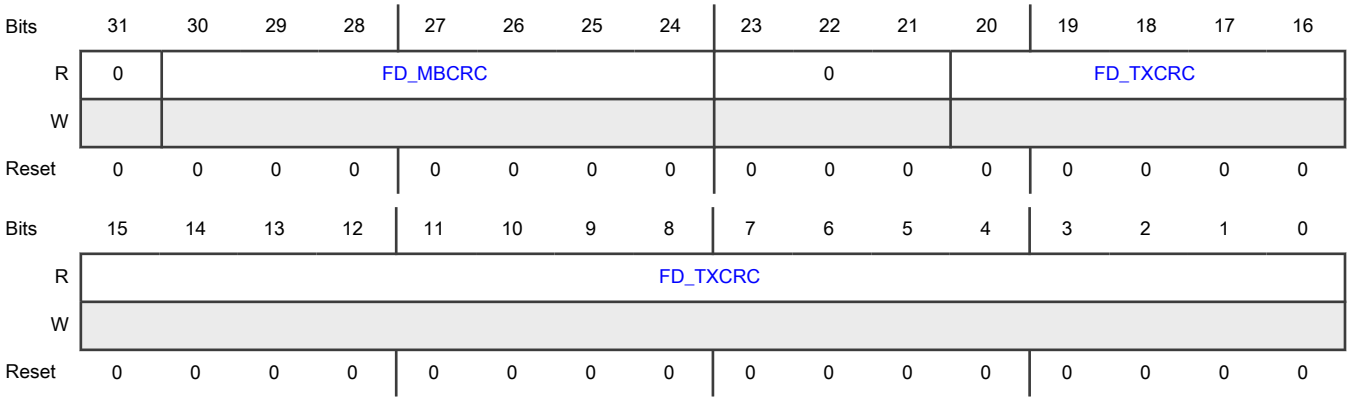
FDCRC	C08h

Diagram



Fields

Field	Description
31 —	Reserved
30-24 FD_MBCRC	CRC Message Buffer Number for FD_TXCRC Indicates the number of the message buffer corresponding to the value in FDCRC[FD_TXCRC], for both FD and non-FD frames. It reports the same information as in CRCR[MBCRC].
23-21 —	Reserved
20-0 FD_TXCRC	Extended Transmitted CRC value Contains the CRC value calculated over the most recent transmitted message. Different CRC polynomials are used for different frame formats. For CRC_15 and CRC_17, the six most significant bits and the four most significant bits are reported as zeroes, respectively. For CRC_15, this field has the same content as Cyclic Redundancy Check (CRCR).

31.6.2.40 Enhanced RX FIFO Control (ERFCR)

Defines the Enhanced RX FIFO configuration.

This register can be written only in Freeze mode.

Soft reset does not affect any of the contents of this register.

Offset

Register	Offset
ERFCR	C0Ch

Fields

Field	Description
31	Enhanced RX FIFO Underflow Flag

Table continues on the next page...

Table continued from the previous page...

Field	Description
ERFUFW	Indicates whether an underflow condition occurred in the enhanced RX FIFO. If ERFIER[ERFUFWIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - Underflow
30 ERFOVF	Enhanced RX FIFO Overflow Flag Indicates whether an overflow condition occurred in the Enhanced RX FIFO. If ERFIER[ERFOVFIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - Overflow
29 ERFWMI	Enhanced RX FIFO Watermark Indication Flag Indicates whether the number of messages available in the Enhanced RX FIFO is greater than the watermark defined in ERFCR[ERFWM]. If ERFIER[ERFWMIIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - Number of messages in FIFO is greater than the watermark
28 ERFDA	Enhanced RX FIFO Data Available Flag Indicates whether there is at least one message stored in the ERX FIFO. If ERFIER[ERFDAIE] = 1, this field generates an interrupt. 0 - No such occurrence 1 - At least one message stored in Enhanced RX FIFO
27 ERFCLR	Enhanced RX FIFO Clear Writing 1 to this field during Freeze mode resets the internal FIFO pointers, but the FIFO content stored in RAM is not changed. Writing to this field outside Freeze mode, or writing 0 to this field, has no effect. 0 - No effect 1 - Clear enhanced RX FIFO content
26-18 —	Reserved
17 ERFE	Enhanced RX FIFO Empty Flag Indicates whether Enhanced RX FIFO is empty. 0 - Not empty 1 - Empty

Table continues on the next page...

Table continued from the previous page...

Field	Description
16 ERFF	Enhanced RX FIFO Full Flag Indicates whether enhanced RX FIFO is full. 0 - Not full 1 - Full
15 —	Reserved
14-6 —	Reserved
5-0 ERFEL	Enhanced RX FIFO Elements Indicates the number of CAN messages stored in the Enhanced RX FIFO.

31.6.2.43 High-Resolution Timestamp (HR_TIME_STAMP0 - HR_TIME_STAMP95)

Stores a copy of a 32-bit timer at the start or end of a CAN frame.

HR_TIME_STAMP0 stores the 32-bit timestamp associated with MB0, HR_TIME_STAMP1 stores the 32-bit timestamp associated with MB1, and so on.

Reset does not affect these registers.

NOTE

Do not write to these registers outside Freeze mode.

Table 251. High-Resolution Timestamp register operation

TSTAMPCAP	Captured timebase	Capture point
b00	None	None
b01	32 bits of high-resolution on-chip timer	Seventh bit of the end-of-frame field for transmission and sixth bit of the end-of-frame field for reception.
b10	32 bits of high-resolution on-chip timer	Start of frame
b11	32 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

Offset

For n = 0 to 95:

Register	Offset
HR_TIME_STAMPn	C30h + (n × 4h)

R W	TS															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Description
31-0 TS	High-Resolution Timestamp Captures the copy of the timestamp of corresponding message buffer. This field always captures a 32-bit timer value.

31.6.2.44 Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127)

Stores the filter elements of the Enhanced RX FIFO.

For standard ID filtering, each ERFFEL register stores one filter element. For extended ID filtering, each pair of ERFFEL registers stores one filter element.

ERFFEL registers can be written only in Freeze mode; otherwise, the module blocks them. Reset does not affect these registers. They are located in RAM and must be explicitly initialized prior to any reception.

Offset

For n = 0 to 127:

Register	Offset
ERFFELn	3000h + (n × 4h)

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	FEL															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Description
31-0 FEL	Filter Element Bits Stores filter elements. Each filter element is used during the match process. If the matching criteria are met, a message is stored in the Enhanced RX FIFO.

31.6.3 Message buffer structure

The message buffer structure used by FlexCAN is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual message buffer is 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area 80h–67Fh is used by the message buffers. When CAN FD is enabled, the exact address for each message buffer depends on the size of its payload. See FlexCAN memory partition for CAN FD.

Table 252. Message buffer structure example with 64-byte payload

= Unimplemented or reserved

Table 253. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between CAN format and CAN FD format frames. EDL must not be 1 for message buffers configured to RANSWER with code field 1010b (see Table 254).
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive.
CODE	Message Buffer Code	Can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 254 and Table 255. See Functional description.

Table 254. Message buffer code for RX buffers

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	—	Message buffer does not participate in the matching process.
0100b: EMPTY. Message buffer is active and empty.	EMPTY	—	FULL	—	When a frame is received successfully (after Move-in), CODE is automatically updated to FULL.
0010b: FULL. Message buffer is full.	FULL	Yes	FULL	—	The act of reading the Control and Status word followed by unlocking the message buffer (SRV) does not make CODE return to EMPTY. It remains FULL. If a new frame is moved to the message buffer after the message buffer is serviced, the code remains FULL. See Matching process for matching details related to FULL code.
		No	OVERRUN	—	If the message buffer is FULL and a new frame is moved to this message buffer before the CPU services it, CODE is automatically updated to OVERRUN. See Matching process for details about overrun behavior.

Table continues on the next page...

Table 254. Message buffer code for RX buffers (continued)

CODE description	RX code BEFORE RX new frame	SRV[1]	RX code AFTER successful reception[2]	RRS[3]	Comment
0110b: OVERRUN. Message buffer is being overwritten into a full buffer.	OVERRUN	Yes	FULL	—	If CODE indicates OVERRUN and the CPU has serviced the message buffer, when a new frame is moved to the message buffer, CODE returns to FULL.
		No	OVERRUN	—	If CODE already indicates OVERRUN, and another new frame must be moved, the message buffer is overwritten again, and CODE remains OVERRUN. See Matching process for details about overrun behavior.
1010b: RANSWER[4]. A frame was configured to recognize a Remote Request frame and transmit a Response frame in return.[5]	RANSWER	—	TANSWER (1110b)	0	A Remote Answer was configured to recognize a Remote Request frame received. After that, a message buffer is set to transmit a response frame. CODE is automatically changed to TANSWER (1110b). See Matching process for details. If CTRL2[RRS] = 0, transmit a response frame when a remote request frame with the same ID is received.
		—	—	1	This code is ignored during matching and arbitration process. See Matching process for details.
CODE[0] = 1: BUSY. FlexCAN is updating the contents of the message buffer. The CPU must not access the message buffer.	BUSY[6]	—	FULL	—	Indicates that the message buffer is being updated. It automatically becomes 0 and does not interfere with the next CODE.
		—	OVERRUN	—	

1. SRV: Serviced message buffer. Message buffer was read and unlocked by reading TIMER or another message buffer.
2. A frame is considered a successful reception after the frame is moved to a message buffer (move-in process). See Move-in.

3. Remote Request Stored field. See Control 2 (CTRL2).
4. Code 1010b is not considered TX and a message buffer with this code should not be aborted.
5. Code 1010b must be used in message buffers configured in CAN FD format, with EDL = 1.
6. For TX message buffers, the BUSY bit should be ignored upon read, except when MCR[AEN] = 1. If this field is 1, the corresponding message buffer does not participate in the matching process.

Table 255. Message buffer code for TX buffers

CODE Description	TX Code BEFORE TX frame	MB RTR	TX Code AFTER successful transmission	Comment
1000b: INACTIVE. Message buffer is not active.	INACTIVE	—	—	Message buffer does not participate in arbitration process.
1001b: ABORT. Message buffer is aborted.	ABORT	—	—	Message buffer does not participate in arbitration process.
1100b: DATA. Message buffer is a TX data frame (MB RTR must be 0).	DATA	0	INACTIVE	Transmit data frame unconditionally once. After transmission, the message buffer automatically returns to the INACTIVE state.
1100b: REMOTE. Message buffer is a Transmit Remote Request frame (MB RTR must be 1).	REMOTE	1	EMPTY	Transmit remote request frame unconditionally once. After transmission, the message buffer automatically becomes an RX Empty message buffer with the same ID.
1110b: TANSWER. Message buffer is a Transmit Response frame from an incoming Remote Request frame.	TANSWER	—	RANSWER	This intermediate code is automatically written to the message buffer by the CHI as a result of a match to a Remote Request frame. The Remote Response frame is transmitted unconditionally once, then the code automatically returns to RANSWER (1010b). The CPU can also write this code with the same effect. The Remote Response frame can be a data frame or another remote request frame, depending on the value of RTR. See Matching process and Arbitration process for details.

Table 256. RX and TX message buffer field descriptions

Mnemonic	Field	Description
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Write 1 to SRR for transmission (TX Buffers). SRR is stored with the value received on the CAN bus for RX receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss. 1: Recessive value is compulsory for transmission in extended format frames. 0: Dominant is not a valid value for transmission in extended format frames.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 1: Frame format is extended 0: Frame format is standard
RTR	Remote Transmission Request	Affects the behavior of remote frames and is part of the reception filter. See Table 254, Table 255, and CTRL2[RRS]. If FlexCAN transmits this field as 1 (recessive) and receives it as 0 (dominant), it is interpreted as an arbitration loss. If this field is transmitted as 0 (dominant) and it is received as 1 (recessive), FlexCAN treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission. 1: If message buffer is TX, indicates that the current message buffer may have a Remote Request frame to be transmitted. If the message buffer is RX, incoming remote request frames may be stored. 0: Indicates that the current message buffer has a Data frame to be transmitted. In an RX message buffer, it may be considered in matching processes. **NOTE** When configuring CAN FD frames, this field must be 0.
DLC	Data Length Code	Indicates the length (in bytes) of the RX or TX data, which is located in offset 8h–Fh of the message buffer space (see Table 252). In reception, this field is written by FlexCAN, copied from the DLC field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 258).
TIMESTAMP	Free-Running Counter Timestamp	Provides a copy of the Free-Running Timer, captured for TX and RX frames when the beginning of the Identifier field appears on the CAN bus. See Table 257 for Timestamp operation.
PRIO	Local priority	Used only when MCR[LPRIOEN] = 1, and only makes sense for transmit message buffers. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

Table continues on the next page...

Table 256. RX and TX message buffer field descriptions (continued)

Mnemonic	Field	Description
ID	Frame Identifier	In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be used for a data frame, depending on the size of payload selected for the message buffers. For RX frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC, as shown in Table 258.

Table 257. Timestamp operation

TSTAMPCAP	MBTSBASE	TIMER_SOURCE	Captured timebase	Capture point
b00	bxx	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
b00	bxx	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
bxx	b00	0	CAN_TIMER incremented by CAN bit clock	Second bit of identifier field
bxx	b00	1	CAN_TIMER incremented by on-chip timer clock	Second bit of identifier field
b01	b01	x	Lower 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b01	b10	x	Upper 16 bits of high-resolution on-chip timer	Seventh bit of the end of frame field for transmission and sixth bit of the end of frame field for reception
b10	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame
b10	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame
b11	b01	x	Lower 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format
b11	b10	x	Upper 16 bits of high-resolution on-chip timer	Start of frame for classical CAN frame format and res bit for CAN FD frame format

31.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, FlexCAN RAM can be partitioned into blocks of 512 bytes each. Each block can accommodate a number of message buffers depending on the configuration provided by FDCTRL[MBDSR*n*] as shown in Table 259.

Table 259. RAM partition

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
0	0 to 31	MBDSR0	MBDSR0 = 00, 32 MBs with 8-byte payload MBDSR0 = 01, 21 MBs with 16-byte payload MBDSR0 = 10, 12 MBs with 32-byte payload MBDSR0 = 11, 7 MBs with 64-byte payload
1	32 to 63	MBDSR1	MBDSR1 = 00, 32 MBs with 8-byte payload MBDSR1 = 01, 21 MBs with 16-byte payload MBDSR1 = 10, 12 MBs with 32-byte payload MBDSR1 = 11, 7 MBs with 64-byte payload
2	64 to 95	MBDSR2	MBDSR2 = 00, 32 MBs with 8-byte payload MBDSR2 = 01, 21 MBs with 16-byte payload

Table continues on the next page...

Table 259. RAM partition (continued)

RAM block	Number of MBs with 8 bytes (default range)	Size control field in FDCTRL	Number of MBs of different sizes, per block
			MBDSR2 = 10, 12 MBs with 32-byte payload MBDSR2 = 11, 7 MBs with 64-byte payload

Payload sizes of 16, 32, or 64 bytes may be configured in some or all of RAM blocks. In those cases, the total number of MBs and their respective number order may differ from the default configuration of 8 bytes. Consider an example where:

- Block0 is configured to an 8-byte payload
- Block1 is configured to a 16-byte payload
- Block2 is configured to 32-byte payload

In this case, Table 260 indicates how the message buffers are arranged in RAM.

Table 260. RAM partition example

RAM block	Payload size	Number of MBs in the RAM block	Message buffer range
0	FDCTRL[MBDSR0] = 00, 8-byte payload	32	0 to 31
1	FDCTRL[MBDSR1] = 01, 16-byte payload	21	32 to 52
2	FDCTRL[MBDSR2] = 10, 32-byte payload	12	53 to 64

31.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

31.6.6 Legacy RX FIFO structure

When MCR[RFEN] = 1, the memory area 80h–DCh (which is normally occupied by MBs 0–5) is used by the reception Legacy FIFO engine.

The region 80h–8Ch contains the output of the Legacy RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read. The region 90h–DCh is reserved for internal use of the Legacy RX FIFO engine.

An additional memory area, which starts at E0h and may extend up to 2DCh (normally occupied by MBs 6–37) depending on the value of CTRL2[RFFN], contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the Legacy RX FIFO.

Out of reset, the ID filter table flexible memory area defaults to E0h and extends only to FCh, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Legacy RX FIFO data structure.

Table 265. Legacy RX FIFO structure

	31 28 24 23 22 21 20 19 18 17 16 15 8 7 0							
80h	IDHIT		SRR	IDE	RTR	DLC	TIMESTAMP	
84h		ID standard				ID extended		
88h	Data byte 0		Data byte 1				Data byte 2	Data byte 3
8Ch	Data byte 4		Data byte 5				Data byte 6	Data byte 7
90h–DCh	Reserved							
E0h	ID filter table element 0							
E4h	ID filter table element 1							
E8h–2D4h	ID filter table elements 2 to 125							
2D8h	ID filter table element 126							
2DCh	ID filter table element 127							
		= Unimplemented or reserved						

Each ID filter table element occupies an entire 32-bit word. One, two, or four Identifier Acceptance Filters (IDAFs) can compound each element, depending on MCR[IDAM]. The following tables show the IDAF indexing.

Table 266 shows the three different formats of the ID table elements. All elements of the table must have the same format. See Legacy RX FIFO for more information.

Table 266. ID table structure

Format	31	30	29 24	23 16	15	14	13 8	7 1	0
A	RTR	IDE	RXIDA (standard = 29–19, extended = 29–1)						
B	RTR	IDE	RXIDB_0 (standard = 29–19, extended = 29–16)		RTR	IDE	RXIDB_1 (standard = 13–3, extended = 13–0)		

Table continues on the next page...

Table 266. ID table structure (continued)

C	RXIDC_0 (std and ext = 31–24)	RXIDC_1 (std and ext = 23–16)	RXIDC_2 (std and ext = 15–8)	RXIDC_3 (std and ext = 7–0)
		= Unimplemented or Reserved		

Table 267. Field descriptions

Mnemonic	Field	Description
RTR	Remote Frame	Specifies whether remote frames are accepted into the Legacy FIFO if they match the target ID. 1: Remote frames can be accepted and data frames are rejected. 0: Remote frames are rejected and data frames can be accepted.
IDE	Extended Frame	Specifies whether extended or standard frames are accepted into the Legacy FIFO if they match the target ID. 1: Extended frames can be accepted and standard frames are rejected. 0: Extended frames are rejected and standard frames can be accepted.
RXIDA	RX Frame Identifier (Format A)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.
RXIDB_0, RXIDB_1	RX Frame Identifier (Format B)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.
RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3	RX Frame Identifier (Format C)	Specifies an ID to be used as acceptance criteria for the Legacy FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which identifier acceptance filter the received message in the output of the Legacy RX FIFO hit. See Legacy RX FIFO for more information.

31.6.7 Enhanced RX FIFO structure

When ERFCR[ERFEN] = 1, the Enhanced RX FIFO is enabled. The region 2000h–204Ch contains the output of the Enhanced RX FIFO, which the CPU must read as a message buffer. This output contains the oldest message that has been received but not yet read.

Table 268. Enhanced RX FIFO structure

	31	30	29	28	24	23	22	21	20	19	18	17	16	15	8	7	6	0

14	2038h	203Ch
15	2048h	204Ch

Table 270. Field descriptions

Mnemonic	Field	Description
EDL	Extended Data Length	Distinguishes between classical CAN format and CAN FD format frames. 0: Classical CAN frame format 1: CAN FD frame format
BRS	Bit Rate Switch	Defines whether the bit rate is switched inside a CAN FD format frame. 0: Bit rate is not switched in a CAN FD frame. 1: Bit rate is switched in a CAN FD frame.
ESI	Error State Indicator	Indicates whether the transmitting node is error-active or error-passive. This field is meaningful only if EDL = 1. 0: Error-active 1: Error-passive
SRR	Substitute Remote Request	Fixed recessive bit, used only in extended format. Transmitting nodes always send it as recessive and receiving nodes can receive it as either recessive or dominant. If FlexCAN receives this bit as dominant, it is interpreted as an arbitration loss.
IDE	ID Extended Bit	Identifies whether the frame format is standard or extended. 0: Standard 1: Extended
RTR	Remote Frame	Identifies whether the current frame is a data frame or a remote request. 0: Data frame 1: Remote request
DLC	Data Length Code	Defines the number of bytes in the data field of a CAN frame (Data byte 0 to Data byte 63). When RTR = 1, the frame is a remote request and does not include the data field, regardless of the DLC field. See Table 258 for more details.
LEGACY TIMESTAMP	16-bit Timestamp	Provides a copy of the Free-Running Timer, captured during the CAN frame. See Table 257 for details about legacy timestamp operation.

Table continues on the next page...

Table 270. Field descriptions (continued)

Mnemonic	Field	Description
ID	Frame Identifier	In base frame format, only the 11 most significant bits are used for frame identification. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification.
DATA BYTE 0–63	Data Field	Up to 64 bytes can be stored in the data field.
IDHIT	Identifier Acceptance Filter Hit Indicator	Indicates which Enhanced RX FIFO Filter Element (ERFFEL0 - ERFFEL127) the received message in the output of the Enhanced RX FIFO hit. For each filter region, standard-ID filter space, and extended-ID filter space, there is an independent index starting from zero. Table 271 shows how FlexCAN writes IDHIT according to each filter element.
HR TIMESTAMP	High-resolution Timestamp	32-bit timebase captured during the CAN frame. When CTRL2[TSTAMPCAP] is not zero, a 32-bit timebase is captured from a dedicated on-chip timer which operates in free-running mode. See CTRL2[TSTAMPCAP] for details about capture point configuration of the high-resolution timestamp.

Table 271. IDHIT for Enhanced RX FIFO

Enhanced RX FIFO filter element - ERFFEL	IDHIT value	Filter element type
ERFFEL0	0	Extended-ID
ERFFEL1	1	Extended-ID
. . .	. . .	Extended-ID
ERFFEL(m-1)	m-1	Extended-ID
ERFFEL(m)	0	Standard-ID
ERFFEL(m+1)	1	Standard-ID
. . .	. . .	Standard-ID
ERFFEL(2n-m+1)	2x(n-m)+1	Standard-ID

NOTE

Where m = NEXIF and n = NFE. If NEXIF = 0, only standard-ID filter elements exist. If NEXIF > NFE, only extended-ID filter elements exist.

31.7 Glossary

Active message buffer A message buffer is active if it can participate in the current matching or arbitration process.

Bus interface unit FlexCAN submodule responsible for the interface to the CPU.

Bus off	See CAN Specification.[3]
CAN	Controller Area Network, a serial communication protocol defined in CAN Specification[3] and ISO International Standard.[4]
CHI	Controller-host interface, a FlexCAN submodule responsible for message buffer matching and arbitration algorithms.
CRC	Cyclic redundancy check
Dominant bit	A dominant bit wins the arbitration on the CAN bus. It is transmitted as 0.
Doze mode	A system low-power mode where the CPU bus remains active and a global Doze mode request is sent to all peripherals asking them to enter low power mode.
Error active	See CAN Specification.[3]
Error frame	See CAN Specification.[3]
Error passive	See CAN Specification.[3]
Form error	See CAN Specification.[3]
Hard reset	A reset coming from an external pin and/or following power-on. It resets everything.
Idle	See CAN Specification.[3]
Information processing time	See CAN Specification.[3]
Intermission	See CAN Specification.[3]
Matching elements	Data used in the matching process, such as ID, filter, mask, etc.
MB	See Message buffer.
Message buffer	Internal FlexCAN data structure containing bytes received from, or to be transmitted to, the CAN line, as well as information about this data.
Overload frame	See CAN Specification.[3]
Phase buffer segment	See CAN Specification.[3]
Recessive bit	A recessive bit loses the arbitration on the CAN bus. It is transmitted as 1.
Sclock	Serial clock. Obtained by dividing the clock feeding the CAN engine (oscillator or bus clock) by a prescaler factor. The Sclock period defines the time quantum for CAN protocol timing.
Soft reset	Global reset typically used by peripherals to reinitialize some of its registers, but not all of them.
Stop mode	A system low-power mode in which all chip clocks are stopped for maximum power savings.
Stuffing error	See CAN Specification.[3]
Time quantum	This is equal to the Sclock period. It is the minimum time period used to compose the CAN protocol bit timing.

[4] ISO International Standard - ISO 11898 First Edition 1993 Road Vehicles - Interchange of Digital Information - Controller Area Network (CAN) for high-speed Communication.

Chapter 32
Universal Serial Bus Controller (USB)

32.1 Chip-specific USB information

Table 272. Reference links to related information

Topic	Related module	Reference
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing
System Debug		System Debug Overview

The chip includes two instances of USB 2.0 Controllers and PHY that can be used as USB OTG port, USB HOST port or USB Device port.

The chip supports the following USB Controller and PHY output signals.

USB Instance	Signal
USB1 Controller	OTG_PWR
USB2 Controller	OTG_OC
USB1 Controller	OTG_OC
USB2 Controller	OTG_PWR
USB1 PHY	OTG_ID
USB2 PHY	OTG_ID

32.2 Overview

USB provides a high-performance functionality that conforms to *Universal Serial Bus Specification Revision 2.0*.

USB comprises two independent USB controller cores (two on-the-go (OTG) controller cores). Each controller core supports UTMI interfaces according to its feature support. Both the controller cores are single-port cores. For the OTG cores, there is only one port, which can be used as either a downstream or an upstream port.

See Features for more information.

NOTE

The term "OTG" is used throughout this document. The USB core hardware does not support the automatic OTG function. It is a dual-role (Host and Device mode) core, which you can implement in software with the hardware assist.

32.2.1 Block diagram

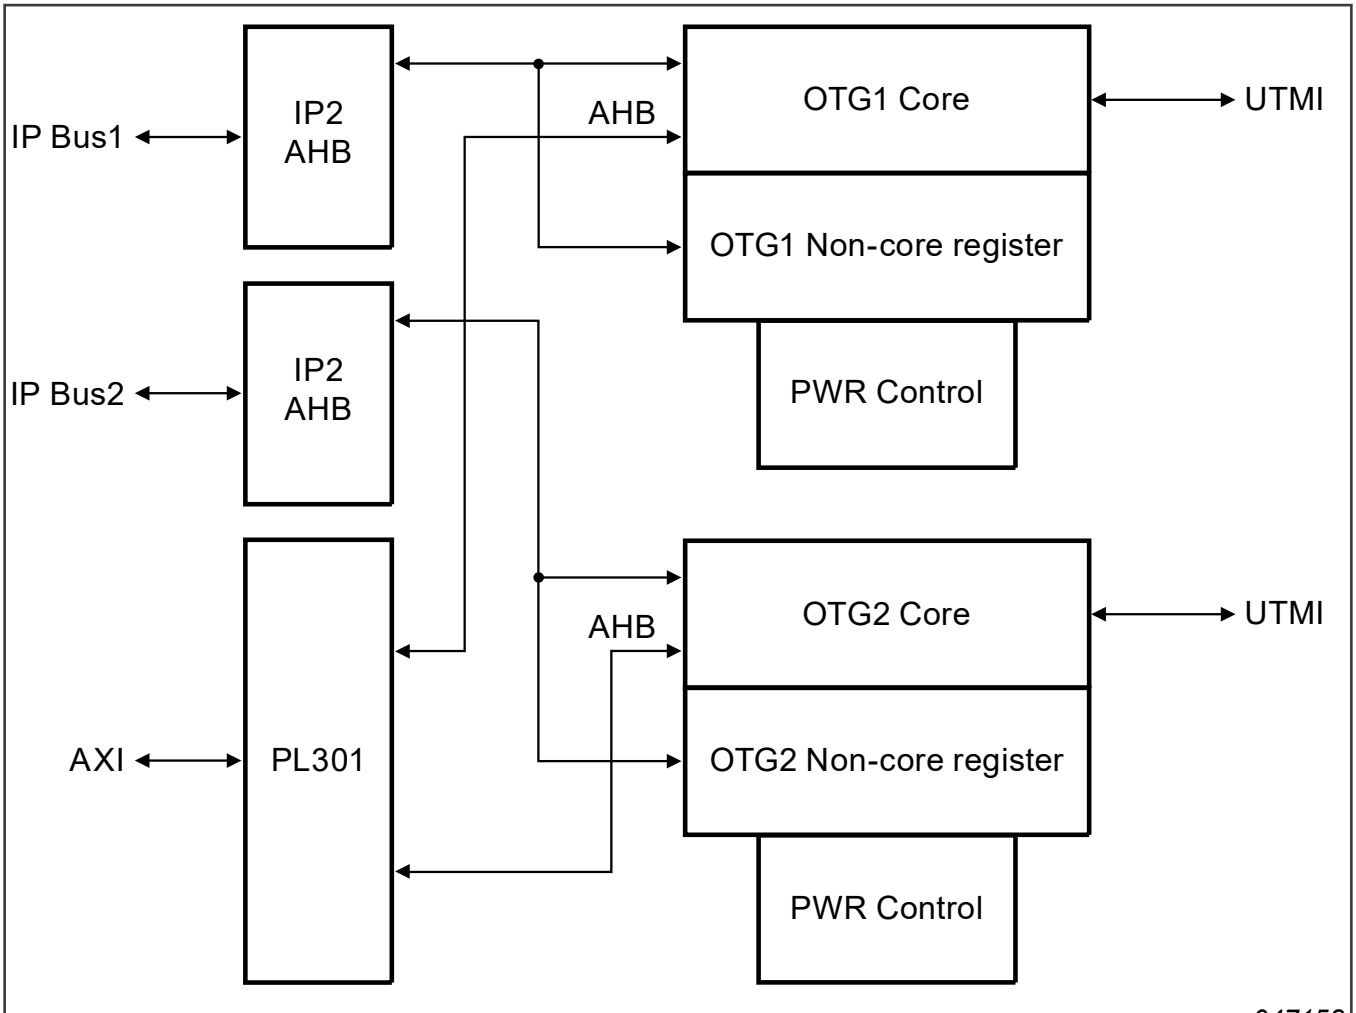

Figure 149. Block diagram

32.2.2 Features

- Includes USB 2.0 controller cores in this chip:
  - Controller core 0 is also named OTG1 core; its connected port is named OTG1 port.
  - Controller core 1 is also named OTG2 core; its connected port is named OTG2 port.
- Support for USB 2.0 controller core 0:
  - High-speed (HS), full-speed (FS), and low-speed (LS) OTG cores
  - HS, FS, and LS UTMI-compliant interface
  - HS, FS, and LS operations in Host mode (with UTMI transceiver)
  - HS and FS operations in Peripheral mode (with UTMI transceiver)
  - OTG signaling, session request protocol, and host negotiation protocol
  - Eight bidirectional endpoints
- USB 2.0 controller core 1:

- HS, FS, and LS OTG core
- HS, FS, and LS UTMI-compliant interface
- HS, FS, and LS operations in Host mode (with UTMI transceiver)
- HS and FS operations in Peripheral mode (with UTMI transceiver)
- Hardware support for OTG signaling, session request protocol, and host negotiation protocol
- Eight bidirectional endpoints

- Low-Power mode with local and remote wake-up capability
- Embedded DMA controller in each core

32.3 Functional description

These sections describe the functionality of the various building blocks of USB.

32.3.1 Submodule sections

32.3.1.1 USB 2.0 controller core 0

USB 2.0 controller 0 is an instantiation of an EHCI-compatible core that supports HS, FS, and LS operations.

In Host mode, this controller core supports HS, FS, and LS operations. In Device mode, it supports HS and FS operations.

32.3.1.1.1 Host mode

The controller supports direct connection of an HS, FS, or LS device with an on-chip UTMI transceiver. The system does not have a separate transaction translator block. The DMA and protocol engine blocks include the transaction translator function, which is normally associated with a USB 2.0 HS hub to support connection to FS and LS devices.

32.3.1.1.2 Peripheral (Device) mode

The following features are supported in this mode:

- Eight bidirectional endpoints
- HS or FS operation
- Support for HNP and SRP
- Remote wake-up capability

32.3.1.2 USB 2.0 controller core 1

The USB 2.0 controller core 1 is an instantiation of the EHCI-compatible core that supports the HS, FS, and LS operations USB 2.0 controller core 1 is identical as core 0.

In Host mode, this controller core supports the HS, FS, and LS operations. In Device mode, it supports HS and FS operations.

32.3.2 Host data structures

For detailed information, see the "Data Structures" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

32.3.3 Operation references

32.3.3.1 Host operational model

For detailed information, see the "Operational Model" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

32.3.3.2 Interrupts: host operational model

For detailed information about interrupt capability provided by the EHCI host controller hardware, see the "Interrupts" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

32.3.3.3 Host controller initialization

For detailed information, see the "Host Controller Initialization" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

32.3.4 EHCI deviations

For the purposes of a dual-role host or device controller with support for On-The-Go (OTG) applications, you must deviate from EHCI specification. Device and OTG operations are not specified in EHCI; therefore, the implementation supported in this core is proprietary.

The Host mode operation of the core is near EHCI compatible, with a few minor differences documented in this section. The following is a summary of these deviations.

Table 273. EHCI deviations

Deviations	Description
Embedded transaction translator	Allows direct attachment of the FS and LS devices in Host mode without the need for a companion controller (see Embedded transaction translator function).
Device operation	Generally disabled; therefore, Device mode is mostly transparent when in Host mode (exceptions are provided in the following sections). See Device operation for more information.
Embedded design interface	Does not have a PCI; therefore, the PCI configuration registers described in the EHCI specification are not applicable (see Embedded design interface for more information).
On-the-Go (OTG) operation	Includes an OTG for port 1.

32.3.4.1 Embedded transaction translator function

The OTG controller supports directly connected FS and LS devices, without requiring a companion controller, by including the capabilities of a USB 2.0 HS hub transaction translator.

Although there is no separate transaction translator block in the system, the transaction translator function that is normally associated with an HS hub is implemented within the DMA and protocol engine blocks. The embedded transaction translator function is an extension of the EHCI interface, but makes use of the standard data structures and operational models that already exist in the EHCI specification to support FS and LS devices.

32.3.4.1.1 Discovery: EHCI deviation

In a standard EHCI controller design, the EHCI host controller driver detects an FS or LS device by analyzing whether PORTSC1[PE] becomes 1 after the port reset operation.

PORTSC1[PE] becomes 1 in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate an HS connection (that is, after chirp completes successfully).

Because this controller has an embedded transaction translator, PORTSC1[PE] always becomes 1 after the port reset operation, regardless of the host device chirp result. PORTSC1[PSPD] indicates the resulting port speed. Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected FS and LS devices or hubs.

Table 274. Summary of EHCI

Standard EHCI	EHCI with embedded transaction translator
After PORTSC1[PE] becomes 1, following a connection and reset sequence, the device or hub is assumed to be in HS.	After PORTSC1[PE] becomes 1, following a connection and reset sequence, PORTSC*n* indicates the device or hub speed.
FS and LS devices are assumed to be downstream from an HS hub; therefore, all port-level controls are performed using the hub class through the nearest hub.	FS and LS devices can either be downstream from an HS hub or directly attached. When an FS or LS device is downstream from an HS hub, the port-level control is performed using the hub class through the nearest hub. When an FS or LS device is directly attached, the port-level control is accomplished using PORTSC*n*.
FS and LS devices are assumed to be downstream from an HS hub with HubAddr = X, where HubAddr > 0 and HubAddr is the address of the hub where the bus transitions from HS to either FS or LS (that is, a split target hub).	FS and LS devices can be either downstream from an HS hub with HubAddr = X [HubAddr > 0] or directly attached, where HubAddr = 0 and HubAddr is the address of the root hub where the bus transitions from HS to either FS or LS (that is, a split target hub is the root hub).

32.3.4.1.2 Operational model

The operational models support the behavior of the transaction translator (see the USB 2.0 specification) and support the EHCI controller moving packets between the system memory and a USB-HS hub. Because the embedded transaction translator exists within the host controller, there is no physical bus between the EHCI host controller driver and the USB FS and LS buses.

The following sections briefly discuss the operational model for how the EHCI and transaction translator operational models are combined without a physical bus existing between them. These sections assume that you are familiar with both the EHCI and USB 2.0 transaction translator operational models.

32.3.4.1.2.1 Microframe pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B). The embedded transaction translator must use the same pipeline algorithms specified in the USB 2.0 specification for a hub-based transaction translator.

All periodic transfers begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 are ready to execute on the bus in B-frame 0.

When programming the S-mask and C-mask fields in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming those fields for downstream hub-based transaction translators.

After periodic transfers are exhausted, any stored asynchronous transfer is moved. Asynchronous transfers are opportunistic: they must execute whenever possible, and their operation is not tied to H-frame and B-frame boundaries. However, an asynchronous transfer cannot babble through the start of B-frame 0 (SOF).

32.3.4.1.2.2 Split-state machines

The start- and complete-split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator.

A start- or complete-split operation occurs by requesting the split to the HS hub. The start-complete split operation is an internal operation to the embedded transaction translator. The following table summarizes the conditions where handshakes are emulated from an internal state instead of actual handshakes to the HS split bus traffic.

Table 275. Summary of handshake conditions

Condition	Emulate TT response
Start-split: All asynchronous buffers full	NAK
Start-split: All periodic buffers full	ERR
Start-split: Success for start of an asynchronous transaction	ACK
Start-split: Start periodic transaction	No handshake (OK)
Complete-split: Failed to find transaction in queue	Bus time out
Complete-split: Transaction in queue is busy	NYET
Complete-split: Transaction in queue is complete	Actual handshake from an LS or FS device

32.3.4.1.2.3 Asynchronous transaction scheduling and buffer management

Table 276. Asynchronous transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.17.3	Sequencing is provided and a packet-length estimator ensures that no FS or LS packet babbles exist in the SOF time.
11.17.4	Transaction tracking happens for two data pipes.

32.3.4.1.2.4 Periodic transaction scheduling and buffer management

Table 277. Periodic transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.18.6.[1-2]	• Terminate of pending start-split conditions: — End of frame (EOF), and not started in six microframes — Idle for more than four microframes • Terminate of pending complete-split conditions: — EOF — Idle for more than four microframes
11.18.[7-8]	• Transaction tracking for up to 16 data pipes • Complete-split transaction searching

Table continues on the next page...

Table 277. Periodic transaction scheduling and buffer management (continued)

USB 2.0 specification items	Implementation in the embedded transaction translator
	NOTE There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes that the number of packets scheduled in a frame does not exceed the frame duration (1 ms); otherwise, it results in an undefined behavior.

32.3.4.1.2.5 Multiple transaction translators

HCSPARAMS[N_TT] indicates the maximum number of embedded transaction translators that USB currently supports.

32.3.4.2 Device operation

The coexistence of a device operational controller within the host controller has little effect on the EHCI compatibility for host operation, except as discussed in the following sections.

32.3.4.2.1 USBMODE

You cannot initialize the dual-role controller in Host or Device modes. Considering this, you must program USB Device Mode (USBMODE) for a host operation before the EHCI host controller driver can begin EHCI host operations.

32.3.4.2.2 Fields with nonzero values in USB core registers

Some of the reserved fields and reserved addresses in the capability and operational registers are used in Device mode. For Device mode, you must adhere to the following requirements:

- Always write 0 to all EHCI reserved fields (some of which are device fields) in the operational registers. This is an EHCI requirement of the device controller driver.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusively for the device are undefined in Host mode.

32.3.4.2.3 SOF interrupt

The start of frame (SOF) interrupt for Device mode is shared as a free-running 125 µs interrupt for Host mode.

EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. See USB Status (USBSTS) and Interrupt Enable (USBINTR) for more information.

32.3.4.3 Embedded design interface

This is an embedded USB host controller, defined by the EHCI specification, and thus does not implement the PCI configuration registers.

32.3.4.3.1 Frame adjust register

Because the optional PCI configuration registers are not included in this implementation, there is no corresponding bit-level timing adjustment (such as the one provided by the Frame Adjust register in the PCI configuration registers). The start of microframes is timed precisely to 125 µs using the transceiver clock as a reference clock. That is, a 60 MHz transceiver clock for 8-bit physical interfaces and full-speed serial interfaces, or a 30 MHz transceiver clock for 16-bit physical interfaces.

32.3.4.4 Miscellaneous variations from EHCI

32.3.4.4.1 Programmable physical interface behavior

This design supports multiple physical interfaces that can operate in different modes if you program the core with software-programmable physical interface modes. Software programmability allows you to select the physical interface part during the board design phase, instead of selection during the chip design phase. Port Status and Control (PORTSC1) provides the control fields for selecting the physical interface operating mode, a capability that EHCI does not define.

32.3.4.4.2 Discovery

32.3.4.4.2.1 Port reset

The port connect methods that EHCI specifies require you to set PORTSC1[PR] for a duration of 10 ms. Because of the complexity involved in supporting the attachment of devices that are not high speed, there are counters already present in the design that can count the 10 ms reset pulse to alleviate the software requirement needed to measure this duration. Perform the following procedure to establish the basic connection.

Table 278. Port reset

Step	Purpose	Programming	Notes
1	Change the port	Wait for the port change interrupt	A port connect change occurs to notify the host controller driver that a device is attached.
2	Reset the device	Write 1 to PORTSC1[PR]	—
3	Reset the device after 10 ms	Write 0 to PORTSC1[PR]	This step, which is necessary in a standard EHCI design, can be omitted with this implementation. If the EHCI host controller driver attempts to write 0 to PORTSC1[PR] when a reset is in progress, the write is ignored and the reset continues until completion.

A port enable change occurs to notify the host controller that the device in now operational, and at this point, the port speed is determined.

32.3.4.4.2.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack must determine the port speed. Unlike the EHCI implementation, which reassigns the port owner for any device that does not connect at HS, this host controller supports direct attachment of non-HS devices.

Consider the following differences for port-speed detection:

- PORTSC1[PO] is read-only and always reads 0.
- PORTSC1[PSPD] provides the current operating speed of the port to the host controller driver.
- PORTSC1[HSP] signifies whether the port is in high speed or in full or low speed. This information is redundant with the aforementioned PORTSC1[PSPD].

32.3.4.4.3 Port Test Control mode

This mode behaves exactly as described in EHCI. An alternate host controller driver procedure is neither necessary nor supported.

32.3.5 Device data structures

This section defines the interface data structures used to communicate control, status, and data between the device controller driver (DCD) software and device controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device queue heads and transfer descriptors.

NOTE

You must ensure that no interface data structure reachable from the device controller spans a 4 KB page boundary.

The data structures defined in this chapter are, from the device controller's perspective, a mix of read-only (RO) and read/write (R/W) fields. The device controller must preserve the RO fields on all data structure writes.

Figure 150 shows the organization of the device endpoint queue head (dQH).

Endpoint queue heads are arranged in an array, in a continuous area of memory indicated by Endpoint List Address (ENDPTLISTADDR). The even-numbered device queue heads in the list support receive endpoints (Out/Setup) and the odd-numbered queue heads in the list are used for transmit endpoints (In/Interrupt). That is, the device queue heads in the list with an even offset support receiver endpoints (Out) and the queue heads in the list with an odd offset are used for the transmit endpoint (In). The device controller indexes into this array based on the endpoint number received from the USB bus. All information necessary to respond to transactions (for all primed transfers) is contained in this list, enabling the device controller to readily respond to incoming requests without having to traverse a linked list.

NOTE

The endpoint queue head list must be aligned to a 2 KB boundary.

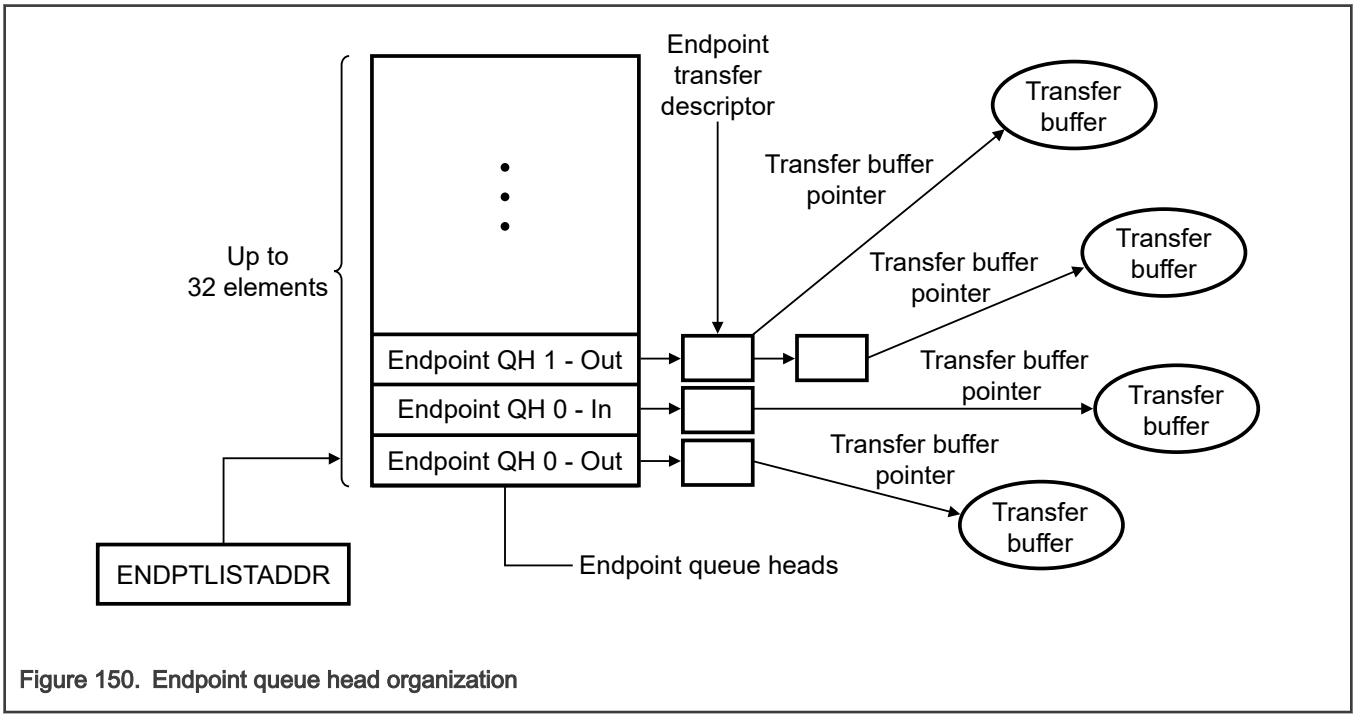

Figure 150. Endpoint queue head organization

32.3.5.1 Device endpoint queue head (dQH)

The dQH is where all transfers for a given endpoint are managed. It is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the device transfer descriptor (dTD) is copied into the overlay area of the dQH, which starts at the next dTD pointer DWORD and continues through the end of the buffer pointer. After a transfer is complete, the dTD status DWORD is updated in the dTD indicated by the current dTD pointer. When a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the device controller can access the required information with minimal latency.

Table 279. Endpoint queue head (dQH) structure

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Host controller read/write Host controller read-only

32.3.5.1.1 Endpoint capabilities and characteristics

This DWORD specifies static information about the endpoint; in other words, this information does not change over the lifetime of the endpoint. The device controller software must not attempt to modify this information when the corresponding endpoint is enabled.

Table 280. Endpoint capabilities and characteristics

Field	Function
31-30 MULT	Multiplier Indicates the number of packets executed per transaction description. • 00 – Execute *n* transactions as demonstrated by the USB variable length packet protocol, where *n* is computed using dQH and dTD. • 01 – Execute one transaction • 10 – Execute two transactions • 11 – Execute three transactions **NOTE** You must write 00b to this field for non-ISO endpoints, and 01b, 10b, or 11b, as needed, for ISO endpoints.
29 ZLT	Zero-Length Termination Select Enables a zero-length packet to terminate transfers, where the total transfer length is a multiple of the maximum packet length. This field is not relevant for isochronous transfer types. • 0 – Enable a zero-length packet to terminate transfers equal to a multiple of the maximum packet length (default) • 1 – Disable the zero-length packet on transfers that are equal in length to a multiple maximum packet length
28-27 Reserved	Reserved for future use; must be 0.
26-16 Maximum Packet Length	Maximum Packet Length Corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field can contain is 400h (1024).
15 IOS	Interrupt On Setup Used for control type endpoints to indicate whether USBSTS[UI] is configured in response to a setup being received.
14-0 Reserved	Reserved for future use; must be 0.

32.3.5.1.2 Transfer overlay-endpoint queue head

The seven DWORDS in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, it does not read the associated endpoint.

After an endpoint is ready, the device controller copies the dTD into the queue head overlay area. Until a transfer is expired, you must not write to the queue head overlay area or the associated transfer descriptor. After the transfer is complete, the device controller writes the results back to the original transfer descriptor and advances the queue.

See Device endpoint transfer descriptor (dTD) for a description of the overlay fields.

32.3.5.1.3 Current dTD pointer

The device controller uses the current dTD pointer to locate the transfer in progress. This word is for device controller (hardware) use only, and the DCD software must not modify it.

The following table describes the dTD pointer.

Table 281. Current dTD pointer

Bit	Description
31-5 Current dTD	Current dTD Points to the dTD that is represented in the transfer overlay area. The device controller modifies this field to the next dTD pointer during endpoint priming or queue advance.
4-0 Reserved	Reserved for future use; must be set to 0.

32.3.5.1.4 Setup buffer

The setup buffer is a dedicated storage for the 8-byte data that follows a setup PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it. Only the RX queue head is used for receiving setup data packets.

Table 282. Multiple mode control (HCCPARAMS)

DWORD	Bits	Description
1	31-0	Setup Buffer 0 Contains bytes 3–0 of an incoming setup buffer packet. The device controller writes to it so you can read it.
2	31-0	Setup Buffer 1 Contains bytes 7–4 of an incoming setup buffer packet. The device controller writes to it so you can read it.

32.3.5.2 Device endpoint transfer descriptor (dTD)

The dTD informs the device controller of the location and quantity of data to be sent and received for a given transfer.

The DCD must not attempt to modify any field in an active dTD except the next like pointer, which you must modify only as described in Managing transfers with transfer descriptors.

Table 283 describes the dTD structure.

Table 283. dTD structure[1]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Next link pointer																											0				T

Table continues on the next page...

Table 283. dTD structure[1] (continued)

0	Total bytes	IOC	0	MULTO	0	Status
Buffer pointer (page 0)				Current offset		
Buffer pointer (page 1)				0	Frame number	
Buffer pointer (page 2)				Reserved		
Buffer pointer (page 3)				Reserved		
Buffer pointer (page 4)				Reserved		

1. The shaded cells indicate host controller read/write fields and unshaded cells indicate host controller read-only fields.

Table 284 describes the dTD pointer.

Table 284. Next dTD pointer

Field	Function
31-5 Next Transfer Element Pointer	Next Transfer Element Pointer Contains the physical memory address of the next dTD to be processed. This field corresponds to memory address signals [31:5], respectively.
4-1 Reserved	Reserved for future use; must be 0.
0 T	Terminate Indicates to the device controller whether there are valid entries in the queue. • 0 – Pointer is valid (points to a valid transfer element descriptor) • 1 – Pointer is invalid

Table 285 describes the dTD token.

Table 285. dTD token

Field	Function
31 Reserved	Reserved for future use; must be 0.
30-16 Total Bytes	Total Bytes Specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes moved during the transaction, after the successful completion of the transaction.

Table continues on the next page...

Table 285. dTD token (continued)

Field	Function
	The maximum value you can store in the field is 5 × 4 KB (5000h). This is the maximum number of bytes that 5-page pointers can access. Although it is possible to create a transfer up to 20 KB, this assumes that the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16 KB. Therefore, the maximum recommended transfer is 16 KB (4000h). If the value of this field is 0 when the host controller fetches this transfer descriptor (and the active bit is 1), the device controller executes a zero-length transaction and retires the transfer descriptor. "In" transfers do not require that dTD be an even multiple of the Maximum Packet Length field in dQH. If you build such a transfer descriptor for an "In" transfer, the last transaction is always less than the value of the Maximum Packet Length field.
15 IOC	Interrupt On Complete Indicates whether USBSTS[UI] will be configured in response to the device controller being finished with this dTD.
14-12 Reserved	Reserved for future use; must be 0.
11-10 MULTO	Multiplier Override Can be used for transmit-ISO (that is, ISO-IN) to override the multiplier in the queue head. This field must be zero for all packet types that are not transmit-ISO. For example, if QH.multiplier = 3, the Maximum Packet Size field = 8, the Total Bytes field = 15, and the MULTO field = 0 (default), then three packets are sent: {Data2(8); Data1(7); Data0(0)}. If QH.multiplier = 3, the Maximum Packet Size field = 8, the Total Bytes field = 15, and the MULTO field = 2, then two packets are sent: {Data1(8); Data0(7)}. For maximum efficiency, you must calculate MULTO = greatest integer of (the Total Bytes field ÷ the Maximum Packet Size field). In cases where the Total Bytes field = 0, the MULTO field must be 1. For non-ISO and non-TX endpoints, you must write 0 to the MULTO field.
9-8 Reserved	Reserved for future use; must be 0.
7-0 Status	Status Used by the device controller to communicate individual command execution states back to the device controller software. This field contains the status of the last transaction performed on this dTD. The following are the bit encodings: • 0, 2, and 4 – Reserved • 3 – Transaction error • 5 – Data buffer error • 6 – Halted • 7 – Active

Table 286 describes the dTD buffer page pointer list.

Table 286. dTD buffer page pointer list

Field	Function
31-12 Buffer Pointer	Selects the page offset in memory for the packet buffer. Nonvirtual memory systems typically set the buffer pointers to a series of incrementing integers.
0, 11-0 Current Offset	Indicates the current offset that offsets into the 4 KB buffer where the packet will begin.
1, 10-0 Frame Number	Indicates the frame number in which a packet finishes. You typically use it to correlate relative completion times of packets on an ISO endpoint. The device controller writes to this field.

32.3.6 Device operational model

The function of the device operation is to transfer a request in the memory image to and from USB.

The device controller performs the data transfers (pointed to by the queue head) using a set of linked list transfer descriptors. The following sections explain the use of the device controller from the point-of-view of the DCD, and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

32.3.6.1 Device controller initialization

After hardware reset, the device is disabled until you write 1 to USBCMD[RS]. In the Disabled state, the pull-up on USB D+ is not active, which prevents an attach event from occurring. The minimum requirement is to have the queue heads setup for endpoint 0 before the device attach occurs.

After you enable the device, a USB reset occurs, followed by a setup packet arriving at endpoint 0. You must prepare a queue head so that the device controller can store the incoming setup packet.

Perform the following procedure to initialize a device:

1. Set Controller mode to Device mode in USB Device Mode (USBMODE).

   NOTE

   Transitioning from Host mode to Device mode requires a device controller reset before modifying USB Device Mode (USBMODE).

2. Allocate and initialize device queue heads in the system memory.

   At a minimum, initialize device queue heads 0 Tx and 0 Rx.

   NOTE

   You must initialize all device queue heads for control endpoints before the endpoint is enabled. Noncontrol device queue heads before the endpoint can be used.

   For information on device queue heads, see Device data structures.

3. Configure the ENDPOINTLISTADDR pointer.
4. Enable the microprocessor interrupt associated with the USB core.

   NXP recommends you to enable all device interrupts including USBSTS[UI], USBSTS[UEI], USBSTS[PCI], USBSTS[URI], and USBSTS[SLI].

   For a list of available interrupts, see Interrupt Enable (USBINTR) and USB Status (USBSTS) register tables.

5. Write 1 to USBCMD[RS]. After this field becomes 1 and the device is connected to a host, the host downstream port issues a bus reset. The DCD must monitor the reset event and adjust the software state as described in Bus reset.

NOTE

Endpoint 0 is designed as a control endpoint only; you do not need to configure it using Endpoint Control 0 (ENDPTCTRL0).

Because the first packet received is always a setup packet, it is not necessary to initially prime endpoint 0. The contents of the first setup packet require a response in accordance with the USB device framework command set.

32.3.6.2 Port state and control

From a chip or system reset, the device controller enters the powered state. A transition from the powered state to the attach state occurs when USBCMD[RS] = 1.

After receiving a reset on the bus, the port enters the defaultFS or defaultHS state in accordance with the reset protocol described in Appendix C.2 of *USB 2.0 Specification Rev. 2.0*.

The following state diagram depicts the state of a USB 2.0 device.

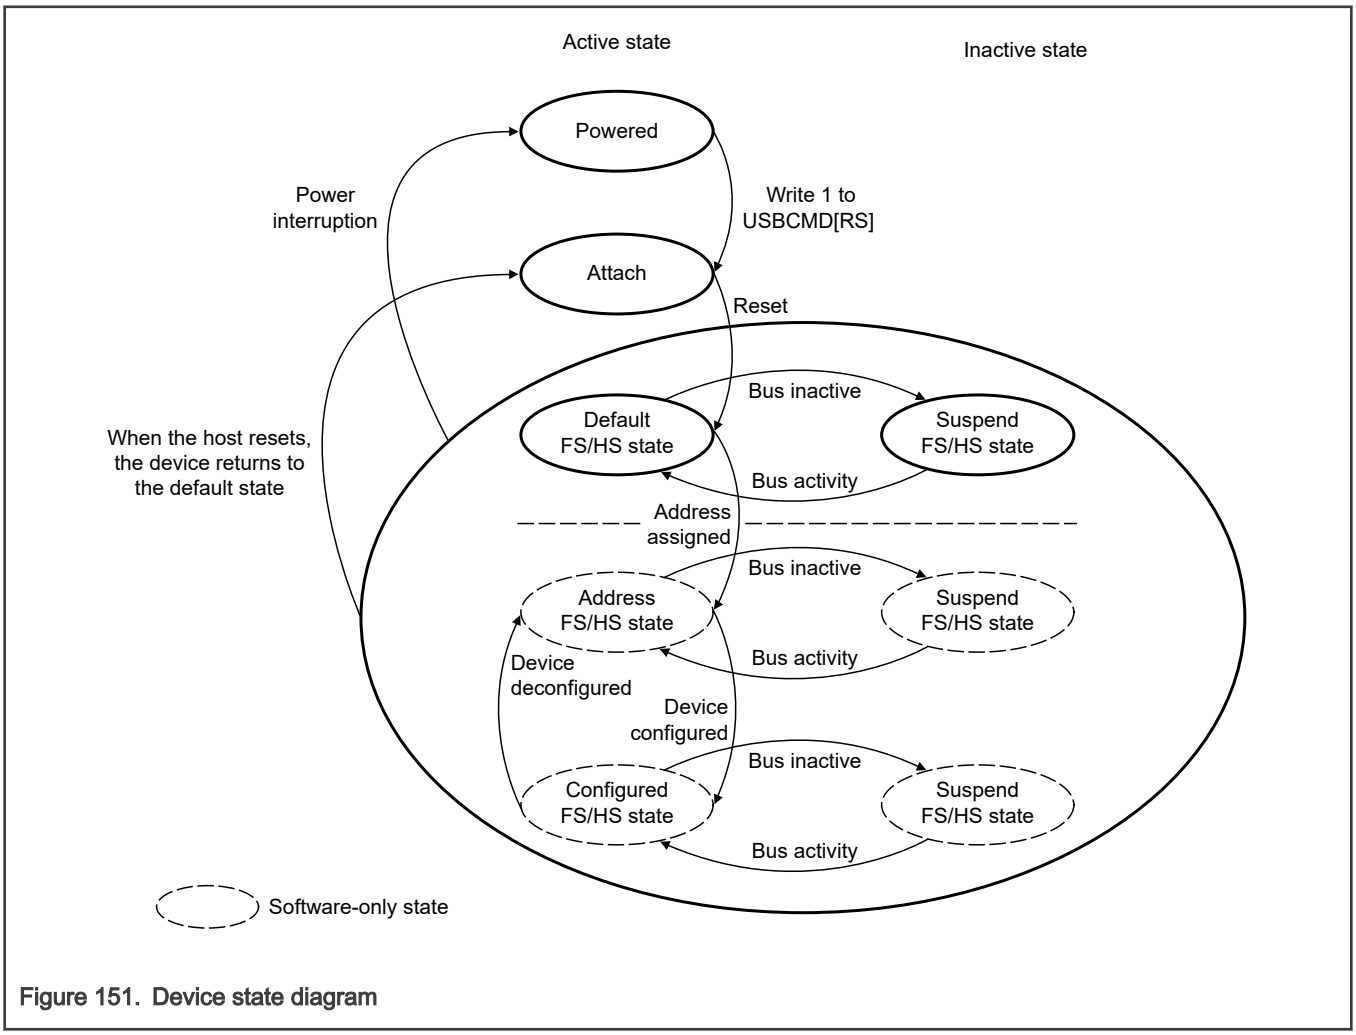

Figure 151. Device state diagram

The powered, attach, defaultFS, defaultHS, suspendFS, and suspendHS states are implemented in the device controller and communicated to the DCD using the following device controller state information fields:

- USBSTS[SLI]
- USBSTS[URI]

- USBSTS[PCI]
- PORTSC1[HSP]

It is the DCD's responsibility to maintain a state variable to differentiate between the defaultFS and defaultHS states, and the Address and Configured states. A change of state from Default to either Address or Configured is part of the enumeration process described in the device framework section of the USB 2.0 specification.

After entering the Address state, the DCD programs Device Address (DEVICEADDR).

Entry into the Configured state indicates that you have properly initialized all endpoints to be used in the operation of the device by programming the ENDPTCTRL*x* registers and initializing the associated queue heads.

32.3.6.2.1 Bus reset

The host uses a bus reset to initialize downstream devices.

When a bus reset is detected, the device controller renegotiates its attachment speed, resets the device address to 0, and notifies the DCD by interrupt (assuming USBINTR[URE] = 1). After a reset is received, all endpoints (except endpoint 0) are disabled, and the device controller cancels any primed transactions. The following table explains the concept of priming, and the tasks that DCD must perform when a reset is received.

Table 287. Bus reset

Step	Purpose	Programming
1	Clear all setup token semaphores	Read Endpoint Status (ENDPTSTAT) and write the same value back to ENDPTSTAT.
2	Clear all the endpoint-complete status fields	Read Endpoint Complete (ENDPTCOMPLETE) and write the same value back to ENDPTCOMPLETE.
3	Cancel primed status	Wait until all fields in Endpoint Prime (ENDPTPRIME) become 0, and then write FFFFFFFFh to Endpoint Flush (ENDPTFLUSH).

Read PORTSC1[PR] and ensure it is still active. A USB reset occurs for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before the end of the reset occurs; otherwise, a hardware reset of the device controller is recommended. This is a rare scenario.

You can perform a hardware reset by writing 1 to USBCMD[RST]. By writing 0 to USBCMD[RS], a hardware reset causes the device to detach from the bus. Thus, the DCD must completely reinitialize the device controller after a hardware reset.

Additionally, you must free up all allocated dTDs because the device controller will no longer execute them. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs are allocated.

At this time, the DCD can release the control back to the OS because no further changes to the device controller are permitted until a port change detect is indicated.

After a port change detect, the device reaches the default state and the DCD can read Port Status and Control (PORTSC1) to determine whether the device is operating in FS or HS mode. At this time, the device controller reaches its normal operating mode and DCD can begin enumeration according to *USB 2.0 specification chapter 9: Device Framework*.

NOTE

The device DCD may use the FS or HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes when in FS mode. There is no difference in DCD operations in FS and HS modes, except for the data rate issue.

32.3.6.2.2 Suspended state and Resume signal

Table 288. Operational models for Suspended state and Resume signal

Suspended	Resume
To conserve power, USB devices automatically enter Suspended state when the device observes no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. The attached devices must be prepared to suspend at any time when they are powered, regardless of whether they are assigned a nondefault address, are configured, or neither of the two conditions exist. Bus activity may cease because of the host entering a suspend mode of its own. In addition, a USB device must enter the Suspended state when the attached hub port is disabled. A USB device exits Suspend mode when there is bus activity. It may also request the host to exit Suspend mode or selectively suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. If the USB device is capable of remote wake-up signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wake-up signaling must be disabled. The device controller moves into the Suspended state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the Suspended state, an interrupt notifies the DCD (assuming that PORTSC1[SUSP] is 1, meaning the device controller is suspended). The DCD response, when the device controller is suspended, is application-specific and may involve switching to a low-power operation. See the USB 2.0 specification for information about bus power limits in Suspended state.	If the device controller is suspended, its operation is resumed when an active signal is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port by writing 1 to PORTSC1[FPR] when the device is in the Suspended state. Sending resume signal to an upstream port must cause the host to issue resume signaling and bring the suspended bus segment (one more device) back to the active condition. **NOTE** Before using resume signaling, the host must enable it via the set feature command defined in the device framework (chapter 9 of the USB 2.0 specification).

32.3.6.3 Managing endpoints

The USB 2.0 specification defines an endpoint (also called a device endpoint or an address endpoint) as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The combination of the endpoint number and endpoint direction specifies the endpoint address.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints that USB supports include bulk, interrupt, and isochronous. Each endpoint type has a specific behavior related to packet response and error handling.

The USB device controller hardware supports up to eight endpoint numbers.

Each endpoint direction is essentially independent, and you can configure it with differing behaviors in each direction. For example, the DCD can configure endpoint "1-In" as a bulk endpoint and endpoint "1-Out" as an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, always a control endpoint and uses both directions.

Each endpoint direction requires a queue head allocated in memory. To support the eight endpoint numbers, 16 queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

See the USB 2.0 specification for more information about endpoint operations.

32.3.6.3.1 Endpoint initialization

After hardware reset, all endpoints except endpoint 0 are uninitialized and disabled. The DCD must configure and enable each endpoint by configuring ENDPTCTRL*x*.

Each 32-bit ENDPTCTRL*x* is split into an upper and a lower half. The lower half of ENDPTCTRL*x* is used to configure the receive or "Out" endpoint, and the upper half is used to configure the corresponding transmit or "In" endpoint. You must configure the control endpoints in the same way for both the upper and lower halves of ENDPTCTRL*x*; otherwise, the behavior is undefined. The following table shows the fields and corresponding values for device controller endpoint initialization.

Table 289. Device controller endpoint initialization: configuration settings

Step	Purpose	Programming
1	Reset the PID sequence.	Write 1 to ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR].
2	Configure receive data toggle sequencing.	Write 0 to ENDPTCTRL*x*[TXI] and ENDPTCTRL*x*[RXI].
3	Select the endpoint type.	Configure ENDPTCTRL*x*[TXT] and ENDPTCTRL*x*[RXT].
4	Configure the endpoint stall condition.	Write 0 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS].

32.3.6.3.2 Stalling

The following are the occasions in which the device controller may need to return a STALL response to the host:

- In case of a functional stall: It is a condition that DCD sets, as described in the USB 2.0 device framework. This kind of a stall is only used on noncontrol endpoints, and can be enabled in the device controller by writing 1 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS], associated with the given endpoint and the given direction. In a functional stall condition, the device controller continues to return STALL responses to all transactions occurring on the respective endpoint and direction until DCD writes 0 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS].
- In case of a protocol stall: Unlike a function stall, it is used on control endpoints. The device controller automatically clears it at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD must enable ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS] (both directions) as a pair. A single write to ENDPTCTRL*x* can ensure that both ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS] become 1 at the same instant.

NOTE

Any write to ENDPTCTRL*x* in Operational mode must preserve ENDPTCTRL*x*[TXT] and ENDPTCTRL*x*[RXT], which means you must perform a read-modify-write operation.

Table 290. Device controller stall response matrix

USB packet	Value of ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS]	Effect on ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS]	USB response
Setup packet that a noncontrol endpoint receives	N/A	None	STALL
In, Out, or Ping packet that a noncontrol endpoint receives	1	None	STALL
In, Out, or Ping packet that a noncontrol endpoint receives	0	None	ACK, NAK, or NYET
Setup packet that a control endpoint receives	N/A	Cleared	ACK
In, Out, or Ping packet that a control endpoint receives	1	None	STALL
In, Out, or Ping packet that a control endpoint receives	0	None	ACK, NAK, or NYET

32.3.6.3.3 Data toggle

Data toggle is a mechanism to maintain data coherency between the host and device for a given data pipe.

For more information about data toggle, see the USB 2.0 specification.

32.3.6.3.3.1 Data toggle reset

The DCD can reset ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR] and cause the data toggle sequence to reset in the device controller by writing 1 to ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR].

This is necessary only when configuring or initializing an endpoint, or returning from a STALL condition.

32.3.6.3.3.2 Data toggle inhibit

Writing 1 to ENDPTCTRL*x*[TXI] and ENDPTCTRL*x*[RXI] causes the device controller to ignore the data toggle pattern that is normally sent, and accepts all incoming data packets regardless of the data toggle state.

During normal operation, the device controller checks the DATA0 and DATA1 fields against the data toggle to determine whether the packet is valid. If the data PID does not match either ENDPTCTRL*x*[TXR] or ENDPTCTRL*x*[RXR] (that the device controller maintains for that endpoint), the data toggle is considered invalid. In this case, the device controller assumes that the packet is already received and discards the packet without reporting it to the DCD. To prevent the host controller from resending the same packet, the device controller responds to the error packet by acknowledging it with either an ACK or NYET response.

NOTE

This feature is for test purposes only; you must never use it during a normal device controller operation.

32.3.6.3.3.3 Priming transmit (TX) endpoints

Priming a transmit endpoint causes the device controller to fetch the device transfer descriptor (dTD) for the transaction that the dQH points to.

After the dTD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host, without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint, with the maximum number of endpoints configured at the device synthesis time.

After a priming request is complete, Endpoint Status (ENDPTSTAT) indicates an endpoint state of primed transmit. For this, the device controller can respond to an "In" request from the host and meet the stringent bus turnaround time of HS USB.

Because only the leading data is stored in the device controller FIFO, the device controller must begin filling in leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that the system memory bus can incur.

32.3.6.3.3.4 Priming receive (RX) endpoints

From the point of view of the DCD, priming receive endpoints is identical to priming transmit endpoints. Considering the device controller, the major difference in the operational model is that there is no data movement of the leading packet data because the data will be received from the host.

As part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the receive FIFO does not scale with the number of endpoints.

32.3.6.4 Operational model for packet transfers

The host initiates all transactions on the USB bus, and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 specification.

With USB 1.1 FS and LS rates, this turnaround time was significant and the USB 1.1 device controllers were architected in a way that enabled the device controller to access the main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller is different because the same methods do not meet the USB 2.0 HS turnaround time requirements from the increased clock rate.

A USB host sends requests to the device controller in an order that cannot be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable if the endpoint number and direction are considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then the host is expected to send "In" requests to that endpoint. This device controller is architected in a way that enables it to prepare packets for each endpoint or direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host-initiated transactions on the bus is referred to as priming the endpoint. This term is used throughout the chapter to describe the device controller operation so you can use priming to appropriately architect the DCD. Furthermore, the term flushing is used to describe the action of clearing a packet that is queued for execution.

32.3.6.4.1 Interrupt and bulk endpoint operational model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid "In" and "Out" transactions to bulk pipes handshake with a NAK unless the endpoint is primed. After the endpoint is primed, data delivery commences.

The device controller retires a dTD after the packets described in the transfer descriptor are completed. Each dTD describes "N" packets to be transferred according to the USB variable length transfer protocol. Equation 38, Table 291, and Table 292 describe how the device controller computes the number and length of packets that USB must send and receive. These vary according to the total number of bytes and maximum packet length. Also, Table 293 describes when TX-dTD and RX-dTD are considered complete.

With ZLT = 0, N = INT (number of bytes ÷ maximum packet length) + 1

With ZLT = 1, N = MAXINT (number of bytes ÷ maximum packet length)

N = MAXINT (number of bytes ÷ maximum packet length)

Equation 38. Formula for N

Table 291. Variable length transfer protocol example (ZLT = 0)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	3	256	256	0
512	512	2	512	0	—

Table 292. Variable length transfer protocol example (ZLT = 1)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	2	256	256	—
512	512	1	512	—	—

NOTE

You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.

Table 293. TX-dTD and RX-dTD completion status

TX-dTD is considered complete when:	RX-dTD is considered complete when:
All packets described in dTD are successfully transmitted. When this occurs, the total bytes in dTD become zero.	• All packets described in dTD are successfully received. When this occurs, the total bytes in dTD become zero. • A short packet (number of bytes < maximum packet length) is received. This is a successful transfer completion. DCD must check the total bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received. • A long packet is received: (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). This is an error condition. The device controller discards the remaining packet and sets the Data Buffer Error bit in the Status field of the dTD (see Device endpoint transfer descriptor (dTD)). In addition, the endpoint is flushed and the USBERR interrupt becomes active.

After the successful completion of the packet(s) that dTD describes, the Active bit in the Status field of the dTD is cleared and the next pointer is followed when the Terminate field in dTD is clear. When the Terminate field is set, the device controller flushes the endpoint or direction and ceases operations for that endpoint or direction.

After an unsuccessful completion of a packet (in the case of a long packet), the dQH points to the dTD in error. To recover from this error condition, the DCD must properly reinitialize the dQH by clearing the Active bit and updating the next dTD pointer before attempting to reprime the endpoint.

NOTE

The device controller automatically retires all packet level errors, such as a missing handshake or CRC error. An interaction with the DCD is not required for handling such errors.

32.3.6.4.1.1 Interrupt and bulk endpoint bus response matrix

The following table shows the device controller's response to packets on interrupt and bulk endpoint, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- NYET or ACK: If the transfer descriptor has packets remaining (according to the USB variable length protocol), the response is ACK. Otherwise, the response is NYET.

A system error (SYSERR) should not occur when the latency FIFOs are correctly sized and the DCD is responsive.

Table 294. Interrupt and bulk endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	Bus error	N/A
Out	STALL	NAK	Receive + NYET or ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

32.3.6.4.2 Control endpoint operation model

32.3.6.4.2.1 Setup phase

All requests to a control endpoint begin with a setup phase, followed by an optional data phase and a required status phase. The device controller always accepts the setup phase unless the setup lockout is engaged.

The setup lockout engages so that future setup packets are ignored. Lockout of setup packets ensures that when software is reading the setup packet stored in the queue head, that data is not written at the same time because this can potentially cause an invalid setup packet.

You can disable the setup lockout mechanism only one time at initialization (by writing 1 to USBMODE[SLOM]), and a new tripwire type semaphore ensures that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. Setup lockout is not necessary when using the tripwire. This is the preferred behavior because ignoring repeated setup packets because of long software interrupt latency leads to a compliance issue.

Leaving the Setup Lockout mode as 0 results in pre-2.3 hardware behavior.

After receiving an interrupt and inspecting Endpoint Setup Status (ENDPTSETUPSTAT) to determine that a setup packet is received on a particular pipe, perform the following procedure.

Table 295. Setup phase: associated procedure

Step	Purpose	Programming	Notes
1	Clear the corresponding bit.	Write 1 to ENDPTSETUPSTAT[ENDPTSETUPSTAT].	—
2	—	Write 1 to USBCMD[SUTW].	—
3	Duplicate contents of the Setup Buffer field (in dTD) into a local software byte array.	—	—
4	—	Read USBCMD[SUTW].	If the field is 1, continue to the next step; if the field is 0, go back to step 2.
5	—	Write 0 to USBCMD[SUTW].	—
6	Process the setup packet using a local software byte array copy, and execute the status and handshake phases.	—	After receiving a new setup packet, the status and handshake phases may still be pending from a previous control sequence. These must be flushed and deallocated before linking a new status or handshake dTD for the most recent setup packet.

32.3.6.4.2.2 Data phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must immediately verify (by reading Endpoint Setup Status (ENDPTSETUPSTAT)) that a new setup packet has not been received. A prime completes when the associated field in Endpoint Prime (ENDPTPRIME) is 0 and the associated field in Endpoint Status (ENDPTSTAT) is 1. If the associated field in Endpoint Prime (ENDPTPRIME) becomes 0 and the associated field in Endpoint Status (ENDPTSTAT) has not become 1, prime fails. This is only due to improper setup of the dQH, the dTD, or a setup arriving during the prime operation. If a new setup packet is indicated after the associated field in Endpoint Prime (ENDPTPRIME) becomes 0, then the transfer descriptor is freed and the DCD must reinterpret the setup packet.

If a setup arrives after the data stage is primed, the device controller automatically clears the prime status (Endpoint Status (ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is performed in the same way as bulk packets.

32.3.6.4.2.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal to 0) and prime the endpoint for the status phase.

The DCD must also perform the same checks associated with ENDPTSETUPSTAT[ENDPTSETUPSTAT], as described in the data phase.

NOTE

- You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is performed in the same way as bulk packets.

32.3.6.4.2.4 Control endpoint bus response matrix

The following table shows the device controller's response to packets on a control endpoint, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- NYET or ACK: If the transfer descriptor has packets remaining (according to the USB variable length protocol), the response is ACK. Otherwise, the response is NYET.
- System error (SYSERR) must never occur when the latency FIFOs are correctly sized and the DCD is responsive.

Table 296. Control endpoint bus response matrix

Token type	Endpoint state					Setup lockout
	Stall	Not primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	—
In	STALL	NAK	Transmit	Bus error	N/A	N/A
Out	STALL	NAK	Receive + NYET or ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

32.3.6.4.3 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data, and their operational model is significantly different from the host throttled bulk, interrupt, and control data pipes.

The device controller accomplishes real-time delivery by using the following techniques:

- Exact MULT packets per microframe are transmitted and received. MULT is a two-bit field in the dQH (see Device endpoint queue head (dQH)). The variable length packet protocol is not used for isochronous endpoints.
- NAK responses are not used. Instead, zero-length packets are sent in response to an "In" request for unprimed endpoints. For unprimed RX endpoints, the response to an "Out" transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next microframe. If the ISO-dTD is still active after that frame, then the ISO-dTD is considered ready until the DCD executes or cancels it.

An EHCI-compatible host controller uses the periodic frame list to schedule data exchanges to isochronous endpoints. The operational model for Device mode does not use such a data structure. Instead, the same dTD used for control, bulk, and interrupt endpoints is also used for isochronous endpoints. The difference between bulk and ISO endpoints is in the handling of the dTD:

- Priming an ISO endpoint is a delayed operation so that an endpoint is primed only after an SOF is received. After the DCD writes to the prime bit, the bit is cleared as usual to indicate to software that the device controller completed priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific microframe.
- With isochronous endpoints, the transaction must fully complete within one microframe. After an ISO transaction is started in a microframe, it retires the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

  The Transaction Error bit in the Status field of the dTD indicates a fulfillment error condition. When a fulfillment error occurs on the frame after the transfer fails to complete, the device controller force retires the ISO-dTD and moves to the next ISO-dTD.

NOTE

Partially completed packets cause fulfillment errors. If no activity occurs on a primed ISO-dTD, the transaction stays primed indefinitely. This means it is up to you to discard transmit ISO-dTDs that pile up from a failure of the host or to move the data.

- The data level error handling for ISO packets is different. When a CRC error occurs on a received packet, the packet is not retried in the same way as bulk and control endpoints. Instead, the CRC error is noted by setting the Transaction Error bit in the Status field of the dTD, and the data is stored as usual for the application software to manage. The following table shows how a retired ISO packet is managed.

Table 297. Conditions that cause transmit and receive packets to retire

Conditions for transmit packet retirement (all conditions must be fulfilled)	Conditions for receive packet retirement (all conditions must be fulfilled)
• The MULT counter reaches zero. • A fulfillment error occurs. The Transaction Error bit is set in the Status field of the dTD: number of packets occurred > 0 AND number of packets occurred < MULT. **NOTE** For TX-ISO, the MULT counter can be loaded with a lesser value in the dTD MULTO field in hardware versions 2.3 and later. If MULTO is 0, the MULT counter is initialized to the multiplier in the queue head.	• The MULT counter reaches zero. • A non-MDATA PID is received. The exit criteria is only valid in hardware version 2.3 or later. Before this version, any PID sequence that did not exactly match the MULTO field was flagged as a transaction error because of a PID mismatch or fulfillment error. • An overflow error occurs. This happens when: — The packet received is greater than the maximum packet length (the Data Buffer Error bit is set in the Status field of the dTD). — The packet received exceeds the total bytes allocated in the dTD (the Data Buffer Error bit is set in the Status field of the dTD). • A fulfillment error occurs (the Transaction Error bit is set in the Status field of the dTD): number of packets occurred > 0 AND number of packets occurred < MULT. • A CRC error occurs (the Transaction Error bit is set in the Status field of the dTD).

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For a continuous microframe-to-microframe operation, the DCD must ensure that the dTD linked-list is ahead of the device controller by at least two microframes.

32.3.6.4.3.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the microframe number (specified by USB Frame Index (FRINDEX)) can be used as a marker.

To cause a packet transfer to occur at a specific microframe number ("N"), the DCD must interrupt on SOF during frame N-1. If USB Frame Index (FRINDEX) = N-1, the DCD must write to the prime bit. The device controller primes the isochronous endpoint in microframe N-1 so that the device controller is able to execute delivery during microframe N.

NOTE

Priming an endpoint towards the end of microframe N-1 does not guarantee delivery in microframe N. The delivery may actually occur in microframe N+1 if the device controller does not have enough time to complete the prime before the SOF for packet N is received.

32.3.6.4.3.2 Isochronous endpoint bus response matrix

The following table shows the device controller's response to packets on isochronous endpoints, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- Null packet refers to zero-length packet.

Table 298. Isochronous endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Stall	Stall	Stall	N/A	N/A
In	Null packet	Null packet	Transmit	Bus error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

32.3.6.5 Managing queue heads

The dQH points to the linked list of transfer tasks; the dTD depicts each of these tasks. An area of memory that Endpoint List Address (ENDPTLISTADDR) points to contains a group of all dQHs in a sequential list, as shown in Figure 152. The even elements in the list of dQHs are used for receive endpoints (Out and Setup) and the odd elements are used for transmit endpoints (In and Interrupt). Device transfer descriptors are linked, head to tail, starting at the queue head and ending at the Terminate bit of the dTD. After the dTD retires, it is no longer a part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers do not exist within the queue head after the dTD is retired (see Software link pointers).

In addition to the current and next pointers, and the dTD overlay examined in Operational model for packet transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier (MULT), Maximum Packet Length, and Interrupt On Setup (IOS). The next section discusses the complete initialization of the dQH, along with these fields.

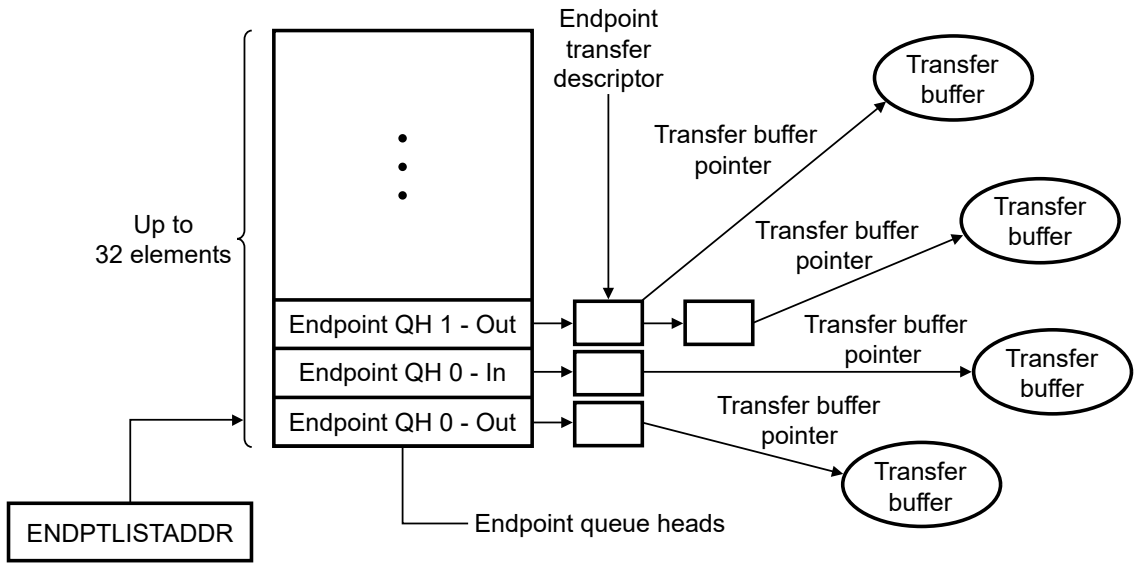

Figure 152. Endpoint queue head diagram

32.3.6.5.1 Queue head initialization

You must initialize a device queue head for each active endpoint. Perform the following procedure to initialize it.

Table 299. Queue head initialization

Step	Programming	Notes
1	Write to the wMaxPacketSize field as either the USB chapter 9 or application-specific protocol requires.	—
2	Write 0 to the MULT field in dQH for control, bulk, and interrupt endpoints.	Set the multiplier to 1, 2, or 3, for ISO endpoints, as the required bandwidth and in conjunction with the USB chapter 9 protocol. In FS mode, the MULT field in dQH can only be 1 for ISO endpoints.
3	Write 1 to the next Terminate field in dTD.	—
4	Write 0 to the Active bit in the Status field of dTD.	—
5	Write 0 to the Halt bit in the Status field of dTD.	—

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

32.3.6.5.2 Operational model for setup transfers

As discussed in Control endpoint operation model, the DCD gives special treatment to setup transfer. It does not use a dTD, but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

After receiving a notification of the setup packet, the DCD must manage the setup transfer as provided in the following procedure.

Table 300. Setup transfers: associated procedure

Step	Purpose	Programming	Notes
1	Copy setup buffer contents from dQH–RX to software buffer.	—	—
2	Acknowledge setup backup.	Write 1 to the corresponding bit in ENDPTSETUPSTAT[ENDPTSETUPSTAT].	• The acknowledgement must occur before continuing to process the setup packet. • After the acknowledgement has occurred, the DCD must not attempt to access the setup buffer in the dQH–RX. Only the local software copy must be examined.
3	Check for pending data or status dTDs from previous control transfers and flush, if any exist.	See Flushing and de-priming an endpoint.	—
4	—	Decode the setup packet, and prepare data phase (optional) and status phase transfers as required by either the USB chapter 9 or application-specific protocol.	—

NOTE

The device controller can receive setup packets before the completion of previous control transfers. Existing control packets in progress must be flushed and the new control packet must be completed.

32.3.6.6 Managing transfers with transfer descriptors

32.3.6.6.1 Software link pointers

The DCD software must maintain head and tail pointers to the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the currently working dTD and the next dTD to be executed. The operations described in the next section for managing the dTD assume that the DCD can use the head and tail of the dTD linked list. The following figure shows the software link pointers.

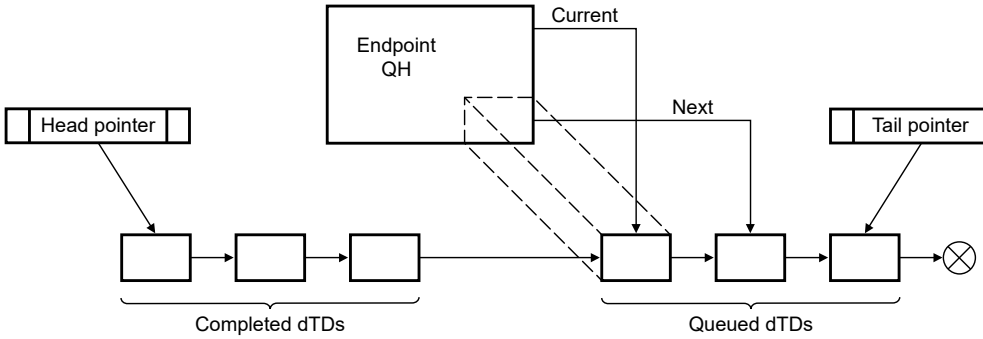

Figure 153. Software link pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the head and tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

32.3.6.6.2 Building a transfer descriptor

Before executing a transfer from the linked list, you must build a dTD to describe the transfer.

As a prerequisite, allocate 8-DWORD dTD block of memory aligned to 8-DWORD boundaries. For example, bit address 4:0 is equal to 00000. Then perform the following procedure to build a dTD.

Table 301. Building a transfer descriptor: associated procedure

Step	Purpose	Programming
1	—	Write 0 to the first seven DWords.
2	—	Write 1 to the Terminate field in dTD.
3	—	Write the transfer size to the Total Bytes field in dQH.
4	—	Write 1 to the Interrupt On Complete (IOC) field in dTD, if desired.
5	Initialize the Status field.	Write 1 to the Active bit of the Status field and write 0 to all remaining Status bits.
6	Point to the start of the data buffer.	Fill in buffer pointer page 0 and the current offset.
7	—	Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointers.

32.3.6.6.3 Executing a transfer descriptor

To safely add a dTD, the DCD must perform the procedures listed in Table 302, based on the case. These procedures manage the event in which the device controller reaches the end of the dTD list at the same time a new dTD is added to the end of the list.

Determine whether the link list is empty by checking the DCD driver. This evaluates whether the pipe is empty (the internal representation of the linked list must indicate whether any packets are outstanding).

Table 302. Executing a transfer descriptor

Step	Case 1: If the link list is empty	Step	Case 2: If the link list is not empty
1	Write to the dQH next pointer and write 0 to the dQH Terminate bit as a single DWORD operation.	1	Add dTD to the end of linked list.
2	Clear the active and halt bits in dQH (in case they are set from a previous error).	2	Read the appropriate field in Endpoint Prime (ENDPTPRIME). If it is 1, it is done; otherwise, continue to read the field.
3	Prime the endpoint by writing 1 to the appropriate field in Endpoint Prime (ENDPTPRIME). You must check that the dTD and dQH content in external memory is updated before writing 1 to the field in Endpoint Prime (ENDPTPRIME).	3	Write 1 to USBCMD[ATDTW].
—	—	4	Read the appropriate status field in Endpoint Status (ENDPTSTAT) (store in a temporary variable for later use).
—	—	5	Read USBCMD[ATDTW]: • If the field is 0, go back to step 3. • If the field is 1, move forward to step 6.
—	—	6	Write 0 to USBCMD[ATDTW]: • If the status field read at step 4 is 1, the procedure is complete. • If the status field read at step 4 is 0, then go to step 1 of case 1.

32.3.6.6.4 Transfer completion

After you initialize a dTD and prime the associated endpoint, the device controller executes the transfer on the host-initiated request. The DCD is notified with a USB interrupt if the Interrupt On Complete (IOC) bit in the dTD is set. Alternately, the DCD can poll Endpoint Complete (ENDPTCOMPLETE) to find when the dTD was executed. After a dTD is executed, the DCD can also check the associated status bits to determine execution success or failure.

NOTE

Multiple dTDs can be completed in a single endpoint-complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that are complete (the Active bit in the dTD Status field is cleared).

By reading the status fields of the completed dTDs, the DCD can determine whether the transfers completed successfully. The following combination of status bits determine the transfer completion success:

- Active = 0
- Halted = 0
- Transaction Error = 0

- Data Buffer Error = 0

If any combination other than the aforementioned one exists, the DCD must take proper action. Device error matrix indicates the transfer failure mechanisms.

In addition to checking the status bit, the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the total bytes transferred is decremented by the actual bytes transferred. For transmit packets, a packet is considered complete only after the actual byte count is zero. For receive packets, the host can send fewer bytes in the transfer according to the USB variable length packet protocol.

32.3.6.6.5 Flushing and de-priming an endpoint

The DCD must flush to de-prime another endpoint on a USB device reset or during a broken control transfer.

Some application-specific requirements may exist to stop transfers in progress. The DCD can perform the following procedure to stop a transfer in progress:

1. Write 1 to the corresponding field(s) in Endpoint Flush (ENDPTFLUSH).
2. Wait until all fields in Endpoint Flush (ENDPTFLUSH) become 0.

   NOTE

   This operation may take quite a long time, depending on the USB bus activity. You must not have this wait loop within an interrupt service routine.

3. Read Endpoint Status (ENDPTSTAT) to ensure that the corresponding fields are now 0 for all endpoints commanded to be flushed. The following is the reason for a flush failure, if the corresponding bits are still 1 after completion of step 2:

   In very rare cases, a packet is already in progress to a particular endpoint when the previous endpoint commands the flush operation by writing to Endpoint Flush (ENDPTFLUSH). A safeguard is in place to refuse the flush, to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1–3 until each endpoint is successfully flushed.

32.3.6.6.6 Device error matrix

Table 303 summarizes packet errors that the device controller does not manage automatically.

Table 303. Device error matrix

Error	Direction	Packet type	Data buffer error bit	Transaction error bit
Overflow	RX	Any	1	0
ISO packet error	RX	ISO	0	1
ISO fulfillment error	Both	ISO	0	1

The device controller manages all errors on bulk, control, and interrupt endpoints, except for a data buffer overflow. However, for ISO endpoints, error packets are not retried and errors are tagged as indicated in Table 304.

Table 304. Error descriptions

Error	Description
Overflow	Indicates that the number of bytes received exceeded the maximum packet size or total buffer length.

Table continues on the next page...

Table 304. Error descriptions (continued)

Error	Description
	This error also sets the Halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, then those are not executed.
ISO packet error	Indicates a CRC error on the received ISO packet. Contents are not guaranteed to be correct.
ISO fulfillment error	Indicates that the host failed to complete the number of packets, defined in the dQH MULT field, within the given microframe. For scheduled data delivery, the DCD may need to readjust the data queue because a fulfillment error causes the device controller to cease data transfers on the pipe for one microframe. During the dead microframe, the device controller reports an error on the pipe and primes for the following frame.

32.3.6.7 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency, and error operations, and consider the order of interrupts accordingly.

32.3.6.7.1 High-frequency interrupts

You must manage high-frequency interrupts in the order shown in the following table. The most important of these is listed first because the DCD must acknowledge a setup buffer as promptly as possible.

Table 305. High-frequency interrupt events

Execution order	Interrupt	Action
1a	USB interrupt (see Endpoint Setup Status (ENDPTSETUPSTAT))	Copy the contents of the setup buffer and acknowledge the setup packet (as indicated in Figure 152). Process the setup packet according to USB 2.0 chapter 9 or the application-specific protocol.
1b	USB interrupt[1] (see Endpoint Complete (ENDPTCOMPLETE))	Handle the completion of dTD as indicated in Figure 152.
2	SOF interrupt	Perform the action that the application considers necessary. This interrupt may not be used in all applications.

1. It is common for multiple interrupts to stack up on any call to and during the interrupt service routine.

32.3.6.7.2 Low-frequency interrupts

Low-frequency interrupts do not occur often compared to high-frequency interrupts. You can handle low-frequency interrupts in any order.

Table 306. Low-frequency interrupt events

Interrupt	Action
Port change	Change software state information.
Sleep enable (suspend)	Change software state information. Perform low-power handling as necessary.
Reset received	Change software state information. Terminate pending transfers.

32.3.6.7.3 Error interrupts

Error interrupts are infrequent. You must place them last in the interrupt service routine.

Table 307. Error interrupt events

Interrupt	Action
USB error interrupt	This error is redundant because it combines a USB interrupt and an error status in the dTD. The DCD handles packet-level errors more appropriately by checking the dTD status field upon receipt of the USB interrupt (by using Endpoint Complete (ENDPTCOMPLETE)).
System error	Unrecoverable error that requires immediate reset of core; you must free up transfer buffers in progress and restart the DCD.

32.3.7 Modes of operation

USB includes two main modes of operation: Normal mode and Low-Power mode. Each USB OTG controller core can operate at high speed (480 Mbps), full speed (12 Mbps), and low speed (1.5 Mbps).

32.3.7.1 Normal mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

Each controller supports only the interface type listed in this section. Selecting a different interface type in the PORTSC1[PTS] field results in an unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.

32.3.7.2 Low-Power mode

Each USB controller core has a low-power mode (Suspend mode) to save power.

As the USB 2.0 specification describes, the device can go into the Suspend state after it sees a constant Idle state on the upstream-facing port (UFP). The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. The host controller does not suspend automatically; you can place it in Suspend mode.

Either the local Arm platform, the remote USB host, or a peripheral can initiate a wake-up sequence to resume USB communication. For more information on Suspend and Resume states, see Power control.

32.3.7.2.1 Power control

USB supports suspend and wake-up functionalities.

The power control block allows you to place the transceiver in Low-Power mode when the USB bus is in the Idle state, and supports local and remote wake-up to bring the transceiver out of Low-Power mode, when needed. Additionally, the power control block can wake up the Arm platform by generating an interrupt.

32.3.7.2.1.1 Entering low-power Suspend mode

In Host Operation mode, low-power Suspend mode is entered as follows:

1. If needed, set UTMIPHY_CFG1[COMMONONN] to power down most analog blocks and stop clocks during Suspend mode.
2. Write 0 to USBCMD[ASE] and USBCMD[PSE], and wait until USBCMD[AS] and USBCMD[PS] become 0.

3. Write 1 to PORTSC1[SUSP].
4. Write 1 to PORTSC1[PHCD].

NOTE

Step 3 shall be done in atomic operation. That is, interrupt should be disabled during this step.

For Device Operation mode, low-power Suspend mode is entered as follows:

1. If needed, set UTMIPHY_CFG1[COMMONONN] to power down most analog blocks and stop clocks during Suspend mode.
2. After the host drive is in the Idle state for 3 ms, an SLI interrupt is issued (USBSTS[SLI]).
3. Write 1 to PORTSC1[PHCD].

NOTE

Step 2 shall be done in atomic operation. That is, interrupt should be disabled during this step.

32.3.7.2.1.2 Wake-up events

The power control block monitors the USB bus when the USB core is in the USB Suspend state.

Depending on whether the controller is in Host or Device mode, the core monitors a number of wake-up conditions. If the related wake-up interrupt enable field is 1, an interrupt is generated to the Arm platform upon detection of a wake-up condition.

The USB wake-up interrupt also reactivates the Arm platform clocks if they are stopped during the Suspend state.

32.3.7.2.1.2.1 Host mode events

The host controller wakes up after any of the following events:

- Remote wake-up request: A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM or DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on the DM or DP line is detected.
- Wake-up on overcurrent: If a wake-up on overcurrent is enabled (PORTSC1[WKOC] = 1), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.
- Wake-up on disconnect: If wake-up on disconnect is enabled (PORTSC1[WKDC] = 1), the power control block sends a wake-up request to the USB core when a disconnection event is detected (a J-SE0 or K-SE0 transition on the DM or DP line).
- Wake-up on connect: If a wake-up on connect is enabled (PORTSC1[WKCN] = 1), the power control block sends a wake-up request to the USB core when a connection event is detected (an SE0-J or SE0-K transition on the DM or DP line).

32.3.7.3 Disable mode

To disable the USBPHY analog to achieve low power:

1. Write 0 to UTMIPHY_CFG2[DRVVBUS0] to disable the VBUS valid comparator.
2. Write 1 to UTMIPHY_CFG1[PHY_POR_SW] to reset all test registers and state machines in the PHY.

32.3.8 Clocking

The following are USB clock sources:

- AHB bus clock
- Peripheral access clock
- PL301 peripheral clock

See the "Clock Controller (CLKCTL)" chapter for clock setting, configuration, and gating information.

32.3.9 Reset

Table 308. USB high-speed PHY resets

Reset	Description
Chip reset	Resets the USB controller logic and registers to their default states.
USB controller reset (USBCMD[RST])	Resets the controller. The host or device controller writes 0 to this field after the reset process is complete. You cannot terminate the reset process early by writing 0 to this register.

32.3.10 Interrupts

32.3.10.1 USB core interrupts

The USB core uses a dedicated vector in the interrupt table. In the Interrupt section, you can find the vector numbers for each core.

With the exception of wake-up interrupts, the USB core controls all interrupt sources. See Interrupt Enable (USBINTR) for more information.

32.3.10.2 USB wake-up interrupts

The USB core has an associated wake-up interrupt. These interrupts are generated outside the USB core, but use the same vector as the corresponding USB core interrupt.

The power control blocks generate these interrupts, which run on a low-power, low-speed clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled so that a wake-up condition on the USB bus can reactivate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a low-power, low-speed clock, this interrupt request responds very slowly to clear actions. For this reason, you must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously because it is clocked by the Arm platform clock. You must wait for at least three low-power clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is used only during USB low-power modes, it is sufficient to enable the wake-up interrupt just prior to entering the USB Suspend mode.

32.4 External signals

Table 309. External signals

Signal	Description
OTGn_DN	DN OTG signal
OTGn_DP	DP OTG signal
OTGn_ID	ID signal
OTGn_OC	OTG external input for VBUS overcurrent detection
OTGn_PWR	To control PMIC to supply VBUS voltage
USB2_VBUS	USB 5 V signal
USB2_TXRTUNE	Transmitter resistor tune pin

See the chip-specific USB information for the external signals that this chip supports.

32.5 Initialization

See Host controller initialization and Device controller initialization for information on initializing the USB controller.

32.6 Register interface

USB configuration, control, and status registers are divided into the categories shown in the following table.

EHCI registers are listed along with device registers to show the complementary nature of host and device control.

Table 310. Core register sets

Offset	Register sets	Functional description
000h–07Ch	Identification registers	• Used to declare the target interface presence • Include the complete set of hardware configuration parameters
100h–124h	Static, read-only capability registers	• Define the software limits, restrictions, and capabilities of host and device controller implementation • Used as parameters for the host and device controller driver
080h–0FCh 140h–1FCh	Operational registers	• Dynamic control or status registers that can have read-only, read/write, or read/write-to-clear accesses • Used to control and monitor the operational state of the host and device controller

NOTE

- USB control registers support only DWORD (32-bit) accesses.
- You must not access reserved addresses in the memory map. If you do so, there is no bus error response.

32.6.1 Configuration, control, and status register sets

NOTE

Depending on implementation, "*x*" can have the following values: UOG1, UOG2.

Table 311. Device and host capability registers

Offset (hex)	Size (bytes)	Register name and mnemonic	Device mode	Host mode
000	4	Identification (ID)	O[1]	O
004	4	Hardware General (HWGENERAL)	O	O
008	4	Host Hardware Parameters (HWHOST)	X[2]	O
00C	4	Device Hardware Parameters (HWDEVICE)	O	X
010	4	TX Buffer Hardware Parameters (HWTXBUF)	O	O
014	4	RX Buffer Hardware Parameters (HWRXBUF)	O	O

Table continues on the next page...

Table 311. Device and host capability registers (continued)

Offset (hex)	Size (bytes)	Register name and mnemonic	Device mode	Host mode
018–07F	—	Reserved	—	—
080	4	General Purpose Timer 0 Load (GPTIMER0LD)	O	O
084	4	General Purpose Timer 0 Controller (GPTIMER0CTRL)	O	O
088	4	General Purpose Timer 1 Load (GPTIMER1LD)	O	O
08C	4	General Purpose Timer 1 Controller (GPTIMER1CTRL)	O	O
090	4	System Bus Configuration (SBUSCFG)	O	O

Table 311. Device and host capability registers (continued)

Offset (hex)	Size (bytes)	Register name and mnemonic	Device mode	Host mode
	4	Endpoint List Address (ENDPTLISTADDR)	O	X
15C	4	Reserved	—	—
160	4	Programmable Burst Size (BURSTSIZE)	O	O
164	4	TX FIFO Fill Tuning (TXFILLTUNING)	X	O
168	4	Reserved	—	—
170	4	Reserved	—	—
178	4	Endpoint NAK (ENDPTNAK)	O	X
17C	4	Endpoint NAK Indication Enable (ENDPTNAKEN)	O	X
184	4	Port Status and Control (PORTSC1)	O	O
188–1A3	—	Reserved	—	—
1A4	4	On-The-Go Status and Control (OTGSC)	O	O
1A8	4	USB Device Mode (USBMODE)	O	O
1AC	4	Endpoint Setup Status (ENDPTSETUPSTAT)	O	X
1B0	4	Endpoint Prime (ENDPTPRIME)	O	X
1B4	4	Endpoint Flush (ENDPTFLUSH)	O	X
1B8	4	Endpoint Status (ENDPTSTAT)	O	X
1BC	4	Endpoint Complete (ENDPTCOMPLETE)	O	X
1C0 1C4 1C8 1CC 1D0 1D4 1D8 1DC	64	Endpoint Control 0 (ENDPTCTRL0) Endpoint Control 1 (ENDPTCTRL1) Endpoint Control 2 (ENDPTCTRL2) Endpoint Control 3 (ENDPTCTRL3) Endpoint Control 4 (ENDPTCTRL4) Endpoint Control 5 (ENDPTCTRL5) Endpoint Control 6 (ENDPTCTRL6) Endpoint Control 7 (ENDPTCTRL7)	O	X

1. O means that the register is available in Host and Device operation modes.
2. X means that the register is reserved in Host and Device operation modes.

32.6.2 Identification registers

USB uses identification registers to declare the target interface presence. They include hardware configuration parameters.

32.6.3 OTG operations

32.6.3.1 Register fields used for OTG operations

The behavior descriptions of Device mode and Host mode are provided in Register interface. However, for OTG operations, it is necessary to perform tasks independent of Controller mode.

NOTE

The only way to transit Controller mode out of Host or Device mode is by using USBCMD[RST]. Therefore, it is also necessary for the OTG tasks to be performed independent of a controller reset and Controller mode.

The following figure shows Controller mode.

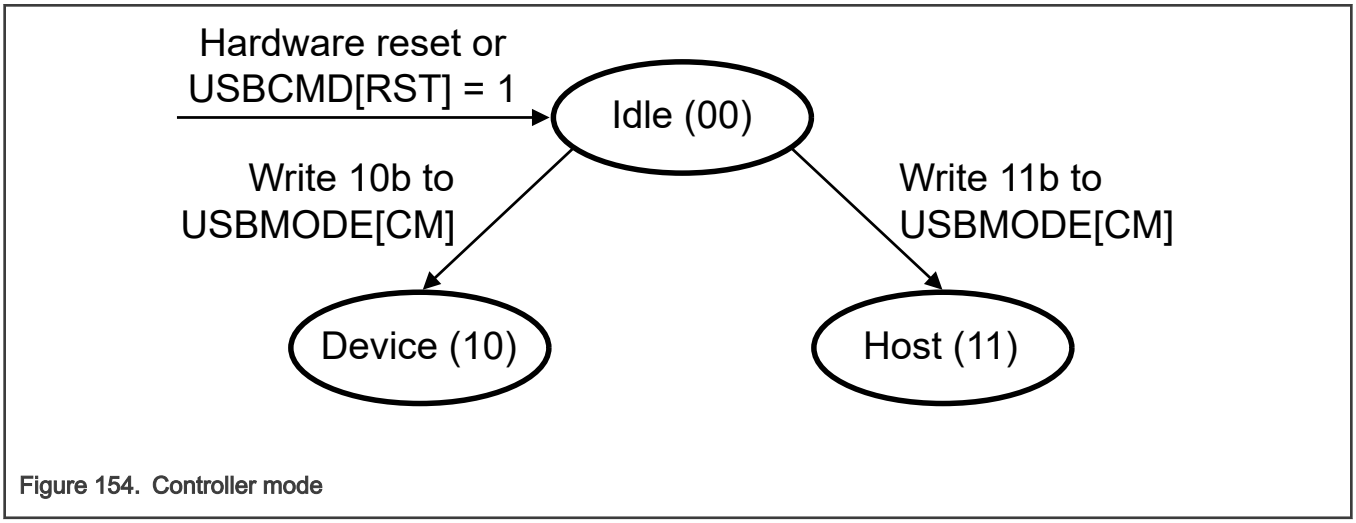

Figure 154. Controller mode

Following are the registers and register fields that are used for OTG operations, which are independent of Controller mode and are also not affected by a write to USBCMD[RST]:

- All identification registers
- All device and host capability registers
- All fields in On-The-Go Status and Control (OTGSC)

Additionally, the following fields of Port Status and Control (PORTSC1) are used:

- Physical interface serial select
- Physical interface data width
- Physical interface low power
- Physical interface wake signals
- Port indicators
- Port power

32.7 Register descriptions

There are two kinds of registers in the USB module: USB core (USBC) registers and USB noncore (USBNC) registers.

USBC registers are used to control USB core functions and are more independent of USB features. Each USB controller core has its own core registers.

USBNC registers are additional to USBC registers and are more dependent on USB features. For detailed descriptions of USBC registers, see Register interface. Section USBNC memory map describes only the USBNC registers.

NOTE

For reserved bits, preserve the value when writing (read the reset value, then write this value back).

32.7.1 USBC memory map

32.7.1.1 USBC register descriptions

32.7.1.1.1 USBC memory map

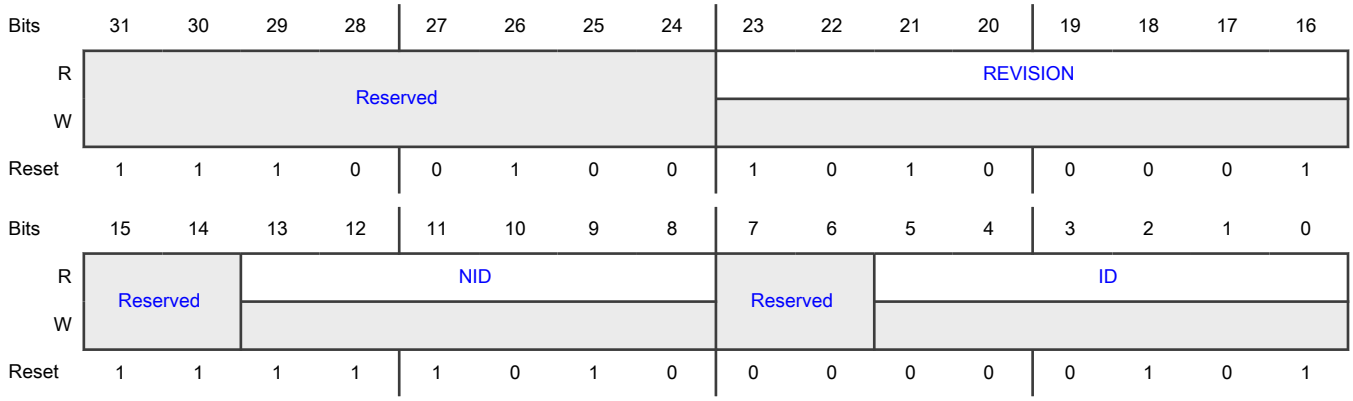
32.7.1.1.2 Identification (ID)

Identifies the USB 2.0 high-speed core and its revision.

Offset

Register	Offset
ID	0h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 REVISION	Revision Number Indicates the revision number of the controller core.
15-14 —	Reserved
13-8 NID	Complement Version Indicates the complement version of the ID.
7-6 —	Reserved
5-0 ID	Configuration Number Indicates the configuration number (05h) and signifies that the peripheral is USB 2.0 HS core.

32.7.1.1.3 Hardware General (HWGENERAL)

Indicates general hardware parameters as defined in system-level issues and core configuration.

NOTE

The reset value can vary from instance to instance. Therefore, for more accurate information, see field descriptions and ignore their reset values.

Offset

Register	Offset
HWGENERAL	4h

R	Reserved								TXBURST							
W																
Reset	0	0	0	0	1	0	1	1	0	0	0	0	1	0	0	0

Fields

Field	Description
31-24 —	Reserved
23-16 TXCHANADD	TX Channel Add Indicates the TX FIFO buffer size.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The TX FIFO buffer size is (2^TXCHANADD) × 4 bytes. This field becomes 08h, so the buffer size is 256 × 4 bytes. For the OTG controller operating in Device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoints, there are eight of these buffers. For the OTG controller operating in Host mode, or for host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only one of this buffer.
15-8 —	Reserved
7-0 TXBURST	TX Burst Indicates the default burst size for memory to TX buffer transfer. This is the reset value of fields in BURSTSIZE.

32.7.1.1.7 RX Buffer Hardware Parameters (HWRXBUF)

Indicates RX buffer hardware parameters, such as the default burst size and total buffer size.

Offset

Register	Offset
HWRXBUF	14h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-16	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
15-8 RXADD	RX Add Indicates the RX FIFO buffer size. The total buffer size for all receive endpoints is (2^RXADD). RX buffer size is (2^RXADD) × 4 bytes. This field becomes 08h, so buffer size is 256 × 4 bytes. There is a single receive FIFO buffer in the USB controller. The buffer is shared for all endpoints for the OTG controller in Device mode.
7-0 RXBURST	RX Burst Indicates the default burst size for memory to RX buffer transfer. This is the reset value of fields in Programmable Burst Size (BURSTSIZE).

32.7.1.1.8 General Purpose Timer 0 Load (GPTIMER0LD)

Controls the load value of the count timer in General Purpose Timer 0 Controller (GPTIMER0CTRL).

Offset

Register	Offset
GPTIMER0LD	80h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	GPTLD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-24	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
23-0 GPTLD	General Purpose Timer Load Value Indicates the general purpose timer load value. This value represents the time in microseconds minus 1 for the timer duration. The value of this field is loaded to GPTIMER0CTRL[GPTCNT], if GPTIMER0CTRL[GPTRST] is 1. For example, for a one millisecond timer, load 1000 - 1 = 999 (or 0003E7h). **NOTE** The maximum value is FFFFFFh or 16.777215 seconds.

32.7.1.1.9 General Purpose Timer 0 Controller (GPTIMER0CTRL)

Contains the control for the general purpose countdown timer 0. A data field can be queried to determine the running count value. This timer has granularity on 1 µs and you can program it to a little over 16 seconds. There are two counter modes that are described in the register. When the timer counter value transitions to zero, an interrupt could be generated if enabled.

USBSTS[TI0] is the interrupt status field, and USBINTR[TIE0] is the interrupt enable field.

Offset

Register	Offset
GPTIMER0CTRL	84h

Fields

Field	Description
31	General Purpose Timer Run

Table continues on the next page...

Table continued from the previous page...

Field	Description
GPTRUN	Specifies whether the general purpose timer is running or has stopped counting. GPTIMER0CTRL[GPTCNT] is not impacted when writing 1 or 0 to this field. 0 - Stop counting 1 - Run
30 GPTRST	General Purpose Timer Reset Loads the counter value from GPTIMER0LD[GPTLD]. 0 - No action 1 - Load counter value
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode Specifies the general purpose timer mode. In One Shot mode, the timer counts down to zero, generates an interrupt, and halts until you reset the counter. In Repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter value from GPTIMER1LD[GPTLD] to start again. 0 - One Shot mode 1 - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Indicates the count value of the countdown timer.

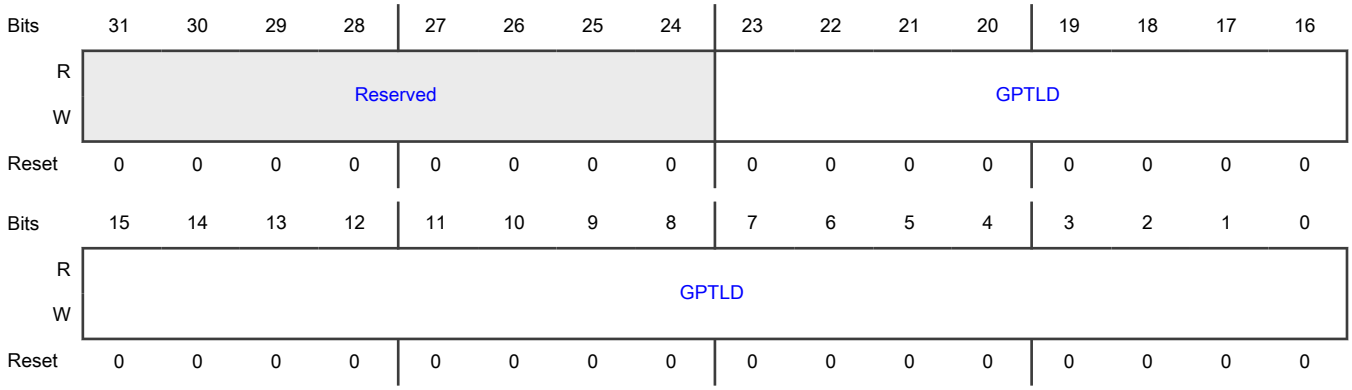
32.7.1.1.10 General Purpose Timer 1 Load (GPTIMER1LD)

Controls the load value of the count timer in General Purpose Timer 1 Controller (GPTIMER1CTRL).

Offset

Register	Offset
GPTIMER1LD	88h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value Indicates the general purpose timer load value. This value represents the time in microseconds minus 1 for the timer duration. The value of this field is loaded to GPTIMER0CTRL[GPTCNT] if GPTIMER0CTRL[GPTRST] is 1. For example, for a one millisecond timer, load 1000 - 1 = 999 (or 0003E7h). **NOTE** The maximum value is FFFFFFh or 16.777215 seconds.

32.7.1.1.11 General Purpose Timer 1 Controller (GPTIMER1CTRL)

Contains the control for the general purpose countdown timer 1. A data field can be queried to determine the running count value. This timer has granularity on 1 µs and you can program it to a little over 16 seconds. There are two counter modes that are described in this register. When the timer counter value transitions to zero, an interrupt can be generated if it is enabled.

USBSTS[TI1] is the interrupt status field, and USBINTR[TIE1] is the interrupt enable field.

Fields

Field	Description
31 GPTRUN	General Purpose Timer Run Specifies whether the general purpose timer is running or has stopped counting. GPTIMER0CTRL[GPTCNT] is not impacted when writing 1 or 0 to this field. 0 - Stop counting 1 - Run
30 GPTRST	General Purpose Timer Reset Loads counter value from GPTIMER0LD[GPTLD]. 0 - No action 1 - Load counter value
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode Indicates the general purpose timer mode. In One Shot mode, the timer counts down to zero, generates an interrupt, and stops until you reset the counter. In Repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter value from GPTLD bits to start again. 0 - One Shot mode 1 - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Indicates the count value of the countdown timer.

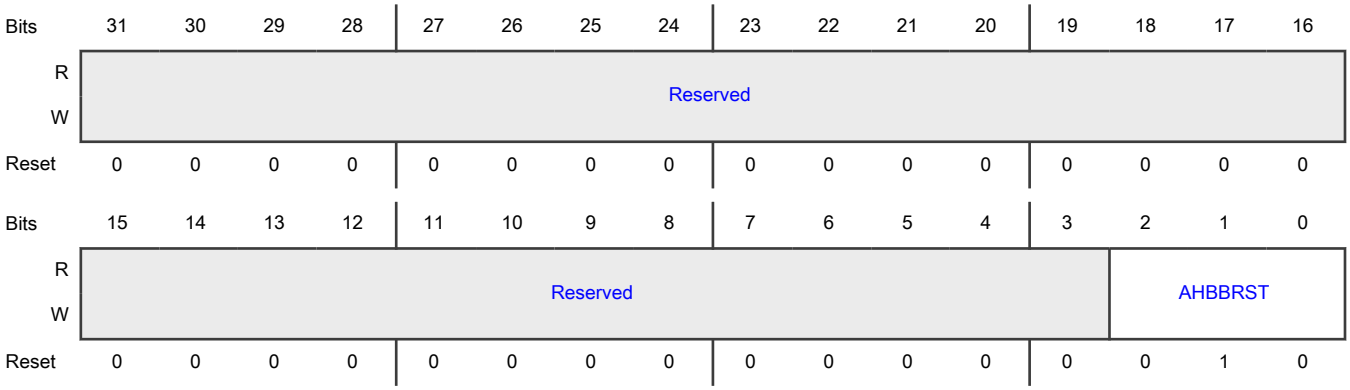
32.7.1.1.12 System Bus Configuration (SBUSCFG)

Defines the system bus configuration.

Offset

Register	Offset
SBUSCFG	90h

Diagram



Fields

Field	Description
31-3 —	Reserved
2-0 AHBBRST	AHB Controller Interface Burst Configuration Controls the AHB controller transfer type sequence (or priority). **NOTE** This register overrides Programmable Burst Size (BURSTSIZE) when the value of AHBBRST is not zero. 000 - Incremental burst of unspecified length only 001 - INCR4 burst, then single transfer 010 - INCR8 burst, INCR4 burst, then single transfer 011 - INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100 - Reserved; do not use 101 - INCR4 burst, then incremental burst of unspecified length 110 - INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111 - INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

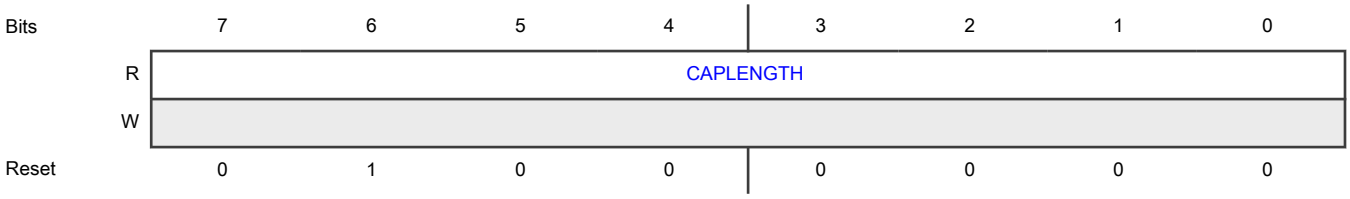
32.7.1.1.13 Capability Registers Length (CAPLENGTH)

Contains the address offset to the operational registers relative to the CAPLENGTH register.

Offset

Register	Offset
CAPLENGTH	100h

Diagram



Fields

Field	Description
7-0 CAPLENGTH	Capability Length Indicates the capability length. This field is used as an offset to add to the register base to find the beginning of the operational register. The default value is 40h.

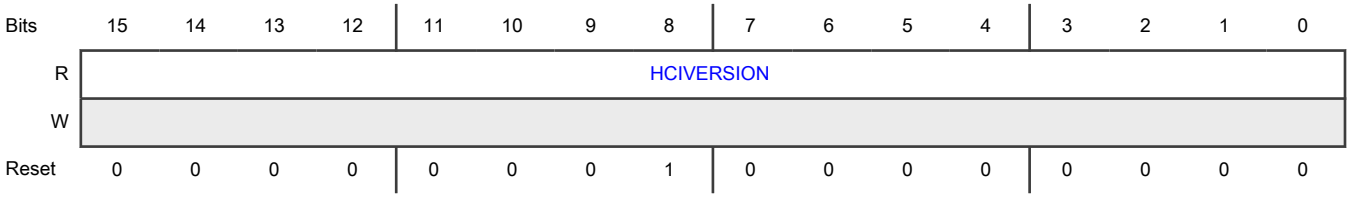
32.7.1.1.14 Host Controller Interface Version (HCIVERSION)

Contains a BCD encoding of the EHCI revision number that this host controller supports. The most significant byte of this register represents a major revision and the least significant byte indicates the minor revision.

Offset

Register	Offset
HCIVERSION	102h

Diagram



Fields

Field	Description
15-0 HCIVERSION	Host Controller Interface Version Number Indicates the host controller interface version number. The default value is 10h, which specifies EHCI rev1.0.

32.7.1.1.15 Host Controller Structural Parameters (HCSPARAMS)

Indicates the port steering logic capabilities of the host control structural parameters (HCSPARAMS).

Offset

Register	Offset
HCSPARAMS	104h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-28 —	Reserved
27-24 N_TT	Number of Transaction Translators Indicates the number of embedded transaction translators associated with the USB 2.0 host controller. The value of this field is 0001b for multi-port host, and 0000b for single-port host. The default value of this field is 0000b.
23-20 N_PTT	Number of Ports Per Transaction Translator Indicates the number of ports assigned to each transaction translator within the USB 2.0 host controller. The value of this field is equal to that of N_PORTS for a multi-port host, and 0000b for a single-port host. The default value of this field is 0000b.
19-17 —	Reserved
16 PI	Port Indicators (P_INDICATOR) Indicates whether the ports support port indicator control.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If this field is 1, the port status and control registers include an R/W field for controlling the state of the port indicator. The value of this field is 1b in all controller cores.
15-12 N_CC	Number of Companion Controller Indicates the number of companion controllers associated with this USB 2.0 host controller. The value of this field is 0000b in all controller cores. If this field is 0, there is no internal companion controller and port-ownership hand-off is not supported. If this field is 1, internal companion controllers exist and port-ownership hand-offs are supported. 0000 - No internal companion controller exists 0001 - Internal companion controllers exist
11-8 N_PCC	Number of Ports Per Companion Controller Indicates the number of ports supported per internal companion controller. This field is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, and so on. In the previous example, N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last 2 are routed to companion controller 2. The value of this field must be consistent with that of N_PORTS and N_CC. The value of this field is 0000b in all controller cores.
7-5 —	Reserved
4 PPC	Port Power Control Indicates whether the host controller implementation includes port power control. The value of this field affects the functionality of PORTSC1[PP] in each port status and control register. 0 - No port power switches 1 - Port power switches exist
3-0 N_PORTS	Number of Ports Indicates the number of downstream ports. This field indicates the number of physical downstream ports implemented on this host controller. The value of this field determines the number of port registers that are addressable in the operational register. The range of valid values is 1h–Fh. A zero in this field is undefined. The value of this field is always 0001b because all controller cores are single-port hosts.

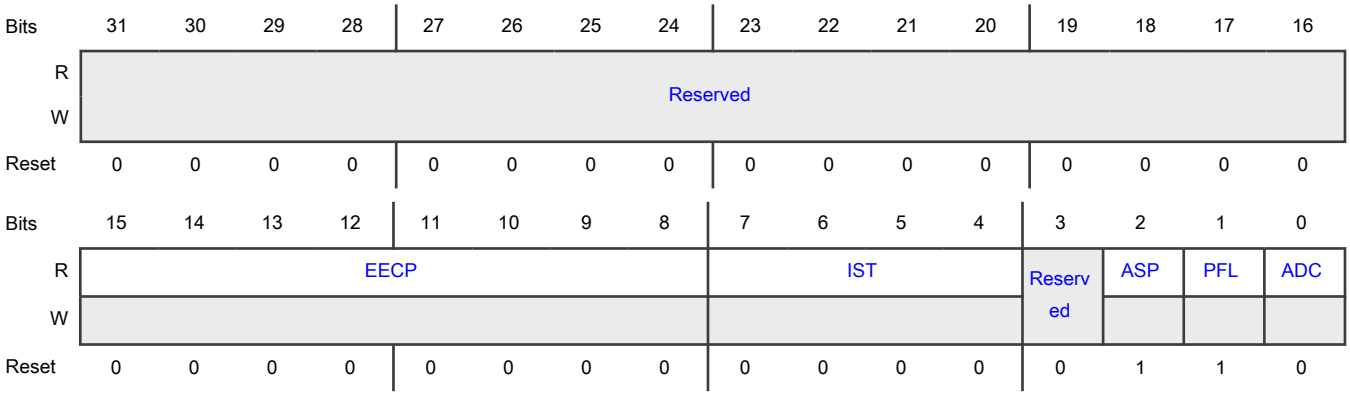
32.7.1.1.16 Host Controller Capability Parameters (HCCPARAMS)

Identifies multiple mode control (time-base bit functionality) and addressing capability.

Offset

Register	Offset
HCCPARAMS	108h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-8 EECP	EHCI Extended Capabilities Pointer Indicates the existence of a capabilities list. A value of 00h indicates that no extended capabilities are implemented. A nonzero value in this field indicates the offset of the first EHCI extended capability in the PCI configuration space. The pointer value must be 40h or greater (if implemented) to maintain the consistency of the PCI header defined for this class of device. **NOTE** The value of this field is 00h in all controller cores.
7-4 IST	Isochronous Scheduling Threshold Indicates, relative to the current position of the executing host controller, where you can reliably update the isochronous schedule. When bit[7] of this field is 0, the value of the least significant three bits indicates the number of microframes during which a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit[7] is 1, then the host software assumes the host controller may cache an isochronous data structure for an entire frame. The value of this field is 00h in all controller cores.
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
2 ASP	Asynchronous Schedule Park Capability Indicates whether the park feature for HS queue heads is supported. If this field is 1, then the host controller supports the park feature for high-speed queue heads in the asynchronous schedule. You can enable or disable this feature and set it to a specific level by using USBCMD[ASPE] and USBCMD[ASP]. **NOTE** ASP bit reset value: 00b for OTG controller core; 11b for host-only controller core.
1 PFL	Programmable Frame List Flag Indicates the frame list length. If this flag is 0, you must use a frame list length of 1024 elements with this host controller. You must write 0 to USBCMD[FS_2] and USBCMD[FS_1]. If this flag is 1, you can specify and use a smaller frame list and configure the host controller via USBCMD[FS_2] and USBCMD[FS_1]. The frame list must always be aligned on a 4 KB page boundary. This requirement ensures that the frame list is always physically contiguous. The value of this flag is 1 in all controller cores.
0 ADC	Addressing Capability Indicates 64-bit addressing capability. This field is 0b in all controller cores, and 64-bit addressing capability is not supported.

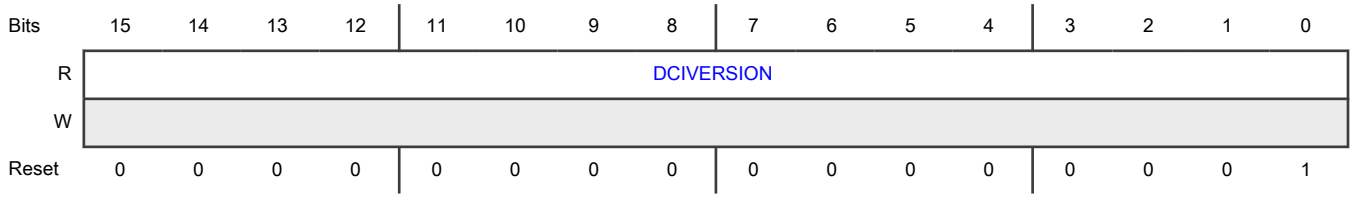
32.7.1.1.17 Device Controller Interface Version (DCIVERSION)

Indicates the 2-byte BCD encoding of the device controller interface version number.

Offset

Register	Offset
DCIVERSION	120h

Diagram



Fields

Field	Description
15-0 DCIVERSION	Device Controller Interface Version Number Indicates the device controller interface version number. The default value of this field is 01h, which specifies rev 0.1.

32.7.1.1.18 Device Controller Capability Parameters (DCCPARAMS)

Indicates the overall device capability of the controller.

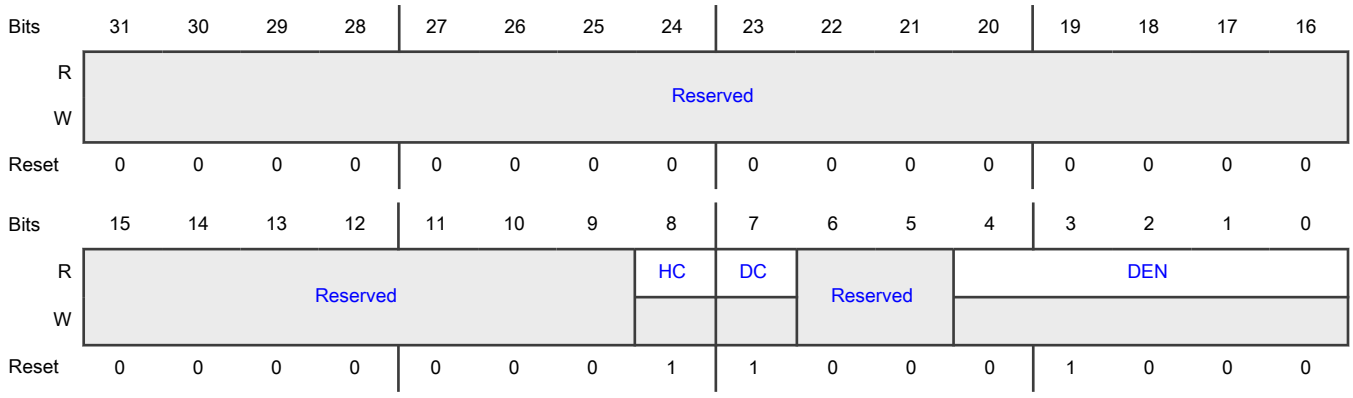
NOTE

This register is only available in the OTG controller core.

Offset

Register	Offset
DCCPARAMS	124h

Diagram



Fields

Field	Description
31-9	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
8 HC	Host Capable Indicates whether the controller is capable of operating as an EHCI-compatible USB 2.0 host controller. 0 - Not host capable 1 - Host capable
7 DC	Device Capable Indicates whether the controller is capable of operating as a USB 2.0 device. 0 - Not device capable 1 - Device capable
6-5 —	Reserved
4-0 DEN	Device Endpoint Number Indicates the number of endpoints built into the device controller. Valid values are 0–15. 0_0000 - Not device capable 0_0001 - Device capable

32.7.1.1.19 USB Command (USBCMD)

Indicates the command that the serial bus host or device controllers must execute. Writing to the register causes a command to be executed.

Offset

Register	Offset
USBCMD	140h

Fields

Field	Description
31-24 —	Reserved
23-16 ITC	Interrupt Threshold Control Sets the maximum rate at which the host or device controller issues interrupts. ITC contains the maximum interrupt interval, measured in microframes. The following values are the valid maximum interrupt intervals: 0000_0000 - Immediate (no threshold) 0000_0001 - 1 microframe 0000_0010 - 2 microframes 0000_0100 - 4 microframes 0000_1000 - 8 microframes 0001_0000 - 16 microframes 0010_0000 - 32 microframes 0100_0000 - 64 microframes
15 FS_2	Frame List Size 2 (Host mode only) Specifies the size of the frame list that controls which fields in USB Frame Index (FRINDEX) you must use for the frame list current index. This field is both readable and writable only if HCCPARAMS[PFL] is 1; otherwise, it is only readable. **NOTE** This field is made up of USBCMD bits 15, 3, and 2. 0b000 - 1024 elements (4096 bytes) (default value) 0b001 - 512 elements (2048 bytes) 0b010 - 256 elements (1024 bytes) 0b011 - 128 elements (512 bytes) 0b100 - 64 elements (256 bytes) 0b101 - 32 elements (128 bytes) 0b110 - 16 elements (64 bytes) 0b111 - 8 elements (32 bytes)
14 ATDTW	Add dTD TripWire (Device mode only) Works as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. You write 1 and 0 to this field; however, the hardware can also write 0 to the field when the state machine is in the hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13	Setup TripWire (Device mode only)

Table continues on the next page...

Table continued from the previous page...

Field	Description
SUTW	Works as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a queue head by the DCD without being corrupted. If the Setup Lockout mode is off (USBMODE[SLOM] is 1), then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the queue head of a previous setup packet. You write 1 and 0 to this field; however, the hardware can also write 0 to the field if a hazard is detected.
12 —	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable Enables Park mode. If HCCPARAMS[ASP] is 1, then this field defaults to 1h, with R/W as its access type. Otherwise, the field is 0, with access type RO. **NOTE** ASPE bit reset value: '0b' for OTG controller . 0 - Disable 1 - Enable
10 —	Reserved
9-8 ASP	Asynchronous Schedule Park Mode Count Contains a count of the number of successive transactions that the host controller is allowed to execute from an HS queue head on the asynchronous schedule, before continuing traversal of the asynchronous schedule. If HCCPARAMS[ASP] is 1, then this field defaults to 3h, with R/W as the access type. Otherwise, the field defaults to 0, with access type RO. Valid values are 1h to 3h. You must not write 0 to this field when USBCMD[ASPE] is 1. Doing so leads to undefined behavior. This field is 3h for all controller cores.
7 —	Reserved
6 IAA	Interrupt on Async Advance Doorbell Acts as a doorbell for the host controller to issue an interrupt the next time it advances asynchronous schedule. You must write 1 to this field to ring the doorbell. After the host controller evicts all appropriate cached schedule states, it writes 1 to USBSTS[AAI]. If USBINTR[AAE] is 1, then the host controller asserts an interrupt at the next interrupt threshold.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The host controller writes 0 to this field after it writes 1 to USBSTS[AAI]. You must not write 1 to this field when the asynchronous schedule is inactive. Doing so yields undefined results. This field is only used in Host mode. Writing 1 to this field in Device mode leads to undefined results.
5 ASE	Asynchronous Schedule Enable Determines whether the host controller skips processing the asynchronous schedule. If this field is 1, Next Asynchronous Address (ASYNCLISTADDR) is used to access the periodic schedule. If this field is 0 (the default value), the asynchronous schedule is not processed. Only the host controller uses this field. 0 - Do not process the asynchronous schedule 1 - Access the asynchronous schedule
4 PSE	Periodic Schedule Enable Determines whether the host controller skips processing the periodic schedule. If this field is 1, Frame List Base Address (PERIODICLISTBASE) is used to access the periodic schedule. If this field is 0 (the default value), the periodic schedule is not processed. Only the host controller uses this field. 0 - Do not process the periodic schedule 1 - Process the periodic schedule
3-2 FS_1	Frame List Size 1 See the description of USBCMD[FS_2].
1 RST	Controller Reset Resets the controller. Use this field to reset the controller. The host or device controller writes 0 to this field after the reset process is complete. You cannot terminate the reset process early by writing 0 to this field. In Host Operation mode, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values when you write 1 to this field. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. You must not write 1 to this field when USBSTS[HCH] is 0. Attempting to reset an actively running host controller results in undefined behavior. In Device Operation mode, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values when you write 1 to this field. Writing 1 to this field when the chip is in the attached state is not recommended because the effect on an attached host is undefined. To ensure that the chip is not in an attached state before initiating a device controller reset, all primed endpoints must be flushed and USBCMD[RS] must be 0.
0 RS	Run/Stop Specifies whether the controller is executing the operation.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	In Host Operation mode, the controller proceeds with the execution of the schedule if the value of this field is 1b. The controller continues the execution as long as this field is 1. If this field becomes 0 (the default value), the host controller completes the current transaction on the USB and then halts. The Halted bit in the Status field of the dTD token indicates when the controller has finished the transaction and has entered the Stopped state. You must not write 1 to this field unless the controller is in the Halted state (that is, USBSTS[HCH] = 1). In Device Operation mode, writing 1 to this field causes the controller to enable a pull-up on D+ and initiate an attach event. This control field is not directly connected to the pull-up enable because the pull-up becomes disabled upon transitioning into high-speed mode. You must use this field to prevent an attach event before the controller is properly initialized. Writing 0 to this field leads to a detach event. 0 - Stop executing 1 - Running

32.7.1.1.20 USB Status (USBSTS)

Indicates various states of the host and device controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Offset

Register	Offset
USBSTS	144h

Fields

Field	Description
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
25 TI1	General Purpose Timer Interrupt 1 (GPTINT1) Flag Indicates when the counter in General Purpose Timer 1 Controller (GPTIMER1CTRL) transitions to 0. This flag is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
24 TI0	General Purpose Timer Interrupt 0 (GPTINT0) Flag Indicates when the counter in General Purpose Timer 0 Controller (GPTIMER0CTRL) transitions to 0. This flag is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
23-20 —	Reserved
19 UPI	USB Host Periodic Interrupt Flag Indicates the cause of a periodic interrupt and whether a short packet is detected. The host controller sets this field when the cause of an interrupt is the completion of a USB transaction, where the transfer descriptor (TD) has the IOC field set and the TD is from a periodic schedule. The host controller also sets this field when a short packet (the actual number of bytes received is less than expected) is detected and the packet is on a periodic schedule. The device controller does not use this field; the field is always 0. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
18 UAI	USB Host Asynchronous Interrupt Flag Indicates the cause of an asynchronous interrupt and whether a short packet is detected. The host controller sets this flag when the cause of an interrupt is the completion of a USB transaction, where the transfer descriptor (TD) has the IOC field set and the TD is from an asynchronous schedule. The host controller also sets this flag when a short packet (the actual number of bytes received is less than expected) is detected and the packet is on an asynchronous schedule. The device controller does not use this field; the field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
17 —	Reserved
16 NAKI	NAK Interrupt Indicates whether a NAK interrupt is detected. Hardware sets this field, when both ENDPTNAK[EPTN] and ENDPTNAK[EPRN] are set for a particular endpoint, and their corresponding fields (ENDPTNAKEN[EPTNE] and ENDPTNAKEN[EPRNE]) are 1. When all enabled TX and RX endpoint NAK fields are cleared, this field is cleared automatically.
15 AS	Asynchronous Schedule Status Reports the current real status of the asynchronous schedule. If this field is 0, the asynchronous schedule status is disabled, and if this field is 1, the status is enabled. The host controller is not required to immediately disable or enable the asynchronous schedule when you transition USBCMD[ASE]. When this field and USBCMD[ASE] have the same value, the asynchronous schedule is either enabled (1) or disabled (0).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field is only used in Host Operation mode. 0 - Disabled 1 - Enabled
14 PS	Periodic Schedule Status Reports the current real status of the periodic schedule. If this field is 0, the periodic schedule is disabled, and if this field is 1, the status is enabled. The host controller is not required to immediately disable or enable the periodic schedule when software transitions USBCMD[PSE]. When this field and USBCMD[PSE] have the same value, the periodic schedule is either enabled (1) or disabled (0). This field is only used in Host Operation mode. 0 - Disabled 1 - Enabled
13 RCL	Reclamation Detects an empty asynchronous schedule. This field is only used in Host Operation mode. 0 - Not detected 1 - Detected
12 HCH	HC Halted Indicates whether the host controller is halted. This field is 0 whenever USBCMD[RS] is 1. The controller writes 1 to this field after it has stopped executing (because of USBCMD[RS] = 0), either by software or by the controller hardware (for example, in case of an internal error). This field is only used in Host Operation mode. The default value is 0b for the OTG core This is because the OTG core is not operating as host by default (see USBMODE[CM]). **NOTE** The reset value of HCH is 0b for the OTG controller core
11 —	Reserved
10 ULPII	ULPI Interrupt Flag Indicates an event completion in the ULPI viewport. Hardware sets this field to 1b when there is an event completion in the ULPI viewport. You can only use this flag if the controller supports UPLI Interface mode.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE This field behaves differently for register reads and writes. When reading 0 - Event completion did not occur 1 - Event completion occurred When writing 0 - No effect 1 - Clear the flag
9 —	Reserved
8 SLI	Device Controller Suspend Flag Indicates whether the device controller entered a suspended state. When a device controller enters a suspended state from an active state, this flag is set to 1. The device controller clears this flag upon exiting from a suspended state. This flag is used only in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Did not enter Suspended state 1 - Entered Suspended state When writing 0 - No effect 1 - Clear the flag
7 SRI	SOF Received Flag Indicates whether a start of (micro) frame (SOF) is received. When the device controller detects an SOF, this flag is set to 1. When the SOF is extremely late, the device controller automatically sets this field to indicate that an SOF is expected. Therefore, this flag is set roughly every 1 ms in device FS mode and every 125 ms in HS mode. It is synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this flag sets at an interval of 1 ms during the prelude to connect and chirp. In Host mode, this field sets every 125 µs; the host controller driver can use it as a time base. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When reading 0 - SOF not received 1 - SOF received When writing 0 - No effect 1 - Clear the flag
6 URI	USB Reset Received Flag Indicates whether a USB reset is received. When the device controller detects a USB reset and enters the default state, this flag is set to 1. This flag is used only in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - USB reset not received 1 - USB reset received When writing 0 - No effect 1 - Clear the flag
5 AAI	Interrupt on Async Advance Flag Indicates the assertion of the interrupt source. You can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing 1 to USBCMD[IAA]. This flag is used only in Host Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
4	System Error Flag Indicates an error response to a read on the system interface.

Table continues on the next page...

Table continued from the previous page...

Field	Description
SEI	This flag is set to 1 when an error response is seen to a read on the system interface. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Error response did not occur 1 - Error response occurred When writing 0 - No effect 1 - Clear the flag
3 FRI	Frame List Rollover Flag Indicates whether the frame list index rolled over. The host controller sets this flag to 1 when the frame list index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in USBCMD[FS_1] and USBCMD[FS_2]) is 1024, USB Frame Index (FRINDEX) rolls over every time FRINDEX[13] toggles. Similarly, if the size is 512, the host controller sets this flag to 1 every time FHINDEX[12] toggles. This field is used only in Host Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Frame list index did not roll over 1 - Frame list index rolled over When writing 0 - No effect 1 - Clear the flag
2 PCI	Port Change Detect Flag Indicates port change detection. The host controller sets this flag to 1 when a connect status occurs on any port, a port enable or disable change occurs, or PORTSC1[FPR] becomes 1 as the result of a J-K transition on the suspended port. The device controller sets this flag to 1 when the port controller enters the FS or HS operational state. When the port controller exits the FS or HS operation state because of reset or suspend events, the notification mechanisms are controlled by USBSTS[URI] and PORTSC1[SUSP], respectively. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - Port change not detected 1 - Port change detected When writing 0 - No effect 1 - Clear the flag
1 UEI	USB Error Interrupt (USBERRINT) Flag Indicates an error condition after the completion of a USB transaction. The host or device controller sets this flag after the completion of a USB transaction results in an error condition. This flag is set along with USBSTS[UI], if the TD on which the error interrupt occurred also has its IOC field set in the dTD token. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag
0 UI	USB Interrupt (USBINT) Flag Indicates the cause of an interrupt. The host or device controller sets this flag when the cause of an interrupt is the completion of a USB transaction where the transfer descriptor (TD) has its interrupt on complete (IOC) field set in the dTD token. The host or device controller also sets this field when a short packet is detected (the actual number of bytes received is less than the expected number of bytes). **NOTE** This field behaves differently for register reads and writes. When reading 0 - Interrupt did not occur 1 - Interrupt occurred When writing 0 - No effect 1 - Clear the flag

32.7.1.1.21 Interrupt Enable (USBINTR)

Enables interrupts to software. An interrupt is generated when a field in this register is 1 and the corresponding interrupt source is active. USB Status (USBSTS) still shows interrupt sources even if they are disabled by USBINTR, allowing you to poll the interrupt events.

Offset

Register	Offset
USBINTR	148h

32.7.1.1.22 USB Frame Index (FRINDEX)

Indexes the periodic frame list.

The host controller uses this register to index the periodic frame list. The register updates every 125 microseconds (once per microframe). Bits[*n*:3] are used to select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list that you define by using USBCMD[FS_2] and USBCMD[FS_1].

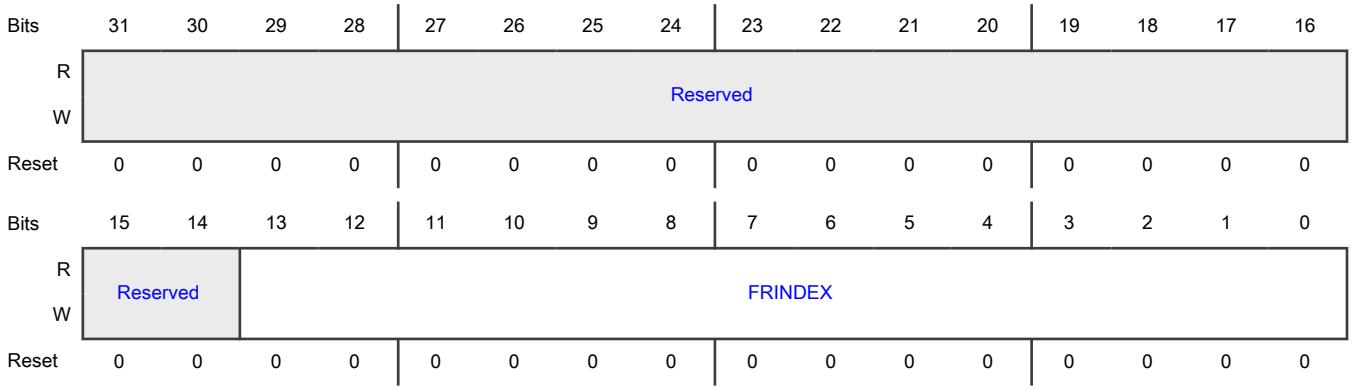
You must write to this register as a DWord. Byte writes produce undefined results. You cannot write to this register unless the host controller is in the Halted state, as indicated by USBSTS[HCH]. A write to this register, when USBCMD[RS] is 1, produces undefined results. Writes to this register also affect the SOF value.

In Device mode, this register is read-only and the device controller updates FRINDEX[13:3] from the frame number indicated by the SOF marker. Whenever the USB bus receives an SOF, FRINDEX[13:3] is checked against the SOF marker. If FRINDEX[13:3] is different from the SOF marker, FRINDEX[13:3] is set to the SOF value and FRINDEX[2:0] is 0 (that is, SOF for 1 ms frame). If FRINDEX[13:3] is equal to the SOF value, FRINDEX[2:0] increments (that is, SOF for 125 µs microframe).

Offset

Register	Offset
FRINDEX	14Ch

Diagram



Fields

Field	Description
31-14 —	Reserved
13-0 FRINDEX	Frame Index Increments at the end of each time frame (microframe). Bits[*n*:3] are used for the frame list current index. This means that each location of the frame list is accessed eight times (frames or microframes) before moving to the next index. In Host mode, the following values of *n* are based on the values of USBCMD[FS_2] and USBCMD[FS_1]. In Device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current microframe. The following values are represented as USBCMD (frame list size) number elements *n*. 00_0000_0000_0000 - (1024) 12 00_0000_0000_0001 - (512) 11 00_0000_0000_0010 - (256) 10 00_0000_0000_0011 - (128) 9 00_0000_0000_0100 - (64) 8 00_0000_0000_0101 - (32) 7 00_0000_0000_0110 - (16) 6 00_0000_0000_0111 - (8) 5

32.7.1.1.23 Device Address (DEVICEADDR)

Contains the device address. The upper seven bits of this register represent the device address.

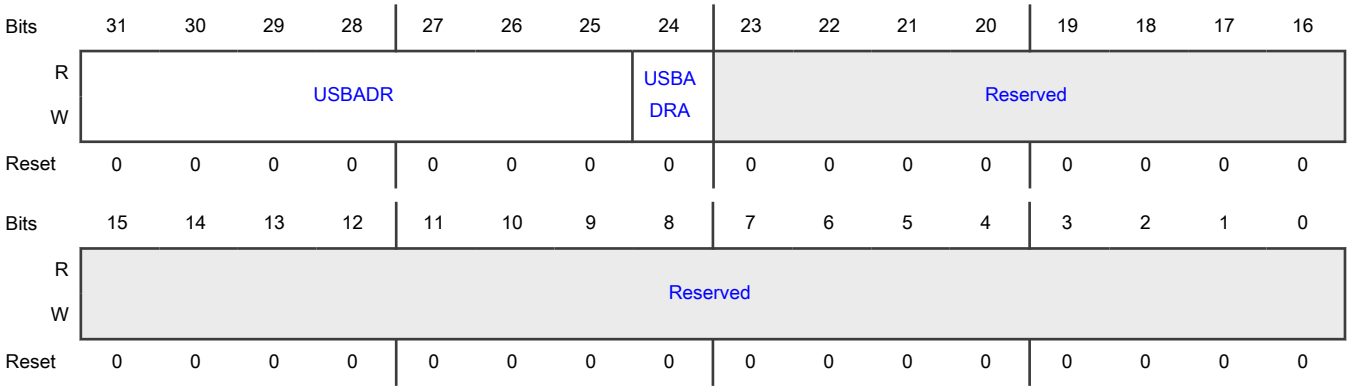
After a controller or USB reset, the device address is set to the default address (0) that matches all incoming addresses. You must reprogram the address after receiving a SET_ADDRESS descriptor.

Only the device controller uses this register.

Offset

Register	Offset
DEVICEADDR	154h

Diagram



Fields

Field	Description
31-25 USBADR	Device Address Represents the USB device address.
24 USBADRA	Device Address Advance Accelerates the SET_ADDRESS sequence by allowing the DCD to preset DEVICEADDR[USBADR] before the status phase of the SET_ADDRESS descriptor. When this field is 0 (the default value), any writes to USBADR are instantaneous. When you write 1 to this field at the same time or before writing to the USBADR field, a write to USBADR is staged and held in a hidden register. After an "In" transaction occurs on endpoint 0 and is ACKed, USBADR loads from the holding register. Hardware automatically writes 0 to this field on the following conditions: • The "In" transaction is ACKed to endpoint 0 (USBADR is updated from the staging register). • "Out" or "Setup" transactions occur to endpoint 0 (USBADR is not updated). • Device reset occurs (USBADR is reset to 0). **NOTE** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism ensures that this specification is met when the DCD is busy and cannot write to this field within 2 ms from the SET_ADDRESS status phase. If the DCD writes to the USBADR field when USBADRA = 1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR field is programmed instantly at the correct time and meets the 2 ms USB requirement.
23-0 —	Reserved

32.7.1.1.24 Frame List Base Address (PERIODICLISTBASE)

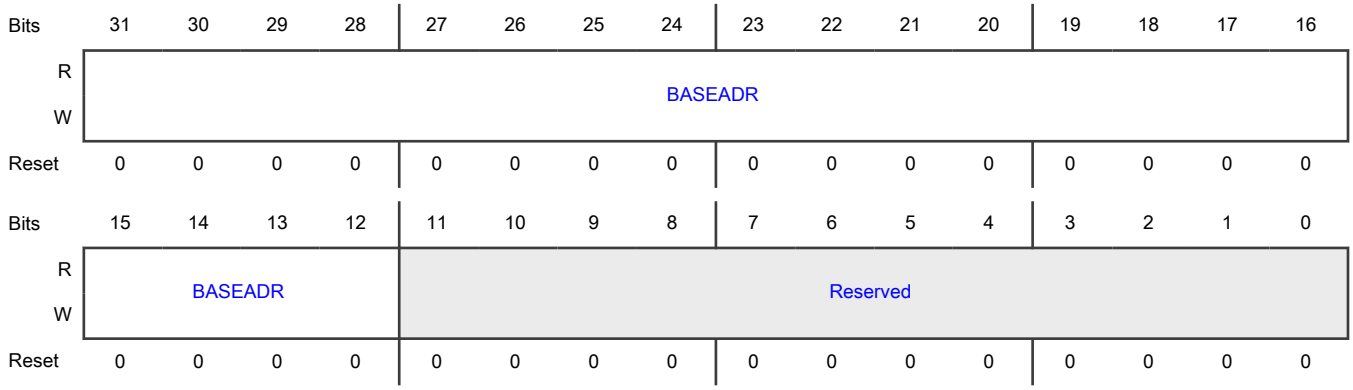
Contains the beginning address of the periodic frame list in the system memory.

The host controller driver (HCD) loads this register before the host controller starts the schedule execution. The memory structure referenced by this physical memory pointer is assumed to be 4-KB aligned. The contents of this register are combined with USB Frame Index (FRINDEX) to enable the host controller to step through the periodic frame list in sequence.

Offset

Register	Offset
PERIODICLISTBASE	154h

Diagram



Fields

Field	Description
31-12 BASEADR	Base Address (Low) Specifies the base address. These bits of this field correspond to memory address signals [31:12], respectively. Only the host controller uses this field.
11-0 —	Reserved

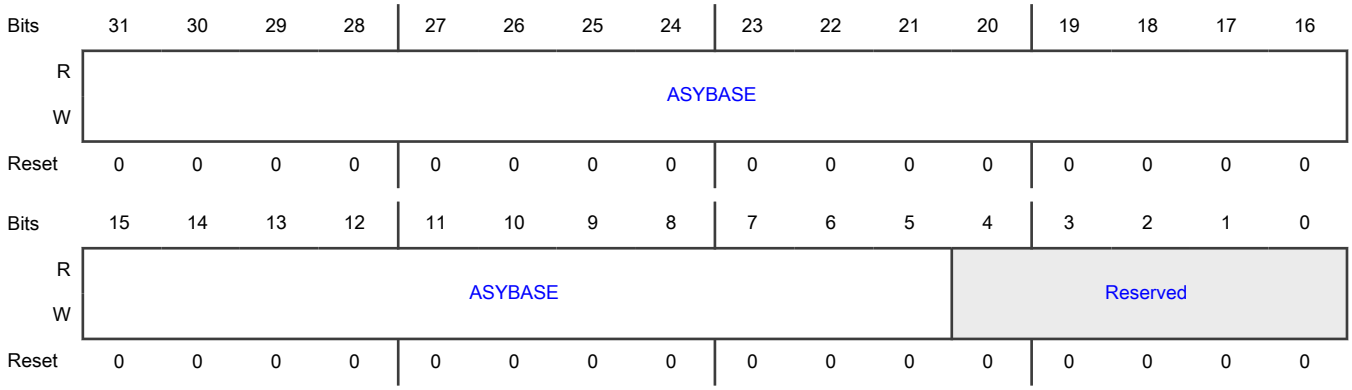
32.7.1.1.25 Next Asynchronous Address (ASYNCLISTADDR)

Contains the address of the next asynchronous queue head to be executed by the host. You cannot modify bits [4:0] of this register; they always return a 0 when read.

Offset

Register	Offset
ASYNCLISTADDR	158h

Diagram



Fields

Field	Description
31-5 ASYBASE	Link Pointer Low (LPL) Specifies the link pointer. The bits of this field correspond to memory address signals [31:5], respectively. This field can only reference a queue head. Only the host controller uses this field.
4-0 —	Reserved

32.7.1.1.26 Endpoint List Address (ENDPTLISTADDR)

Contains the address of the top of the endpoint list in system memory, when in Device mode. You cannot modify bits[10:0] of this register; they always return a 0 when read.

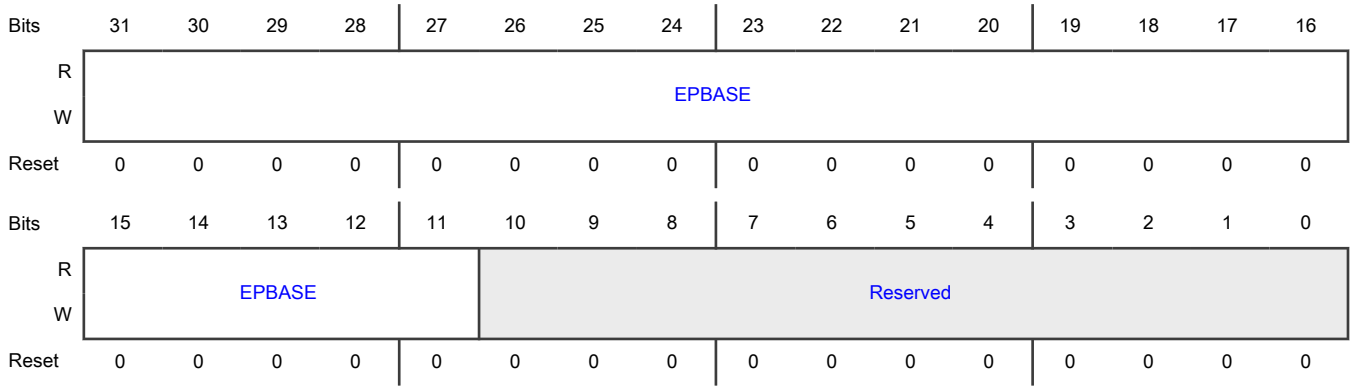
The memory structure referenced by this physical memory pointer is assumed to be 64 bytes.

This is a device-controller-only register.

Offset

Register	Offset
ENDPTLISTADDR	158h

Diagram



Fields

Field	Description
31-11 EPBASE	Endpoint List Pointer (Low) Specifies the endpoint list pointer. These bits of this field correspond to memory address signals [31:11], respectively. This field references a list of up to 32 queue heads (that is, one queue head per endpoint and direction).
10-0 —	Reserved

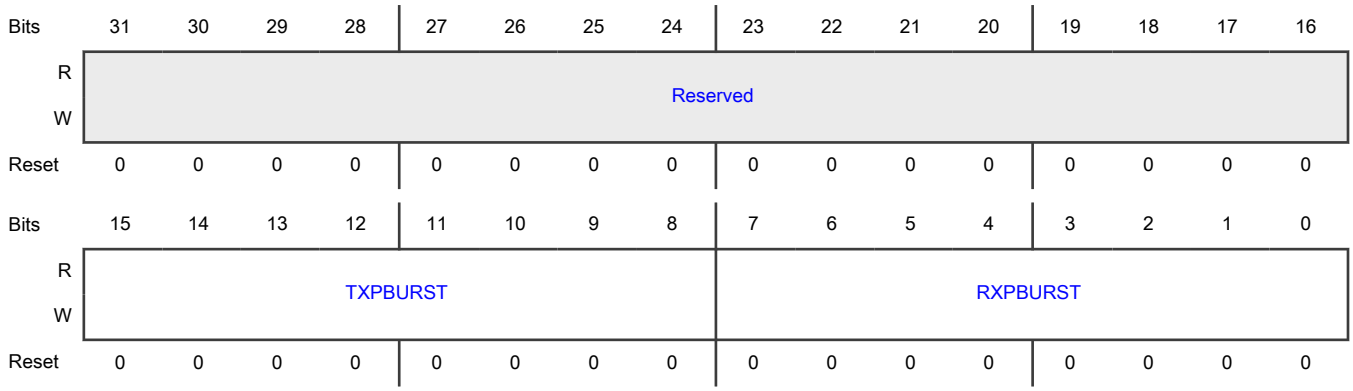
32.7.1.1.27 Programmable Burst Size (BURSTSIZE)

Controls the burst size used during data movement on the AHB controller interface. This register is ignored if SBUSCFG[AHBBRST] has a nonzero value.

Offset

Register	Offset
BURSTSIZE	160h

Diagram



Fields

Field	Description
31-16 —	Reserved
15-8 TXPBURST	Programmable TX Burst Size Represents the maximum length of a burst, in 32-bit words, when moving data from the system memory to the USB bus. HWTXBUF[TXBURST] determines the default value of this field.
7-0 RXPBURST	Programmable RX Burst Size Represents the maximum length of a burst, in 32-bit words, when moving data from the USB bus to the system memory. HWRXBUF[RXBURST] determines the default value of this field.

32.7.1.1.28 TX FIFO Fill Tuning (TXFILLTUNING)

Controls performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus.

The specific areas of performance include how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

Following are some related definitions:

T_0 = Standard packet overhead

T_1 = Time to send data payload

T_{ff} = Time to fetch packet into the TX FIFO up to the specified level

T_s = Total packet flight time (send-only) packet

$T_s = T_0 + T_1$

T_p = Total packet time (fetch and send) packet

$T_p = T_{ff} + T_0 + T_1$

After the discovery of a transmit (out or setup) packet in the data structures, the host controller checks to ensure T_p remains before the end of the [micro]frame. If so, it proceeds to prefill the TX FIFO. If the remaining time in the frame of [micro]frame is < T_s at any time during this operation, then the packet attempt ceases and the packet is tried at a later time.

Although this is not an error condition and the host controller eventually recovers, a mark is created in the scheduler health counter to note the occurrence of a back-off event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and should therefore be minimized (not necessarily eliminated). You can minimize back-off events by using TXFILLTUNING[TXSCHHEALTH](T_{ff}).

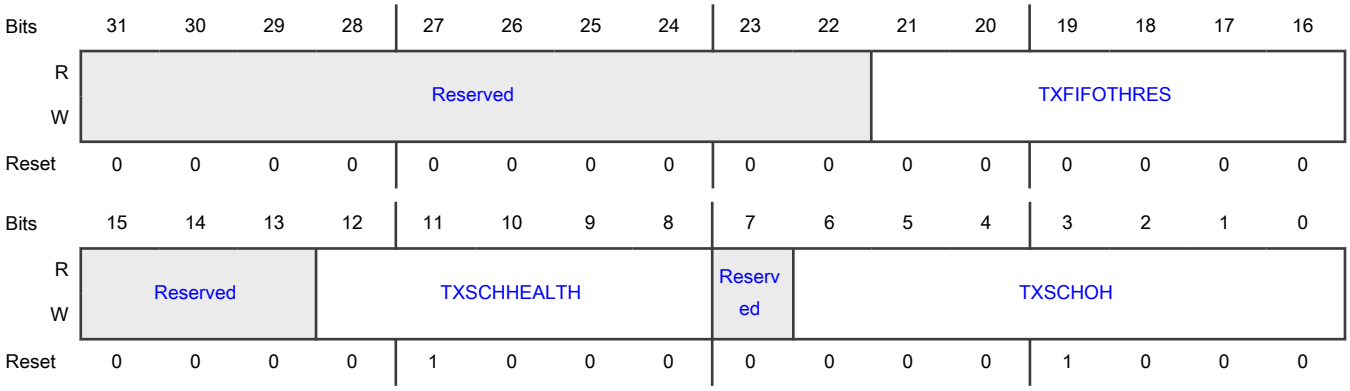
NOTE

The reset value could vary from instance to instance. In that case, see the field descriptions of this register and ignore the reset value in the summary table.

Offset

Register	Offset
TXFILLTUNING	164h

Diagram



Fields

Field	Description
31-22 —	Reserved
21-16 TXFIFOTHRES	FIFO Burst Threshold Controls the number of data bursts that are posted to the TX latency FIFO in Host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth, where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if USBMODE[SDIS] is 1.
15-13 —	Reserved
12-8 TXSCHHEALTH	Scheduler Health Counter Increments when the host controller fails to fill the TX latency FIFO to the level that you program in TXFILLTUNING[TXFIFOTHRES] before running out of time to send the packet before the next SOF. This health counter measures the number of times this occurs to provide feedback for selecting a proper scheduler overhead (TXFILLTUNING[TXSCHOH]). Writing to this register clears the counter that has the maximum value of 31.
7 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
6-0 TXSCHOH	Scheduler Overhead Adds an additional fixed offset to the schedule time estimator described as T_{ff}. As an approximation, the value selected for this register must limit the number of back-off events captured in TXFILLTUNING[TXSCHHEALTH] to less than 10 per second in a highly utilized bus. Selecting a value that is too high for this register is not recommended because it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in High-Speed mode. The time unit represented in this register is 6.333 µs when a device is connected in Low-Speed or Full-Speed mode. The default value is 08h for the OTG controller core .

32.7.1.1.29 Endpoint NAK (ENDPTNAK)

Configures RX and TX endpoint NAKs. Endpoint sends a NAK handshake for the "In", "Out", and "Ping" tokens.

Offset

Register	Offset
ENDPTNAK	178h

Fields

Field	Description
31-24 —	Reserved
23-16 EPTNE	TX Endpoint NAK Enable Enables transmit endpoint NAK. Each bit in this field enables the corresponding TX endpoint NAK bit. If this bit is set and the corresponding TX endpoint NAK bit is set, the NAK interrupt bit is set. Bit[*n*] - Endpoint #[*n*], where *n* is 0–7.
15-8 —	Reserved
7-0 EPRNE	RX Endpoint NAK Enable Enables receive endpoint NAK. Each bit in this field enables the corresponding RX endpoint NAK bit. If this bit is set and the corresponding RX endpoint NAK bit is set, the NAK interrupt bit is set. Bit[*n*] - Endpoint #[*n*], where *n* is 0–7.

32.7.1.1.31 Configure Flag (CONFIGFLAG)

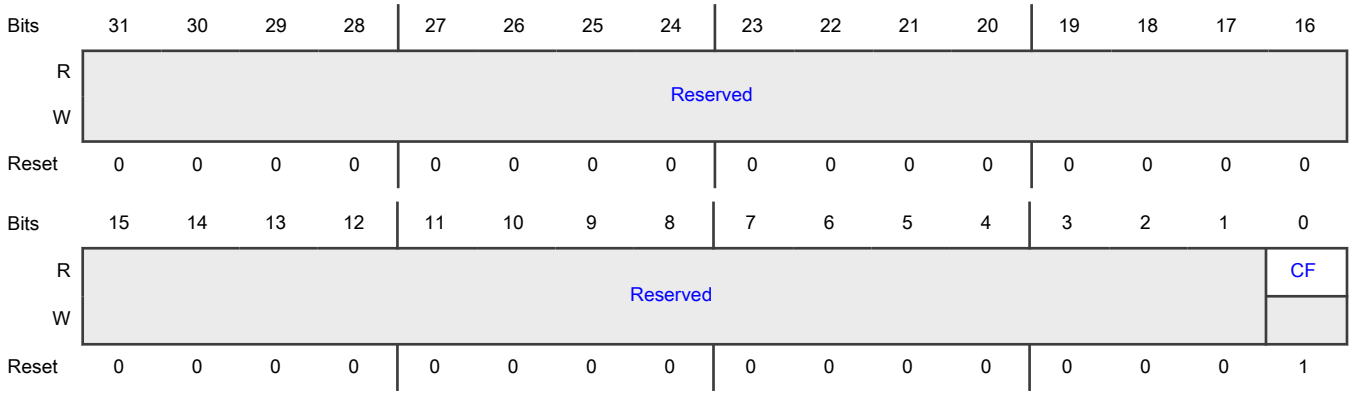
Controls port-routing control logic.

This register is not used in this implementation. A read from this register returns a constant of a 0000_0001h to indicate that all port routings default to this host controller.

Offset

Register	Offset
CONFIGFLAG	180h

Diagram



Fields

Field	Description
31-1 —	Reserved
0 CF	Configure Flag Controls the default port-routing control logic. You must set this flag as the last action in its process of configuring the host controller. If this flag is 0, the port routing control logic routes each port to an implementation dependent on classic host controller by default. If this flag is 1, the port routing control logic routes all ports to this host controller by default. 0 - Port routing to classic host controller 1 - Port routing to this host controller

32.7.1.1.32 Port Status and Control (PORTSC1)

Determines and implements ports that need service.

A host controller can implement one to eight port status and control registers. The number is determined by HCSPARAMS[N_PORTS]. You can read this parameter register to determine how many ports need service.

All controller cores on this product are single-port, so there is only one port status and control register for each controller core.

This register is only reset by POR or controller core reset. The following are the initial conditions of a port:

- No device connected
- Port disabled

If the port supports power control, this state remains until software supplies port power.

A device controller operating in Device mode includes only PORTSC1 and does not support power control in that mode. Port control in Device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate Test mode or force signaling, and allows you to place the PHY into Low-Power Suspend mode and disable the PHY clock.

Offset

Register	Offset
PORTSC1	184h

Fields

Field	Description
31-30 PTS_1	Parallel Transceiver Select 1 Indicates parallel transceiver select 1. Bit field {bit25, bit31, bit30}: 000b - UTMI/UTMI+ 001b - Reserved 010b - ULPI 011b - Serial/USB 1.1 PHY/IC-USB (FS only) 100b - HSIC Parallel Transceiver Select (bit25, bit31, bit30). For the OTG core, it is read-only. For host1, host2, and host3 cores, it is read/write. **NOTE** All USB port interface modes are listed in this field description, but not all are supported. For details related to each controller core, see Features. The behavior is unknown when an unsupported interface mode is selected.
29 STS	Serial Transceiver Select Selects the serial transceiver. The serial interface engine can be used in combination with UTMI+/ULPI physical interface to provide FS and LS signaling instead of the parallel interface signals.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this field is 1, the serial interface engine is used instead of parallel interface signals. This field has no effect unless PORTSC1[PTS_1] is 1 (to select the UTMI+/ULPI interface). The serial/USB1.1 PHY/IC-USB uses the serial interface engine for FS and LS signaling regardless of the value of this field. 0 - Parallel interface signals 1 - Serial interface engine
28 PTW	Parallel Transceiver Width Selects the parallel transceiver width. This field has no effect if the serial interface engine is used. 0 - 8-bit UTMI interface [60 MHz] 1 - 16-bit UTMI interface [30 MHz]
27-26 PSPD	Port Speed Indicates the speed at which the port is operating. 00 - FS 01 - LS 10 - HS 11 - Undefined
25 PTS_2	Parallel Transceiver Select 2 See the description of PORTSC1[PTS_1].
24 PFSC	Port Force Full Speed Connect Specifies the speed at which the port is connected. If this field is 1, the port is forced to connect at FS only. It disables the chirp sequence that allows the port to identify itself as HS. 0 - Normal operation 1 - Forced to full speed
23 PHCD	PHY Low-Power Suspend - Clock Disable (PLPSCD) Disables the PHY clock. Reading this field indicates the status of the PHY clock. **NOTE** You cannot disable the PHY clock if it is being used as the system clock. In Device mode, you can place the PHY into Low-Power Suspend mode when the device is not running (USBCMD[RS] is 0) or the host has signaled suspend (PORTSC1[SUSP] is 1). This field becomes 0

Table continues on the next page...

Table continued from the previous page...

Field	Description
	automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must write 0 to this field. In Host mode, you can place the PHY into Low-Power Suspend mode when the downstream device is placed into Suspend mode or when no downstream device is connected. Low-Power Suspend mode is completely under your control. 0 - Enable 1 - Disable
22 WKOC	Wake on Overcurrent Enable (WKOC_E) Enables wake-up on overcurrent. Writing 1 to this field enables the port to be sensitive to overcurrent conditions as wake-up events. This field is 0 if PORTSC1[PO] is 0.
21 WKDC	Wake on Disconnect Enable (WKDSCNNT_E) Enables wake-up on disconnect. Writing 1 to this field enables the port to be sensitive to device disconnects as wake-up events. This field is 0 if PORTSC1[PO] is 0 or is in Device mode. 0 - Disable 1 - Enable
20 WKCN	Wake on Connect Enable (WKCNNT_E) Enables port sensitivity. Writing 1 to this field enables the port to be sensitive to device connects as wake-up events. This field is 0 if PORTSC1[PO] is 0 or is in Device mode. 0 - Disable 1 - Enable
19-16 PTC	Port Test Control Defines port test control. See Port Test Control mode for the operational model used for these test modes, and chapter 7 of the USB Specification Revision 2.0 for details on each test mode. FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the FORCE_ENABLE_{HS/FS/LS} values to this field forces the port into the connected and enabled states at the selected speed. Writing the TEST_MODE_DISABLE value to this field allows the port state machines to progress normally from that point. **NOTE** *Low-speed operations are not supported as a peripheral device.* Any value other than 0 indicates that the port is operating in Test mode.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Value specific test 0000 - TEST_MODE_DISABLE 0001 - J_STATE 0010 - K_STATE 0011 - SE0 (host) or NAK (device) 0100 - Packet 0101 - FORCE_ENABLE_HS 0110 - FORCE_ENABLE_FS 0111 - FORCE_ENABLE_LS 1000-1111 - Reserved
15-14 PIC	Port Indicator Control Specifies the port indicator. Writing to this field has no effect if HCSPARAMS[PI] is 0. See the USB Specification Revision 2.0 for a description on how these fields must be used. This field is 0 if PORTSC1[PO] is zero. 00 - Port indicators are off 01 - Amber 10 - Green 11 - Undefined
13 PO	Port Owner Indicates port ownership. This field to used to release ownership of the port to a selected host controller (in the event that the attached device is not an HS device). This field unconditionally becomes 0 when the configured field in Configure Flag (CONFIGFLAG) makes a 0 to 1 transition. The field unconditionally becomes 1 whenever the configured field is 0. Write 1 to this field when the attached device is not an HS device. If this field is 1, it means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores; therefore, this field is always 0.
12 PP	Port Power Works in accordance with HCSPARAMS[PPC]. In other words, the functioning of this field depends on the value of HCSPARAMS[PPC]: • PPC = 0b, PP = 0b (read-only): A controller in Device mode does not have port power control switches. • PPC = 1b, PP = 1b or 0b (read/write): A controller in Host mode requires port power control switches.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	OTG controller requires port power control switches. This field represents the current setting of the switch (0 means off; 1 means on). When power is not available on a port (that is, PP = 0), the port is nonfunctional and does not report attachments, detachments, and so on. When an overcurrent condition is detected on a powered port and PPC is 1, this field, in each affected port, may be transitioned by the controller driver from 1 to 0 (removing power from the port). This feature is implemented in all controller cores (PPC = 1). 0 - Off 1 - On
11-10 LS	Line Status Indicates the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In Host mode, the host controller driver may not necessarily use LineState (unlike EHCI) because the port controller state machine and port routing manage the connection of LS and FS. In Device mode, the device controller driver may not necessarily use LineState. The following is the encoding of bits [11:10]. 00 - SE0 01 - K-state 10 - J-state 11 - Undefined
9 HSP	High-Speed Port Indicates whether the host or device connected to the port is in HS mode. The field is redundant for PORTSC1[PSPD] but is included for compatibility. 0 - Not in HS mode 1 - In HS mode
8 PR	Port Reset Specifies whether the port is in reset. In Host mode (read/write), the bus-reset sequence (as defined in the USB Specification Revision 2.0) starts when you write 1 to this field. This field automatically changes to zero after the reset sequence is complete. This behavior is different from that of EHCI where the host controller driver is required to write 0 to this field after the reset duration is timed in the driver. In Device mode, this is a read-only status field. Device reset from the USB bus is also indicated in USB Status (USBSTS). This field is 0 if PORTSC1[PP] is 0. 0 - Port not in reset 1 - Port in reset

Table continues on the next page...

Table continued from the previous page...

Field	Description
7 SUSP	Suspend Specifies whether the port is in the Suspended state. In Host mode (read/write), this field works with PORTSC1[PE] to define the port states as follows: In case of {PE, SUSP} port state: 0x - Disable 10 - Enable 11 - Suspend When in the Suspended state, downstream propagation of data is blocked on this port (except for port reset). Blocking occurs at the end of the current transaction if a transaction was in progress when this field was 1. The port is sensitive to resume detection in the Suspended state. The status of the field does not change until the port is suspended; there may be a delay in suspending a port if a transaction is in progress on USB. The host controller unconditionally writes 0 to this field when you write 0 to PORTSC1[FPR]. The host controller ignores a write of zero to this field. If host software writes 1 to this field when the port is not enabled (that is, PORTSC1[PE] is 0), the results are undefined. This field is 0 if PORTSC1[PP] is 0 in Host mode. In Device mode, this is a read-only status field. 0 - Port not in Suspended state 1 - Port in Suspended state
6 FPR	Force Port Resume Specifies whether force resume is detected or driven on the port. In Host mode, write 1 to this field to drive resume signaling. The host controller writes 1 to this field if a J-to-K transition is detected when the port is in the Suspended state. When this field transitions to 1 because a J-to-K transition is detected, USBSTS[PCI] also becomes 1. This field automatically changes to 0 after the resume sequence is complete. This behavior is different from that of EHCI where the host controller driver is required to write 0 to this field after the resume duration is timed in the driver. When the host controller owns the port, the resume sequence follows the defined sequence documented in USB specification revision 2.0. The resume signaling (full-speed "K") is driven on the port until this field remains 1 (that is, until the port has switched to the high-speed idle state). Writing 0 to this field has no effect because the port controller times the resume operation, clears the field, and the port control state switches to HS or FS idle. This field is not-EHCI compatible and remains 0 if PORTSC1[PP] is 0 in Host mode. In Device mode, you must write 1 to this field to drive resume signaling after the device is in the Suspended state for 5 ms or more. The device controller writes 1 to this field if a J-to-K transition is detected when the port is in the Suspended state. The field becomes 0 when the device returns to normal operation. Additionally, when this field becomes 0 because of a K-to-J transition detection, USBSTS[PCI] also becomes 1. 0 - No resume (K-state) detected or driven on port

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Resume detected or driven on port
5 OCC	Overcurrent Change Flag Indicates whether an overcurrent change occurred. Hardware sets this field to 1 when there is a change in an overcurrent active condition. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change occurred 1 - Change occurred When writing 0 - No effect 1 - Clear the flag
4 OCA	Overcurrent Active Indicates whether the port currently has an overcurrent condition. This field automatically transitions from 1 to 0 when the overcurrent condition is removed. 0 - Overcurrent condition exists 1 - No overcurrent condition exists
3 PEC	Port Enable and Disable Change Flag Indicates whether the port enabled and disabled status has changed. In Host mode (for the root hub), this flag is set to 1 only when a port is disabled because of disconnect on the port or because of appropriate conditions existing at the EOF2 point (see chapter 11 of the USB specification). This field is 0 if PORTSC1[PP] is 0. In Device mode, the device port is always enabled; therefore, this field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change occurred 1 - Change occurred When writing 0 - No effect 1 - Clear the flag
2	Port Enable and Disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
PE	Enables a port. In Host mode, this field is reset to 0b. Only the host controller can enable ports as part of reset and enable. You cannot enable a port by writing 1 to this field, and either a fault condition (such as a disconnect event) or host software can disable a port. The status of this field does not change until the port state actually changes. There may be a delay in disabling or enabling a port because of other host controller and bus events. When this field is 0 (the port is disabled), downstream propagation of data is blocked except for reset. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device mode, this field is always 1 (the device port is always enabled). 0 - Disable 1 - Enable
1 CSC	Connect Status Change Flag Indicates whether a change has occurred in the port's current connect status. In Host mode, the host or device controller sets this field for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the connect status (PORTSC1[CCS]) changes twice before you clear PORTSC1[CSC]. The hub hardware sets an already-set field (that is, CSC remains set). You can clear this field by writing 1 to it. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device Controller mode, this field is undefined. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change occurred 1 - Change occurred When writing 0 - No effect 1 - Clear the flag
0 CCS	Current Connect Status Indicates the current port connection status. In Host mode, if this field is 1, the device is present on port, and if this field is 0 (default), no device is present. This value reflects the current state of the port, and may not correspond directly to the event that causes this field to be set. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device mode, if this field is 1, it indicates that the device is successfully attached and is operating in either high speed or full speed, as indicated by PORTSC1[HSP]. If this field is 0, it indicates that the device is not

Table continues on the next page...

Table continued from the previous page...

Field	Description
	attached successfully or is forcibly disconnected by writing 0 to USBCMD[RS]. It does not state the device being disconnected or suspended.

32.7.1.1.33 On-The-Go Status and Control (OTGSC)

Provides OTG status and control.

This register is available only in OTG controller core and includes fields for:

- OTG interrupt enables (read/write)
- OTG interrupt status (read/write to clear)
- OTG status inputs (read-only)
- OTG controls (read/write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status input register, or cause an OTG interrupt.

See USB Device Mode (USBMODE) for more information.

Offset

Register	Offset
OTGSC	1A4h

31 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
30 DPIE	Data Pulse Interrupt Enable Enables the data pulse interrupt. Writing 1 to the field enables the interrupt.
29 EN_1MS	1 Millisecond Timer Interrupt Enable Enables the 1 ms timer interrupt. Writing 1 to the field enables the interrupt.
28 BSEIE	B Session End Interrupt Enable Enables the B session end interrupt. Writing 1 to the field enables the interrupt.
27 BSVIE	B Session Valid Interrupt Enable Enables the B session valid interrupt. Writing 1 to the field enables the interrupt.
26 ASVIE	A Session Valid Interrupt Enable Enables the A session valid interrupt. Writing 1 to the field enables the interrupt.
25 AVVIE	A VBUS Valid Interrupt Enable Enables the A VBUS valid interrupt. Writing 1 to the field enables the interrupt.
24 IDIE	USB ID Interrupt Enable Enables the USB ID interrupt. Writing 1 to the field enables the interrupt.
23 —	Reserved
22 DPIS	Data Pulse Interrupt Status Flag Indicates the status of the data pulse interrupt. This field becomes 1 when data bus pulsing occurs on a DP or DM line. Data bus pulsing is detected only when USBMODE[CM] = 11b and PORTSC1[PP] = 0b. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Data pulse did not occur 1 - Data pulse occurred When writing 0 - No effect 1 - Clear the flag
21 STATUS_1MS	1 Millisecond Timer Interrupt Status Flag Indicates the status of the timer interrupt. This field becomes 1 once every millisecond.

Table continues on the next page...

Table continued from the previous page...

Field	Description
20 BSEIS	B Session End Interrupt Status Flag Indicates the status of the B session end interrupt. This field becomes 1 when VBUS has fallen below the B session end threshold. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Fallen below the threshold When writing 0 - No effect 1 - Clear the flag
19 BSVIS	B Session Valid Interrupt Status Flag Indicates the status of the B session valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the B session valid threshold. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Risen above or fallen below the threshold When writing 0 - No effect 1 - Clear the flag
18 ASVIS	A Session Valid Interrupt Status Flag Indicates the status of the A session valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the A session valid threshold. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Risen above or fallen below the threshold When writing 0 - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Clear the flag
17 AVVIS	A VBUS Valid Interrupt Status Flag Indicates the status of the A VBUS valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the VBUS valid threshold on A device. **NOTE** This field behaves differently for register reads and writes. When reading 0 - No change 1 - Risen above or fallen below the threshold When writing 0 - No effect 1 - Clear the flag
16 IDIS	USB ID Interrupt Status Flag Indicates the status of the USB ID interrupt. This field becomes 1 when a change on the ID input is detected. **NOTE** This field behaves differently for register reads and writes. When reading 0 - Change not detected 1 - Change detected When writing 0 - No effect 1 - Clear the flag
15 —	Reserved
14 DPS	Data Bus Pulsing Status Indicates the status of data bus pulsing. If this field is 1, it indicates that data bus pulsing is detected on the port.
13 TOG_1MS	1 Millisecond Timer Toggle Toggles once per millisecond.
12	B Session End

Table continues on the next page...

Table continued from the previous page...

Field	Description
BSE	Indicates that VBUS is below the B session end threshold.
11 BSV	B Session Valid Indicates that VBUS is above the B session valid threshold.
10 ASV	A Session Valid Indicates that VBUS is above the A session valid threshold.
9 AVV	A VBUS Valid Indicates that VBUS is above the A VBUS valid threshold.
8 ID	USB ID Indicates the USB ID. 0 - A device 1 - B device
7-6 —	Reserved
5 IDPU	ID Pullup Provides control over the ID pull-up resistor. If this field is 0, the functionality is off and the ID input is not sampled. If this field is 1 (default), the functionality is on and the ID input is sampled.
4 DP	Data Pulsing Controls pullup on the DP line. Writing 1 to this field causes the pullup on the DP line to be asserted for data pulsing during SRP.
3 OT	OTG Termination Controls pulldown on the DM line. This field must be 1 when the OTG device is in Device mode to control the pulldown on the DM line.
2 —	Reserved
1 VC	VBUS Charge Controls VBUS pulsing during SRP. Writing 1 to this field causes the VBUS line to be charged.
0 VD	VBUS Discharge Discharges VBUS through a resistor.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	Writing 1 to this field causes VBUS to discharge through a resistor.

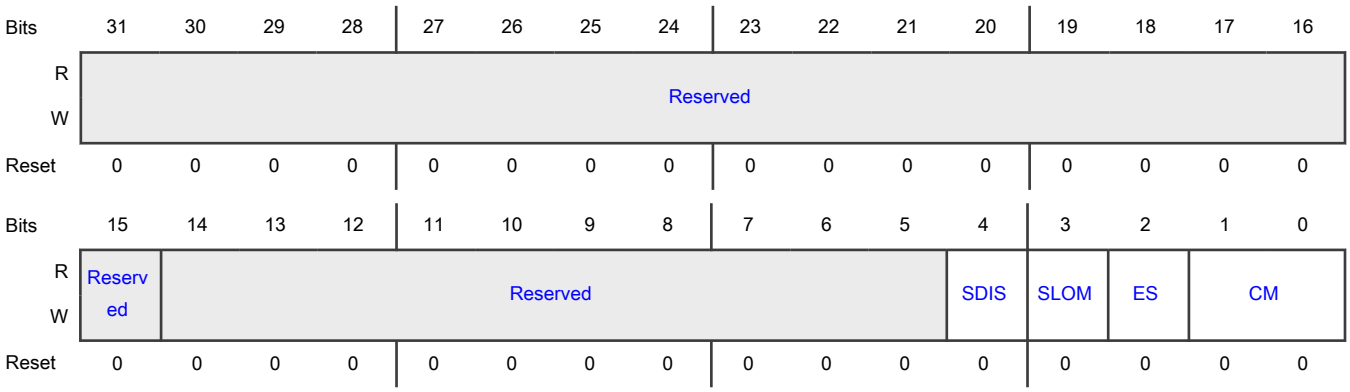
32.7.1.1.34 USB Device Mode (USBMODE)

Selects the USB device mode.

Offset

Register	Offset
USBMODE	1A8h

Diagram



Fields

Field	Description
31-16 —	Reserved
15 —	Reserved
14-5 —	Reserved
4 SDIS	Stream Disable Mode Disables double priming for low-bandwidth systems. In Device mode, writing 1 to this field disables double priming on both RX and TX for low-bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet, the standard double buffering scheme is disabled to prevent overruns and underruns in bandwidth limited systems.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE In High-Speed mode, all packets received are responded to with an NYET handshake when stream disable is active. In Host mode, writing 1 to this field ensures that overruns and underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also ensures that the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE** The time duration to prefill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (TXFILLTUNING) and TXTTFILLTUNING (MPH only) to characterize the adjustments needed for the scheduler when using this feature. The use of this feature substantially limits the overall USB performance that can be achieved. 0 - Disable 1 - Enable
3 SLOM	Setup Lockout Mode Specifies whether the setup lockouts are on. In Device mode, this field controls the behavior of the setup lock mechanism. See Control endpoint operation model for more information. DCD requires you to use the setup data buffer tripwire in USB Command (USBCMD). 0 - On (default) 1 - Off
2 ES	Endian Select Selects the endianness. You can use this field to change the byte alignment of the transfer buffers to match the host microprocessor. The fields in the microprocessor interface and the data structures are unaffected by the value of this field because they are based on the 32-bit word. 0 - Little endian (default) 1 - Big endian
1-0 CM	Controller Mode Specifies the controller mode. Controller mode is defaulted to the proper mode for host-only and device-only implementations. For those designs that contain both host & device capability, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host and device controllers, you can write to this register only once after reset. If it is necessary to switch modes, you must reset the controller by writing to USBCMD[RST] before reprogramming this register. For the OTG controller core, the reset value is 00b.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	00 - Idle (default for host and device combination) 01 - Reserved 10 - Device controller (default for device-only controller) 11 - Host controller (default for host-only controller)

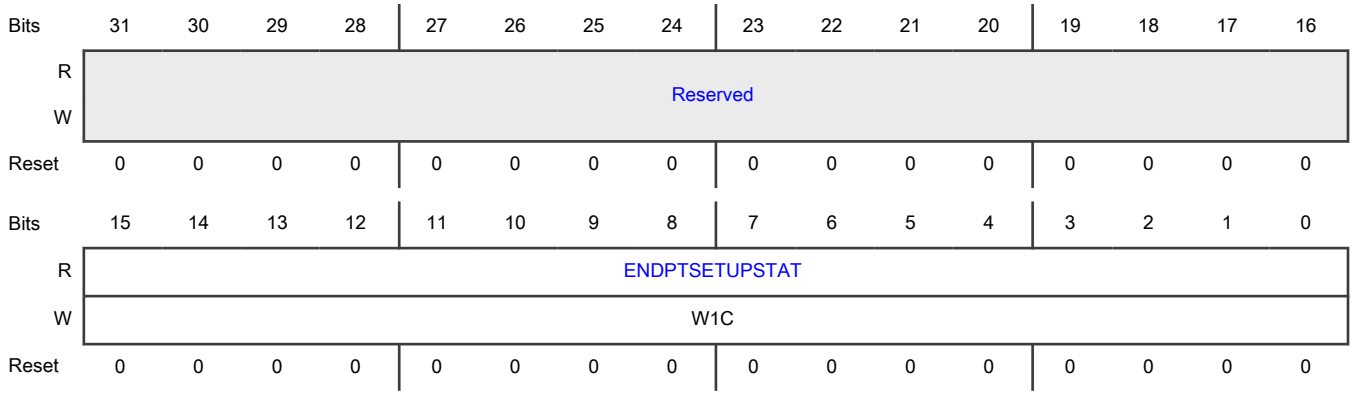
32.7.1.1.35 Endpoint Setup Status (ENDPTSETUPSTAT)

Indicates the endpoint setup status.

Offset

Register	Offset
ENDPTSETUPSTAT	1ACh

Diagram



Fields

Field	Description
31-16 —	Reserved
15-0 ENDPTSETUPSTAT	Endpoint Setup Status Flag Indicates the endpoint setup status and whether the setup transaction is received. For every setup transaction that is received, a corresponding bit in this field becomes 1. You must clear or acknowledge the setup transfer by writing 1 to the respective bit after it has read the setup data from the queue head.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The response to a setup packet includes many operations in an order. The total response time is crucial to limit bus timeouts if the setup lockout mechanism is engaged. See Managing endpoints in the device operational model. This register is used only in Device mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000 - Not received 0000_0000_0000_0001 - Received When writing 0000_0000_0000_0000 - No effect 0000_0000_0000_0001 - Clear the flag

32.7.1.1.36 Endpoint Prime (ENDPTPRIME)

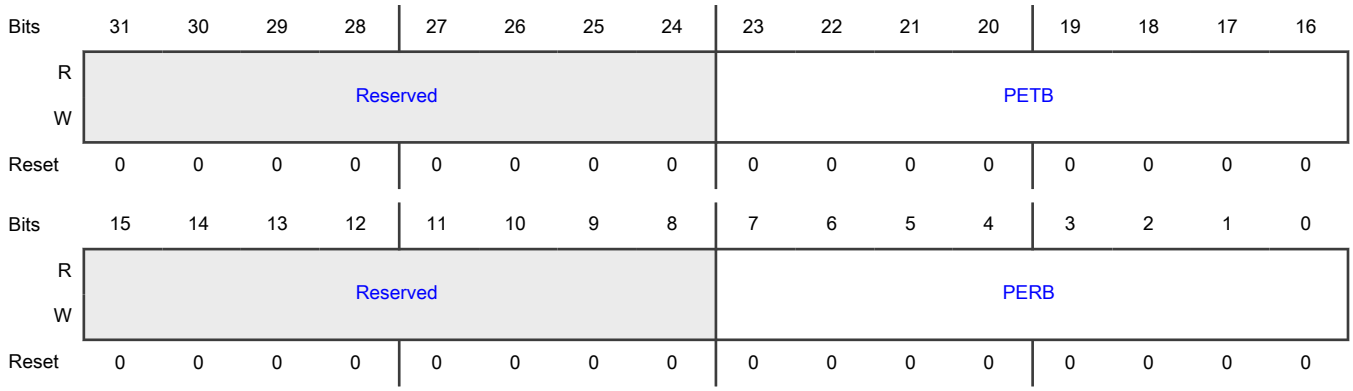
Primes the endpoint.

When you set the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, so that the endpoint is ready to transmit or receive when the host sends a request ("In" or "Out" token). The endpoint NAKs all requests from the host until the endpoint is primed. The controller automatically reprimes the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Therefore, you must set the prime bit only when a descriptor is added to the queue head.

Offset

Register	Offset
ENDPTPRIME	1B0h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 PETB	Prime Endpoint Transmit Buffer Parses a new transfer descriptor from the queue head and prepares for a transmit buffer. For each endpoint, a corresponding bit is used to request that a buffer is prepared for a transmit operation to respond to a USB "In" or "Interrupt" transaction. You must write 1 to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this bit to begin parsing for a new transfer descriptor from the queue head and preparing a transmit buffer. Hardware writes 0 to this field when the associated endpoint is successfully primed. PETB[*n*] - Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily writes 1 to this field during hardware repriming operations when a dTD is retired and the dQH is updated.
15-8 —	Reserved
7-0 PERB	Prime Endpoint Receive Buffer Parses a new transfer descriptor from the queue head and prepares for a receive buffer. For each endpoint, a corresponding bit is used to request that a buffer is prepared for a receive operation when a USB host initiates a USB "Out" transaction. You must write 1 to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this field to begin parsing for a new transfer descriptor from the queue head and preparing a receive buffer. Hardware writes 0 to this field when an associated endpoint is successfully primed. PERB[*n*] - Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily writes 1 to this field during hardware repriming operations when a dTD is retired and the dQH is updated.

32.7.1.1.37 Endpoint Flush (ENDPTFLUSH)

Flushes the endpoint.

Offset

Register	Offset
ENDPTFLUSH	1B4h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Description
31-24 —	Reserved
23-16 FETB	Flush Endpoint Transmit Buffer Clears any primed transmit buffers. When you write 1 to this field, it causes the associated endpoints to clear any primed transfer buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[*n*]: Endpoint [*n*], *n* is in 0–7
15-8 —	Reserved
7-0 FERB	Flush Endpoint Receive Buffer Clears any primed receive buffers. When you write 1 to this field, it causes the associated endpoints to clear any primed receive buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[*n*]: Endpoint [*n*], *n* is in 0–7

32.7.1.1.38 Endpoint Status (ENDPTSTAT)

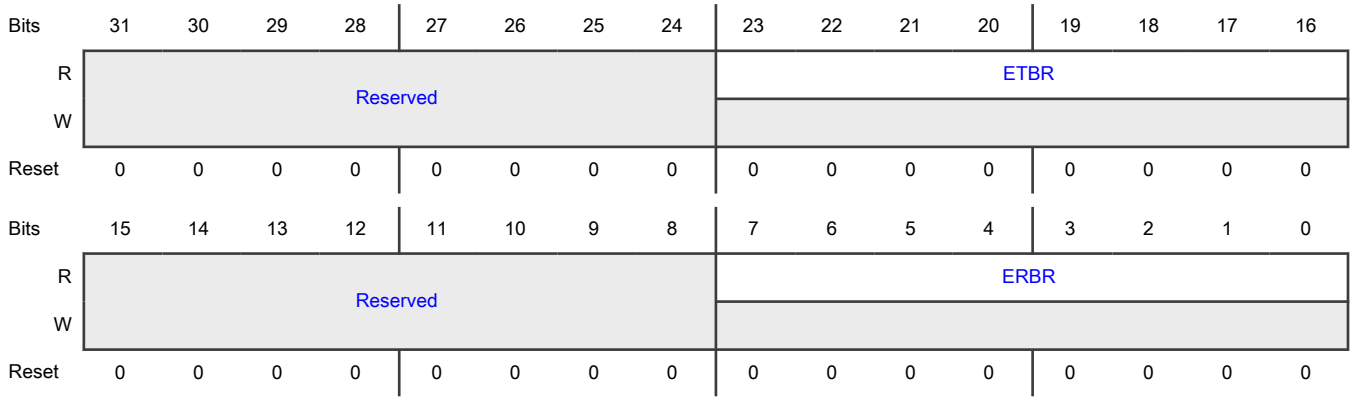
Indicates endpoint transmit and receive buffer ready status.

This register is only used in Device mode.

Offset

Register	Offset
ENDPTSTAT	1B8h

Diagram



Fields

Field	Description
31-24 —	Reserved
23-16 ETBR	Endpoint Transmit Buffer Ready Indicates the endpoint transmit buffer ready status. One bit for each endpoint indicates the status of the respective endpoint buffer. Hardware writes 1 to this field as a response to receiving a command from a corresponding field in Endpoint Prime (ENDPTPRIME). There is always a delay between writing 1 to the corresponding field in Endpoint Prime (ENDPTPRIME) and the endpoint indicating the ready status. This delay time varies based on the current USB traffic and the number of fields with value 1 in Endpoint Prime (ENDPTPRIME). This field becomes 0 via the USB reset, USB DMA system, or through Endpoint Flush (ENDPTFLUSH). ETBR[*n*]: Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily clears this field during hardware endpoint repriming operations when a dTD is retired and the dQH is updated.
15-8 —	Reserved
7-0 ERBR	Endpoint Receive Buffer Ready Indicates the endpoint receive buffer ready status. One bit for each endpoint indicates status of the respective endpoint buffer. Hardware writes 1 to this field as a response to receiving a command from a corresponding field in Endpoint Prime (ENDPTPRIME). There is always a delay between writing 1 to the corresponding field in Endpoint Prime (ENDPTPRIME) and the endpoint indicating the ready status. This delay time varies based on the current USB traffic and the number of fields with value 1 in Endpoint Prime (ENDPTPRIME). This field becomes 0 via the USB reset, USB DMA system, or through Endpoint Flush (ENDPTFLUSH). ERBR[*n*]: Endpoint [*n*], *n* is in 0–7

Fields

Field	Description
31-24 —	Reserved
23 TXE	TX Endpoint Enable Enables transmit endpoint. You must enable an endpoint only after it is configured. 0 - Disable 1 - Enable
22-20 —	Reserved
19-18 TXT	TX Endpoint Type Indicates the transmit endpoint type. If this field is 0, endpoint 0 is fixed as a control endpoint.
17 —	Reserved
16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. If you write 1 to this field, it forces the endpoint to return a STALL handshake to the host. The field continues returning a STALL response until you write 0 to it or if the field automatically becomes 0 after it receives a new Setup request. After receiving a Setup request, hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and the hardware continuing to write 0 to this field. In most systems, it is unlikely for the DCD to observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1 or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables the receive endpoint. Endpoint 0 is always enabled. 0 - Disable 1 - Enable
6-4 —	Reserved
3-2 RXT	RX Endpoint Type Indicates the receive endpoint type. If this field is 0, endpoint 0 is fixed as a control endpoint.
1 —	Reserved
0 RXS	RX Endpoint Stall Specifies whether the receive endpoint is stalled. If you write 1 to this field, it forces the endpoint to return a STALL handshake to the host. The field continues returning a STALL response until you write 0 to it or if the field automatically becomes 0 after it receives a new Setup request. After receiving a Setup request, hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	NOTE There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and the hardware continuing to write 0 to this field. In most systems, it is unlikely for the DCD to observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled

32.7.1.1.41 Endpoint Control 1 (ENDPTCTRL1)

Enables endpoint control 1.

This register is used for endpoint 1 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

31-24 —	Reserved
23 TXE	TX Endpoint Enable Enables the transmit endpoint. You must enable an endpoint only after it is configured. 0 - Disable 1 - Enable
22 TXR	TX Data Toggle Reset Resets transmit data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0 - Does not reset 1 - Resets
21 TXI	TX Data Toggle Inhibit Inhibits transmit data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to this field causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0 - Allow 1 - Inhibit
20 —	Reserved
19-18 TXT	TX Endpoint Type Indicates the transmit endpoint type. 00 - Control 01 - Isochronous 10 - Bulk 11 - Interrupt
17 TXD	TX Endpoint Data Source Specifies the transmit endpoint data source. This field is 0 by default, which refers to dual port memory buffer and DMA engine. You must always write 0 to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Description
16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. If this endpoint is configured as a control endpoint, this field automatically becomes 1 after receiving a Setup request. Hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) becomes 0. You can write 1 to this field to force the endpoint to return a STALL handshake to the host. This control continues to stall until you write 0 to this field or when it becomes 0 automatically for control endpoints. **NOTE** Control endpoint only: There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and hardware continuing to write 0 to this field. In most systems, it is unlikely that DCD will observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0 - Endpoint OK 1 - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables the receive endpoint. You must enable an endpoint only after it is configured. 0 - Disable 1 - Enable
6 RXR	RX Data Toggle Reset Resets receive data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0 - Does not reset 1 - Resets
5 RXI	RX Data Toggle Inhibit Inhibits receive data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to this field causes this endpoint to ignore the data toggle sequence and always accept data packets regardless of their data PID. 0 - Allow 1 - Inhibit

Table continues on the next page...

32.7.1.1.44 Endpoint Control 4 (ENDPTCTRL4)

Enables endpoint control 4.

This register is used for endpoint 4 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

Fields

Field	Description
31 WIR	Wake-Up Interrupt Request Indicates whether a wake-up interrupt request is received. This field becomes 0 by disabling the wake-up interrupt (writing 0 to CTRL1[WIE]).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This field indicates that a wake-up interrupt request is received on the OTG1 port and becomes 0 by disabling the wake-up interrupt (writing 0 to the OWIE field). 0 - No wake-up interrupt request received 1 - Wake-up interrupt request received
30 —	Reserved
29 WKUP_DPDM_EN	Wake-Up on DP/DM Change Enable Enables wake-up on DP/DM change. If this field is 0, wake-up on DP/DM changes are to be disabled only when VBUS is 0. If this field is 1, wake-up on DP/DM changes are to be enabled (default) (it is for device only). 0 - Disable 1 - Enable
28-22 —	Reserved
21 —	Reserved
20 —	Reserved
19-18 —	Reserved
17 WKUP_VBUS_EN	Wake-Up After VBUS Change Enable Enables wake-up after VBUS change. 0 - Disable 1 - Enable
16 WKUP_ID_EN	Wake-Up ID Enable Enables wake-up on ID change. 0 - Disable 1 - Enable
15 WKUP_SW	Software Wake-Up Forces software wake-up. 0 - Inactive

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Force wake-up
14 WKUP_SW_EN	Software Wake-Up Enable Enables software wake-up. 0 - Disable 1 - Enable
13-11 —	Reserved
10 WIE	Wake-Up Interrupt Enable Enables the OTG1 wake-up interrupt. CTRL1[WIR] also becomes 0 when disabling the interrupt. Prior to entering Suspend mode, you must turn off the wake-up interrupt enable after receiving a wake-up interrupt and turn it on again. 0 - Disable 1 - Enable
9 PWR_POL	Power Polarity Specifies the PMIC power pin polarity. 0 - Active low 1 - Active high
8 OVER_CUR_POL	Overcurrent Polarity Specifies the polarity of the OTG1 and OTG2 port overcurrent event, representing an overcurrent condition. 0 - High active (high on this signal represents an overcurrent condition) 1 - Low active (low on this signal represents an overcurrent condition)
7 OVER_CUR_DIS	Overcurrent Disable Disables overcurrent detection. 0 - Enable 1 - Disable
6-0 —	Reserved

32.7.2.1.3 USB OTG Control 2 (CTRL2)

Controls the integration-specific features of the USB module.

These features are not directly related to USB functionality, but they control special features, interfacing on the USB ports, and power control and wake-up functionality.

Fields

Field	Description
31 UTMI_CLK_VLD	UTMI Clock Valid Flag Indicates whether the UTMI clock from the USB PHY is valid. 0 - Default
30-28 —	Reserved
27-24 —	Reserved
23 SHORT_PKT_EN	Short Packet Interrupt Enables short packet interrupt. When enabled, the USB controller issues an interrupt when a short packet is received in Device mode, even if IoC of QTD is not set. 0 - Default
22-9 —	Reserved
8 OPMODE_OVERRIDEEN	UTMI_OpMode[1:0] Override Enable Overrides the controller's utmi_OpMode[1:0] signal to the PHY. 0 - Override disable

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Override enable
7-6 OPMODE_OVERRIDE	UTMI_OpMode[1:0] Override Value Overrides the controller's utmi_OpMode[1:0] signal to the PHY. 00 - Override to 2'b00 01 - Override to 2'b01 10 - Override to 2'b10 11 - Override to 2'b11
5-4 —	Reserved
3 LOWSPEED_EN	Low-Speed Enable Enables low speed. This field is 1 when AUTURESUME_EN is 1 and works on low speed. 0 - Default
2 AUTURESUME_EN	Auto Resume Enable Enables auto resume. This field is for the OTG1/OTG2 core UTMI PHY. The UH core has no such feature because the HSIC PHY does not support auto resume. To set USB, it sends resume with a 32 KHz clock when it detects remote wake-up from device. This feature is useful if the device drives a very short remote wakeup (minimum value is 1 ms for the USB2 spec) and system 24 MHz is off during Suspend mode. 0 - Default
1-0 VBUS_SOURCE_SEL	VBUS Source Select Specifies VBUS source select when detecting a VBUS wake-up event; it is for the UTMI PHY only. 00 - vbus_valid 01 - sess_valid 10 - sess_valid 11 - sess_valid

32.7.2.1.4 HSIC DLL Configure Register 4 (HSIC_DLL_CFG4)

Holds the internal control register bits of PHY.

Chapter 33
Universal Serial Bus 2.0 PHY (USB2_PHY)

33.1 Overview

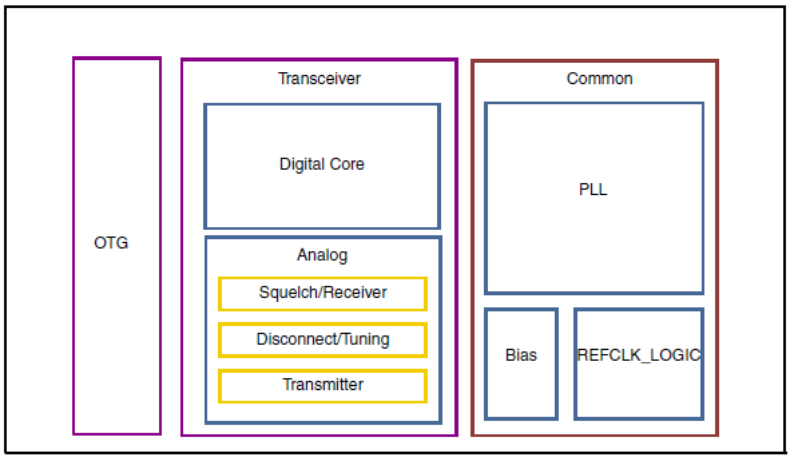
The USB 2.0 PHY, connects a USB controller to a USB system. This chapter provides an introduction to the USB 2.0 PHY and its features.

NOTE

The sections in this chapter are Synopsys Proprietary. Used with permission.

33.1.1 Block Diagram

The following figure shows the USB 2.0 PHY functional block diagram for a one-port macro.



33.1.1.1 System Level Block Diagram

The following figure shows the USB 2.0 PHY and its external interface connections.

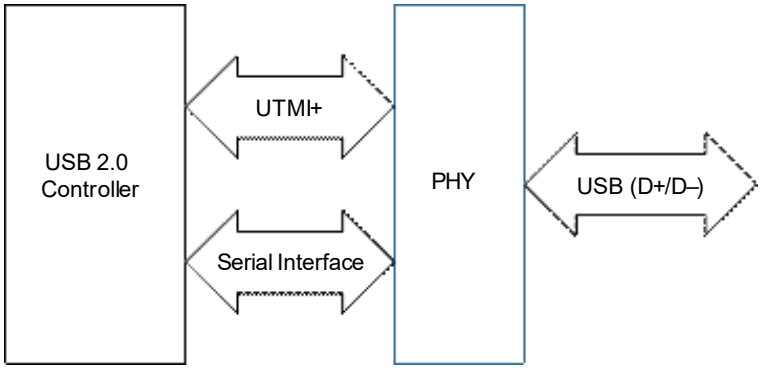


Figure 155. System Level Block Diagram

33.1.2 Features

The USB 2.0 PHY provides the following features.

General Features:

- Implements low power dissipation while active, idle, or on standby
- Fully integrates high-, full-, and low-speed (Host mode only) termination and signal switching
- Implements one parallel data interface and clock for high-, full-, and low-speed (Host mode only) USB data transfers
- Provides on-chip PLL to reduce clock noise and eliminate the need for an external clock generator
- Provides Universal Asynchronous Receiver/Transmitter (UART) support to enable the USB 2.0 PHY to receive and transmit asynchronous, serial data

USB 2.0 Features:

- Supports 480-Mbps high-speed, 12-Mbps full-speed, and 1.5-Mbps low-speed (Host mode only) data transmission rates
- Supports 8/16-bit unidirectional parallel interfaces for HS, FS, and LS (Host mode only) modes of operation, in accordance with the UTMI+ specification
- Provides dual (HS/FS) mode host support
- Implements data recovery from serial data on the USB connector
- Implements SYNC/End-of-Packet (EOP) generation and checking
- Implements Non Return to Zero Invert (NRZI) encoding and decoding Implements logic to support suspend, sleep, resume, and remote wakeup operations
- Supports battery charging to enable devices to draw current in excess of the USB 2.0 specification for charging and/or powering up from dedicated charging ports or charging downstream ports

33.1.3 Interfaces

Each USB 2.0 PHY port has three distinct external interfaces:

- USB Data Plus (D+) and Data Minus (D–) lines: These lines are USB 1.1 and 2.0 specificationcompliant. The USB 2.0 PHY supports high-speed, 480-Mbps transfers, as well as USB 1.1 fullspeed and low-speed transfers through the USB.
- USB 2.0 Transceiver Macrocell Interface (UTMI+): The USB 2.0 PHY supports the following modes through the UTMI+:
  - High-Speed (HS)
  - Full-Speed (FS)
  - Low-Speed Preamble (LS Preamble)

  The UTMI+ contains a receive port, a transmit port, and associated control lines to interface with a USB host controller or device controller. The receive and transmit ports can be configured as 8/16-bit parallel ports for all applicable modes of operation.
- Serial interface: This is the USB 1.1 controller interface that supports full-speed (FS-Serial mode) and low-speed (LS-Serial mode) data transmission rates to and from a USB 1.1 controller.

The USB 2.0 PHY handles low-level USB protocol and signaling. The USB 2.0 PHY supports SYNC detection, data serialization and deserialization, and data recovery.

33.1.4 Standards Compliance

The USB 2.0 PHY complies with the following standards:

- Universal Serial Bus Specification, Revision 2.0, with a High-Speed (HS) Transmit to Receive Inter- Packet Delay requirement of 38 bit-times provided by the UTMI specification version 1.05.
- Embedded Host Supplement to the USB Revision 2.0 Specification, Revision 2.0, USB Implementers Forum, Inc. ADP (Attach Detach Protocol) is not supported.
- UTMI+ Specification, Revision 1.0 (Level 3)

33.2 Clock Generation

The following figure shows the USB 2.0 PHY clock generation and distribution architecture, and the functional behavior of blocks that generate various clocks in the USB 2.0 PHY.

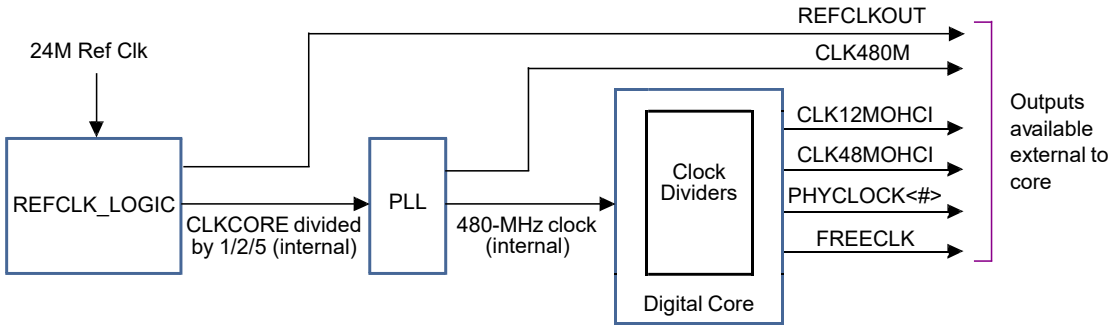

Figure 156. Clock Generation

33.3 Device Initialization

According to the USB 2.0 specification, a host must provide 100 ms between first detecting the D+ line at a high state and initiating a USB reset (SE0). The device pulling up the D+ line is expected to complete initialization within the 100-ms interval and be ready to respond to the host.

If the device requires more than 100 ms to initialize the device might connect the D+ resistance prior to initialization. After the 100-ms interval, the host initiates a USB reset. If the D+ pull-up resistance is enabled and remains enabled after the 100-ms interval, and if the device has not completed initialization, the device does not respond to the host correctly, and the transaction times out.

33.4 Tuning

The USB 2.0 PHY has an internal tuning circuit that ensures that the driver's impedance is within the USB 2.0 specification.

The USB 2.0 PHY performs two types of tuning:

- Incremental tuning: Incremental tuning occurs during an EOP, SOF, or SYNC pattern.
- Full tuning: Full tuning occurs during a power-on reset or after resume operation.

Chapter 34
Ethernet Controller with TSN (ENET_QoS)

34.1 Chip-specific ENET information

Table 312. Reference links to related information

Topic	Related module	Reference
A55	Arm Cortex CA55 Platform (CA55)	CA55 Platform
System memory map		System memory map
Clocking		Clock generation
Signal multiplexing	Port control	External signals and pin multiplexing

The chip includes has two 1G-bit Ethernet with AVB support (ENET).

34.3 Overview

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The EQoS-TSN module supports the 10/100/1000Mbps applications in compliance with IEEE802.3-2015 specifications. It can support advanced applications such as Time-Sensitive Networking (TSN) and Audio Video Bridge (AVB). Other prominent features of the MAC core include a flexible receive parser, media clock recovery and generation, and safety.

34.3.1 Block diagram

The following figure shows the block diagram of this module. The module has four main blocks to perform all functions. The AHB interface is connected to all DMA channels. The DMA arbiter helps in arbitration of all paths (transmit and receive) in channels. Each channel has a separate set of control and status registers (CSR) for managing the transmit and receive functions, descriptor handling, and interrupt handling.

NOTE

In multi queue/channel configurations, enable only Q0/CH0 on Tx and Rx for half-duplex operation. If you want to enable single queue/channel in full-duplex operation, any queue/channel can be enabled.

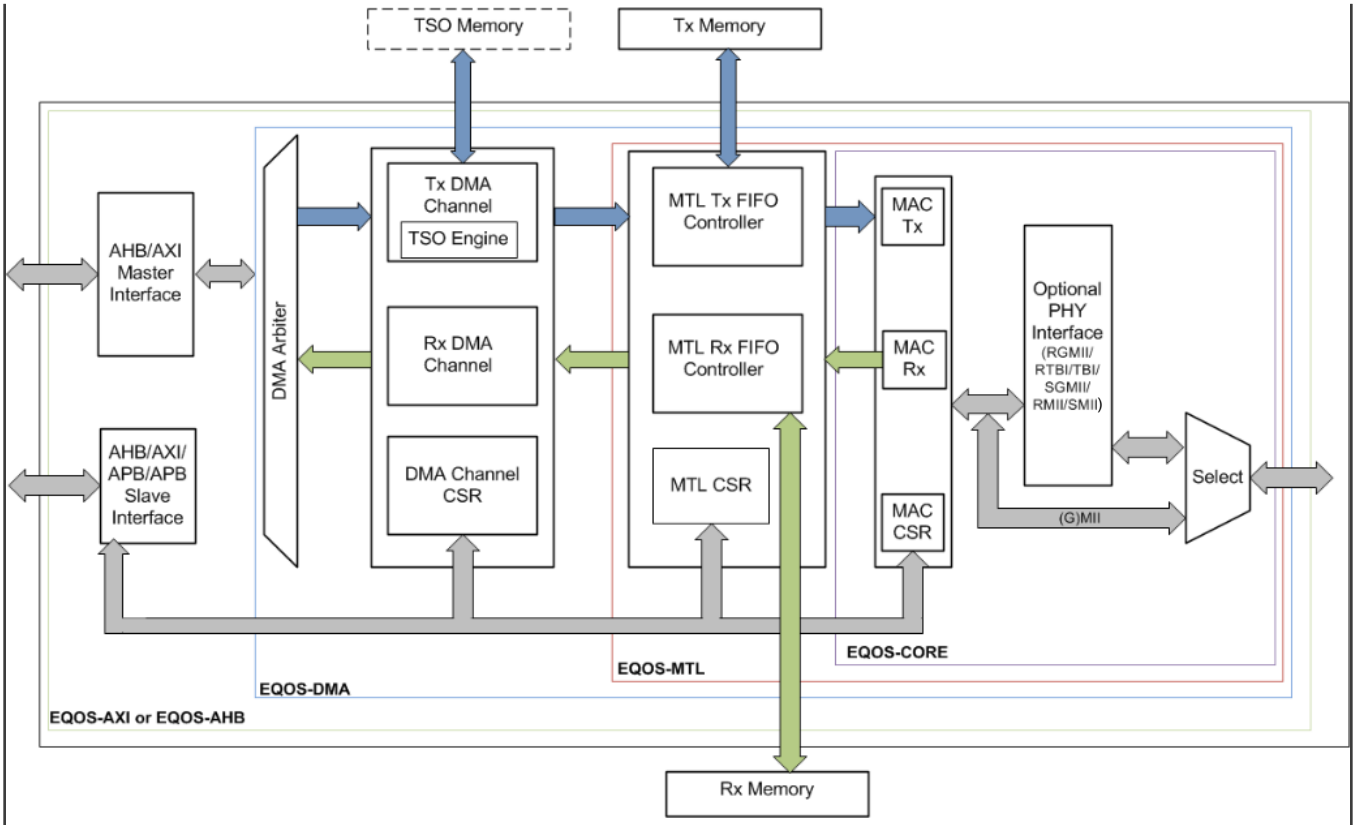

Figure 157. System-Level Block Diagram

34.3.2 Features

This module supports the following features in addition to the default features defined in IEEE802.3 specification

- RMII (10/100Mbps), RGMII (10/100/1000Mbps)
- Time aware shaper (IEEE802.1Qbv), Time synchronization (IEEE1588-2008), and Frame pre-emption (IEEE802.1Qbu) for Time-Sensitive Networking (TSN)
- Media clock recovery and generation for AVB
- RMII specification version 1.2 from RMII consortium
- RGMII specification version 2.6 from HP/Marvell
- Separate interface for Transmit, Receive and Control path
- Broadcast/Multicast Packet duplication
- Full duplex flow control operations (IEEE 802.3x pause packet and priority flow control)
- Network statistics with MAC management (RMON) counters
- Flexibility to control the Pulse per second (PPS) output signal
- MDIO (clause 22 and Clause 45) interface for configuration and management of PHY device
- Preamble and start of packet data (SFD) insertion/deletion
- Automatic CRC and pad generation/stripping option, option to disable CRC checking
- Programmable inter-packet gap
- Source address insertion/replacement

- VLAN insertion, replacement and deletion in transmitted packets with per-packet or static-global control
- Insertion, replacement and deletion of up to two VLAN tags
- Insertion, replacement and deletion of queue/channel based VLAN tags
- IEEE802.1Q VLAN tag detection and option to delete from received packets
- Programmable safety watchdog timeout limits
- Flexible address filtering modes:
  - Up to 2 additional 48-bit perfect (DA) address filters with masks for each byte
  - Up to 2 48-bit SA address comparison check with masks for each byte
  - 64-bit Hash filter for multicast and unicast (DA) addresses
  - Option to pass all multi-cast addressed packets
  - Promiscuous mode to pass all packets without any filtering for network monitoring
  - Pass all incoming packets (as per filter) with a status report
- Additional packet filtering:
  - VLAN tag-based: Perfect match and Hash-based filtering. Filtering based on either outer or inner VLAN tag is possible
  - Layer 3 and Layer 4-based: TCP or UDP over IPv4 or IPv6
  - Extended VLAN tag based filtering 4 filter selections

34.4 Functional description

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

The following sections describe functional details of the ENET module.

34.4.1 Architecture

This section describes the interfaces, protocols, and functionality. Following are the main blocks of the ENET QOS block.

- DMA Controller
- MAC Transaction Layer (MTL)
- MAC
- Interrupts

34.4.1.1 DMA controller

The DMA has independent Transmit (Tx) and Receive (Rx) engines, and a control and status register (CSR) space. The Tx engine transfers data from the system memory to the MTL interface, whereas the Rx engine transfers data from the MTL interface to the system memory. The DMA engine uses descriptors to efficiently move data from source to destination with minimal Host intervention. The DMA is designed for packet-oriented data transfers such as packets in Ethernet. The DMA controller can be programmed to interrupt the Host for situations such as Packet Transmit and Receive Transfer completion, and other normal or error conditions.

The DMA and Host communicate through the following two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

The DMA supports up to 5 Tx and 5 Rx Descriptor lists (or DMA channels). The base address of each list is written to the respective Tx Descriptor List Address register and Rx Descriptor List Address register. The descriptor list is forward linked and the next descriptor is always considered at a fixed offset to the current one. The offset is controlled by the DSL field of DMA_Ch[n]_Control register. The number of descriptors in the list is programmed in the respective Tx (or Rx) Descriptor Ring Length register. Once the DMA processes the last descriptor in the list, it automatically jumps back to the descriptor in the List Address register to create a descriptor ring.

The descriptor lists reside in the physical memory address space of the application. Each descriptor can point to a maximum of two buffers in the system memory. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the application physical memory space and consists of an entire packet or part of a packet but cannot exceed a single packet. Buffers contain only data. Buffer status is maintained in the descriptor. Data chaining refers to packets that span multiple data buffers. However, a single descriptor cannot span multiple packets. The DMA skips to the data buffer of next packet when end of packet (EOP) is detected.

This module supports the ring structure for the DMA descriptor. For more information on Descriptor, see the Descriptors .

Following sections describes the operation of DMA Controller.

34.4.1.1.1 DMA Controller Bus Burst Access

The DMA engines attempt to transfer data in a burst of maximum size as programmed in the PBL bit fields of Transmit Control and Receive Control registers of the respective DMA. The Rx and Tx descriptors are always accessed in the maximum possible (limited by PBL or 16 * 8/bus width) burst length for 16 bytes to be read. The burst transfers initiated by the DMA can be split into multiple burst transfers as per the AHB requirements and the settings of DMA_SysBus_Mode register.

The Tx DMA initiates a data transfer only when sufficient space is available in the MTL Tx Queue to accommodate either of the following:

- Bytes corresponding to the configured burst (PBL * bus_width/8)
- Remaining bytes in Tx Buffer without EOP
- Number of bytes till EOP

The Rx DMA initiates a data transfer in the following conditions:

- Sufficient data is available in MTL Rx Queue to accommodate the configured burst
- EOP (when it is less than the configured burst length) is detected in the Rx Queue

34.4.1.1.2 DMA application data buffer alignment

The Tx and Rx data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for buffers can be aligned to any of the four bytes. However, the DMA always initiates write transfers with address aligned to the bus width and dummy data (old data) in the invalid byte lanes. This typically happens during the transfer of the beginning or end of an Ethernet packet. For the receiver, the software driver should discard the dummy bytes based on the start address of the buffer and size of the packet.

Table 313. Data buffer alignment examples

Examples	
Buffer Read	If the Tx buffer address is 32'h00000FF2 (for 32-bit data bus), and 15 bytes need to be transferred, the DMA reads five full words from address 32'h00000FF0, but when transferring data to the MTL Tx queue, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are also ignored. The DMA always ensures that it transfers a full 32-bit data to the MTL Tx queue, unless it is the end of packet.

Table continues on the next page...

Table 313. Data buffer alignment examples (continued)

Buffer Write	If the Rx buffer address is 32'h0000FF2 (for 64-bit data bus) and 16 bytes of a received packet need to be transferred, the DMA writes 3 full words from address 32'h00000FF0. However, the first 2 bytes of the first transfer and the last 6 bytes of the third transfer have dummy data. The DMA considers the offset address only if it is the first Rx buffer of the packet. The DMA ignores the offset address and performs full word writes for the middle and the last Rx buffer of the packet.

34.4.1.1.3 DMA buffer size calculations

The DMA does not update the size fields in the Tx and Rx descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver has to perform the size calculations.

The Tx DMA transfers the exact number of bytes (indicated by buffer size field of TDES2) towards the MAC. If a descriptor is marked as first (FD bit of TDES3 is set), the DMA marks the first transfer from the buffer as SOP. If a descriptor is marked as last (LD bit of TDES3), the DMA marks the last transfer from that data buffer as EOP to the MTL.

The Rx DMA transfers data to a buffer until the buffer is full or the end of packet is received from the MTL. When the FD bit of a descriptor is set, the amount of valid data in a buffer is accurately indicated by the buffer size field (programmed in DMA Channel Receive Control register) minus the data buffer pointer offset. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, the buffer may not be full (as indicated by the buffer size in Bits [14:1] of Receive Control register). To compute the amount of valid data in this final buffer, the driver must read the packet length (PL bits of RDES3[14:0]) and subtract the sum of the buffer sizes of the preceding buffers in this packet. The Rx DMA always transfers the start of next packet with a new descriptor.

34.4.1.2 MAC transaction layer

The MAC Transaction Layer (MTL) provides the FIFO memory Interface to buffer and regulate the packets between system memory and the MAC. It also enables the data to be transferred between the system clock and MAC clock domains. The MTL layer has two data paths: Transmit path and Receive Path. The size of the FIFO is 8 Kb for Tx and Rx. The MTL communicates with the host through Application Transmit Interface (ATI) on the Transmit path and Application Receive Interface (ARI) on the receive path.

34.4.1.2.1 Transmit path

Internal DMA handles all transactions for the transmit path through ATI. Internal DMA pushes the Ethernet packets read from system memory into the corresponding queue. The packet is then popped out and transferred to the MAC when the queue threshold is reached (threshold mode) or complete packet is in the queue (store-and-forward mode). When EOP is transferred, the status of the transmission is taken from the MAC and transferred back to the internal DMA.

34.4.1.2.1.1 Transmit control word

The following control information related to packet transmission is provided as a part of the Control Word through ATI interface:

- Packet Length (if DCB is enabled with WFQ scheduling algorithm)
- CRC Pad Control
- Source Address Insertion Control
- VLAN Insertion and Replacement Control and VLAN Tag for Outer and Inner VLAN Tags
- TCP/IP Checksum Insertion Control
- One-step Timestamping Control Correction
- Transmit Timestamp Enable

34.4.1.2.1.2 Transmit operation

The following two modes of operation triggers reading of the data towards the MAC:

- Threshold mode: In Threshold (or cut-through) mode, as soon as the number of bytes in the Queue cross the configured threshold level (or when the end of packet is written before the threshold is crossed), the data is ready to be popped out and forwarded to the MAC. The threshold level is configured by using the TTC bits of MTL_TxQ0_Operation_Mode register corresponding to an MTL queue.
- Store-and-forward mode:

In store-and-forward mode, the MTL pops out the packet towards the MAC only when one or more of the following conditions are true:

- A complete packet is stored in the Queue
- The Tx FIFO becomes almost full
- The ATI watermark becomes low

The watermark becomes low when the requested queue does not have space to accommodate the requested burst length on the ATI. Therefore, the MTL when operating in the store-and-forward mode allows packet transmission even if the packet length is bigger than the Tx queue size.

The application can flush complete content of the Tx queue by setting Bit 0 (FTQ) of Transmit Operation Mode register corresponding to an MTL queue. This bit is self-clearing and initializes the Queue pointers to the default state. If the FTQ bit is set during a packet transfer from the MTL to the MAC, the MTL stops further transfer because the queue is considered to be empty. Therefore, an underflow event occurs at the MAC transmitter.

34.4.1.2.1.3 Initialization flow

Upon reset, the MTL is ready to manage the flow of data to and from the DMA, and MAC. For configurations with a single Transmit Queue, there are no initialization requirements for enabling the MTL. For configurations with multiple Transmit Queues, initialize the queue size for each of the queues by programming the TQS bits of MTL_TxQ0_Operation_Mode register corresponding to a Transmit queue. Also, initialize the MAC block. Internal DMA controllers must be individually enabled through their respective CSRs.

34.4.1.2.2 Receive path

The MTL Rx module receives the packets from the MAC and pushes them into the Rx Queue. The status (fill level) of the queue is indicated to DMA when it crosses the configured Receive threshold (RTC bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue), or the complete packet is received. The MTL also indicates the fill level of the queue so that the DMA can initiate preconfigured burst transfers towards the AHB interface.

For more information on queues, see Multiple Channels and Queues Support.

34.4.1.2.2.1 Receive Operation

During a Receive operation, the MTL is a slave for the MAC. The general sequence of events is as follows:

1. When the MAC receives a packet, it indicates the availability of receive data.
2. The MAC indicates the SOP and EOP delimiters.
3. The MTL accepts the data and pushes it into corresponding Rx queue.
4. After the EOP is transferred, the MAC drives the status word which is also pushed into the corresponding Rx queue by the MTL.
5. If IEEE 1588 timestamp feature is enabled and the 64-bit timestamp is available along with the packet status, it is pushed into the Rx queue as a part of the status word. Therefore, two additional locations are taken per packet to store the timestamp in the Rx queue.
6. The MTL takes the data out of the queue and sends it to the DMA depending on the following modes:

34.4.1.2.2.1.1 Threshold mode

In the (default) Threshold mode, the MTL reads the data and indicates its availability to the application or DMA when one of the following occurs:

- Data bytes equal to the threshold amount are written to the Rx queue (RTC bits[1:0] of MTL_RxQ0_Operation_Moderegister of corresponding MTL queue)
- A full packet of data is received into the queue

34.4.1.2.2.1.2 Store and forward mode

In the store-and-forward mode (when Bit 5 of MTL_RxQ0_Operation_Mode register of a queue is set to 1), the initial Rx queue locations are reserved for the status words before writing the SOP. A packet is read out only after it is completely written into the Rx queue. In this mode, all error packets are dropped (if configured through Bit 4 of MTL_RxQ0_Operation_Mode register of a queue) such that only valid packets are read and forwarded to the application.

34.4.1.2.2.2 Multi packet receive operation

In Threshold mode, the packet status is available immediately after the packet data. In store-and-forward mode, the packet data is available after the packet status. The MTL is capable of storing any number of packets into the queue as long as it is not full.

If the MAC receives a packet when the corresponding Rx queue is full, the MTL ignores that packet and overflow pulse is generated on the corresponding Rx queue. In addition, the MTL increments the overflow counter in the MTL_RxQ0_Missed_Packet_Overflow_Cnt of corresponding queue.

34.4.1.2.2.3 Error handling in receive operation

Following things would happen, If the MTL Rx queue is full before it receives the EOP data from the MAC.

1. An overflow is declared
2. The whole packet (including the status word) is dropped
3. The overflow counter in the DMA (Overflow Counter register of corresponding MTL queue) is incremented.

This is true even if Bit 4 (FEP) of MTL_RxQ0_Operation_Mode register of corresponding MTL queue is set.

If the start address of such a packet has already been transferred to the Read Controller, the rest of the packet is dropped and a dummy EOP is written to the queue along with the status word with overflow status. The status indicates a partial packet because of overflow. In such packets, the Packet Length field is invalid. If the MTL Receive Queue is configured to operate in the store-and-forward mode and the length of the received packet is more than the queue size, overflow occurs and all such packets are dropped.

The MTL Rx Control logic can filter error and undersized packets, if enabled by using the FEP and FUP bits of MTL_RxQ0_Operation_Mode register of corresponding MTL queue. If the start address of such a packet has already been transferred to the Rx Queue Read Controller, that packet is not filtered. The start address of the packet is transferred to the Read Controller after the packet crosses the receive threshold set by Bits[1:0] of MTL_RxQ0_Operation_Mode register of corresponding MTL queue.

If the MTL Receive Queue is configured to operate in the store-and-forward mode, all error packets can be filtered and dropped. For the application or DMA to flush the error packet being read from the queue, it must assert the flush signal. The MTL then stops transferring data to the application (DMA). It internally reads the rest of the packet and drops it. The MTL then starts the transfer of next packet (if available).

34.4.1.3 MAC

MAC can support RMII or RGMII Phy interface. MAC consists of Mac Transmit interface (MTI), MAC Receive Interface (MRI) and MAC Control Interface (MCI).

34.4.1.3.1 MAC transmission

The MAC transmission process is as follows:

1. Transmission is initiated when the MAC Transaction Layer (MTL) pushes in data with the SOP signal asserted.
2. When the SOP signal is detected, the MAC accepts the data and begins transmitting to the RMII or RGMII.

3. After the EOP is transferred to the MAC, the MAC does one of the following:
   - The MAC completes the normal transmission and gives the transmission status to the MTL.
   - If a normal collision (in half-duplex mode) occurs during transmission, the MAC gives the Transmit Status with retry bit set to the MTL. The MAC gives the Retry request till one of the following is true:
     - Packet is successfully transmitted
     - Maximum retry requests expire
     - When maximum retry requests expire, the MAC aborts the packet transmission with Excessive Collision Transmit Status. The MAC accepts and drops all further data until the next SOP is received. The MTL block should retransmit the same packet from SOP on observing a Retry request (in the Status) from the MAC.
   - If any one of the following happens, the MAC aborts the packet transmission:
     - No carrier (half-duplex mode)
     - Loss of carrier (half-duplex mode)
     - Excessive deferral (half-duplex mode)
     - Late collisions (half-duplex mode)
     - Jabber
     - The MAC accepts and drops all further data until the next SOP is received
4. The MAC issues an underflow status if the MTL is not able to provide the data continuously during the transmission. The MAC accepts and drops all further data until the next SOP is received.
5. During the normal transfer of a packet from MTL, if the MAC receives a SOP without getting an EOP for the previous packet, it ignores the SOP and considers the new packet as continuation of the previous packet.

34.4.1.3.2 MAC reception

A receive operation is initiated when the MAC detects an SFD on RMII, RGMII, or MII. The MAC strips the preamble and SFD before proceeding to process the packet. The header fields are checked for filtering and the FCS field used to verify the CRC for the packet. The received packet is stored in a shallow buffer until the address filtering is performed. The packet is dropped in the MAC if it fails the address filter.

34.4.2 Using PHY interfaces

This module support the following modes:

- RMII 10/100 Mbps interface
- RGMII 10/100/1000 Mbps interface

The internal Phy_intf_sel input signal decides which mode has been selected. Phy_intf_sel signal gets sampled at reset. PS and FES bit of MAC configuration register selects the speed of mode.

The module supports the IEEE802.3-2015 specification for RMII (RMII specification version 1.2 from the RMII consortium) and RGMII specification.

NOTE

RMII reference clock (50 MHz) can be fed to IP from an external source or internally from PLL on SoC.

The module supports can access the phy registers through Station Management Agent (SMA) which is a two wire Station management interface (MIM). One wire is management data clock (MDC) and other wire is management data input/output (MDIO). As per IEEE 802.3 specification, maximum operating frequency of MDC is 2.5 Mhz which can be derived from system clock using a divider. The CR bit of MAC_MDIO_Address register can be programmed to generate different MDC clock frequency.

SMA supports both MDIO clause 45 and clause 22 frame structure as per IEEE802.3 specification. The C45E bit of MAC_MDIO_Address register can be set to enable the clause 45 frame structure.

34.4.3 VLAN and double VLAN insertion, deletion, replacement and tagging

These sections describes the VLAN and Double VLAN features.

34.4.3.1 Double VLAN processing

The module can support processing of two VLAN tags in double VLAN tagging processing. These two VLAN tags can also be named as inner (C-VLAN) and outer (S-VLAN) VLAN tag. If packet is having only one tag then it would be considered as outer tag.

It supports the following function in Double VLAN processing feature using the MAC_VLAN_Incl, MAC_Inner_VLAN_Incl and MAC_VLAN_Tag registers.

- Insertion, replacement, or deletion of up to two VLAN tags in the Transmit path.
- Packet filtering and stripping based on any one of the two VLAN Tags in the Receive path. Stripping and providing up to two VLAN Tags in the Receive path as a part of the Receive status.

34.4.3.1.1 Transmit path

Following table describes the features supported by the MAC on the Transmit side.

Table 314. Double VLAN Processing Features in Transmit Path

Feature	Description
Support for C-VLAN and S-VLAN Tag types	The inner or outer VLAN tag can be of C-VLAN and S-VLAN type. The VLAN type is specified through the CSVL bit of MAC_VLAN_INCL and MAC_INNER_VLAN_INCL registers. The module supports processing of any sequence of outer and inner VLAN tags. **NOTE** The module does not support the C-VLAN S-VLAN sequence. The MAC does not check whether the packet provided by the application has a valid sequence of the VLAN Tag types or the insertion or replacement operation results in invalid sequence of VLAN Tag type. Therefore, the application must provide correct sequence of VLAN Tag types and program the MAC in such a way that it results in correct sequence of VLAN Tag types in the transmitted packet. The application must ensure the following: • The inner tag should not be S-VLAN when outer C-VLAN Tag insertion is enabled. • The outer tag should not be C-VLAN when inner S-VLAN Tag insertion is enabled. • The inner tag should not be S-VLAN when outer tag should be replaced with C-VLAN. • The outer tag should not be C-VLAN when inner tag should be replaced with S-VLAN.
VLAN Tag deletion	VLAN tag deletion for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN deletion is enabled, the MAC deletes the tag present at the corresponding position. When a packet has only one tag, it is considered as the outer tag. If inner tag deletion is enabled and the packet has only one tag, the MAC does not delete the inner tag.
VLAN Tag Insertion or Replacement	VLAN tag insertion or replacement for outer or inner tag can be enabled through VLC field in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register, respectively. When VLAN tag insertion or replacement is enabled, the VLTI bit in the MAC_VLAN_Incl or MAC_Inner_VLAN_Incl register is used to determine whether the VLAN tag should be taken from the register or the Control Word.

34.4.3.1.2 Receive path

Following table describes the features supported by the MAC on the receive side and the corresponding bits in the MAC_VLAN_Tag register.

Table 315. Double VLAN Processing in Receive Path

Feature	Description
Outer or inner VLAN tag-based filtering	The MAC can filter packets based on the outer or inner VLAN tag through the ERIVLT bit.
C-VLAN or S-VLAN tag-based filtering	The MAC can filter packets based on the C-VLAN or S-VLAN type based on the ERSVLM bit.
Outer and Inner VLAN Tag stripping	The MAC can strip the outer and inner VLAN Tags from received frame based on the EVLS and EIVLS bits.
16-bit outer and inner VLAN Tag and Type in Rx status	The MAC can provide the 16-bit outer and inner VLAN Tag and Type in the Rx status based on the EVLRXS and EIVLRXS bits, respectively.
Disabling or skipping checking of outer VLAN Tag type	The MAC can disable or skip checking of outer VLAN Tag type to match C-VLAN or SVLAN based on the DOVLTC bit.

34.4.3.1.3 Source address and VLAN insertion, replacement, or deletion

The module supports the SA and VLAN insertion, replacement and deletion. The source address (SA) and VLAN fields are Tx packet-related control information that are provided as part of the control word through interfaces. IP supports the feature to insert or replace the source address based on the information in the MAC Address Registers, and also the feature to insert, replace or delete the VLAN fields (VLAN Type and VLAN Tag) based on the setting of the VLTI bit in the MAC_VLAN_Incl register. SA insertion or replacement feature can be enabled for all Transmit packets or selective packets. Similarly, VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets or selective packets.

34.4.3.1.4 Programming source address insertion or replacement

The software can use the SA insertion or replacement feature to instruct the MAC to do the following for Tx packets:

- Insert the content of the MAC Address Registers in the SA field
- Replace the content of the SA field with the content of the MAC Address Registers

When SA insertion is enabled, the application must ensure that the packets sent to the MAC do not have the SA field. The MAC does not check whether the SA field is present in the Transmit packet and it inserts the content of MAC Address Registers in the SA field. Similarly, when SA replacement is enabled, the application must ensure that the SA field is present in the packets sent to the MAC.

The MAC replaces the six bytes following the Destination Address field in the Transmit packet with the content of the MAC Address Registers.

- SARC bit of MAC_Configuration register can be program to enable the SA insertion or replacement for all Tx packets.
- SA insertion for selective packet can be enabled by programming the SA Insertion Control field (bits [25:23] of TDES3) in the first Transmit descriptor of the packet. When Bit 25 of TDES3 is set, the SA Insertion Control field indicates insertion or replacement by MAC Address1 registers. When Bit 25 of TDES3 is reset, it indicates insertion or replacement by MAC Address 0 registers.

If MAC Address1 Registers are not enabled, the MAC Address0 registers are used for insertion or replacement irrespective of the value of the most-significant bit of the SA Insertion Control field.

34.4.3.1.5 Programming VLAN insertion, replacement, or deletion

The software can use the VLAN insertion, replacement, or deletion feature to instruct the MAC to do the following for Tx packets:

- Delete the VLAN Type and VLAN Tag fields

- Insert or replace the VLAN Type and VLAN Tag fields

Insertion or replacement is done based on the setting of VLTI bit in the MAC_VLAN_Incl register as described in the following table:

Table 316. VLAN Insertion or Replacement Based on VLTI Bit

Condition	Description
VLTI bit is set	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field depending on the Content of the VT field of Transmit context descriptor of the packet
VLTI bit is reset	The MAC inserts or replaces the following: • VLAN Type field (C-VLAN or S-VLAN as indicated by the CSVL bit of MAC_VLAN_Incl register) • VLAN Tag field with the VLT field of MAC_VLAN_Incl register

When VLAN replacement or deletion is enabled, the MAC checks if the VLAN Type field (0x8100 or 0x88a8) is present after the DA and SA fields in the Transmit packet. The replace or delete operation does not occur if the VLAN Type field is not detected in two bytes following the DA and SA fields. However, when VLAN insertion is enabled, the MAC does not check the presence of VLAN Type field in the Transmit packet and just inserts the VLAN Type and VLAN Tag fields.

VLAN insertion, replacement, or deletion feature can be enabled for all Tx packets by programming the VLC and VLP fields of MAC_VLAN_Incl register.

VLAN insertion, replacement, or deletion for selective packets can be enabled by programming the VTIR field of TDES2 Normal Descriptor.

In addition, the VLP (VLAN Priority control) bit must be reset in MAC_VLAN_Incl register (for outer VLAN) and MAC_Inner_VLAN_Incl register (in inner VLAN) for the MAC to take the control inputs from the host, depending on the configuration.

34.4.3.1.6 Queue/Channel Based VLAN Tag Insertion on Tx

This module supports channel/queue based VLAN tag insertion on all transmitted packets.

34.4.3.1.6.1 Accessing Queue/Channel Specific VLAN Tag Registers

Queue/Channel specific VLAN tag registers are accessed using indirect addressing through the MAC_VLAN_Incl register. VLAN type and tag value can be independently programmed for each queue/channel.

34.4.4 Packet Filtering

There are various packets filtering scheme available in MAC receiver. Filtering sequence in their precedence order of received packet is shown in the following figure.

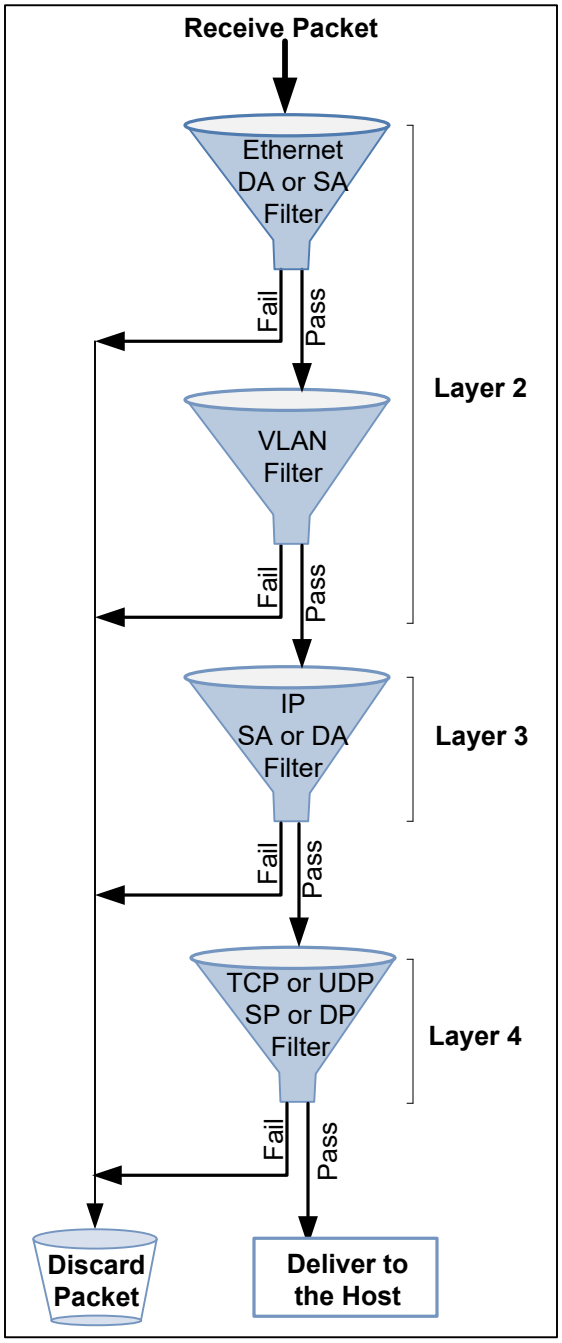

Figure 158. Packet Filtering Sequence

If any of the Layer filters are not enabled, that filter is bypassed and the subsequent filter is applied. A packet that fails any of the filters, is discarded. However, depending on the entry address and the number of parsed entries of the frame offset, discarded packets can be routed to RX_DMA_CH0 and a parser interrupt can be generated.

Even if no parser matched, the frame can be routed into the DMA channel indicated in DMA_CH_NO[2:0].

34.4.4.1 Source address or destination address filtering

The Address Filtering Module of the MAC checks the source address (SA) and destination address (DA) fields of each incoming packet. Programming of different type of address filtering is described in the following sections.

34.4.4.1.1 Unicast destination address filtering

MAC supports up to 64 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of MAC_Packet_Filter register is reset), the MAC compares all 48 bits of received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled. The MacAddr1 to MacAddr63 addresses are selected with an individual enable bit. Each byte of MacAddr1 to MacAddr31 can be masked during comparison with corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This enables group address filtering for the DA.

In hash filtering mode (when HUC bit is set), the MAC performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the MAC uses the upper 6 bits CRC(by CRC32) of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register, and a value of 111111 selects Bit 63 of Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast packet is considered to have passed the Hash filter; otherwise, the packet is considered to have failed the Hash filter.

34.4.4.1.2 Multicast destination address filtering

PM bit of MAC_Packet_Filter register can be enabled to pass all multicast packets or disabled to do multicast addresses filtering based on HMC bit of MAC_Packet_Filter register. The multicast address is compared with the programmed MAC Destination Address registers (1–31). Also, Group address filtering is supported.

In Hash filtering mode, the MAC performs imperfect filtering using a 64-bit Hash table. The MAC uses the upper 6-bits CRC(by CRC32) of received multicast address to index the content of the Hash table. A value of 000000 selects Bit 0 of selected register and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit is set to 1, the multicast packet is considered to have passed the Hash filter. Otherwise, the packet is considered to have failed the Hash filter.

34.4.4.1.3 Hash or perfect address filtering

HPF bit of MAC_Packet_Filter register must be configured for enabling or disabling the destination address filtering by either Hash filter or Perfect filter. HUC and HMC bit of MAC_Packet_Filter register must be configured to select the Hash filtering or Perfect filtering for Unicast/Multicast packet.

34.4.4.1.4 Broadcast address filtering

The MAC does not filter any broadcast packets by default. DBF bit of MAC_Packet_filter register must be set to reject the broadcast packets.

34.4.4.1.5 Unicast source address filtering

By default, MAC compares the source address field with the value programmed in the source address registers. Bit 30 of MAC address register [1-2] can be configure to use it for source address instead of destination address comparison. The MAC also supports group filtering with source address(SA) . You can filter a group of addresses by masking one or more bytes of the address. The MAC drops the packets that fail the SA filter if the SAF bit is set in MAC_Packet_Filter register. Otherwise, the result of the SA filter is given as a status bit in the Receive Status word. When the SAF bit is set, the SA filter and DA filter result is AND'ed to decide whether the packet needs to be forwarded. This means that the packet is dropped if either filter fails. The packet is forwarded to the application only if the packet passes both filters in-order.

34.4.4.1.6 Inverse filtering

For DA and SA filtering, you can invert the filter-match result at the final output by setting the DAIF and SAIF bits of MAC_Packet_Filter register. The DAIF bit is applicable for both Unicast and Multicast DA packets. The result of the unicast or multicast destination address filter is inverted in this mode. Similarly, when the SAIF bit is set, the result of unicast SA filter is reversed.

Following two tables summarize the DA and SA filtering based on the type of packets received.

Table 317. Destination Address Filtering

Packet Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	DA Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all packets
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all packets
	X	X	X	X	X	1	X	Pass all packets
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause packets if PCF = 0x
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Pause packets if PCF = 0x
	0	1	X	1	1	0	X	Fail on Hash or Perfect/Group filter match and drop Pause packets if PCF = 0x

Table 318. Source Address Filtering

Packet Type	PR	SAIF	SAF	SA Filter Operation
Unicast	1	X	X	Pass all packets.

Table continues on the next page...

Table 318. Source Address Filtering (continued)

Packet Type	PR	SAIF	SAF	SA Filter Operation
	0	0	0	Pass status on Perfect or Group filter match but do not drop packets that fail
	0	1	0	Fail status on Perfect or Group filter match but do not drop packet
	0	0	1	Pass on Perfect or Group filter match and drop packets that fail
	0	1	1	Fail on Perfect or Group filter match and drop packets that fail

NOTE

When the RA bit of MAC_Packet_Filter register is set, all packets are forwarded to the system along with the correct result of the address filtering in the Rx Status.

34.4.4.2 VLAN Filtering

VLAN tag filter can be done by either perfect match or hash table. Depending upon the configuration, MAC can compare either lower 12 bits or all 16 bits of received VLAN tag for perfect match. MAC forwarded the VLAN tagged packet with match status while it drops all the packets which don't matches.

MAC uses 16-bit VLAN hash table for group address filtering based on the VLAN tag. If hash filtering is enabled then most significant 4-bit of CRC-32 of VLAN tag are used to index the content of the VLAN Hash Table Register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the VLAN tag of the packet matched and the packet should be forwarded. A value of 0 indicates that VLAN-tagged packet should be dropped.

The MAC also supports the inverse matching for VLAN packets. In the inverse matching mode, when the VLAN tag of a packet matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a packet is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.

Table below shows the different possibilities for VLAN matching and the final VLAN match status. When the RA bit of MAC_Packet_Filter register is set, all packets are received and the VLAN match status is indicated in the VF bit of RDES2 Normal Descriptor (Write-Back Format). When the RA bit is not set and the VTFE bit is set in MAC_Packet_Filter register, the packet is dropped if the final VLAN match status is Fail.

When VLAN VID is programmed to 0 in the VL field of MAC_VLAN_Tag register, all VLAN-tagged packets are considered as perfect matched but the status of the VLAN hash match depends on the VTHM and VTIM bits in MAC_VLAN_Tag register.

Table 319. VLAN Match Status

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
VID = 0	Pass	0	X	X	Pass
	Pass	1	X	0	Pass
	Pass	1	Fail	1	Pass
	Pass	1	Pass	1	Fail
VID!= 0	Pass	X	X	0	Pass

Table continues on the next page...

Table 319. VLAN Match Status (continued)

VID	VLAN Perfect Filter Match Result	VTHM Bit	VLAN Hash Filter Match Result	VTIM Bit	Final VLAN Match Status
	Fail	0	X	0	Fail
	Fail	1	Fail	0	Fail
	Fail	1	Pass	0	Pass
	Fail	0	X	1	Pass
	Pass	X	X	1	Fail
	Fail	1	Pass	1	Fail
	Fail	1	Fail	1	Pass

In this table, X represents any value.

34.4.4.3 VLAN Filter Fail Packets Queue

When VLAN filtering is enabled, the VLAN Filter Fail Packets can be routed to a programmable Queue (VFFQ) when Bit RA = 1 or VTFE = 0 of MAC_Packet_Filter register and the enable bit (VFFQE of MAC_RXQ_CTRL4) for the queue is set.

The packets that passes the VLAN filtering, are routed to Rx queues based on the VLAN TAG priority field by programming the PSRQ in the corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers. The packets that fail the VLAN filter are discarded if RA=0 or VTFE=1. However, when RA=1 or VTFE=0, the VLAN filter fail packets are still forwarded to the application. In such a scenario, when the VLAN Filter Fail Queue Enable (VFFQE) bit is set, the VLAN filter fail packets are forwarded to the Rx queue number programmed in the VFFQ bit. If VFFQE=0, the Rx queue number is determined by the VLAN priority mapping as per the PSRQ fields.

Table below shows the Rx Queue routing table for Unicast tagged packets, with DA/SA Filter enabled.

Table 320. Rx Queue Routing table for Unicast Tagged Packets

RA	VFTE	SA/DA Filter Result	VLAN Filter Result	VFFQE	Queue Routing
X	X	PASS	PASS	X	PSRQ
0	0	PASS	FAIL	0	PSRQ
0	0	PASS	FAIL	1	VFFQ
0	X	FAIL	X	X	DROPPED
0	1	PASS	FAIL	X	DROPPED
1	X	FAIL	X	0	UFFQ*/PSRQ
1	X	FAIL	X	1	UFFQ*/VFFQ
1	X	PASS	FAIL	0	PSRQ
1	X	PASS	FAIL	1	VFFQ

X : Don't care condition * : When UFFQE is enabled else PSRQ

34.4.4.4 Extended Receive VLAN Filtering and Routing

When Extended Rx VLAN filtering and routing is enabled then both perfect filtering and Hash filtering can be enabled. The overall VLAN filter result is based on the Perfect filter result and Hash filter result (if enabled). Filter result is passed to application/software as part of the status bit. Extended Routing will happen only if VLAN filter has passed. Routing is only based on Perfect filter result. Each Perfect filter has a DMA channel enable and DMA channel number filed which should be programmed for routing.

For more details about routing, see details on 'Extended VLAN Based DMA Selection' in Dynamic (Per Packet) Mapping.

34.4.4.4.1 Comparison mode

Software/Application has following comparison option for each VLAN tag filter

- It can program the MAC to compare the inner or outer VLAN tag with either 12 bits or 16 bits programmed VID.
- It can choose that VID comparison is for SVLAN or CVLAN type frames, if type check is enabled for a filter.

34.4.4.4.2 Filtering

Perfect Filtering is done based on the MAC_VLAN_Tag_Filter registers. For each VLAN Tag Filter, the MAC will compare the relevant VLAN Tag ID and gives a result. If any one of the VLAN Tag Filters gives a match then the frame is considered to have passed the VLAN Tag Filters. If the frame mismatches all the filters, then the frame is considered to have failed the VLAN filter. This behavior is applicable only when the Inverse Filtering is not enabled in MAC_VLAN_Tag_Ctrl Register.

If inverse Filtering is enabled and the frame has mis-matched all the relevant filters then it is considered to have passed the VLAN filter. If the frame matches any one of the relevant filters then it is considered as a fail. If none of the enabled filters can perform a comparison or if none of the filters are enabled, then the frame is bypassed to the application.

The overall filter result and the programming on the VTFE and RA bits of the MAC Filter Register determine if the frame will be dropped or forwarded to the application. If RA = 1 or VTFE = 0, it does not matter if the filter result is a pass or fail. The frame is always forwarded. If RA = 0 and VTFE = 1, only then, if the VLAN Tag Filter result is a pass does the MAC forward the frame. If the frame is forwarded to the application, then the relevant filter result is indicated through the Status bits.

34.4.4.4.3 Filter Status

The Extended Receive VLAN Filtering and Routing feature provides two status bits to indicate the comparison result of the VLAN tags.

By default, the MAC indicates the VLAN Filter Status through one bit in the status – VF field in RDES2. When Extended RX VLAN Filtering and Routing is enabled, two status bits are used to indicate the comparison result of VLAN tags. The Outer VLAN Tag Filter Pass and Inner VLAN Tag Filter Pass bits are defined in the following positions. The status indicated through these bits is highly dependent on the programming as explained below.

In RDES2:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In ARI status: MAC Filter Status:

- Bit 15 – Outer VLAN Tag Filter Status
- Bit 14 – Inner VLAN Tag Filter Status

In MRI Status:

- Bit 47 – Outer VLAN Tag Filter Status
- Bit 46 – Inner VLAN Tag Filter Status

Outer VLAN Tag Filter Status (OTS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Outer VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Outer VLAN Tag has either failed the relevant Outer VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Outer VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Outer VLAN Tag Comparison.
- This bit is valid for both Single and Double VLAN Tagged frames.

Inner VLAN Tag Filter Status (ITS)

- In perfect Filtering, without inverse filtering enabled, if this bit is set, it indicates that the frame's Inner VLAN Tag has matched one of the VLAN Tag Filters.
- If this bit is reset, it indicates that the frame's Inner VLAN Tag has either failed the relevant Inner VLAN Tag Filters or bypassed them.
- If none of the filters are enabled for Inner VLAN Tag Comparison, then this bit is reset.
- If Inverse Filtering is enabled and this bit is set, then the frame's VLAN Tag has passed all the relevant VLAN Tag Filters. If it is reset, then it has failed at least one of or bypassed all the Filters programmed for Inner VLAN Tag Comparison.
- This bit is valid for only Double VLAN Tagged frames, when Double VLAN Processing is enabled.

The application must look at the status bits and the programming to determine if the Frame has passed or failed the VLAN Filter.

Following two tables 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled' and 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' show the possible Filter combinations and the corresponding filter results. These tables explain the scenarios when Double VLAN Processing and Hash VLAN filter are enabled in the design.

Legend for the table 'OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled'

- VTIM: VLAN Tag Inverse Match Enable – bit 17 in VLAN_Tag_Ctrl Register.
- HFO: Hash Filter enabled for Outer VLAN Tag Comparison - bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- HFI: Hash Filter enabled for Inner VLAN Tag Comparison – bit 25 and bit 27 in VLAN_Tag_Ctrl Register.
- PFO – Perfect Filter comparison enabled for Outer VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Outer VLAN Tag comparison (bit 20 is set to 0).
- PFI – Perfect Filter comparison enabled for Inner VLAN Tag - Any of the MAC_VLAN_Tag_Filter Registers is enabled (bit 16 is set) and programmed for Inner VLAN Tag comparison (bit 20 is set to 1).
- OTS – Outer VLAN Tag Filter Status
- ITS – Inner VLAN Tag Filter Status

Following table shows the possible values of status bits (OTS and ITS) when at least one Perfect filter is enabled.

Table 321. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	0	0	0	1	0	1/0
0	0	0	1	0	1/0	0
0	0	0	1	1	1/0	1/0
0	1	0	1	1	1/0	1/0

Table continues on the next page...

Table 321. OTS and ITS Bit Values with At Least 1 Perfect Filter Enabled (continued)

VTIM	HFO	HFI	PFO	PFI	OTS	ITS
0	1	0	1	0	1/0	0
0	1	0	0	1	1/0	1/0
0	0	1	1	1	1/0	1/0
0	0	1	1	0	1/0	1/0
0	0	1	0	1	0	1/0
1	0	0	0	1	0	1/0
1	0	0	1	0	1/0	0
1	0	0	1	1	1/0	1/0
1	1	0	1	1	1/0	1/0
1	1	0	1	0	1/0	0
1	1	0	0	1	1/0	1/0
1	0	1	1	1	1/0	1/0
1	0	1	1	0	1/0	1/0
1	0	1	0	1	0	1/0

Following table shows the possible values of status bits (OTS and ITS) when none of the perfect filters are enabled and only the VLAN Hash Filter is enabled.

Table 322. OTS and ITS Bit Values with Only VLAN Hash Filter Enabled

VTIM	HFO	HFI	OTS	ITS
0	0	0	0	0
0	1	0	1/0	0
0	0	1	1/0	1/0
1	0	0	1/0	0
1	1	0	1/0	0
1	0	1	1/0	1/0

With no perfect filters enabled, any VLAN packet is considered to have bypassed the perfect filter. If Hash Filter is enabled for one of the Tags, then the respective Status bit depends on the Filter's result. The Status bits are set to 0 if VLAN Hash Filter is also not enabled.

If the value of ITS/OTS is shown as 1/0; then it indicates that the final result is dependent on the enabled relevant filter's result.

Example 1: The second row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that at least one Perfect Filter is enabled for Outer VLAN tag comparison and none of the filters are enabled for Inner VLAN tag comparison. Inverse VLAN Filtering is not enabled. The bit OTS is given as 1/0. If the received frame passes at least one of the enabled Outer VLAN Tag filters then the bit is set to 1. If the frame doesn't pass any of the enabled Outer VLAN Tag filters, then the bit is set to 0.

Example 2: Last Row of table 'OTS and ITS Bit Values with Only VLAN Hash Filter Enabled' indicates that Inverse Filtering is enabled, Hash Filter and at least one perfect filter is enabled for Inner VLAN Tag comparison, then if the received frame's Inner VLAN tag mismatches with both the Hash Filter and all the enabled Perfect filters, then the frame will have the ITS bit set to 1 else it is set to 0. OTS will be set to 0 as no comparison is performed.

34.4.4.4.4 Stripping

Each of the VLAN Tags has individual control over stripping. The programming options of always strip, never strip, strip on pass and strip on fail are available. Inner or Outer VLAN Tag Stripping is based on the pass or fail results of the individual tag. If a tag is bypassed by all the relevant filters, stripping is not applicable for the tag.

- If strip on Pass is enabled for the outer VLAN Tag, then the stripping occurs only if the Outer VLAN tag has passed the relevant filters. The Outer VLAN Tag Filter Result bit will be set.
- If strip on Fail is enabled for the outer VLAN Tag, then stripping occurs only if the Outer VLAN Tag has failed relevant filters. The Outer VLAN Tag Filter Result Bit will be reset.
- If the Outer VLAN tag of the received frame is bypassed by the entire filter (no comparison has been made), then the tag is not stripped, though the Status Bit is still 0.
- As multiple filters are enabled, it is possible that the received VLAN frame could have matched any one or more of the filters. The VLAN Tag's value is not always deterministic from the filter status bits.

If the software/application strips the VLAN Tag based on the filter result, it might lose the VID. So the suggested use is, if stripping is enabled for any of the tags, the tag can be put in the status. For this the software/application will have to enable the respective "VLAN Tag in Status" bit - 24 or 31 in the MAC VLAN Tag Control Register.

See section Programming Guidelines for Extended VLAN Filtering and Routing on Receive

34.4.4.5 Layer 3 and Layer 4 Filtering

IP supports the Layer 3 based packet filtering which is IP Source or Destination Address filtering in the IPv4 or IPv6 packets, and Layer 4 based packet filtering which is Source or Destination Port number filtering in TCP or UDP. When layer 3 and layer 4 packet filtering is enabled then packets are filtered in the following manner.

- Matched Packets: The MAC forwards the packets that match all enabled fields to the application along with the status. The MAC gives the matched field status only if the IPC bit of MAC_Configuration register is set and one of the following conditions is true:
  - All enabled Layer 3 and Layer 4 fields match
  - At least one of the enabled field matches and other fields are bypassed or disabled

When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides the status of the lowest filter where Filter 0 is the lowest filter and Filter 3 is the highest filter.

- Unmatched Packets: The MAC drops the packets that do not match any of the enabled fields. You can use the inverse match feature to block or drop a packet with specific TCP or UDP over IP fields and forward all other packets.
- Non-TCP or UDP IP Packets: By default, all non-TCP or UDP IP packets are bypassed from the Layer 3 and Layer 4 filters. MAC can optionally be programmed to drop all non-TCP or UDP over IP packets.
- IP has a control register “MAC_L3_L4_Control” to control the Layer L3 and L4 packet filtering along with address registers to program the Layer L3 and L4 fields to be matched.

34.4.4.6 Flexible Receive Parser

When this function is enabled, all incoming packets are parsed as per the programmable instruction stored in memory. It does the following function

- Packet Filter (Accept or Reject)
- DMA Channel Selection

Flexible receive parser block operates over the first 128 bytes data of receive packet based on 64 bytes of instruction on each packet. Following figure shows the functional block diagram of Flexible Receive Parser.

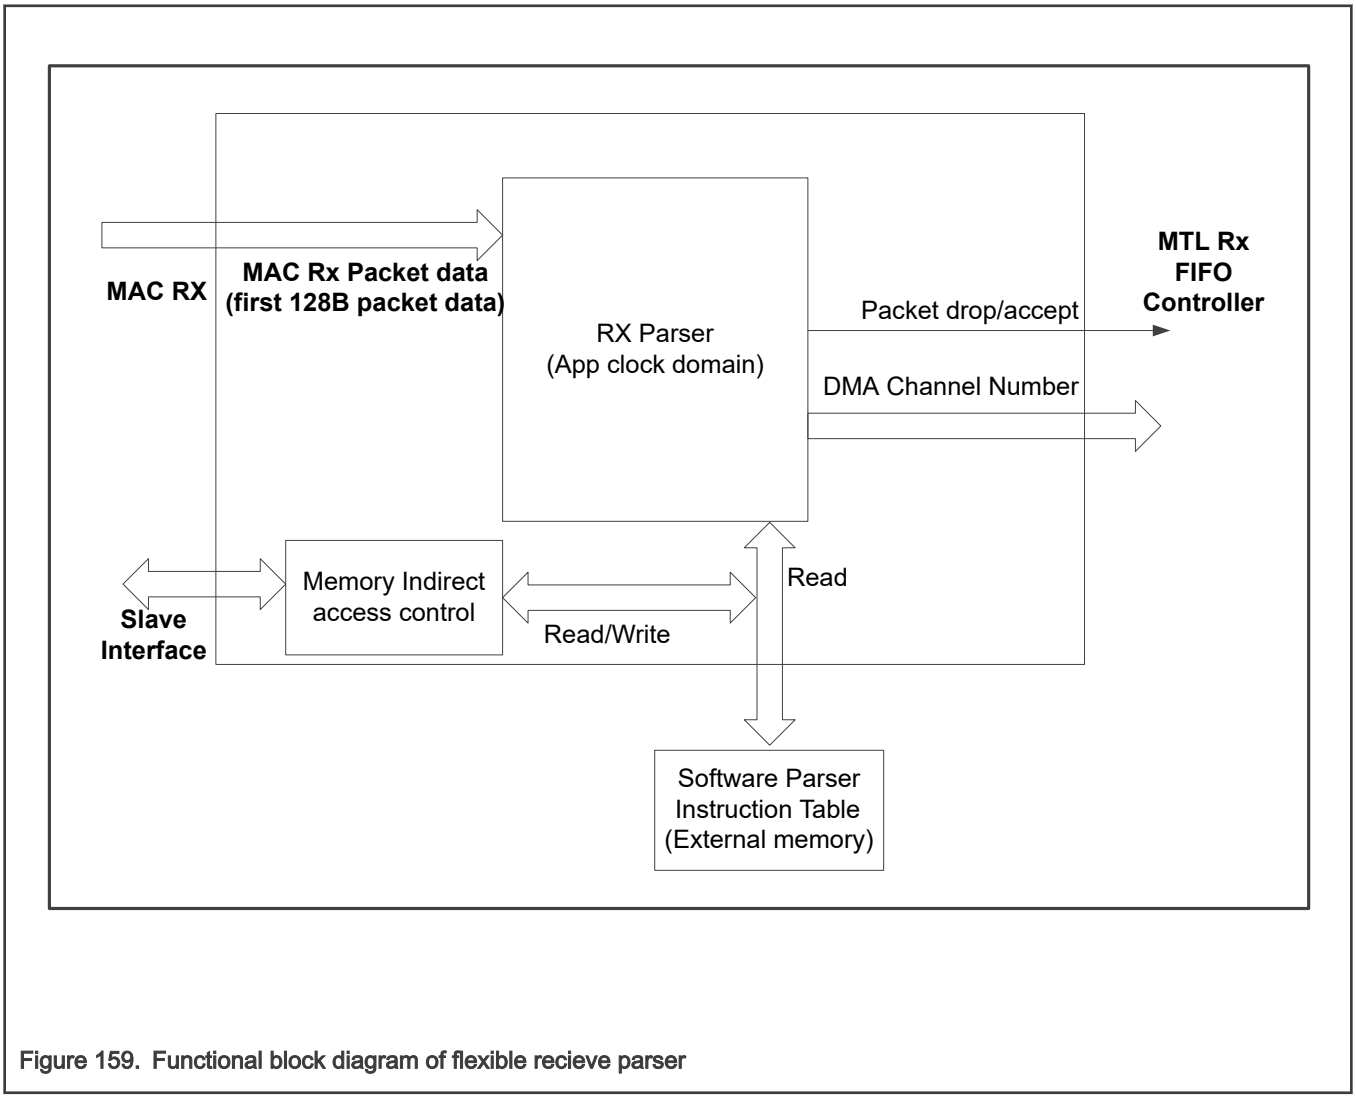

Figure 159. Functional block diagram of flexible recieve parser

34.4.4.6.1 Instruction Table Format of the Flexible Receive Parser

Software must build the 96-bit wide instruction before enabling the receive parser feature. Each instruction is programmed as an entry in the instruction memory.

The format of each entry in the Instruction table is shown in the following table.

Table 323. Rx Parser Instruction Entry Format

Field	Field Name	Description
31:0	MATCH_DATA	The 4-byte data. This data is used for comparing with incoming packet data starts at the frame offset as defined in [79:72] of the entry. The comparison is done only on those bits whose corresponding mask bits are set to 1 (MATCH_EN bits of [63:32]). See the Notes (below this table) on the byte order relative to Ethernet arrival data and endianness supported by QoS IP on the slave interface. The programming of this instruction table should adhere to the same.
62:32	MATCH_EN	When the MATCH_EN is set to 1, the corresponding Packet data bit is used for comparing. Otherwise, corresponding data bit is don't care.
64	AF	Accept frame
65	RF	Reject frame
66	IM	Inverse match
67	NIC	Next instruction control
71:68	Reserved	-
79:72	Frame Offset	[77:72] indicates the frame offset in terms of 4 bytes. (Here [79:78] always 0)Frame offset in the packet data to be compared for Match.This is in terms of 4 bytes. Value Actual Frame offset in bytes 0 01 42 8… ..63 252 The max value programmed in this Instruction Table is 128 B. The 'Actual Frame Offset' should not cross this limit.
87:80	OK Index	If (NIC==0) Memory Index to be used next when ENTRY_MATCH==1 and neither AF or RF is set to 1. If (NIC==1) Memory Index to be used next when ENTRY_MATCH==0 Note: ENTRY_MATCH is a calculated value based on MATCH_DATA, MATCH EN, and IM. It is not a field.
92:88	DMA CH NO	Indicates the DMA Channel Number (1-bit for each). This will be used when ENTRY_MATCH==1 and AF==1 (Accept frame). The encoding is as follows: • bit[0]- DMA Channel Number 0 • bit[1]- DMA Channel Number 1 • bit[2]- DMA Channel Number 2 • bit[3]- DMA Channel Number 3 • bit[4]- DMA Channel Number 4. Note: The DMA Channel number is encoded using bit wise as QoS IP support multicasting/ broadcast across DMA Channels. See section 3.3.12 for more details and proper usage.
128:93	Reserved	0 (This field is only for software view and reserved for future enhancements. The memory width remains as 93-bits for now)

The parser begins parsing from the 0th entry, for each received packet. The subsequent parsing entry location (next entry or OK_INDEX[]) depends on the parser result of the current entry. Following figure shows the detailed flow.

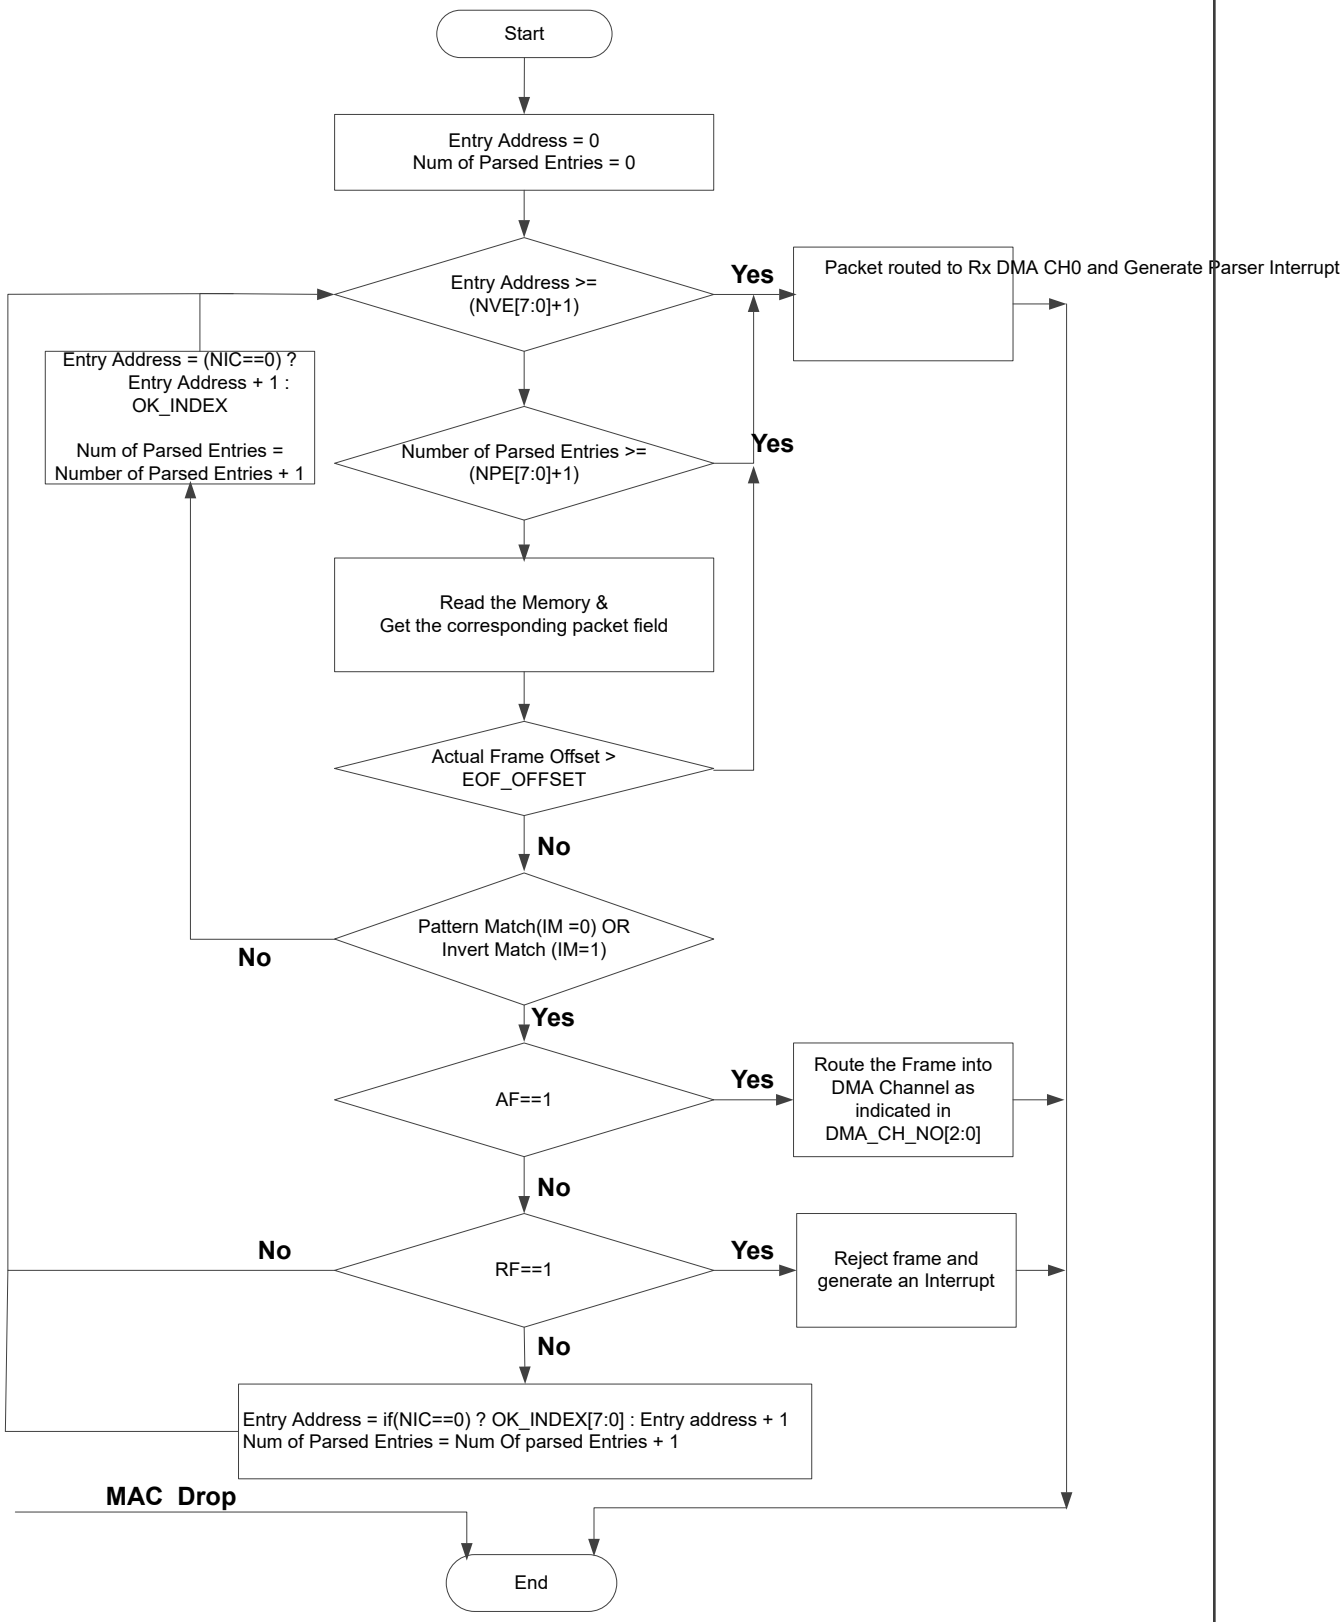

Figure 160. Flexible recieve parser flow chart

In the above figure, MAC Drop means the packet is dropped by the MAC due to another filter condition (for example, DA filter) and will not reach the Flexible Receive Parser.

The EOF_OFFSET shown in the figure is equal to the least among the following:

- Actual Packet size
- 128 Byte when frame pre-emption feature is not enabled/configured
- 128 Byte when frame pre-emption feature is enabled and packet is pre-emptible.
- 64 Byte when frame pre-emption feature is enabled and packet is Express Packet

34.4.4.6.2 Number of Valid Entries (NVE)

NVE indicates the number of valid entries in the instruction table. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NVE[7:0].

While parsing, if the Entry address is found to be is greater than NVE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[0], NVEOVIS (Number of Valid Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status)).

34.4.4.6.3 Number of Parsable Entries (NPE)

NPE indicates the number of entries that can be parsed on an incoming packet. The default value is 64. Software can change this value by writing into MTL_RXP_Control_Status registers field NPE[7:0] (Number of Parsable Entries) bits [21:16].

While parsing, if the number of parsed entries is more than NPE[7:0]+1, an error is flagged in the MTL_RXP_Interrupt_Control_Status register bit[1], NPEOVIS (Number of Parsable Entries overflow status). IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

While NVE[] indicates is the number of valid entries in the Rx parser memory built by software, NPE[] indicates the worstcase parsable entries considering the various possible paths that the parser can take. (NVE[] >= NPE[]).

34.4.4.6.4 Frame Offset

It indicates the frame offset, in terms of 4 bytes which is used while comparing against the current table entry.

In an entry, an error is flagged in the TL_RXP_Interrupt_Control_Status register bit[2], FOOVIS (Frame Offset Overflow Interrupt Status) in any of the following cases:

When Frame Offset is more than

- Packet size
- 128B if pre-emption is disabled
- 128B if pre-emption is enabled and packet is pre-empitble
- 64B if pre-emption is enabled and packet is an Express packet

IP generates an interrupt status (MTL_Interrupt_Status bit[23]) and MTLPIS (MTL Parser Interrupt Status).

NOTE

If the frame ends after the (frame_offset *4) bytes but before ((frame_offset *4)+4) bytes, the Receive parser declares Frame Offset Error if comparison is enabled (via MASK bits) for the non-received bytes; from (frame_offset *4) to ((frame_offset *4)+4).

34.4.4.6.5 Frame Reject

In cases where an Entry matches (considering the Inverse match, IM bit in the instruction table) and Frame Accept bit is not set, and Frame Reject bit (RF) is set, the frame is dropped.

When a frame is dropped due to RF = 1, IP generates an interrupt status (MTL_Interrupt_Status, bit[23], MTLPIS (MTL Parser Interrupt Status).

34.4.4.6.6 Out of Order Processing

The Rx parser flow can be out of order. The decision tree need not be based on the order in which packet arrives. That is, the decision tree can be out of order; the decision tree need not be based on the same order as the packet data arrival (data within one packet). This implies that the next entry and next frame offset (OK_INDEX[]/FRAME_OFFSET[]) can be less than the current entry address and current Frame Offset.

34.4.4.6.7 DMA Channel Selection

When the Rx parser is enabled (FRPE bit[16] is set to 1 in MTL_Operation_Mode register) the Rx parser overrides the DMA selection criteria of the MAC.

When the Rx parser is disabled (FRPE bit[16] is set to 0 in MTL_Operation_Mode register) the MAC/MTL determines the DMA channel number.

34.4.4.6.8 Receive Queue Selection

The Rx Queue is determined by the existing MAC functionality, irrespective of the enabling/disabling of the Rx Parser. This is because the Rx parser is mainly designed for selecting the DMA channel and Rx queuing is decided by the MAC to enable the proper functioning of the Pause/PFC feature.

NOTE

When there are multiple queues and multiple DMA Channels are enabled, a particular DMA channel might receive out of order packets. This is because queue selection is based on MAC criteria (VLAN Priority and other criteria) and Rx DMA channel selection is based on Rx parser.

34.4.4.6.9 MAC Packet Filtering/Drop/Error Handling

The MAC does the packet filtering based on the received packet fields. Disable the Packet Filtering features inside the MAC when the Rx parser is enabled. To disable the Packet Filtering features inside the MAC,

1. Set Promiscuous Mode (PR, bit[0] of MAC_Packet_Filter register)
2. Set all other bits in the MAC_Packet_Filter register to its default values

When MAC decides to drop the packet (due to Rx MAC dependent Error such as GMII Error, Receive Watch Dog Error, CRC Error and Giant Frame Error) the packet is dropped irrespective of the Rx parser decision.

34.4.4.6.10 PAD Strip/CRC Strip Handling

The pad strip and CRC strip are controlled by the software and applicable to all the received packets. When these features are enabled, software must build the Rx parser instructions accordingly.

NOTE

Enable PAD and CRC stripping in real use case.

34.4.4.6.11 VLAN Strip Handling

The MAC supports stripping the VLANs, outer as well as inner VLAN. When MAC is programmed to strip the VLAN, the Rx parser considers those VLAN tags to be part of the incoming packet.

34.4.4.6.12 Multicast and Broadcast Support

IP supports multicast and broadcast packet and the packet is routed to the highest queue number.

When Rx Parser is enabled, the packet routing is decided by the DMA Channel Numbers (DMA CH NO, Bits [95:88]) in the Instruction Table.

When Rx Parser is disabled, the packet routing is determined by DCS (DMA Channel Select) field of the MAC_AddressX_High register. For more details, see Broadcast/Multicast Packet Duplication.

NOTE

DCS/DMA CH NO field is per DMA Channel control and therefore, multiple DMA channels can be selected for routing the packet.

34.4.4.6.13 Pre-emption Support

The MAC supports the frame pre-emption feature when the Flexible Rx parser feature is enabled. The minimum packet size for Frame Preemption is 64 bytes. This means that:

- The Rx parser can operate on 64 bytes of Express traffic.
- The Rx parser can operate on 128 bytes of pre-emptible traffic, as a 64 bytes packet of pre-emptible traffic might be interrupted by Express traffic before that packet is fully received, so the parser needs to have 64 bytes on either side of the express traffic in order to capture the full 64-bytes of a pre-empted packet.

34.4.4.6.14 Software Access to the Flexible Receive Parser Memory

Software can read/write into the Rx parser memory, using the following registers via indirect addressing.

- MTL_RXP_Indirect_Acc_Control_Status
- MTL_RXP_Indirect_Acc_data

For more details, see ENET_QOS register descriptions.

34.4.4.6.15 Statistical Counters

IP supports the following statistics counters for flexible receive parser.

1. MTL_RXP_Drop_Cnt
2. DMA_RXP_Error_Cnt

DMA_CH(#i)_Rxp_Accept_cnt (i=0; i<2)

For more details, see ENET_QOS register descriptions.

34.4.4.6.16 Changing the Instruction Table by Software

Software can update the instruction table in the memory in the following ways

- Disable the MAC Receiver and Receive Parser by setting the RE field of the MAC_Configuration register to 0 and FRPE bit of MTL_Operation_mode register to 0. Wait for Rx Parser to become inactive (RXPIA, MTL_RXP_Control_Status register bit[31]).
- (Optional) Program in the Entry address 0 to unconditionally (all MATCH_EN bit 0) skip to OK_INDEX[] (to certain location in the memory) where it is programmed to reject or accept all packets.

34.4.4.6.17 Receive Cut-Through Functionality

In the case of cut-through mode, the Rx controller attempts to transfer the received packets to DMA just after the cut-through threshold amount of packet data is received (RTC field in the MTL_RxQx_Operation_Mode register).

However due to Rx parser's result worst case arrival time can be more than the programmed cut-through threshold. So, the Rx controller delays the packet transfer to DMA accordingly. So, the cut-through functionality is re-defined as follows

The Rx controller attempts to transfer packet to DMA after at least RTC number of bytes have been received and Rx parser results are available.

34.4.4.6.18 Receive Packet Drop Indication

In most cases, the packet drops internally in the Rx Queue. However, back-to-back packets can arrive for the same queue and first packet's Rx parser result is not available when the second packet arrives. In such cases, the packet cannot be flushed internally and forwarded to DMA or the Application Interface and status is indicated accordingly. For more details, see RDES2, bit 16(RXPD) in Receive Normal Descriptor (Write-Back Format) .

34.4.4.6.19 Runt Packet Handling

The Rx parser can perform the operation with 64B minimum size packet. If the runt packet is received (should be indicated by MAC), the Rx parser assumes that it gets dropped in the MAC. This is because, back-to-back runt packets (< 64B) cannot be handled in the Rx parser.

34.4.4.6.20 Uncorrectable ECC Error Handling

When the parser detects an uncorrectable ECC error while parsing the parser memory, the packet is not dropped. Instead, the packet is sent to the application with an Error Indication. The RXPI (RX Parser Incomplete) is set in the packet status along with Error Summary (ES) bit.

For more details, see Receive Normal Descriptor (Write-Back Format) .

34.4.5 IEEE 1588 Timestamp Support

The MAC supports the IEEE 1588 Precision Time Protocol (PTP). The MAC is able to do precise time stamping and capturing of incoming and outgoing frame to enable support of PTP with its associated software. The MAC supports the all clock types defined in IEEE 1588-2008. Typical frequency of PTP timestamp clock is 125 MHz. The MAC supports:

- Taking a timestamp snapshot of all packets or only PTP type packets.
- Taking a timestamp snapshot of only event messages.
- Identifying the PTP message type, version, and PTP payload in packets sent directly over Ethernet and sending the PTP message type status given by the MAC. The PTP status is finally written back to the Receive Descriptor: RDES1 Normal Descriptor (Write-Back Format).
- Measuring sub-second time in decimal or binary format.

34.4.5.1 Delay Request-Response Mechanism

The system or network is classified into the master and slave nodes for distributing the timing and clock information. Following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

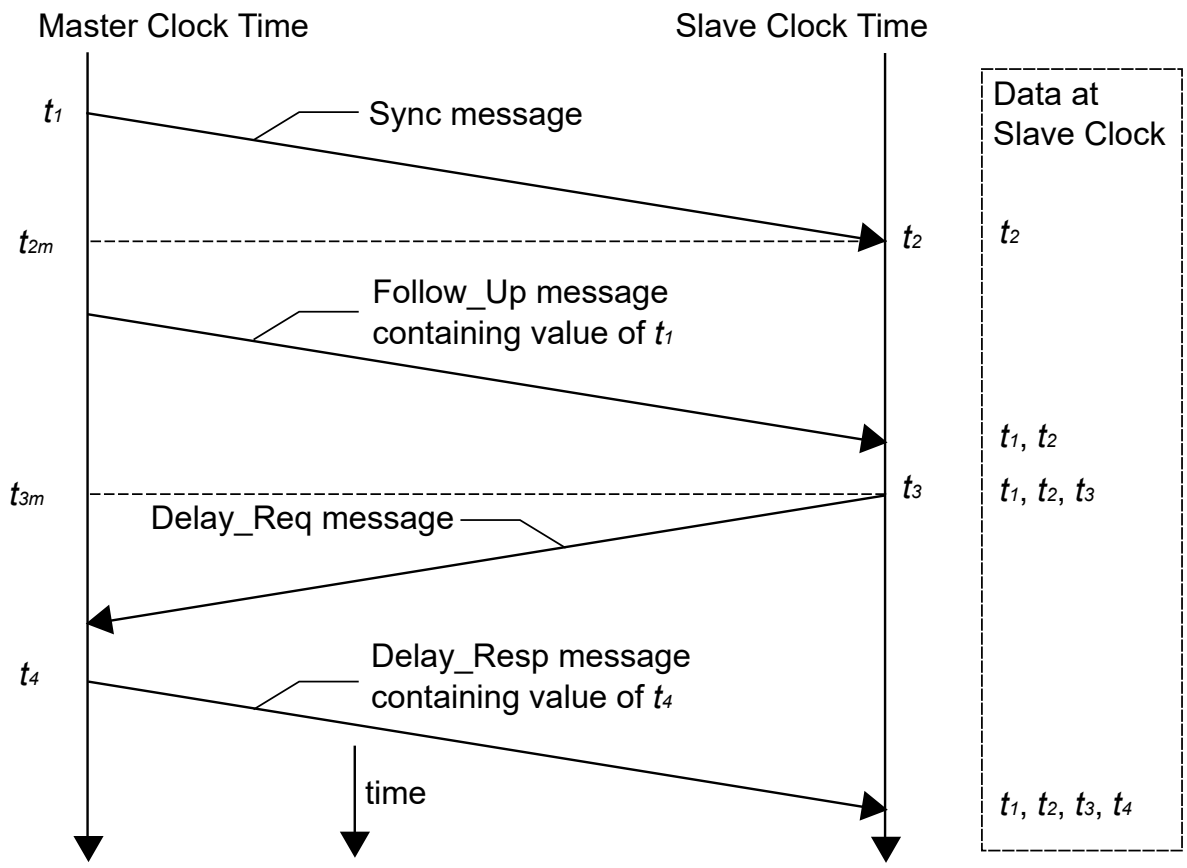

Figure 161. Networked Time Synchronization

As shown in the figure, PTP uses the following process:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the reference time information of the master. This message leaves the system of the master at t1. This time must be captured for Ethernet ports at the internal GMII interface.
2. The slave receives the Sync message and also captures the exact time, t2, using its timing reference.
3. The master sends a Follow_up message to the slave, which contains t1 information for later use.
4. The slave sends a Delay_Req message to the master and notes the exact time, t3, at which this packet leaves the internal GMII interface.
5. The master receives the message, capturing the exact time t4, at which the message enters its system.
6. The master sends the t4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the timing reference of the master.

Most of the PTP implementation is done in the software above the Ethernet layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the internal GMII interface. This timing information must be captured and returned to the software for proper implementation of PTP with high accuracy.

34.4.5.2 Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 supports peer-to-peer PTP (Pdelay) message in addition to the SYNC, Delay Request, Follow-up, and Delay Response messages. Following figure shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

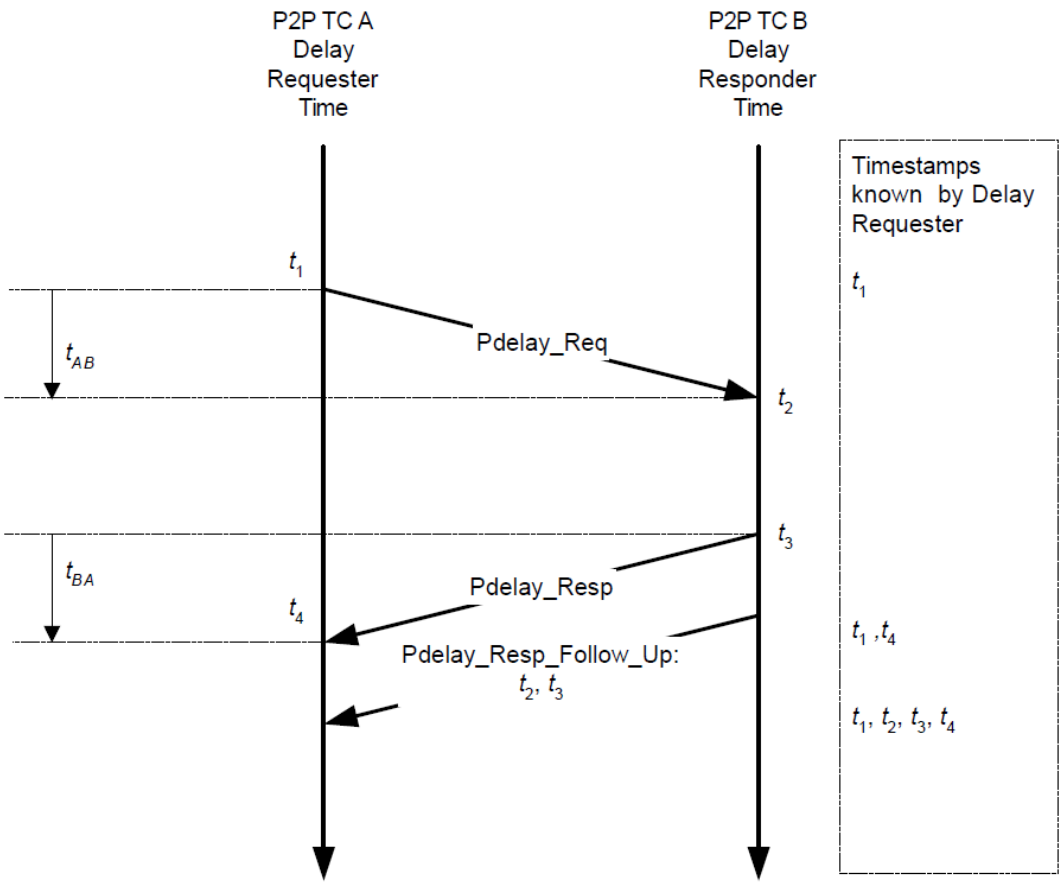

Figure 162. Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

As shown in the above figure, the propagation delay is calculated in the following way:

1. Port 1 issues a Pdelay_Req message and generates a timestamp (t1) for the Pdelay_Req message.
2. Port 2 receives the Pdelay_Req message and generates a timestamp (t2) for this message.
3. Port 2 returns a Pdelay_Resp message and generates a timestamp (t3) for this message. To minimize errors because of any frequency offset between the two ports, Port 2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message. Port 2 returns any one of the following:
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp message
   - Difference between the timestamps t2 and t3 in the Pdelay_Resp_Follow_Up message
   - Timestamps t2 and t3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages, respectively
4. Port 1 generates a timestamp (t4) on receiving the Pdelay_Resp message.
5. Port 1 uses all four timestamps to compute the mean link delay.

34.4.5.3 Timestamp Correction

According to the IEEE 1588 specification, a timestamp must be captured when the PTP message timestamp point (leading edge of the first bit of the octet immediately following the Start Frame Delimiter octet) crosses the boundary between the node and the network. As the MAC takes the timestamp at an internal point far from the actual boundary of the node and network, this captured timestamp is corrected/updated for the ingress/egress path latency (including the delay in the PHY layers). Further correction is done for the inaccuracies/errors introduced due to the clock (internal GMII Tx, Rx clock) being different at the capture point as compared to the PTP clock (clk_ptp_ref_i) that is used to generate the time. The resultant CDC (Clock Domain Crossing) circuits add error depending on the clock period of the internal GMII or MII and PTP clocks.

34.4.5.3.1 Ingress Correction

In the Receive side the timestamp captured at the internal snapshot point is delayed (later in time) as compared to the time at which that packet's SFD bit is received at the port's boundary. Therefore, the captured timestamp must be reduced by the ingress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Ingress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between boundary point and the input of the core.

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum ingress latency. The software can read these registers and determine the average ingress latency in the PHY. Alternatively (if the PHY does not support these registers), the ingress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the input of the core to the internal capture point.

   The internal ingress latency can be read from the MAC_Ingress_Timestamp_Latency register. This is a read-only register and gives the latency in scaled Nanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency differs based on the active PHY interface (for example, RMII) and the operating speed. Therefore, the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC Synchronization

   The CDC synchronization error is almost equal to 2 times the clock-period of the PTP clock (clk_ptp_ref_i).

The values determined from these 3 components should be added by the software and must be written into the TSIC and TSICSNS fields of the MAC_Timestamp_Ingress_Corr_* registers.

NOTE

The value written to the register must be negative (two's complement as explained below), because it has to be subtracted from the captured timestamp. The MAC Receiver adds the value in this register to the captured timestamp and then gives the resultant value as the timestamp of the received packet.

When TSCTRLSSR bit in MAC_Timestamp_Control register is set, the nanoseconds field of the captured timestamp is in decimal format with a granularity of 1ns. So the Bit31 of TSIC must be set to 1 (for negative value) and bits[30:0] must be written with "10^9 - total ingress_correction_value[nanosecond part]" represented in binary. For example, if the required correction value is -5 ns, then the value is 0xBB9A_C9FB.

When TSCTRLSSR bit in MAC_Timestamp_Control register is reset, the nanoseconds field of the captured timestamp is in binary format with a granularity of ~0.466ns. Therefore, bits[30:0] must be written with "2^31 - total ingress_correction_value" represented in binary with bit[31] = 1.

34.4.5.3.2 Egress Correction

In the Transmit side the timestamp captured at the internal snapshot point is earlier (advanced in time) as compared to the time at which that packet's SFD bit is output at the port's boundary. Therefore, the captured timestamp must be compensated by the egress latency and the errors in CDC sampling. This correction value must be determined/calculated by the software and written into the MAC_Timestamp_Egress_Corr_* registers.

The correction value consists of the following 3 components:

1. External latency in the PHY layer between the output of the core and the boundary of the port and the network

   If the PHY is compliant to the IEEE 802.3 Clause 45 MMD registers, it has a register indicating the maximum and minimum egress latency. The software can read these registers and determine the average egress latency in the PHY. Alternatively (if the PHY does not support these registers), the egress latency must be determined from its datasheet or timing characteristics.

2. Internal latency from the internal capture point and the output of the core

   This internal egress latency can be read from the MAC_Egress_Timestamp_Latency register. This is a read-only register and gives the latency in scaledNanoseconds format defined in IEEE 1588 Clause 5.3.2. The latency will differ based on the active PHY interface (for example, RMII) and the operating speed. Hence the software must read this register after any speed change in the MAC to determine the current internal latency.

3. CDC synchronization error

   The CDC synchronization error value for one-step timestamping would be = (1 * period of clk_ptp_ref_i + 4 * period of clk_tx_i). Otherwise (Two-step timestamping mode), the value = -(2 * period of clk_ptp_ref_i).

34.4.5.3.3 Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the MAC clock domain to the application/system clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is 4 clock cycles of RMII and 3 clock cycles of PTP clocks. If the delay between two timestamp captures is less than this delay, the MAC does not take a timestamp snapshot for the second packet.

34.4.5.3.4 PTP Processing and Control

Following table shows the common message header for the PTP messages. This format is taken from the IEEE 1588-2008.

Table 324. Message Format Defined in IEEE 1588-2008

Bits								Octet	Offset
7	6	5	4	3	2	1	0		
transportSpecific				messageType				1	0
Reserved				versionPTP				1	1
messageLength								2	2
domainNumber								1	4
Reserved								1	5
flagField								2	6
correctionField								8	8
Reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
controlField (*)								1	32
logMessageInterval								1	33

(*) – control Field is used in version 1. In version 2, message Type field is used for detecting different message types.

There are some fields in the Ethernet payload that are being use to detect the PTP packet type and control the snapshot to be taken. These fields are given below in table for PTP packets over Ethernet.

Following table provides information about the fields that are matched to control the snapshots for the PTP packets sent over Ethernet for IEEE 1588 version 1 and 2. The octet positions for the tagged packets are offset by 4. This is based on the IEEE 1588-2008, Annex D and the message format.

Table 325. Ethernet PTP Packet Fields Required for Control And Status

Field Matched	Octet Position	Matched Value	Description
MAC Destination Multicast Address[1]	0–5	01-1B-19-00-00-00 01-80-C2-00-00-0E	All PTP messages can use any of the following multicast addresses[2]: • 01-1B-19-00-00-00 • 01-80-C2-00-00-0E[3]
MAC Packet Type	12, 13	0x88F7	PTP Ethernet packet
PTP Control Field (IEEE 1588 version 1)	46	0x00, 0x01, 0x02, 0x03, or 0x04	• 0x00: SYNC • 0x01: Delay_Req • 0x02: Follow_Up • 0x03: Delay_Resp • 0x04: Management
PTP Message Type Field (IEEE 1588 version 2)	14 (nibble)	0x0, 0x1, 0x2, 0x3, 0x8, 0x9, 0xB, 0xC, or 0xD	• 0x0: SYNC • 0x1: Delay_Req • 0x2: Pdelay_Req • 0x3: Pdelay_Resp • 0x8: Follow_Up • 0x9: Delay_Resp • 0xA: Pdelay_Resp_Follow_Up • 0xB: Announce • 0xC: Signaling • 0xD: Management
PTP Version	15 (nibble)	0x1 or 0x2	• 0x1: Supports PTP version 1 • 0x2: Supports PTP version 2

1. The unicast address match of destination addresses (DA), programmed in MAC address 0 to 31, is used if the TSENMACADDR bit of MAC_Timestamp_Control register is set.
2. IEEE 1588-2008, Annex F
3. The MAC does not consider the PTP version 1 messages with Peer delay multicast address (01-80-C2-00-00-0E) as valid PTP messages.

34.4.5.4 Transmit Path Functions

The MAC captures a timestamp when the Start Packet Delimiter (SFD) of a packet is sent on the internal GMII interface. The packets, for which the timestamps has to be captured can be controlled on per-packet basis. Each Transmit packet can be marked

to indicate whether a timestamp should be captured for it. The MAC does not process the transmitted packets to identify the PTP packets. You can specify the packets by using the control bits in the Transmit descriptor. The MAC returns the timestamp to the software inside the corresponding Transmit descriptor, thus connecting the time-stamp automatically to the specific PTP packet. The 64-bit timestamp information is written to the TDES0 and TDES1 fields. The TDES0 field holds the 32 least significant bits of the timestamp.

34.4.5.5 Receive Path Functions

The MAC can be programmed to capture the timestamp of all packets received on the internal GMII interface or to process packets to identify the valid PTP messages. Use the following options of the MAC_Timestamp_Control register to control the snapshot of the time to be sent to the application:

- Enable snapshot for all packets
- Enable snapshot for IEEE 1588 version 1 or version 2 timestamp
- Enable snapshot for PTP packets transmitted directly over Ethernet
- Enable timestamp snapshot for the received packet for IPv4 or IPv6
- Enable timestamp snapshot only for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP)
- Enable the node to be a master or slave and select the snapshot type

Table 326. Timestamp Snapshot Dependency on Register Bits

SNAPTYPSEL	TSMSTRENA	TSEVNTENA	PTP Messages
00	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp
00	0	1	SYNC
00	1	1	Delay_Req
01	x	0	SYNC, Follow_Up, Delay_Req, Delay_Resp,Pdelay_Req, Pdelay_Resp,Pdelay_Resp_Follow_Up
01	0	1	SYNC, Pdelay_Req, Pdelay_Resp
01	1	1	Delay_Req, Pdelay_Req, Pdelay_Resp
10	x	x	SYNC, Delay_Req
11	x	x	Pdelay_Req, Pdelay_Resp

The DMA returns the timestamp to the software inside the corresponding Receive Descriptor. The extended status, containing the timestamp message status and the IPC status, is written in normal descriptor RDES1 and the snapshot of the timestamp is written in RDES0 and RDES1 fields of context descriptor. The RDES0 field holds the 32 least significant bits of the timestamp.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (System Time Correction), see System Time Correction

34.4.5.6 IEEE 1588 System Time Source

The ENET QOS block supports both external and internal time source for reference timestamping.

- External Time source uses the 64-bit external time reference and clock as input in IP. The clock input is used to synchronize the external timing reference into MAC clock domain. Upper 32-bit indicates the time in seconds while lower 32-bit indicates the time in nanoseconds.
- Internal time source takes only the reference clock input and uses it to internally generate the Reference time (also called the system time) and capture timestamps.
  - UInteger48 seconds Field: The seconds field is the integer portion of the timestamp in units of seconds. It is 48-bits wide.

    For example, 2.000000001 seconds are represented as seconds Field = 0x0000_0000_0002.
  - UInteger32 nano secondsField The nanoseconds field is the fractional portion of the timestamp in units of nanoseconds.

    For example, 2.000000001 seconds are represented as nanoSeconds = 0x0000_0001. The nanoseconds field supports the following two modes:
    - Digital rollover mode: In this mode, the maximum value in the nanoseconds field is 0x3B9A_C9FF, that is, (10e9-1) nanoseconds.
    - Binary rollover mode: In this mode, the nanoseconds field rolls over and increments the seconds field after value 0x7FFF_FFFF. Accuracy is ~0.466 ns per bit.

There is a system time register module which is being used when internal time reference is being used. The 80-bit time is maintained in this module and updated using the input reference clock (clk_ptp_ref_i). This time is the source for taking snapshots (timestamps) of Ethernet packets being transmitted or received at the internal GMII interface.

The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, the system time counter is written with the value in the Timestamp Update register. For system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, the frequency offset and/or frequency drift of a slave clock (clk_ptp_ref_i) with respect to the master clock (as defined in IEEE 1588-2002) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals.

NOTE

For Programming Guidelines for IEEE 1588 Timestamping (For Internal Time-stamp Source Configuration). see Initialization Guidelines for System Time Generation

34.4.5.7 IEEE 1588 Higher Word Register

If system time source is internal, then higher word register can be invoked. MAC timestamp is 64-bit wide. The values of the upper 16-bits of the seconds field can be read from the CSR register.

34.4.5.8 Flexible Pulse-Per-Second Output

The ENET QOS block supports the flexibility of programming the start or stop time, width and interval of pulse generated on pulse per second (PPS) output. IP supports 4 such output signals. By default, the block is in fixed pulse per second output mode with an interval of 1 second.

Initially. the start time should be programmed in target time registers "MAC_PPSx_Target_Time_Seconds and MAC_PPSx_Target_Time_Nanoseconds" for all desired/enabled PPS output. Reprogramming the start or stop time must be done after the synchronization of the earlier programmed value. Bit 31 of the MAC_PPS#_Target_Time_Nanoseconds register indicates that the synchronization is complete. If the application programs a start or stop time that has already elapsed, the MAC sets an error status bit indicating the programming error. If enabled, the MAC also sets the Target Time Reached interrupt event. The application can cancel the start or stop request only if the corresponding start or stop time has not elapsed. If the time has elapsed, the cancel command has no effect.

The PPS width and interval are programmed in terms of granularity of system time, that is, number of the units of sub-second increment value. For example, to have a PPS pulse width of 40 ns and interval of 100 ns with PTP reference clock of 50 MHz, you

should program the width and interval to values 2 and 5, respectively. You can achieve smaller granularity by using a faster PTP reference clock. Before giving the command to trigger a pulse or pulse train on the PPS output, you should program or update the interval and width of the PPS signal output.

NOTE

See Programming Guidelines for Flexible Pulse-Per-Second Output

34.4.5.9 Media Clock Generation and Recovery

Media clock recovery and generation needs a dedicated hardware and software to complete the operation. IP generates a reference clock with the help of dedicated hardware which is then multiplied to get the desired media clock. Software extracts the presentation time from the incoming PTP 1722 frames and programs these value into CSR registers so IP can read them for media clock recovery.

As shown in the following figure, the timestamp array and the DMA module are external to IP. IP supports a 32-bit presentation time counter in nanoseconds that wraps at the full32 bit value to match up with 1722 presentation time format and an handshake mechanism with external application(such as DMA) to program the presentation time into CSR register.

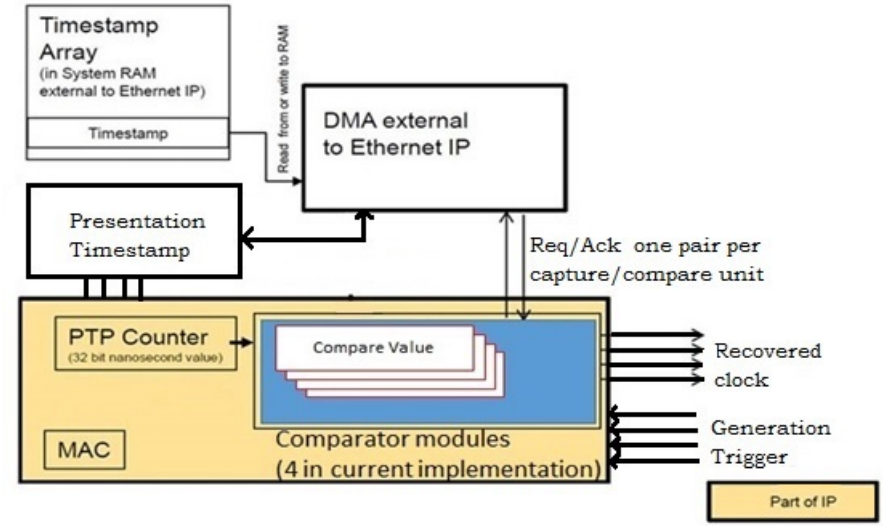

Figure 163. Block Diagram of Media Clock Generation and Recovery

34.4.5.9.1 Presentation Time Counter

Presentation time counter is another view of the PTP System time (1588 timer). For a given PTP System time (PTP[63:32] represents time in seconds and PTP[31:0] represents time in nanoseconds), there exists a corresponding Presentation Time (32-bit value in nanosecond). The Presentation time computed is referred to as Current Presentation Time (CPT).

The Current Presentation Time (CPT) can be viewed as derived from 64bit PTP System Time. PTPNS[63:0] = (PTP[63:32] * 32'd1,000,000,000) + PTP[31:0] where, PTPNS is the PTP system time converted into a 64bit nanosecond value.

Current Presentation Time[31:0] = PTPNS[31:0]

Media Clock Recovery is possible when the System Time is internally generated in IP and CPT is computed in the same way as the Internal PTP System Time generation. Because CPT and System Time values are in nanoseconds, and must be synchronous, the increment cycle of both the timers are same. The timer is updated at the same instance, but the updated value could be different. The software must compute a separate 32-bit update value in nanoseconds for the CPT update. CPT sampled at different edges of a triggering input results in the generation of Media Clock timestamps which are inserted in 1722 based AVBTP packets, to recover the clock at the destination.

34.4.5.9.2 Comparator Modules

As shown in the figure 'Block Diagram of Media Clock Generation and Recovery' the module supports four comparator modules to handle multiple media clocks that might be required. The Comparator modules hand shake with the application to

Program the timestamps into the MAC_PPS(#i)_Target_Time_Seconds register when PTGE field of MAC_Timestamp_Control register is set.

Set the Presentation Time Control bits of the particular instance for recovery mode.

The timestamps received from the application are referred as Target Presentation Time (TPT).

When MCGREN#i field of MAC_PPS_Control register is set to 1, the IP operates in MCGR mode. The comparator module sends up to two requests to the application for TPT write, when PTGE field of MAC_Timestamp_Control register is set and the Presentation time control bits of the particular instance is set for MCGR mode. Subsequent requests are generated each time a Presentation Time match occurs. (CPT transitions from a value less than TPT, to a value greater than or equal to CPT). The first request is asserted when a specific comparator instance is set to MCGR mode with a non-zero Presentation Time Control and an additional request is made when the first data is received into the Comparator. This allows the application to write the next TPT value while IP processes the previous TPT value for a match.

The TPT read from the MAC_PPS(#i)_Target_Time_Second is considered as a future time. A toggle/pulse is generated in the next cycle when a match is detected. When a match is detected, the mcgr_dma_req_o#i request for that comparator is asserted (to obtain next TPT) until the corresponding application acknowledgment is set.

The presentation control bits (PPSCMD#i field of MAC_PPS_Control register) determine the shape of the generated waveform. Also, these bits can be programmed to either toggle or generate a high/low pulse for one PTP clock cycle, upon match.

Media Clock Recovery: A match is when the free-running CPT value matches the received TPT value. A output signal EMAC_TMR signal as shown in the IO mux sheet is asserted (toggle, low pulse, or high pulse) based on the presentation control value programmed.

Media Clock Generation: Based on the presentation control value programmed in MAC_PPS_Control register, the particular comparator captures the presentation time and programs it into MAC_PPS(#i)_Target_Time_Second register. A request is raised to the application to read the captured timestamp. Until the acknowledgment is received from the application, acknowledging that the read operation is complete, no new timestamps are captured.

34.4.5.9.3 Media Clock Generation and Recovery Flow

Following figure shows the media clock generation and recovery flow. For both media clock generation and recovery, set the PTGE field of MAC_Timestamp register for CPT generation and set the MCGREN#i field of MAC_PPS_Control Register for the corresponding instance to be enabled in the MCGR mode.

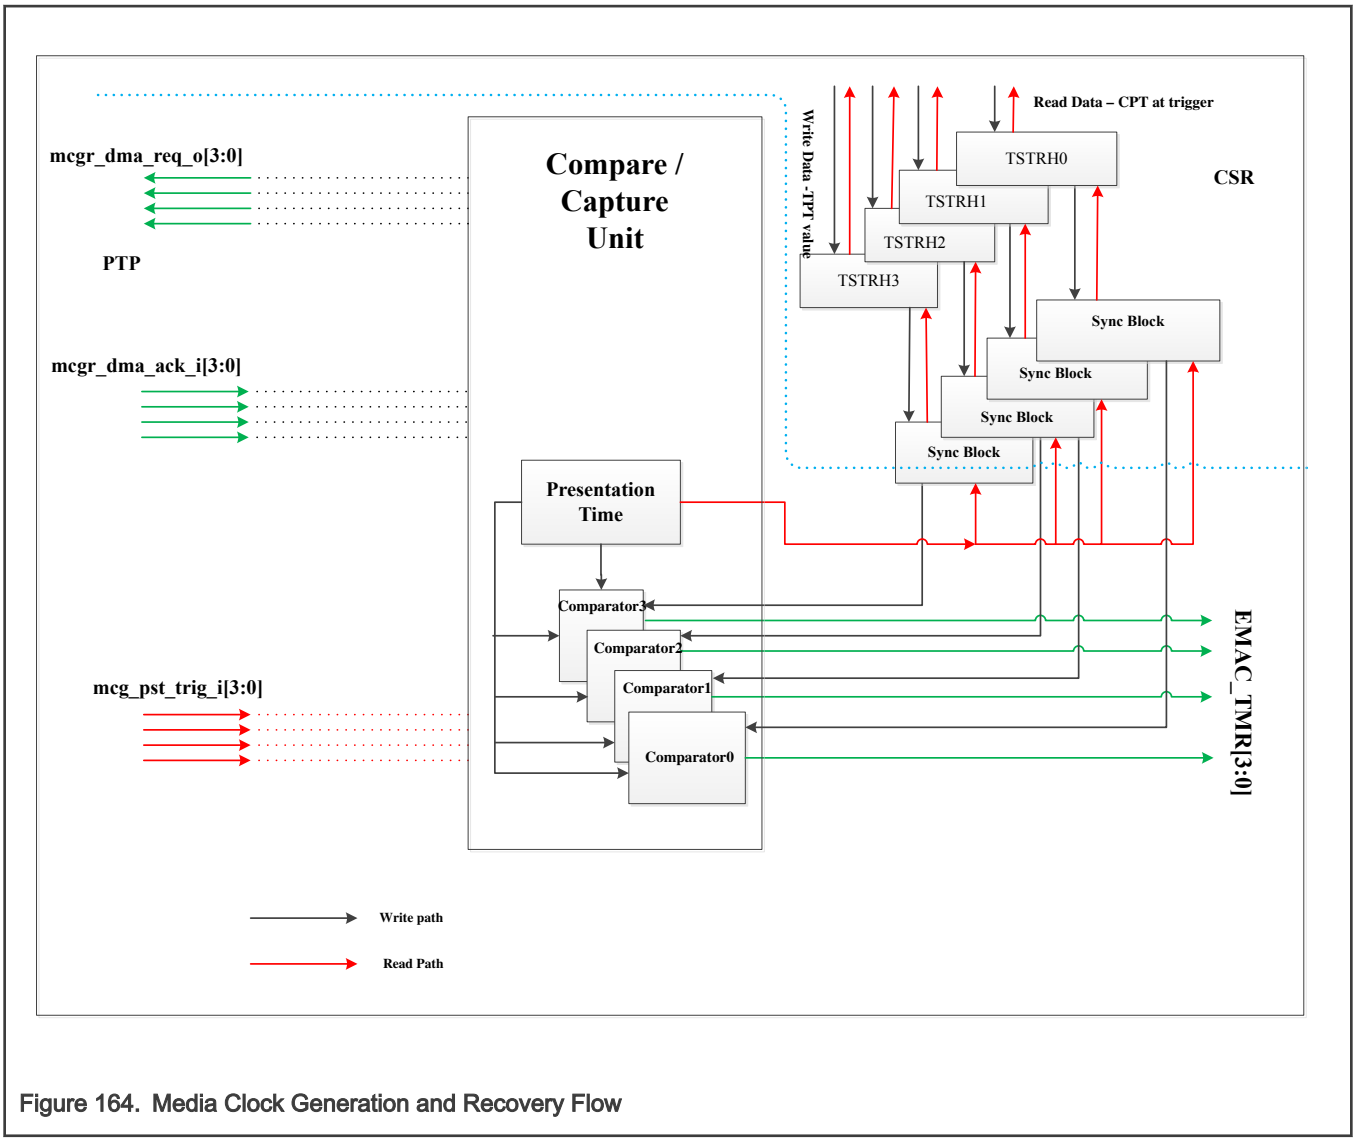

Figure 164. Media Clock Generation and Recovery Flow

NOTE

1. The consecutive triggers to sample the presentation time should always be asserted after a few PTP clock cycles to allow for synchronization delays. (This is not an issue when the input trigger maximum frequency is 8KHz and the PTP clock is running at least at 1MHz)
2. DMA acknowledgment can be both posted as well as non-posted, in the Media Clock Recovery Mode.
3. See "Programming Guidelines for Media Clock Generation and Recovery"

34.4.5.10 One step timestamp

IP supports the one step time stamp feature. It can be enabled for a packet by setting the Bit 20 (OSTC) in the control word.

NOTE

See Programming Guidelines for IEEE 1588 Timestamping .

34.4.5.11 IEEE 1588 Sub Nanoseconds Timestamp

The ENET QOS block supports the ingress and egress correction accuracy in sub-nanoseconds. It is programmed in the TSICSNS and TSECSNS fields of the MAC Timestamp Ingress Correction Subnanosecond and MAC Timestamp Egress

Correction Subnanosecond registers, respectively. In this case, the correction has an unit of nanosecond, multiplied by 2^8. The least significant 8 bits of the value should be programmed in the sub-nanoseconds register.

For example, if the required egress correction is 3.6 nS and TSCTRLSSR bit is set, then TSEC must be 0x3 and TSECSNS must be 0x99 (0.6 * 256). Similarly, if the required ingress correction is -3.6 ns and TSCTRLSSR bit is set, then TSIC must be 0xBB9A_C9FC and TSICSNS must be 0x66 (fractional part of (10^9 - 3.6) * 256).

34.4.6 Multiple Channels and Queues Support

IP supports the five queues and channel on Tx and Rx paths.

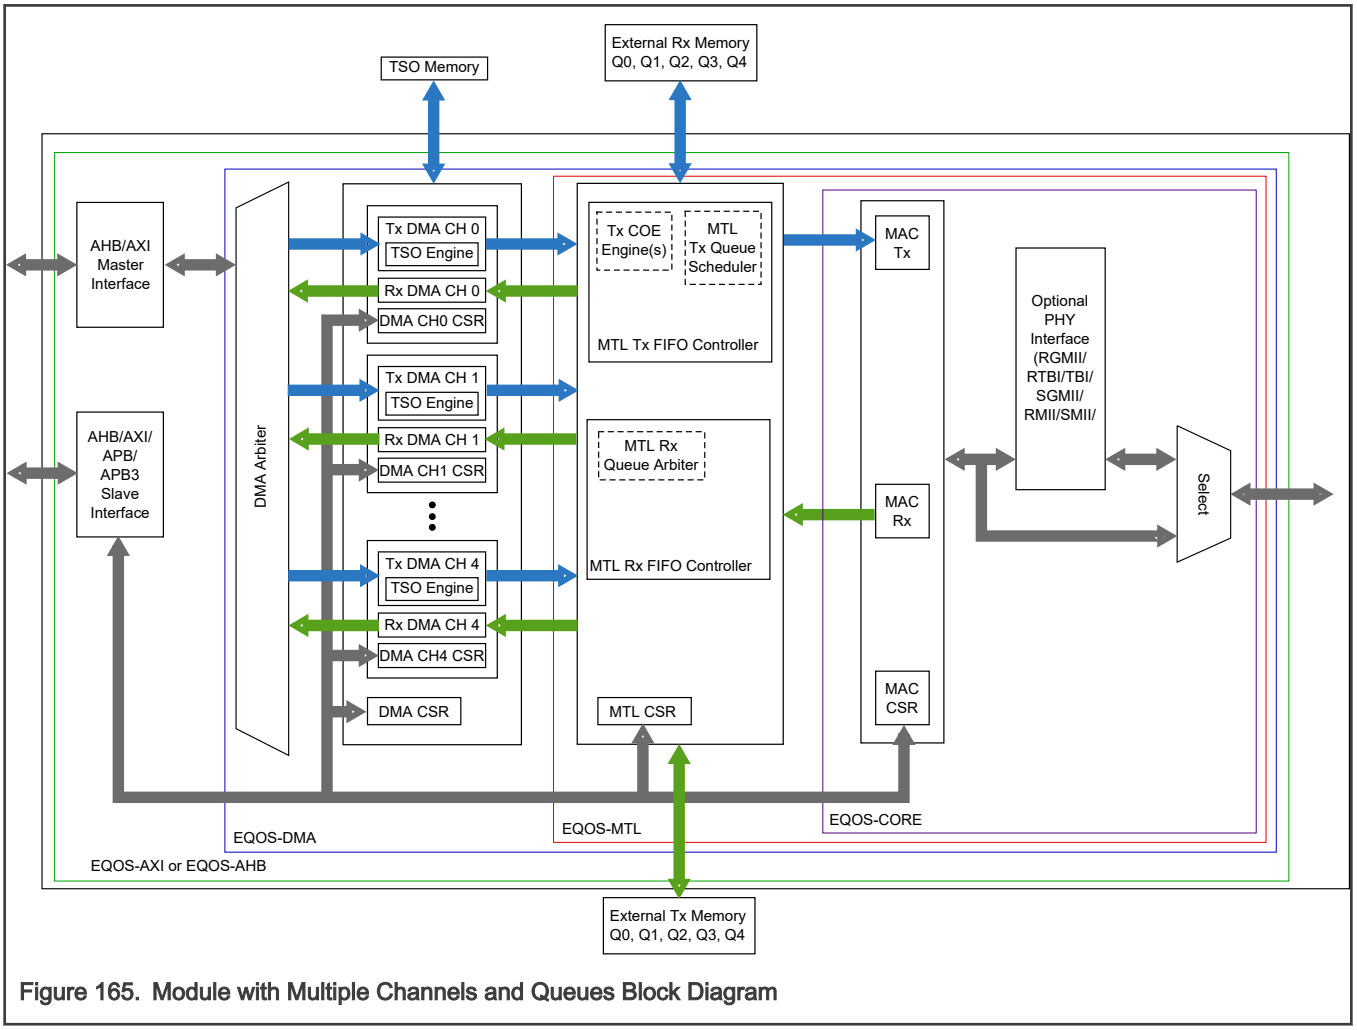

Figure 165. Module with Multiple Channels and Queues Block Diagram

DMA arbiter of IP supports two types of arbitration scheme, fixed priority and weighted round-robin. The DMA arbiter performs the arbitration between the Tx and Rx paths of DMA channels for accessing descriptors and data buffers. The DA bit of the DMA_Mode register specifies the arbitration scheme (fixed or weighted round-robin) between the Tx and Rx DMA of a channel.

Priority between the corresponding Tx DMA and Rx DMA can be set by using TXPR field of the DMA_Mode register. PR field of the DMA_Mode register can be set to specify the weighted priority between the Tx DMA and Rx DMA in round robin arbitration scheme.

Following table provides information about the priority scheme between Tx DMA and Rx DMA.

Table 327. Priority Scheme for Tx DMA and Rx DMA

Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Priority Schemes
x	x	x	0	1	Rx always has priority over Tx
0	0	0	0	0	Tx and Rx have equal priority. Rx gets the access first on simultaneous requests
0	0	1	0	0	Rx has priority over Tx in ratio 2:1
0	1	0	0	0	Rx has priority over Tx in ratio 3:1
0	1	1	0	0	Rx has priority over Tx in ratio 4:1
1	0	0	0	0	Rx has priority over Tx in ratio 5:1
1	0	1	0	0	Rx has priority over Tx in ratio 6:1
1	1	0	0	0	Rx has priority over Tx in ratio 7:1
1	1	1	0	0	Rx has priority over Tx in ratio 8:1
x	x	x	1	1	Tx always has priority over Rx
0	0	0	1	0	Tx and Rx have equal priority. Tx gets the access first on simultaneous requests
0	0	1	1	0	Tx has priority over Rx in ratio 2:1
0	1	0	1	0	Tx has priority over Rx in ratio 3:1
0	1	1	1	0	Tx has priority over Rx in ratio 4:1
1	0	0	1	0	Tx has priority over Rx in ratio 5:1
1	0	1	1	0	Tx has priority over Rx in ratio 6:1
1	1	0	1	0	Tx has priority over Rx in ratio 7:1
1	1	1	1	0	Tx has priority over Rx in ratio 8:1

34.4.6.1 Multiple Queues and Channels Support in the Transmit Path

IP supports the five transmit queues and five channels.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing

34.4.6.2 Multiple Queues and Channels Support in the Receive Path

IP supports five receive channels and five queues.

In the Receive direction, the MTL Rx Controller selects the Rx DMA for which it is transferring or reading the data from the Rx FIFO memory. This scheduling is based on the programming done in the respective MTL_RxQ[x]_Control register.

Each Rx DMA indicates when it is ready to transfer data and the size of the burst-length (number of beats) that it has to transfer. The scheduler checks whether sufficient data (of requested burst length) is available to be transferred to these DMAs and then selects the Rx DMA that gets serviced using the programmed priorities.

NOTE

See Programming Guidelines for Multi-Channel Multi-Queuing .

34.4.6.3 Rx Queue to DMA Mapping

The packets in the MTL Rx Queues can be routed to any one of the multiple DMA channels by programming the register MTL_RxQ_DMA_Map0 Register for queues 0 through 3, and MTL_RxQ_DMA_Map1 for queue 4.

The following types of Rx Queue to DMA mapping are possible through programming.

34.4.6.3.1 Static Mapping

In this mode, all of the packets of an Rx Queue are connected to a specific DMA channel. For example, all the packets from Rx Queue 0 can be routed to a DMA channel by programming Q0MDMACH (bit[3:0]) and Q0DDMACH (bit[7] = 0) of the MTL_RxQ_DMA_Map0 Register.

Similarly, packets from other Rx Queues can be routed to any DMA channel by programming register fields corresponding to each Queue.

34.4.6.3.2 Dynamic (Per Packet) Mapping

In this mode, the destination DMA channel of a packet being read from a Rx Queue is not constant but decided independently for each packet. For example, if you set the Q1DDMACH bit of the MTL_RxQ_DMA_Map0 register, the static mapping is disabled for Rx Queue 1 and the value in Q1MDMACH is ignored. The destination DMA channel is decided by the MAC receiver for each packet, depending on the following in decreasing order of priority:

1. L3-L4 filter Based DMA Selection: The TCP/UDP and IP header fields of the received packet are matched against the corresponding values programmed and enabled for comparison in the MAC_L3_L4_Address_Control register. If the match is successful, the DMA channel number programmed in the DMCHN field of the MAC_L3_L4_Ad-dress_Control register is selected as the destination DMA channel number provided DMCHEN bit of the same register is set. If none of the L3-L4 Registers give a comparison match, then the module proceeds to the next step below.
2. Extended VLAN Based DMA Selection: Extended routing is applicable only if the VLAN Filter has passed. Routing is only based on Perfect Filter Result. Each perfect filter has a DMA Channel Enable and a DMA Channel Number field which can be programmed. Routing is applicable for a filter, only if the DMA Channel Enable bit is set. The frame is routed to the smallest Matching Filter's DMA Channel provided it is enabled. If that filter's DMA Channel number is not enabled, the frame gets routed to Channel 0. For example, if a frame's VLAN tag matches filters 7, 3, and 1. Then the MAC checks if Filter 1's DMA Channel Number is enabled through programming. If yes, the frame gets routed to the programmed value; otherwise it gets routed to DMA. When the inverse filter is enabled; is routed to the least mismatched filter's DMA channel number provided it is enabled. If the DMA Channel enable bit is not set, then the frame is routed based on DA based addressing or to Channel 0.

   If Hash Filter is also enabled, it is used to determine the Filter result only. Routing will still depend on the Perfect Filters enabled. If none of the perfect filters are enabled or if all of them are bypassed, then the VLAN Filter based routing will not take place. The frame will be routed via DA Based addressing or to Channel 0. If all the perfect filters give a fail result and the Hash Filter has passed, then the VLAN Filter result is a pass but routing will be based on DA Based Addressing or to Channel 0. Similar behavior is seen when inverse Filtering is enabled as well.
3. Ethernet DA-Based DMA Selection: The DA address of the received packet is compared against the programmed DA values in MAC Address Registers. If the address matches any of the programmed values, the corresponding DCS field (when enabled) determines the destination DMA channel number.

If none of the previous operations is able to make a successful match/decision, then the packet is routed to DMA Channel 0 by default.

34.4.6.3.2.1 Broadcast/Multicast Packet Duplication

Broadcast/Multicast Packet Duplication feature provides a mechanism to send the received Broadcast/Multicast packets to multiple DMA channels.

The DCS field of the of MAC_Address0_High and other optional MAC_Address(#i)_High (i=1 to 2) registers determines the DMA channel number to which the received packet (that matches the MAC Address present in that register) must be routed.

Packet duplication is not supported in other DMA channel routing mechanisms such as Extended VLAN, or L3-L4 based routing.

The Packet Duplication feature is supported only on the highest MTL Queue configured. Therefore, packet duplication for Broadcast/Multicast packets requires that the MCBCQ field of MAC_RxQ_Ctrl1 register is programmed to the highest RxQ present in the configuration.

34.4.6.4 Selection of Tag Priorities Assigned to Rx Queues

The VLAN Tag priorities can be assigned to Rx Queues by programming the PSRQ field in the corresponding MAC_RxQ_Ctrl2 registers. The bit corresponding to the VLAN Tag priority can be set in the PSRQ field for assigning that priority to the Rx Queue. For example, if you want to assign VLAN Tag priority of 3 to Rx Queue 0, set bit [3] in PSRQ field of MAC_RxQ_Ctrl2 register. The VLAN Tag priority assigned to particular Rx Queue must be unique, that is, more than one Rx Queue cannot be assigned the same VLAN Tag priority. However, more than one VLAN Tag priorities can be assigned to same Rx Queue.

The settings in the PSRQ field is used for VLAN Tagged Rx packet routing to Rx Queues as well as for PFC based Tx flow control. The received VLAN Tagged Rx packet is routed to Rx Queue that has the VLAN Tag priority match. In PFC based Tx flow control, PSRQ field corresponding to a particular Rx Queue is used for enabling VLAN Tag priorities in the PFC packet transmitted when corresponding Rx Queue threshold levels are reached.

34.4.6.5 Rx Side Routing from MAC to Queues

IP supports Rx Side Routing from the MAC to Queues. The MAC routes the Rx packets to the Rx Queues based on following packet types in that order

- Unicast/Multicast destination address packets that fail the destination address filter
- Multicast/Broadcast destination address packets that pass the destination address filter
- VLAN Tag Priority field in VLAN Tagged AV data packets
- AV Control packets
- VLAN Tagged IEEE 1588 PTP over Ethernet packets
- Untagged IEEE1588 PTP over Ethernet packets
- VLAN Tag Priority field in VLAN Tagged packets
- Untagged packets

The outer C-VLAN Tagged AV data Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The AV Control Rx packets can be routed based on the Rx Queue number specified in the AVCPQ field in MAC_RxQ_Ctrl1 register and corresponding Rx Queue is enabled for AV through RXQ#EN field in MAC_RxQ_Ctrl0 register. These packets may be single VLAN Tagged with C-VLAN type or Double VLAN Tagged with outer VLAN Tag of C-VLAN type when Double VLAN feature is enabled (EDVLP bit in MAC_VLAN_Tag register is set) with inner C-VLAN Tagged or inner S-VLAN Tagged when SVLAN processing is enabled (ESVL bit in MAC_VLAN_Tag register is set). This type of Rx packet routing is available when AV feature and Multiple Rx Queues are selected in the configuration.

The VLAN Tagged Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers and the corresponding Rx Queue is enabled for DCB/generic through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. The VLAN tagged IEEE 1588 PTP over Ethernet Rx packets can be routed based on the priorities assigned to Rx Queues through PSRQ field in corresponding MAC_RxQ_Ctrl2 and MAC_RxQ_Ctrl3 registers or the Rx Queue number specified in the PTPQ field in MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This is determined by programming in TPQC field of MAC_RxQ_Ctrl1 register. This type of Rx packet routing is available when IEEE 1588 Timestamp feature support and Multiple Rx Queues are selected in the configuration. The VLAN Tagged IEEE 1588 PTP over Ethernet Rx packets are detected only when 802.1AS mode is disabled (AV8021ASMEN bit in MAC_Timestamp_Control register is set to 0), otherwise this type of Rx packets are routed as generic VLAN Tagged Rx packets.

The multicast/broadcast destination address Rx packets that pass the destination address filter can be routed based on the Rx Queue number specified in the MCBCQ field of MAC_RxQ_Ctrl1 register when enabled through MCBCQEN bit of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The untagged Rx packets can be routed based on the Rx Queue number specified in the UPQ field of MAC_RxQ_Ctrl1 register and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The unicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the UFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through UFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

The multicast destination address Rx packets that fail the destination address filter can be routed based on the Rx Queue number specified in the MFFQ field of MAC_RxQ_Routing_Ctrl register when enabled through MFFQE bit of MAC_RxQ_Routing_Ctrl register, RA bit of MAC_Packet_Filter register is set to 1 and the corresponding Rx Queue is enabled through RXQ#EN field in MAC_RxQ_Ctrl0 register. This type of Rx packet routing is available when Multiple Rx Queues are selected in the configuration.

If the Rx packet cannot be classified in any of the defined packet type for routing, it will be routed through Rx Queue 0.

34.4.6.6 Rx Side Arbitration Between DMA and MTL

IP controller supports Rx side arbitration between the DMA and the MTL.

After completing the current packet processing, the DMA Channel Controller fetches the next descriptor. After the descriptor fetching is complete, the DMA Channel Controller evaluates the amount of data to be to be transferred to the Rx Buffer based on the programmed PBL and Rx Buffer Length. Accordingly, it requests the MTL to transfer the data.

After servicing the current request, the MTL Rx Queue arbitration scheme selects Rx Queue based on the arbitration scheme (RAA field of the MTL_Operation_Mode register) and the weights programmed in the Queue <n> Receive Control Register. The arbitration is done among Queues for which DMA is ready to service. After the Rx Queue is selected, PBL (Programmable Burst Length) amount of data is read out from that Queue and is routed to the Rx DMA Channel based on the Rx Channel selection criteria.

The arbitration takes place when every PBL data transfer is completed and descriptors are ready for the processing from at least one DMA Channel.

34.4.6.7 Tx Side Arbitration between DMA and MTL

IP support Tx side arbitration between the DMA and the MTL. Since the number of Tx DMA channels is always equal to the number of Tx Queues in the MTL, they are always mapped directly. For instance, each Tx DMA pushes data into its respective Tx Queue assigned to it.

The data inside each Tx Queue is stored in packets. Hence, if two DMAs are allowed to transfer data into the same queue, when a Tx DMA starts a packet transfer, the other DMA cannot transfer data unless the previous packet is completely pushed-in. This means that the second DMA remains idle until the first packet is transferred. Hence, each DMA is always connected directly to its corresponding Tx Queue.

34.4.6.8 Time-Sensitive Networking (TSN)

The ENET QOS block supports TSN in 100 Mbps or 1000 Mbps mode, which enables the transfer of time-sensitive traffic over a network. The block implements the IEEE 802.1Qbv-2015 (Enhancements to Scheduling Traffic), IEEE 802.3br (Interspersing Traffic) and IEEE 802.1Qbu (Frame Preemption) TSN protocol.

The Transmit path of Queue 0 supports the strict priority algorithm and is used for best-effort traffic while transmit paths of additional queues support traffic management by using the credit-based shaper algorithm. For a queue, the credit-based shaper algorithm determines that a queue is available for transmission if the following conditions are true:

- The queue contains one or more packets.
- The credit for the queue is positive as per the algorithm.
- AV traffic can be received on all queues. The block can also receive untagged PTP packets in addition to AV traffic on any queue.

34.4.6.8.1 Enhancements to Scheduled Traffic (EST)

The IEEE 802.1Qbv-2015 defines the schedule for each of the queues on every egress port which makes the implementation aware of traffic arrival schedule. This information can be used to block the lower priority traffic from transmission in this time window/slot. This ensures that scheduled traffic is forwarded from sender to receiver through all the network nodes with a deterministic delay.

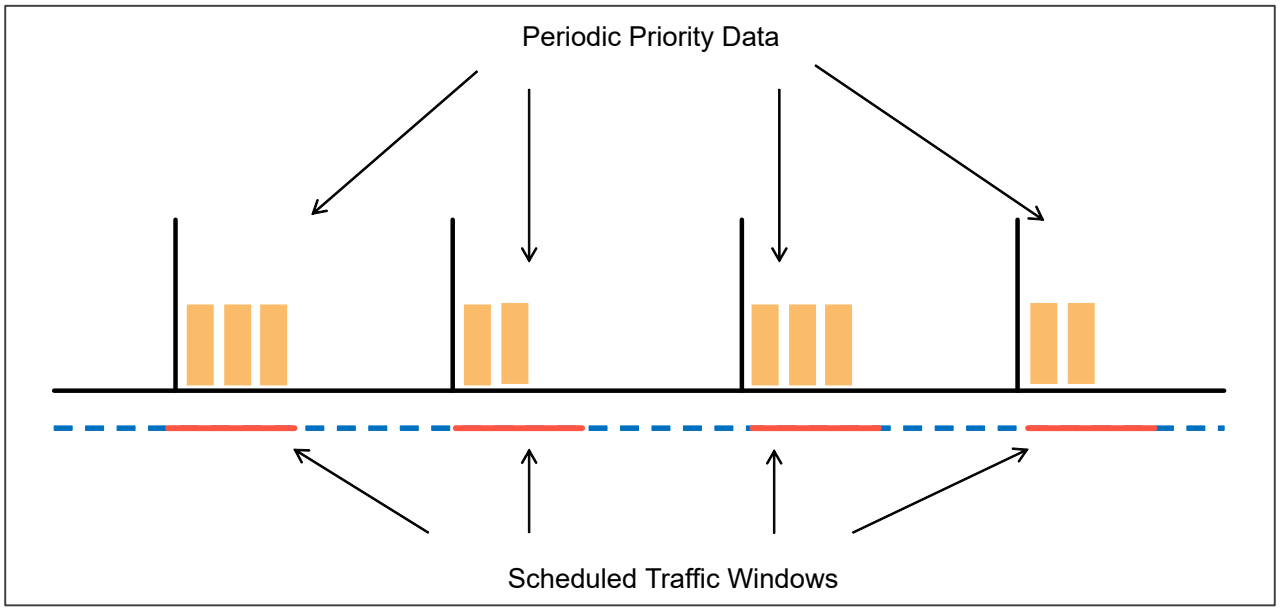

Figure 166. Time Aware Shaper Implementation for Traffic Scheduling

One of the important requirements to achieve a low latency is to ensure there are no interfering frames during the scheduled windows that are reserved for high priority traffic. The use of scheduled traffic imposes limitations while starting a transmission.

As shown in the following figure, if an interfering frame begins transmission just before the start of a reserved time period, it can extend transmission into the reserved window, and potentially interfere with higher priority traffic. Therefore, a guard band whose size is equal to the largest possible interfering frame is required before the window starts.

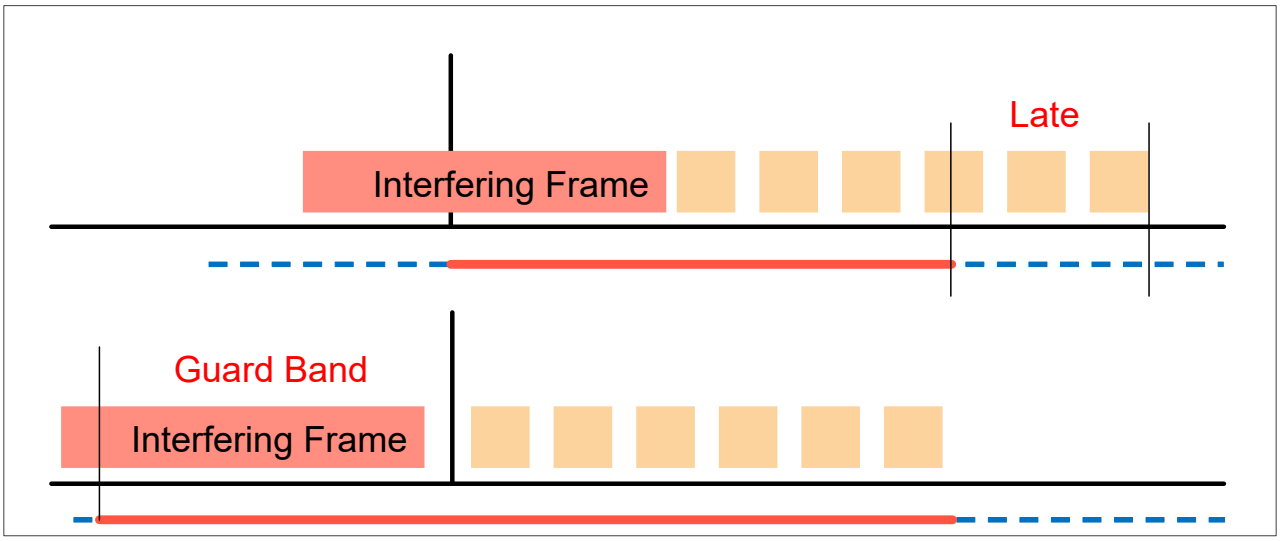

Figure 167. Implementing a Guard Band to Avoid Delays Due to Interfering Frames

A larger guard band equates to a less efficient use of network bandwidth. However, with the implementation of IEEE802.1Qbu (frame preemption), this issue is addressed. Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame.

During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

34.4.6.8.1.1 Frequently Used Terms in EST

- Gate Control List: The list in the hardware memory that holds the gate controls and the associated time intervals.
- Gate Controls: For a given schedule (row in gate control list) there is a Gate Open (O) and Gate Close (C) state associated with each traffic class. The set of O or C values, whose width is same as configured TCs is called the Gate Controls. Example: CCOCO means TC4=C, TC3=C, TC2=O and so on.
- Time Interval: Time interval (in nanoseconds) is a 16, 20, or 24-bit configurable field in the Gate Control list that indicates the time for which the associated gate controls are valid.
- Base Time Register: Each Gate Control List is associated with a 64-bit Base Time Register that holds the start time (in PTP format) for the list.

34.4.6.8.1.2 Updates to the Transmit Scheduling to Support EST

To support EST, following updates are required to the transmit scheduling:

- Implementation of Gate Control List (GCL)
- Enforcing gate controls in the scheduler
- Accounting for Gate Open (O) duty cycle in the computation of idleSlope (CBS)

34.4.6.8.1.2.1 Implementation of Gate Control List (GCL)

Following figure shows block diagram from the IEEE 802.1Qbv spec that illustrates how the gate control list governs the gate close(C) and open(O) events based on the schedule provided for each event. GCL has the following two parts:

- Time Interval: Defines the time in nano seconds for which the gate controls are valid and should be applied before reading the next gate controls from the list. Configurable width of 16, 20 or 24 to represent a maximum of 64us, 1ms, or 16ms

schedule interval respectively. Supports left shift of the time interval upto 7 bits to be able to apply a multiplication factor from 1 to 128ns (in steps of 2(power)n). The maximum value (post shifting) of this field must be 999,999,999 ns.

- Gate Control: Defines the Open (O) represented by logic 1 or Close (C) represented by logic 0 state for the gate of each TC.

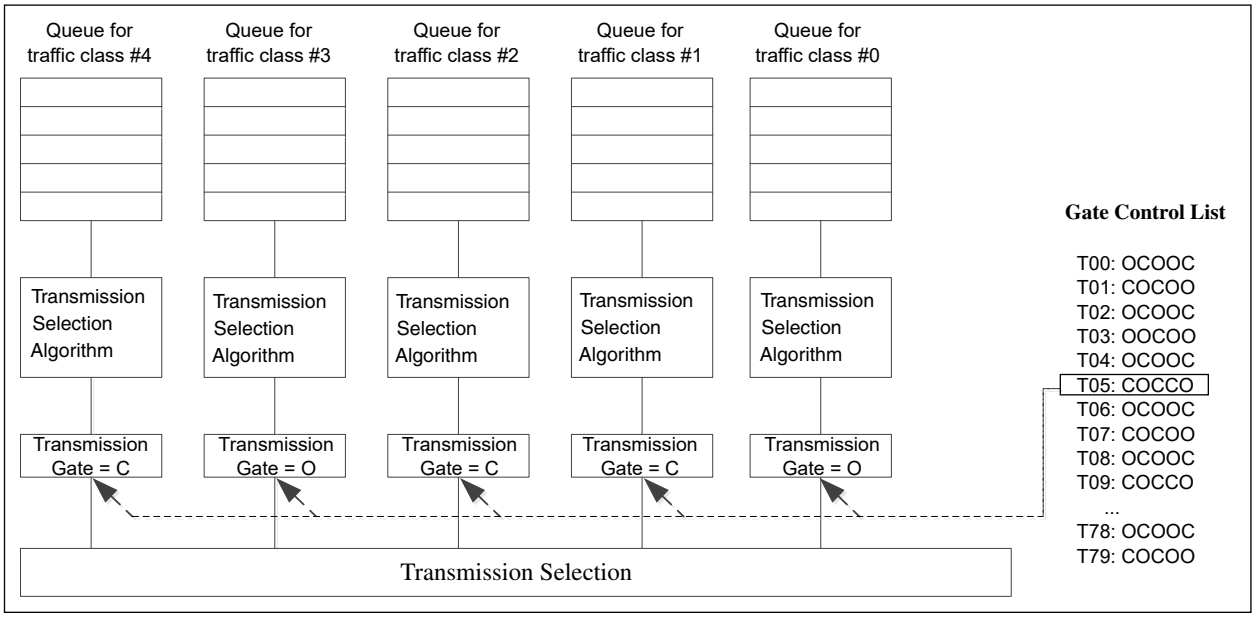

Figure 168. Block Diagram from IEEE 802.1 Qbv Specification - GCL Governing Gate Close and Open Events

The implementation of GCL consists of the following two Gate Control Lists:

- HWOL - Hardware Owned List which is a list for hardware access.
- SWOL - Software Owned List which is a list for software access.

The access to these lists is mutually exclusive. The ownership to the list is set by hardware in the SWOL field of MTL_EST_Status register. Following table provides the implementation details of GCL.

Table 328. External Memory Used for Holding the Two Gate-Control Lists

Gate Control (up to 5 bits)	Time Interval (ns) 16, 20, or 24 bits	
OOCCC	T0	HWOL or SWOL
OOOOC	T1	
CCCCO	T2	
CCCCC	T3

34.4.6.8.1.2.2 Registers Related to Gate Control List

Following are the set of 4 registers (one for each GCL) related to GCL. These registers are implemented through Indirect Addressing using the GCL_Control and GCL_Data registers.

1. 64-bit Base Time Register (BTR)

2. 40-bit Cycle Time (CTR)

3. m-bit Time Extension (TER)

4. n-bit [Gate Control] List Length (LLR) (n depends of the configured GCL depth)

34.4.6.8.1.2.2.1 Base Time Register (BTR)

Base Time Registers is a 64-bit register that holds the start time to execute the GCL. The format of the BTR is same as the PTP format (upper 32-bits holds time in seconds and lower 32 bits hold time in nano seconds). Once the execution of a given list begins, the implementation can update the value in BTR to indicate the next list execution begin time.

34.4.6.8.1.2.2.2 Cycle Time Register (CTR)

Cycle Time Register is a 40-bit register that holds the time at which the execution of the GCL should be repeated. The Cycle Time Register consists of an 8-bit value in seconds, and a 32-bit value in nano seconds (similar to the PTP time format with truncated seconds register). For a given Gate Control List the start time is "Base Time" + N * "Cycle Time" where N is an integer value representing the iteration number starting with 0 for first iteration. If the Gate Control List execution takes longer than the Cycle time, then the list is truncated at the Cycle Time and the subsequent loop begins at Cycle Time.

34.4.6.8.1.2.2.3 Time Extension Register (TER)

Time Extension Register (TER) is a m-bit (where m = Configured Time Interval width + 7) register that holds the amount of time (in nano seconds) the current Gate Control List can be extended before switching to the new Gate Control List. This will be useful in avoiding small fragments of the current list being executed before switching to a new list.

34.4.6.8.1.2.2.4 List Length Register (LLR)

List Length Register (LLR) is an n-bit register (when n is 7, 8, 9, 10, or 11 for a GCL configured depth of 64, 128, 256, 512, or 1024 respectively) that holds the integer value of the length of the GCL (that is the number of valid rows in each GCL). The processing of the GCL stops after the number of rows read equals to the LLR value.

34.4.6.8.1.2.3 Transmission Gating Implementation

A Bridge or an end station can be enhanced to allow transmission from each TC that is yet to be scheduled relative to a known timescale. To achieve this, a transmission gate is associated with each TC; the state of the transmission gate determines if the queued frames can be selected for transmission.

For a TC, the transmission gate can be in one of the following two states:

1. OPEN:Queued frames are selected for transmission, in accordance with the definition of the transmission selection algorithm associated with the TC.
2. CLOSED: Queued frames are not selected for transmission.

A frame on a traffic class queue is not available for transmission if the transmission gate is in the closed state or if there is insufficient time available to transmit the entirety of that frame before the next gate-close event associated with that queue.

The implementation has visibility to the current schedule of gate controls and the immediate next schedule of the gate controls. So the maximum Gate Open period does not exceed the sum of the two Time Intervals. This is because, a frame is selected for transmission only if the gate is currently Open and the duration of gate open interval is greater than the time taken to transfer the entire frame.

The implementation must know the frame size before the transmission, so that the transmission overruns can be avoided and only the frames that can complete are scheduled at all times.

The implementation adequately compensates for the implementation delays in the data transfer from the buffer to the line by offsetting the current time with all the relevant delays (provided by the CTOV field of MTL_EST_Control register). This ensures that the schedule provided is always accurately implemented at the line.

34.4.6.8.1.3 Idle Slope Computation Updates

When EST is enabled, credit is accumulated only when the gate is open; therefore, the effective data rate of the idleSlope must be increased to reflect the duty cycle for the transmission gate associated with the queue.

The idleSlope is computed based on the GateOpenTime and OperCycleTime values. Program the idleSlope registers (implemented one per CBS enabled TC) based on the following equation. The existing MTL register has sufficient bit width to accommodate the new values for idleSlope.

idleSlope = (operIdleSlope(N) * OperCycle/GateOpenTime)

34.4.6.8.1.4 Operational Details of GCL

Set the switch to software List, the SSWL field of the MTL_EST_Control Register, so that hardware can access the programmed gate control list. The first set of gate controls are applied when the current time is equal to the value in the Base Time Register (BTR) and is held until the programmed "Time Interval" value.

To avoid transmission overruns, one additional gate control event is always read ahead from the list. This enables the GCL to determine the next gate close events (if any) for the TCs that are open.

The scheduling based on the Gate Open state and Time Interval of only the current and subsequent schedule. An internal accumulator is used to add the time intervals when gate controls are applied. BTR + Accumulator holds the time at which the next set of gate controls are to be applied.

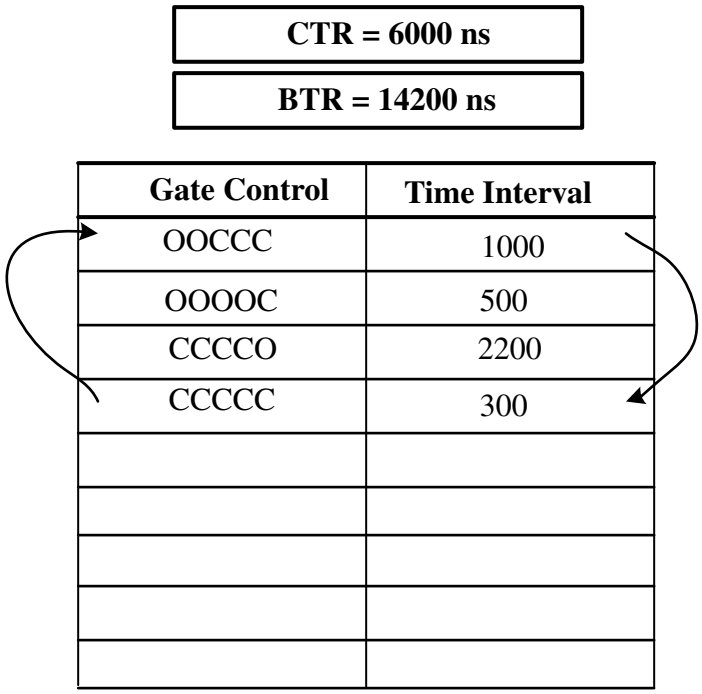

Figure 169. GCL and Associated Registers - BaseTime and CycleTime

The GCL is read progressively from the first row adhering to the schedule. The read operations continue until the List Length (from LLR Register) is reached and the execution of the list restarts at BTR + CTR time. At this point the BTR is incremented by value in CTR to mark the beginning of a new cycle. In the absence of any gate controls, all the gates are deemed to be in Open state, during the execution of the list.

In cases where the execution time of the list is greater than the CycleTime, the list is truncated and the next iteration starts when the current time equals BTR + CTR.

Table 329. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17900	CCCCC	4000	14200
18200	OOOOO	0	20200
20200	OOCCC	1000	20200
21200	OOOOC	1500	20200

In the example in table, the execution starts at 14200 and the first set of Gate Controls "OOCCC" are applied immediately. As the time interval is 1000ns the next set of gate controls are applied at 14200 (BTR) + 1000 (Accumulator) = 15200 ns . As there are no

gate controls available after the execution of the last gate control and before the next iteration of the loop, the gates are deemed to be in open state during that time period as depicted at time 18200 in the table.

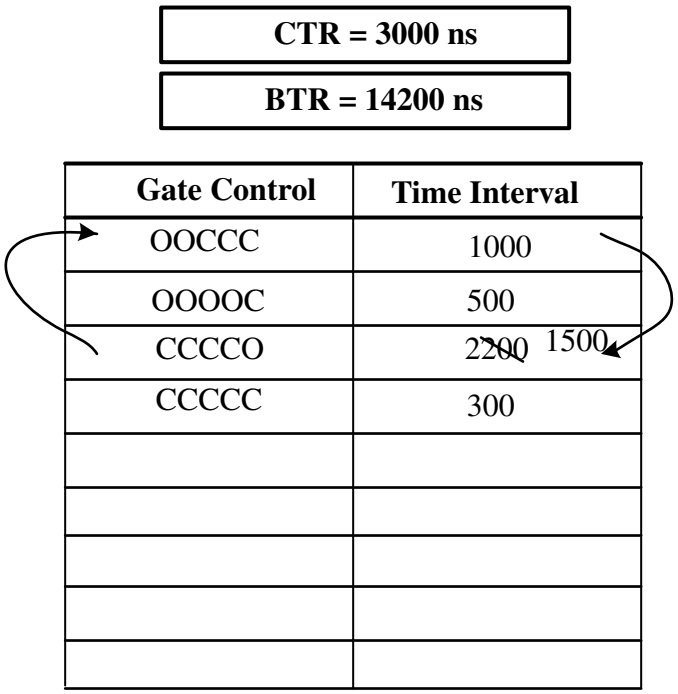

Figure 170. GCL and Associated Registers - BaseTime and CycleTime List Execution Time > CycleTime

As the list execution takes longer than the allocated CycleTime, the list is truncated and the list is started from the BTR+CTR as shown in the following table.

Table 330. GCL and Associated Registers - BTR and CTR, Execution Time > Cycle Time

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
14200	OOCCC	1000	14200
15200	OOOOC	1500	14200
15700	CCCCO	3700	14200
17200	OOCCC	1000	17200
18200	OOOOC	1500	17200
18700	CCCCO	3700	17200

While applying the third set of gate controls, the BTR + CycleTime (17200) < BTR + Accumulator (17900), so the list is truncated and execution switches to a new iteration at 17200.

34.4.6.8.1.5 Installing a New GCL

When a new software programmed GCL is available and must be executed at the new BTR value, the switch to the new GCL can happen in one of the following ways.

- New Base Time aligned with current schedule
- New Base Time unaligned with current schedule

34.4.6.8.1.5.1 New Base Time Aligned with Current Schedule

If the choice of cycle time for the new gating cycle is unchanged from the cycle time for the current gating cycle, and if the BTR chosen for the new gating cycle (new BTR) is an integer multiple of the current cycle time (+ current BTR), then the new gating cycle exactly lines up with the old gating cycle, that is, the cycle start times for the new gating cycle is same as they would have been for the old configuration. This could be considered to be the ideal case and allows the new gating cycle to be installed and executed with no timing issues. The implementation completes the execution of an iteration of the current list and switches to the new list at the beginning of the BaseTime listed in the new list.

If (New BaseTime > = Current Time)

ConfigChangeTime = New BaseTime

Else If (New BaseTime < Current Time)

1. Set the BTRError

2. ConfigChangeTime = (New BaseTime + N* New CycleTime)

where N is the smallest integer for which the relation ConfigChangeTime >= CurrentTime and (N =< 8) is TRUE.

When N > 8 the hardware cannot auto recover and the loop count value in BTRError reporting is set to 1111 requiring the software to reprogram the New Base Time.

Following figure illustrates the installation of the new GCL along with the timelines.

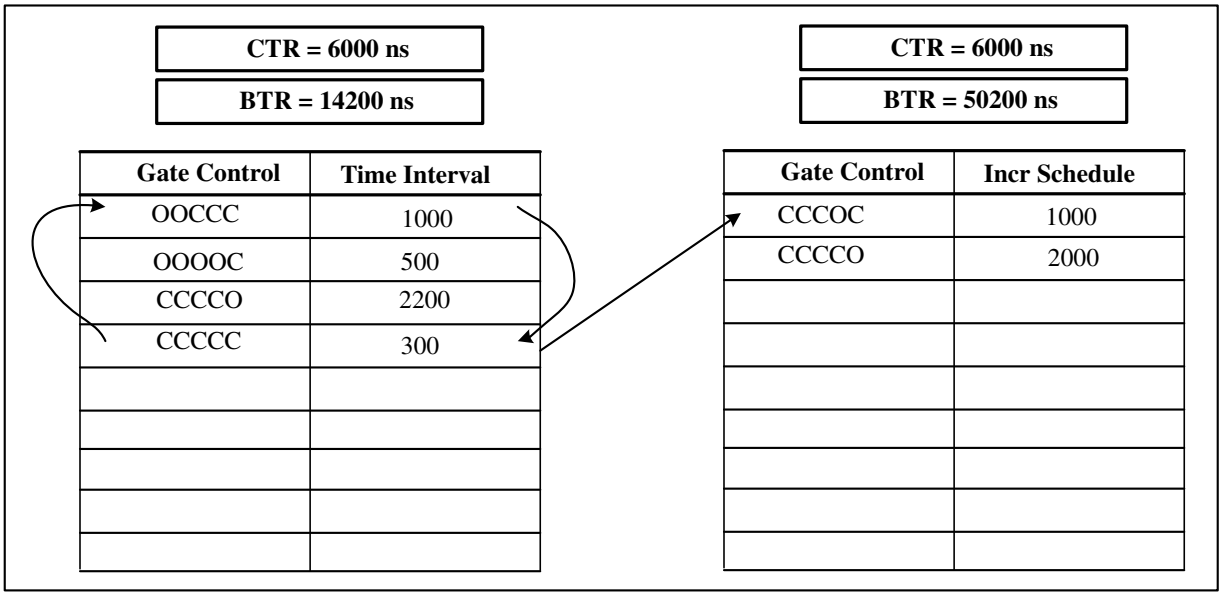

Figure 171. Switching to a New Configuration that is Aligned with the Existing Configuration

In the above example, after the sixth iteration of the first GCL, the BTR values of the old and new GCL are equal. At that point the new GCL is processed as a natural extension to the existing GCL.

Table 331. GCL and Associated Registers - BTR and CTR

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47900	CCCCC	4000	44200
48200	OOOOO	0	50200
50200	CCCOC	1000	50200
51200	CCCCO	3000	50200
53200	OOOOO	0	56200

34.4.6.8.1.5.2 New Base Time Unaligned with Current Schedule

If new CycleTime differs from current CycleTime or New BaseTime is in the future and is not an integer multiple of current CycleTime, then the old and new cycles do not line up; when new BaseTime is reached (when the new configuration is installed and starts to execute), the last old cycle is normally truncated to start the first new cycle. This could be undesirable if it results in a very short last old cycle; arguably it would be better to simply extend the penultimate old cycle by that small amount, rather than starting a very short cycle. The Cycle Time Extension Register (related to the current config list) allows this extension of the last old cycle to be done in a defined way; if the last complete old cycle ends normally in less than current Cycle Time Extension (TER) ns before the new base time, then the last complete cycle before new BaseTime is reached is extended so that it ends at new BaseTime.

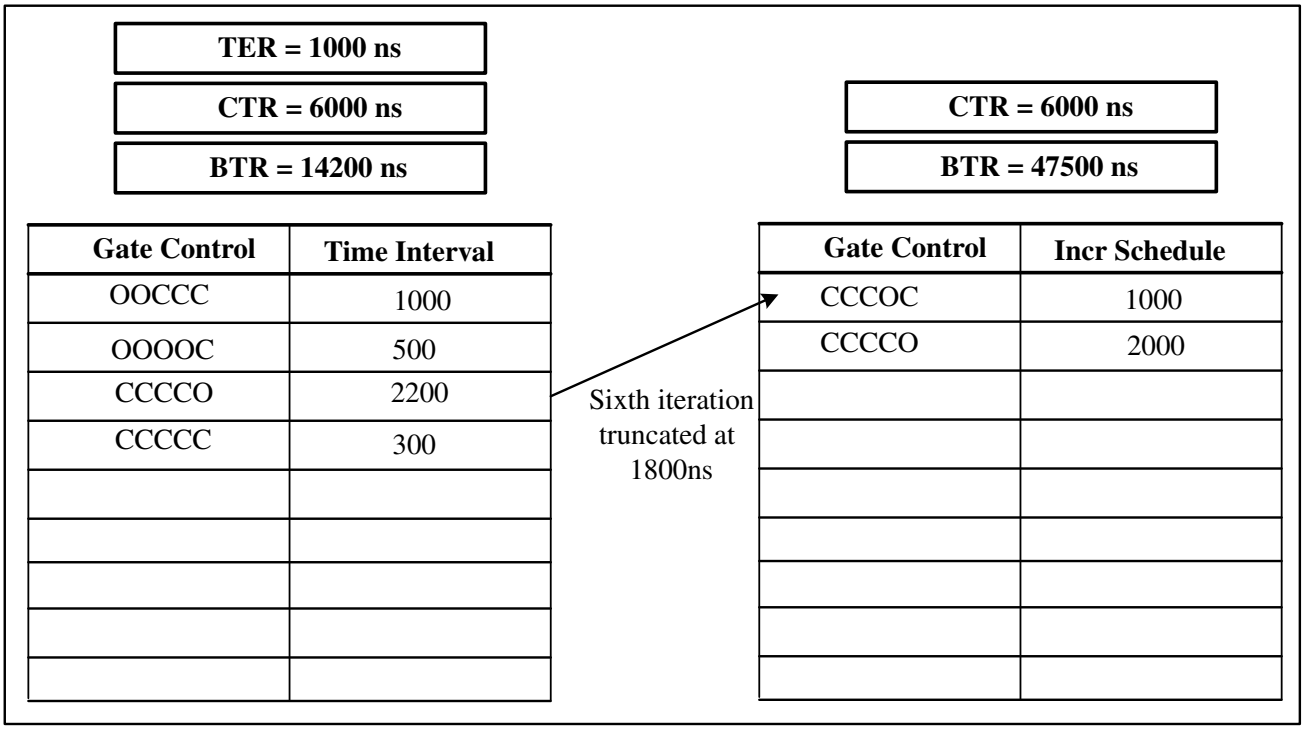

Figure 172. Switching to New List Truncating the Current List

At the end of the fifth iteration the Current time + Cycle time extension (TER) < New BTR so the sixth iteration of current configuration is started. During the sixth iteration of the current list when the new BTR value is smaller than the next schedule in the current list, it switches to the new list.

Table 332. Extending to New List By Truncating the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
44200	OOCCC	1000	44200
45200	OOOOC	1500	44200
45700	CCCCO	3700	44200
47500	CCCOC	4000	44200
48500	CCCCO	0	50200
50500	OOOOO	1000	50200

Below is an example where the current config list is extended instead of starting a new iteration as the extension time of 800ns is less than the allowed cycle extension time (TER) of 1000ns.

Figure 173. Switching to New List By Extending the Current List

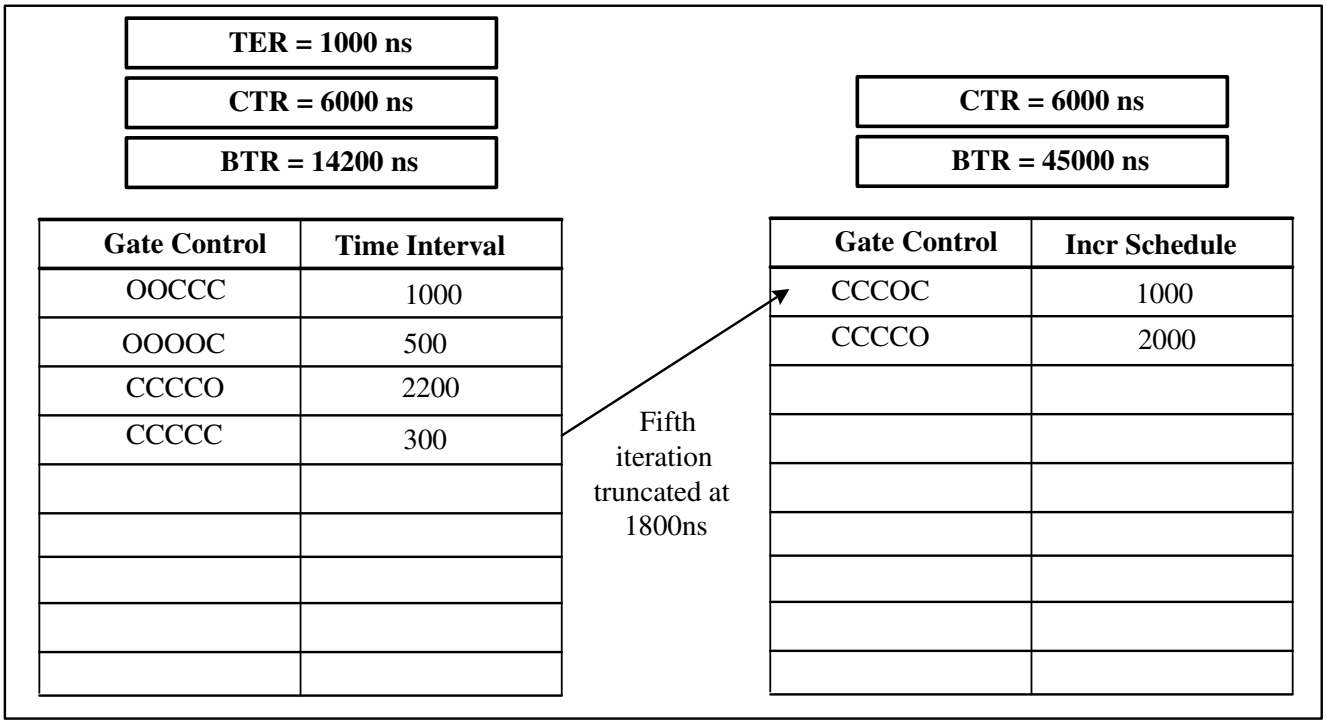

Table 333. Switching to New List By Extending the Current List

Current Time	Gate Control Applied	Accumulator Value	BTR (with updates)
38200	OOCCC	1000	38200
39200	OOOOC	1500	38200
39700	CCCCO	3700	38200
41900	CCCCC	4000	38200
42200	OOOOO	0	44200
45000	CCCOC	1000	45000
46000	CCCCO	3000	45000
48000	OOOOO	0	51000

34.4.6.8.1.6 Impact of Transmit Scheduling Algorithms on EST

When EST is used in isolation, the Gate Control List manages the final open/close state of the Queues along with the checks carried out by the Transmission Selection Algorithm in MTL. As the Gate Controls operate on a predefined repetitive schedule, it is recommended to use Strict Priority or Credit Based Shaper (CBS) scheduling algorithms.

Other algorithms such as the Weighted Round Robin (WRR), Deficit Weighted Round Robin (DWRR) and Weighted Fair Queuing (WFQ) implement masking of the queues based on the current winning queue. The algorithm is applied only among the group of queues that open simultaneously. To ensure Queues whose gates are "Open" get priority, these algorithms are modified to treat "gate open" queues and "gate closed" queues as separate groups giving priority to gate open queues.

For example, consider 4 queues (Q3, Q2, Q1, Q0) with weights 4:3:2:1; Q3 and Q2 are in Open state in slot one slot, while Q1 and Q0 are in Open state in another slot. In this case, the scheduler works as follows:

1. In the first slot, the Q3 and Q2 are serviced in the ratio of 4:3 for the duration the slot is open.
2. In the second slot, the queues Q1 and Q0 are serviced in the ratio of 2:1.
3. Fresh arbitration is started every time a slot is opened.

In other words, the traffic does not get distributed in the intended ratio of 4:3:2:1; but as two groups with different ratios and only for the duration of the slot when the gates are open continuously

NOTE

See Programming Guidelines for EST

34.4.6.8.2 Frame Preemption (FPE)

Frame preemption breaks the interfering frame into smaller fragments. Therefore, the guard band needs to be only as large as the largest possible interfering fragment instead of the largest possible interfering frame. During the guard band, only the frames that can complete the transmission of the entire frame before the next gate close event are permitted. This ensures that the high priority traffic can always start at the beginning of the window reserved for it.

Preemption allows one or more higher priority (express) frames to interrupt the transmission of a lower priority (preemptable) frame; the preemptable frame transmission is resumed and completed after the express frame transmission is complete. To support frame preemption, the following two abstractions of the MAC are used:

- A preemptable MAC, called pMAC, which carries the preemptable traffic.
- An express MAC, called eMAC, which carries the express traffic.

In the implementation, only the parts of the MAC that hold the state during preemption are replicated and represented as pMAC and eMAC. The MAC uses the following two ways to put the transmission of the preemtable traffic on hold, in the presence of express traffic:

- The MTL scheduler interrupts the preemptable traffic that is currently being transmitted. When the preemption capability is active, the MAC interrupts the transmission and reception of preemptable frames. A preempted fragment can be followed by zero or more express frames, before the continuation fragments. The preemptable frame can be fragmented any number of times, however, the minimum final and non-final fragment length criterion must be met. However, interleaving of more than 1 preemptable packet is not permitted. This implies that if a preemptable packet is fragmented by an express packet, another preemptable packet cannot be transferred until all the remaining fragments of the first preempted packet are transferred.
- The MTL scheduler prevents starting the transmission of preemptable traffic. When the preemption capability is inactive, the pMAC entity is disabled and only express traffic is transmitted or received. Frame preemption feature can be enabled by setting EFPE field of the MAC_FPE_CTRL_STS register.

34.4.6.8.2.1 GCL Modification to Support FPE

In the EST-only configuration, the GCL entry has up to 24 bits of Time Interval and up to 8 high order bits representing the Gate Open/Close state requirements as shown in the following figure.

Gate Control (up to 5 bits)	Time Interval(ns) 16, 20 , or 24 bits
OOCCC	T0
OOOOC	T1
CCCCO	T2
CCCCC	T3
|	|
|	|
OCOCO	T126
OOOOC	T127

Figure 174. Gate Control List When FPE is Disabled

EST only supports SetGate operation, which implies that the gates are set to either open or close at a given time interval. However, when both Frame Preemption (FPE) and EST are enabled, the GCL also supports Set-and-Hold-MAC and Set-and-Release-MAC operations, in addition to the SetGate operation. To enable the support of hold and release operations, the format of the GCL is slightly changed while configuring and enabling the FPE. The first Queue (Q0) is always programmed to carry preemption traffic and therefore it is always Open. The bit corresponding to Q0 is renamed as Release/Hold MAC control. The TX Queues whose packets are preemptable are indicated by setting the PEC field of the MTL_FPE_CTRL_STS register. The GCL bit of the corresponding Queue are ignored and considered as always "Open". So, even if the software writes a "0" ("C"), it is ignored for such queues.

Gate Control (up to 4 bits)	Release/Hold Indication	Time Interval(ns) 16, 20, or 24 bits
CCCO	0	T0
CCCC	0	T1
OCCC	1	T2
COCC	1	T3
CCOC	1	T4
CCCO	0	T5
CCCC	0	T6

Figure 175. Gate Control List When FPE is Enabled

When the Release/Hold bit transitions from a '0' to '1', a Set-and-Hold-MAC operation is performed. This marks the cease of the preemptable traffic. This is achieved by sending a Hold request to MTL "ha" ns in advance (where ha is the time interval mentioned in the Hold Advance (HADV) field of the MTL_FPE_Advance register). When the Release/Hold bit transitions from a '1' to '0' a Set-and-Release-MAC operation is performed. This marks the resuming of the preemptable traffic. This is achieved by sending a Release request to MTL "ra" ns in advance (where ra is the time interval mentioned in the Release Advance (RADV) field of the MTL_FPE_Advance register). The preemptable traffic is blocked for the time duration the Release/Hold bit is set to a '1' in the Gate Control List.

34.4.6.8.2.2 Impact of Preemption on CBS

In Credit Based Shaper (CBS), the definition of "Transmit" is:

- TRUE for the duration of frame transmission from the queue.
- FALSE when frame transmission from the queue is complete.
- When CBS algorithm is used with frame preemption, the value of "Transmit" is TRUE only while the frame is being transmitted by the MAC. If the frame transmission is delayed or interrupted (for instance, a preemptable frame transmission is interrupted to allow the transmission of an express frame from a different queue, or the start of an express frame is delayed because a preemptable frame is being transmitted) the value of "Transmit" is FALSE until transmission of the frame commences or is resumed.

Also, the value of "Transmit" is FALSE during the transmission of any overhead that is a consequence of frame preemption, (for example, when additional frame overhead, such as mCRC or Fragment Count, is added to the preemptable frame.

At any given time, if there are no frames in the queue, and the value of Transmit is FALSE, and credit is positive value, the credit value is set to zero if there is no preemptable frame from the queue for which transmission is in progress but has been interrupted.

34.4.6.8.2.3 mPacket Format

When the preemption capability is active, MAC sends mPackets to the PHY. An mPacket can be one of the following:

1. A express packet
2. A preemptable packet
3. An initial fragment of a preemptable packet
4. A continuation fragment of a preemptable packet

Start mPacket Delimiter (SMD)

The value of the SMD indicates whether the mPacket contains an express packet, the start of a preemptable packet (initial fragment or complete packet), or any of continuation fragments of a preemptable packet. Following table shows the valid SMD values.

Table 334. Possible SMD Values of mPacket

mPacket Type	Notation	Frame Count	Value
verify packet	SMD-V	-	0x07
respond packet	SMD-R	-	0x19
express packet	SMD-E	-	0xD5
preemptable packet start	SMD-S0	0	0xE6
	SMD-S1	1	0x4C

Table continues on the next page...

Table 334. Possible SMD Values of mPacket (continued)

mPacket Type	Notation	Frame Count	Value
	SMD-S2	2	0x7F
	SMD-S3	3	0xB3
continuation fragment	SMD-C0	0	0x61
	SMD-C1	1	0x52
	SMD-C2	2	0x9E
	SMD-C3	3	0x2A

frag_count

A frag_count is a modulo-4 counter that increments for each continuation fragment of the preemptable packet. The frag_count protects against mPacket reassembly errors by enabling detection of the loss of up to 3 packet fragments.

The frag_count field is present only in mPackets with SMD-C notation (continuation fragment). The frag_count is zero in the first continuation fragment of each preemptable packet.

Table 335. Possible frag_count Values

frag_count	Value
0	0xE6
1	0x4C
2	0x7F
3	0xB3

mData

The contents of the packet from the MAC, starting with the first byte after the SFD to the last byte before the FCS are sent in the mData fields of one or more mPackets for that frame. The minimum size of the mData field is 60 bytes.

CRC The CRC field contains a cyclic redundancy check (CRC) and has an indication of the final mPacket of a frame. In the final mPacket of a frame, the CRC field contains the last 4 octets of the MAC frame (the FCS field).

For other mPackets, the CRC field contains an mCRC value. The mCRC is calculated on the octets of the packet from the first octet of the frame (the octet following the SFD of preemption frames) to the last octet of the packet transmitted in that mPacket by performing an XOR of the calculated 32 bit CRC value of the fragment and a value of 0x0000FFFF.

Summary of Packet Formats

- Express Packet: 7bytes of PREAMBLE, SMD-E, Data, and CRC
- Complete Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, CRC
- Initial Fragment (non-final) of Preemptable Packet: 7 bytes of PREAMBLE, <Current Preemptable packet SMD>, Data, mCRC
- Continuation fragments (non-final) of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, mCRC

- Final fragment of Preemptable packet: 6 bytes of PREAMBLE, <Current Preemptable continuation fragment SMD>, <Current Preemptable continuation fragment FC>, Data, CRC

34.4.6.8.2.4 Transmit Preemption

When FPE is enabled (setting EFPE=1 in MAC_FPE_CTRL_STS register), the MTL preempts a preemptable frame, when a "hold" request is asserted (EST/Qbv configured and enabled) express frames are available for transmission, that is, frame is present in MTL FIFO and is qualified for arbitration, after ensuring that the minimum mPacket mData field size is met. Therefore, preemption occurs only if at least 60 bytes of the preemptable frame have been transmitted and at least 64 bytes (including the frame CRC) remain to be transmitted.

The earliest starting position of preemption is controlled by the AFSZ field of the MTL_ FPE_CTRL_STS Register. Preemption does not occur until at least 64 * (1+ AFSZ) - 4 bytes of the preemptable frame have been sent.

When preemption occurs, all the preemptable queues are blocked and only the express queues are allowed to arbitrate (if more than one express queue has traffic) and transmit.

Continuation fragment of the preempted frame is the first frame to be transmitted after "release" request is asserted (EST/Qbv configured and enabled) and all the express traffic transmission completes.

NOTE

PTP packets should be transmitted as express packets.

MTL communicates the following frame-type information to the MAC using a 2-bit preemption control signal on the MTI interface qualified by SoF and EoF.

- Express Frame
- Preemption Frame (Full or Fragment)
- Continuation Fragment (non-Final or Final)

Table 338. Preemption Control Values on MTI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

MTL should wait for the previous fragment status to be received before resuming the continuation fragments of a preempted frame. Fragment status is described in detail in the Tx Fragment Status section.

34.4.6.8.2.4.1 MAC Tx Preemption

MAC supports preemption by implementing the functionality needed to generate the mPackets as described in “mPacket Format”.

Based on the Preemption Control value received on the MTI interface (qualified with SoF and EoF), MAC determines the frame type (shown in the above table 'Preemption Control Values on MTI Interface for Various Frame Types') and generates mPackets accordingly.

When the preemption capability is active, MAC replaces the SFD of a preemption packet with an SMD-S value. A 2-bit rolling frame count is encoded in the SMD-S value.

The SMD-E value is the same as the SFD value so the SFD of an express packet does not need to be replaced.

34.4.6.8.2.4.1.1 Tx Fragment Status

MAC sends Tx fragment status to indicate successful transmission of fragmented mPackets.

In case of a transmission error (underflow, jabber, and so on) the frame status is sent (and not a fragment status) with an error indication along with all other relevant status fields. In case of receiving an error status for a transmitted fragment, the MTL drops the remaining fragments and does not send any more continuation fragments.

34.4.6.8.2.5 Receive Preemption

34.4.6.8.2.5.1 MAC Receive Preemption

When FPE is enabled, the MAC Receiver pases the incoming packets and differentiates between Express packets and preemptable packets. An SMD containing an SMD-E indicates express packet, and SMD containing an SMD-S indicates the first mPacket of a preemptable packet.

If an mPacket containing an SMD-S is received when MAC has not completed receiving the previous preempted packet, MAC sets a CRC Error status for the previously received partial packet.

When an SMD-S is detected, MAC records the frame count indicated by the SMD and then begins sending data on the MRI interface.

The MAC checks the last four bytes of the mPacket . If the last four bytes of the mPacket do not match CRC, that indicates the end of the packet with or without a CRC error as per the CRC check result. If the last four octets of the mPacket match, that indicates that the packet was preempted.

An SMD containing an SMD-C indicates an mPacket that continues the data for a preempted packet. Upon receiving an SMD value of SMD-C, MAC checks the following:

1. A preempted packet is in progress
2. The frame count indicated by the SMD matches the frame count of the packet in progress
3. The frag_count value indicates the next fragment count.

If any of the above check fails, the mPacket is discarded and MAC sets a CRC Error status for the partially received packet.

If all the checks pass, the next fragment count is incremented modulo 4.

When a packet is preempted, the MAC saves the state of the partially received packet (filter check status, timestamp, length fields etc.) and will be able to process any received Express packets before the continuation fragment is received.

The MAC Receiver sends a "dummy status" for all the mPacket fragments successfully received and sends the Rx status with the final fragment. If an error is detected during any of the fragments the Rx status is sent and the fragment is marked as final fragment. All subsequent continuation fragments received for this packet are dropped in the MAC.

The MAC communicates the following frame type information to the MTL using a 2-bit preemption control signal.

1. Express Frame
2. Preemption Frame (Full or Fragment)
3. Continuation Fragment (non-Final or Final)

Table 339. Preemption Control Values on MRI Interface for Various Frame Types

Qualifier	Preemption Control Value	Frame Type
SoF	00	Start Express
SoF	01	Start Preemption
SoF	10	Continuation Fragment
SoF	11	Reserved
EoF	00	End of Frame
EoF	01	End of Fragment

34.4.6.8.2.5.1.1 Data Alignment

When a received frame cannot be fragmented on any byte boundary, MAC retains the unaligned bytes of data in the previous fragment and resends them with the next fragment as shown in the following figure.

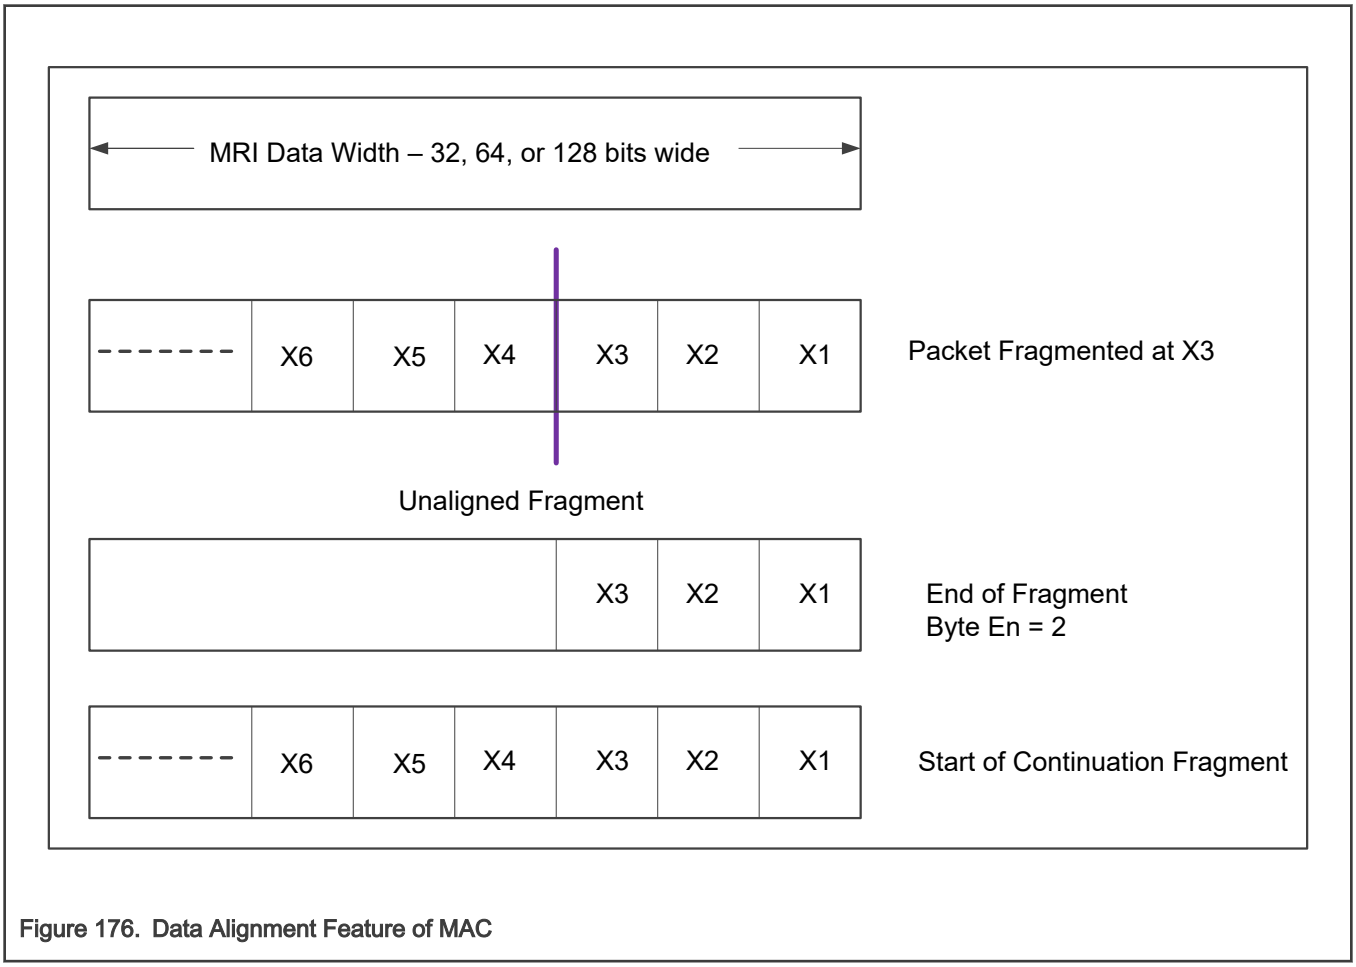

Figure 176. Data Alignment Feature of MAC

34.4.6.8.2.5.1.2 MTL Receive Preemption

The MTL Rx must have at least 2 Rx queues to support FPE function as the preemptable packets and the express packets must be routed to separate Rx queues. The destination Rx queue of a received packet is controlled by MAC_RxQ_Ctrl[n] registers.

Program these registers such that Preemptable traffic and express traffic are not routed to the same Rx queue. As the queue mapping for tagged packets is based on VLAN user-priority field, this implies that priority of preemptable and express packets are mutually exclusive. In other words, packets of a certain priority (traffic class) are either express or preemptable but cannot be both.

For the preemptable frames, in addition to the PSRQ (Priority Selected in Rx queue) based queue routing, a programmable "Frame Preemption Residue Queue" (FPRQ) is supported to route all other Preemption Packets received (Untagged, SA/ DA or VLAN Filter Fails forwarded due to RA being set or VTFE being reset).

Table 340. Preemption Control Values on MRI Interface for Various Frame Types

Preemption Packet Type	Queue Routing
AV Tagged Packets passing the SA/DA and VLAN filters	PSRQ*
DCB/Generic Tagged Packets passing the SA/DA and VLAN filters	PSRQ**
Tagged Packets failing the SA/DA and VLAN filters without setting the Receive All (RA = 0) or setting VTFE = 1	Dropped
All other packets OR when RA = 1	FPRQ

34.4.6.8.2.5.1.3 MTL Receive Arbitration

On the ARI Interface, data is fetched from the MTL Rx FIFO based on the arbitration selected in the MTL_Operation_Mode register. Frame based arbitration can be used only when all the MTL Preemption Queues are operating in Store and Forward mode, else there will be loss of bandwidth on the ARI interface because all the fragments of a preemptable packet is not available. Therefore, any express packets received between the fragments are blocked until all the fragments are received and transferred; this defeats the purpose of express traffic.

When operating in either Threshold (cut through) or Store and forward modes of operation, PBL based arbitration is recommended over Frame based arbitration. In case of PBL based arbitration, the watermark check is always performed and the arbitration/ transfer of data in terms of chunks of "PBL" size of data which is almost similar to the concepts of "fragments". Therefore the express queue packets get blocked for less time as well as the ARI interface transfers the data without loss of efficiency.

34.4.6.8.2.6 Verify and Respond mPackets

When FPE function is present, the MAC can receive and detect the Verify and Respond mPackets, even when FPE is not enabled by software. When MAC detects valid Verify/Respond mPackets, it notifies the software by setting the RVER and RRSP fields of MAC_FPE_CTRL_STS register respectively. Optionally an interrupt can be generated. As such packets have empty (all-zero) data payload, they are dropped inside the MAC and not forwarded to the MRI.

Software can set the SVER and SRSP fields of MAC_FPE_CTRL_STS register to request MAC to transmit Verify and Respond mPackets respectively. Upon successful transmission of these frames, MAC clears the SVER/SRSP bits and sets the TVER & TRSP fields of MAC_FPE_CTRL_STS register. Optionally an interrupt can be generated when these events occur.

34.4.6.8.2.7 Frame Preemption and MMC Counter and Interrupt Registers

The following MMC counters and associated Interrupt registers are instantiated/present in the MAC when Frame Preemption feature is enabled.

Table 341. MMC Counters and Associated Interrupt Registers

Frame Assembly Error Counter	Description	Associated MMC Counter
Frame Assembly Error Counter	A 32-bit counter that provides the number of MAC frames with reassembly errors on the Receiver, due to mismatch in the Fragment Count value.	MMC_Rx_Packet_Assembly_Err_Cntr
Frame SMD Error Counter	A 32-bit counter that provides the number of received MAC frames rejected due to arriving with an SMD-C when there was no preceding preempted frame.	MMC_Rx_Packet_SMD_Err_Cntr
Frame Assembly OK Counter	A 32-bit counter that provides the number of MAC frames that were successfully reassembled.	MMC_Rx_Packet_Assembly_Ok_Cntr
MAC Rx Fragment Counter	A 32-bit counter that provides the number of additional mPackets received due to preemption.	MMC_Rx_FPE_Fragment_Cntr
MAC Tx Fragment Counter	A 32-bit counter that provides the number of additional mPackets transmitted due to preemption.	MMC_Tx_FPE_Fragment_Cntr
Hold Request Counter	A 32-bit counter that maintains the count of number of times a hold request is given to MAC.	MMC_Tx_Hold_Req_Cntr

34.4.6.8.2.7.1 Additional Registers Associated With MMC Interrupts

Following are the additional registers associated with MMC interrupts for the MMC error counters:

- MMC_FPE_Tx_Interrupt
- MMC_FPE_Tx_Interrupt_Mask
- MMC_Rx_Interrupt
- MMC_FPE_Rx_Interrupt_Mask

34.4.6.8.3 Time-Based Scheduling

Time-based scheduling feature is suitable for traffic whose periodicity and rate are predictable. To improve the quality-of-service of such traffic,

- The transmit DMA fetches the packet from the host memory for transmission at designated time. This helps the software to setup the Transmit descriptors in advance even before packet is ready/available. It reduces the overhead on the software and avoids constant monitoring of the time and preparing descriptors just in time when the packet is targeted to be transmitted.
- The MAC transmits the packet only at the designated/pre-determined time even if the packets are fetched in advance. This helps in maintaining a constant transmission rate that can be consumed by the receiver station; therefore avoiding congestion and excessive buffering in the network.

The time-based scheduling feature supports fetching and launching an Ethernet packet at (or after) a pre-determined time. The time-based scheduling is supported only in the following modes/configurations:

- Full duplex mode
- Link speed is 100Mbps or higher

The following figure shows the time-based scheduling flow.

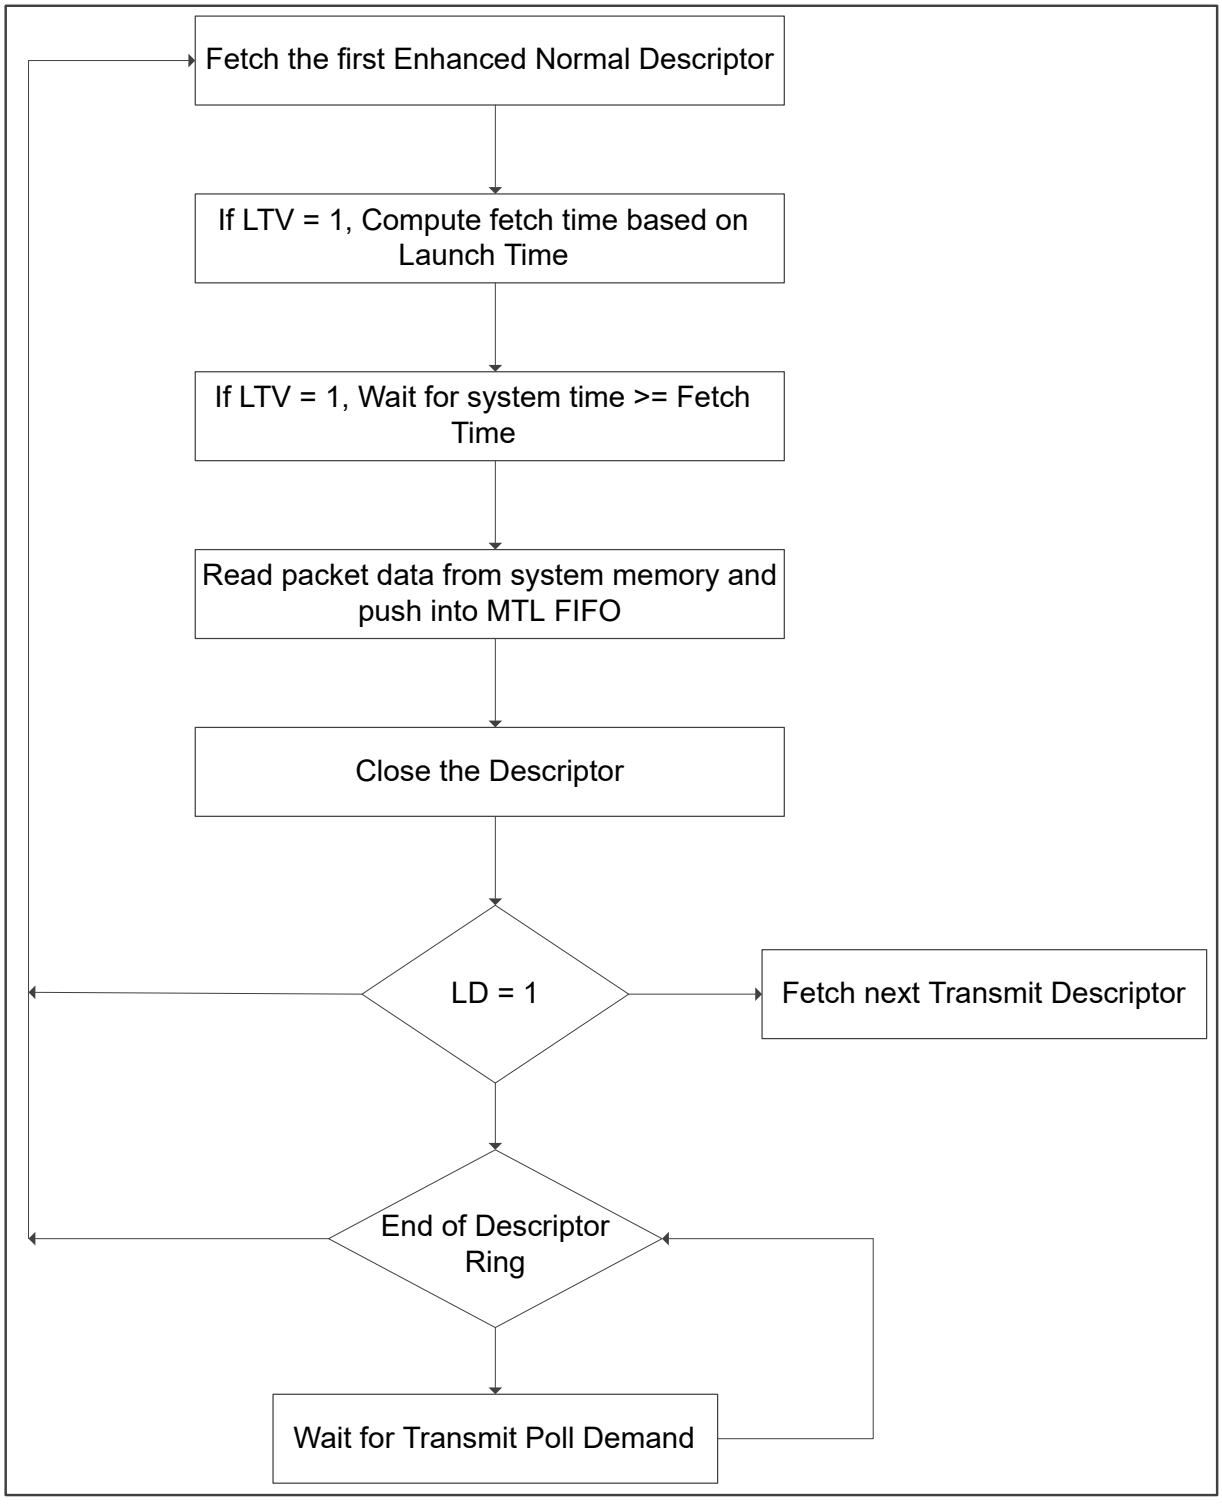

Figure 177. Time-Based Scheduling Flow

Following are the definitions specific to the time-based scheduling feature:

34.4.6.8.3.1 Launch Time

Launch time is the time beyond which the MTL can schedule the packet for transmission. The launch time is reset after the transmission of one frame. Following are the two formats of the launch time.

Normal/Absolute Format:

In this format, the launch time is interpreted in the Normal/Absolute format if the ESTM bit of the MTL_TBS_CTRL register is set to 0.

The launch time is a 32-bit value, where most-significant 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns. The launch time is compared against the IEEE 1588 based System/PTP Time (bits[39:8]) and rolls over after 256 seconds.

The maximum value of the lower 32-bits of System Time is 999,999,999 decimal (0x3B9AC9FF) and it wraps to 0 when reaching this value (representing a full second). Therefore, the maximum value of the lower 24 bits of the Launch Time (after multiplying by 256) must be 0x3B9AC9.

As the maximum value of Launch time is 256 seconds,

- Launch Time is greater than current System Time when its value is between System Time[39:8] and System Time[39:8] + 128 sec
- Launch Time is less than current System Time when its value is between "System Time[39:8] + 128sec" and "System Time[39:8] + 256 sec", because this is a modulo 256 computation.

EST/Offset Format

In this format, the Launch time is an offset value relative to the time indicated by the Base Time Register (BTR) of the GCL list provided in the GCL Slot Number (GSN). The value in the BTR is always updated to the start time of the current loop of the GCL.

For each packet, the GSN value and the Launch Time value are specified in the Enhanced Transmit Descriptor in the DMA configurations, or as Control Word in the MTL configurations.

The launch time offset is a 32-bit value; the upper 8-bits represent the time in seconds and the rest 24 bits represent the time in 256 ns, which is added to the BTR value corresponding to GCL Slot Number. The value of the Launch Time Offset must be smaller than the value of the Cycle Time (specified in the CTR register that is implemented when EST is enabled). If the CTR is greater than or equal to 1s, the maximum value of the lower-24 bits of Launch Time offset should be 999,999,999 decimal (0x3B9AC9FF).

In this format, the launch time is a 64-bit value, which is interpreted as, Launch Time = Launch GSN BTR[63:0] + (Launch Time Offset[31:0] << 8), which is compared with the System Time [63:0].

GSN BTR is the Base Time value at which the Launch GSN loop started execution.

GCL Slot Number (GSN) A modulo 16 count of the GCL loop count is implemented and known as GSN. The count is incremented for every new GCL loop; installation of new GCL list does not impact the count. The current GCL slot number can be obtained by reading the CGSN field of the MTL_EST_Status register.

The maximum value of GSN is 15. Therefore GSN values between Current GSN (CGSN field of MTL_EST_Status register) and CGSN+8 represent current or future slots; all other GSN values are interpreted as elapsed slots or past slots. So, for the correct interpretation of time, GSN value must be between CGSN and CGSN+8, for correct interpretation of time.

34.4.6.8.3.2 Launch Expiry Time

Normal/Absolute Mode

In the normal mode, when the LEOV (Launch Expiry Offset Valid bit of MTL_TBS_CTRL register) is set, the Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determines the maximum amount of time a frame is eligible for launch, starting from the time the frame becomes eligible for launch.

The Launch Expiry Offset is a 24-bit value defined in 256ns units, with a maximum possible value of 999,999,999 ns (0x3B9AC9FF).

Launch Expiry Time = (Launch Time[39:8] + LEOS[32:8]) * 256ns

The packet with a specific Launch time is considered eligible for transmission when the Launch time is less than the System Time and (if LEOV is set) the System Time is less than the Launch Expiry time.

When the System time is greater than the Launch Expiry time the frame is categorized as expired and will be dropped from the MTL FIFO.

NOTE

- For correct interpretation and meaningful operation, the Fetch, Launch, and Launch Expiry time should never be set to a value larger than Current System Time + 128 sec; such a value is interpreted as time that has already elapsed.
- In full duplex mode, the frames dropped from the MTL FIFO have Error Summary (Bit 15) and Excessive Deferral (bit 3) of TxStatus set.

EST/Offset Mode

In the EST mode of operation, when the LEOV field of the MTL_TBS_CTRL register is set, the launch expiry GSN offset (LEGOS field of the MTL_TBS_CTRL register) and Launch Expiry Offset (LEOS field of MTL_TBS_CTRL register) determine the maximum amount of time a frame remains eligible for launch, starting from the time the frame becomes eligible for launch.

Launch Expiry Offset = (LEGOS: LEOS)

LEGOS holds the GSN offset (multiples of CTR time) and LEOS holds maximum value of CTR (sub CTR values) in ns.

Launch Expiry offset is a 24-bit value defined in the units of 256 ns, with a maximum possible value of the smaller of 999,999,999ns or CTR-1 ns.

The Launch Expiry GSN is computed as follows:

Launch Expiry GSN = (Launch GSN + LEGOS + CCMA) Where, CCMA is the CTR Carry due to Modulo addition. This value is 1 if ((Launch Time Offset + LEOS) << 8) is equal to or greater than CTR.

When CCMA = 1, Launch Expiry Offset = (Launch Time Offset+ LEOS) - CTR

When CCMA = 0,

Launch Expiry Offset = (Launch Time Offset + LEOS).

Launch Expiry Time = Launch Expiry GSN BTR[63:0] + Launch Expiry Time Offset.

When LEOV is not set, Launch Expiry Time is not checked.

When LEOV is set, and

- the system time is greater than the Launch Expiry time, the frame is dropped from MTL FIFO. The frame is considered as expired.
- the launch time is smaller than the System Time and Launch Expiry Time is greater than system time, the frame is considered eligible for launch.

NOTE

- Max value of LEGOS is 7. This implies that when LEOV is set, the frame has a maximum life time of <8 GCL loop iterations after it becomes eligible for Launch.
- The slot number of the First GCL List executed each time after EST is enabled, is zero.

34.4.6.8.3.3 Fetch Time

The fetch time accounts for all possible delays in the DMA fetch operation and ensures that the frame is present in the MTL FIFO before the launch time.

If FTOV field of DMA_TBS_CTRL register is set, then fetch time can be indicated for each packet. If the FTOV filed is not set, the Fetch Time Offset is not valid and the DMA fetches packets without any time constraints.

Normal/Absolute Mode

In the Normal mode fetch time derived/calculated by reducing the time specified in the Fetch Time Offset (FTOS) field of DMA_TBS_CTRL register from the given Launch time.

Normal mode of operation, the Fetch Launch Time is computed as:

Fetch Time[39:8] = (Launch Time[39:8] - FTOS[31:8])

The Fetch time is 32-bits and is compared against System Time[39:8] to determine the Eligible for fetching the frame:

- The Fetch time is defined as "greater" than System Time if the Fetch Time is in the range of "System Time[39:8]" and "System Time[39:8] + 128 sec". The frame is considered as not-eligible for fetch.
- The Fetch time is defined as "smaller" than the System Time if the Fetch time is in the range of "System Time[39:8] + 128 sec" and "System Time[39:8] + 256 sec". The frame is considered as eligible for fetch.

This is a modulo 256 computation.

EST/Offset Mode

In the EST/Offset mode, the Fetch GSN Offset (FGOS field of MTL_TBS_CTRL register) provides the Slot Number offset to be deducted from the Launch GSN. In this case the FTOS value should be the smaller of 999,999,999ns or CTR-1 ns.

If (Launch Time Offset >= FTOS):

Fetch Time Offset = ((Launch Time Offset - FTOS) * 256ns)

CBFS(CTR Borrow for Fetch Subtraction) = 0

If (Launch Time Offset < FTOS) Fetch Time Offset = CTR + ((Launch Time Offset - FTOS) * 256ns)

CBFS (CTR Borrow for Fetch Subtraction) = 1

The Fetch GSN is computed as follows:

Fetch GSN = Launch GSN - FGOS - CBFS

Fetch Time = Fetch GSN BTR[63:0] + Fetch Time Offset

The frame is marked eligible for DMA fetch when the fetch time is smaller than the System Time.

DMA Operations Sequence

Following is the sequence of operation when FTOV = 1:

1. Fetch the first Enhanced Normal Descriptor (FD is set)
2. If LTV is set and Fetch enabled, compute the Fetch Time based on the Launch Time Wait for the System Time to be greater than Fetch Time
3. Read the Frame (Data) from the host memory and transfer to MTL FIFO
4. Close the Normal Descriptor
5. Fetch the next Normal Descriptor (if the previous Descriptor was not the Last)
6. Repeat steps 4 to 6, until the last descriptor of the frame (LD is set)

After the Last Descriptor of a frame, the next enhanced normal descriptor should be programmed with a new Launch Time and with LTV bit set. Otherwise, the subsequent frames will be processed without any time restrictions.

NOTE

See Programming the Launch Time in Time-Based Scheduling

34.4.6.8.4 Credit-Based Shaper Algorithm

The MTL Queue Scheduler (shown in Figure 157) uses the credit-based shaper algorithm to arbitrate the AV traffic in all queues and the legacy Ethernet traffic in Queue 0. You can program the additional queues to use the credit-based shaper algorithm.

The following sections provide information about how you can implement the credit-based shaper algorithm:

- Credit Value
- idleSlopeCredit and sendSlopeCredit Values
- Bandwidth Status

34.4.6.8.4.1 Credit Value

The credit value is part of the credit-based sharper algorithm used by the MTL Queue Scheduler.

The credit value is accumulated every transmit clock cycle, that is, 40 ns for 100 Mbps and 8 ns for 1000 Mbps. The credit to be added or subtracted per cycle can be fractional based on the required idleSlope and sendSlope values, as described in the table below.

Table 342. Credit Value Per Transmit Cycle Example

Mode	Values	Description
100 Mbps	• portTransmitRate = 100 Mbps • idleSlope = 70 Mbps (assuming 70% bandwidth reserved for a higher priority traffic class) • sendSlope = 30 Mbps	• credit = 2.8 bits accumulates per cycle (40 ns) for the higher priority traffic class when best-effort packet is being transmitted. • credit = 1.2 bits drains per cycle (40 ns) when higher priority traffic class packet is being transmitted.

The DMA stores the queue traffic in the respective part of the Tx FIFO based on the slot number in the transmit descriptor (if enabled) or the bandwidth availability on the AMBA AHB application bus.

The credit for a queue builds up only when the packet is available but it cannot be transmitted because the MAC is sending a packet from another queue. The module supports another mode in which the credit can build up in advance for a queue in which no packet is available in respective part of the FIFO. This enables sending a burst of high priority traffic in a queue as soon as the data is available. You can enable this mode with Bit 3 of the CBS Control registers of corresponding queues.

When reset, the accumulated credit parameter in the credit-based shaper algorithm is set to zero if there is positive credit, and there is no packet to transmit in a queue. The credit does not accumulate when there is no packet waiting in a queue and other queues are transmitting. When set, the accumulated credit parameter in the credit-based shaper algorithm is not reset to zero if there is positive credit and no packet to transmit in a queue. The credit accumulates even when there is no packet waiting in a queue and other queues are transmitting.

34.4.6.8.4.2 idleSlopeCredit and sendSlopeCredit Values

The idleSlopeCredit and sendSlopeCredit values are programmable.

The software must program the idleSlopeCredit and sendSlopeCredit values. The programmed values should be the credit accumulated or drained per clock cycle scaled by 1024, such as, 2.8 x 1024 = 2867 and 1.2 x 1024 = 1229. In addition, the software must program the hiCredit and loCredit values, scaled by 1024, to adjust for scaling of the idleSlopeCredit and sendSlopeCredit values. This means that if computed hiCredit and loCredit values are 12,000 bits and 3,036 bits respectively, the values to be programmed in the hiCredit and loCredit registers of the corresponding channel are 12000 x 1024 bits and two's complement of 3036 x 1024, respectively.

34.4.6.8.4.3 Bandwidth Status

The hardware maintains the status of the actual bandwidth consumed by each higher priority queue in the CBS status registers. This enables the software to estimate the average bandwidth consumed by numerically higher traffic classes as compared to the reserved bandwidth.

The CBS status register gives the average number of bits transmitted during the previous programmed slot interval (1, 2, 4, 8, or 16 slots of 125 µs) in a queue. The status register is updated even if the credit-based shaper algorithm is not enabled for a queue. The number of slots over which the average bits transmitted per slot are computed is programmed in Bits[6:4] of the CBS control register of the respective queue. For example, if you have programmed two slots, the average bits are computed over slot numbers 0–1, 2–3, 4–5, and so on.

The value programmed in the idleSlopeCredit register of a queue is proportional to the bandwidth reserved for the queue. The software can allocate any bandwidth that is not used by the higher priority queue to the reserved bandwidth of the lower priority queue.

A lower priority queue, which is using the credit-based shaper algorithm, cannot use the unused reserved bandwidth of any higher priority queue that is using the credit-based shaper algorithm. However, a lower priority queue, which is using the strict-priority algorithm, can use the unused reserved bandwidth of any higher priority queue that uses the credit-based shaper algorithm. For example, Queue 1 and Queue 2 use the credit-based shaper algorithm (with reserved bandwidth of 50% and 25%, respectively) and Queue 0 uses the strict-priority algorithm. If Queue 1 uses only 40% of reserved bandwidth, the remaining 10% is used by Queue 0. Queue 2 cannot exceed the reserved bandwidth of 25%.

34.4.6.9 Queue Modes

Both Tx and Rx queues can handle AV traffic.

Queueing is based on WRR (Weighted Round Robin) or WSP (Weighted Strict Priority) algorithm for generic traffic while it is based on CBS (Credit Base Shaper) and SP (Strict Priority) algorithm for AV traffic.

Whether an Rx Queue is configured for generic or AV-based routing depends on the RXQ#EN field of corresponding queue. Queueing is done based on VLAN tag priority. The VLAN tag priority should match the PSRQ field of the MAC_RXQ_CTRL2 registers. The Rx packets can also be routed to a particular DMA channel based on the DCS field of perfectly-matched MAC Address register.

By default, untagged packets in generic traffic are routed to Receive queue specified in UPQ field of MAC_RXQ_CTRL1 register. Queue 0 is the default value of UPQ field. You can override the default value with any other value, for the UPQ field.

AV control packets (tagged or untagged) are routed based on the AVCPQ field of the MAC_RXQ_CTRL1 register. The PTP over Ethernet packets are routed based on the AVPTPQ field of MAC_RXQ_CTRL1 register.

34.4.6.10 Queue Priorities

Priority of an Rx queue can be programmed in corresponding field of MAC_RxQ_Ctrl2 registers. AV queue (high priority) should be programmed as higher priority than the Best-effort queue (low priority).

34.4.7 TCP/IP Offloading Features

34.4.7.1 Transmit Checksum Offload Engine

The MAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the Transmit path, using which, the software can offload the task of checksum insertion to the hardware. In the transmit path MAC calculates the checksum and inserts it in the Tx packet. This feature helps in reducing the load on the software and can improve the overall throughput of the system. This feature is supported for only Q0 queue.

The checksum offload engine module supports two types of checksum calculation and insertion. The checksum engine can be controlled for each packet by setting the CIC bits (TDES3 Bits[17:16]).

Note: The checksum for TCP, UDP, or ICMP is calculated over a complete packet, and then inserted into its corresponding header field. Because of this requirement, when this function is enabled, the Tx FIFO automatically operates in the store-and-forward mode even if IP is configured for Threshold (cut-through) mode.

34.4.7.1.1 IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Type field of Ethernet packet has the value 0x0800 and the Version field of IP datagram has the value 0x4. The checksum field of the input packet is ignored during calculation and replaced with the calculated value.

NOTE

IPv6 headers do not have a checksum field. Therefore, the COE does not modify the IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (TDES3[0]). This status bit is set whenever the values of the Ethernet Type field and the Version field of IP header are not consistent, or when the Ethernet packet does not have enough data, as indicated by the IP header Length field. In other words, this bit is set when an IP header error is asserted under the following circumstances:

- For IPv4 datagrams:
  - The received Ethernet type is 0x0800, but the Version field of IP header is not equal to 0x4.
  - The IPv4 Header Length field indicates a value less than 0x5 (20 bytes).
  - The total packet length is less than the value given in the IPv4 Header Length field.
- For IPv6 datagrams:
  - The Ethernet type is 0x86dd but the IP header Version field is not equal to 0x6.
  - The packet ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

34.4.7.1.2 TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP. The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. The Tx COE can work in the following two modes:

- The TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the Checksum field of the input packet. This engine includes the Checksum field in the checksum calculation, and then replaces the Checksum field with the final calculated checksum.
- The engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

NOTE

For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16’h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (TDES3[12]). This engine sets the Payload Checksum Error status bit when:

- It detects that the packet has been forwarded to the MAC Transmitter engine in the store-and-forward mode without the end of packet (EOP) being written to the FIFO.
- when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received.

When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field. The following table describes the functions supported by

Transmit Checksum Offload engine based on the packet type. When the MAC does not insert the checksum, it is indicated as "No" in the table.

NOTE

You should not enable checksum insertion for IPv4 or IPv6 packets that are greater than the frame size constraint specified in Description of Transmit Checksum Offload Engine because it may result in incorrect checksum insertion or unexpected behavior.

Table 343. Transmit Checksum Offload Engine Functions for Different Packet Types

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
Non-IPv4 or IPv6 packet	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in MAC) but less than or equal to the frame size constraint specified in Transmit Checksum Offload Engine.	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers:		
Hop-by-hop options (in IPv6 main header)	Not Applicable	Yes
Hop-by-hop options (in IPv6 extension header)	Not Applicable	No
Destinations options	Not Applicable	Yes
Routing (with segment left 0)	Not Applicable	No
Routing (with segment left > 0)	Not Applicable	No
TCP, UDP, or ICMP	Not Applicable	Yes
Authentication	Not Applicable	No
Any other next header field in main or extension headers	Not Applicable	No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:	nbsp;	nbsp;

Table continues on the next page...

Table 343. Transmit Checksum Offload Engine Functions for Different Packet Types (continued)

Packet Type	Hardware IP headerchecksum insertion	Hardware TCP/ UDPchecksum insertion
IPv4 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 packet in an IPv4 tunnel	Yes (IPv4 tunnel header)	No
IPv6 Tunnels:	nbsp;	nbsp;
IPv4 packet in an IPv6 tunnel	Not applicable	No
IPv6 packet in an IPv6 tunnel	Not applicable	No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled).	Not applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not applicable	No

34.4.7.2 Receive Checksum Offload Engine

IP provides the Checksum Offload Engine that is used to detect any error in an IPv4 or IPv6 packet in the receive path. The MAC verifies the checksum field of the received packet with the internally calculated checksum and provides the status.

The Receive Checksum Offload engine is used to detect errors in IP packets by calculating the header checksum and further matching it with the received header checksum. This engine also identifies a TCP, UDP, or ICMP payload in received IP packets and calculates the checksum of such payloads appropriately.

Here, the IPv4 or IPv6 packets in the received Ethernet packets are detected and processed for data integrity. The MAC receiver identifies IPv4 or IPv6 packets by checking for value 0x0800 or 0x86DD, respectively, in the Type field of the received Ethernet packet. This identification is applicable to single VLAN-tagged packets. It is also applicable to double VLAN-tagged packets when the Enable Double VLAN Processing option is selected and the EDVLP bit of the MAC_VLAN_Tag register is set.

The Rx COE calculates the IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received packet does not have enough bytes, as indicated by the Length field of the IPv4 header (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP, or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP, UDP, or ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not match the expected payload length given in the IP header.

Following table describes the functions supported by the Rx COE based on the packet type. When the payload of an IP packet is not processed (indicated as "No" in the table), the information (whether the checksum engine is bypassed or not) is given in the receive status.

NOTE

The MAC does not append any payload checksum bytes to the received Ethernet packets.

Table 344. Receive Checksum Offload Engine Functions for Different Packet Types

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
Non-IPv4 or IPv6	No	No
IPv4 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Yes	Yes
IPv6 packet is greater than 1,522 bytes (2,000 bytes when IEEE 802.3ad Support for 2K Packets is enabled in the MAC)	Not Applicable	Yes
IPv4 with TCP, UDP, or ICMP	Yes	Yes
IPv4 header's protocol field contains a protocol other than TCP, UDP, or ICMP	Yes	No
IPv4 packet has IP options (IP header is longer than 20 bytes)	Yes	Yes
Packet is an IPv4 fragment	Yes	No
IPv6 packet with the following next header fields in main or extension headers: • Hop-by-hop options (in IPv6 main header) • Hop-by-hop options (in IPv6 extension header) • Destinations options • Routing (with segment left 0) • Routing (with segment left > 0) • TCP, UDP, or ICMP • Any other next header field in main or extension headers	• Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable • Not Applicable	• Yes • No • Yes • Yes • No • Yes • No
IPv4 packet has TCP header with Options fields	Yes	Yes
IPv4 Tunnels:	• Yes (IPv4 tunnel header) • Yes (IPv4 tunnel header)	• No • No

Table continues on the next page...

Table 344. Receive Checksum Offload Engine Functions for Different Packet Types (continued)

Packet type	Hardware IP header checksum checking	Hardware TCP/UDP/ICMP checksum checking
• IPv4 packet in an IPv4 tunnel • IPv6 packet in an IPv4 tunnel		
IPv4 Tunnels: • IPv4 packet in an IPv6 tunnel • IPv6 packet in an IPv6 tunnel	• Not Applicable • Not Applicable	• No • No
IPv4 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Yes	Yes
IPv6 packet has 802.3ac tag (with C-VLAN Tag or S-VLAN Tag when enabled)	Not Applicable	Yes
IPv4 frames with security features (such as encapsulated security payload)	Yes	No
IPv6 frames with security features (such as encapsulated security payload)	Not Applicable	No

Set the IPC bit of the MAC_Configuration register for enabling Receive Checksum offload.

34.4.8 MAC Management Counters

IP supports storing the statistics about the received and transmitted packets in registers that are accessible through the application/software. The MMC module maintains a set of registers for gathering statistics on the received and transmitted packets. The MMC counters are free running.

For MMC register details, see registers "MMC_Control" to "MMC_Rx_FPE_Fragment_Cntr" in ENET_QOS register descriptions.

34.4.9 Flow Control

34.4.9.1 Transmit Flow Control

The Transmit Flow Control involves transmitting Pause packets in full-duplex mode and backpressure in half-duplex mode to control the flow of packets from the remote end.

34.4.9.1.1 Flow control in Full duplex mode

IP supports the IEEE802.3x Pause Packets.

Pause packet structure is shown in the following table.

Table 345. Pause Packet Fields

Field	Description
DA	Contains the special multicast address
SA	Contains the MAC address 0
Type	Contains 8808
MAC Control opcode	Contains 0001 for IEEE 802.3x Pause Control packets; 0101 for PFC packets
PT	Contains Pause time specified in the PT field of the MAC_Q#_Tx_Flow_Ctrl register

34.4.9.1.2 Pause Packet Control

When the FCB bit is set, the MAC generates and transmits a single Pause packet. If the FCB bit is set again after the Pause packet transmission is complete, the MAC sends another Pause packet irrespective of whether the pause time is complete or not. To extend the pause or terminate the pause prior to the time specified in the previously-transmitted Pause packet, the application should program the Pause Time register with appropriate value and then again set the FCB bit.

34.4.9.1.3 Flow Control in Half-Duplex Mode

In half-duplex mode, the MAC uses the deferral mechanism for the flow control (backpressure). When the application requests to stop receiving packets, the MAC sends a JAM pattern of 32 bytes when it senses a packet reception, provided the transmit flow control is enabled. This results in a collision and the remote station backs off. If the application requests a packet to be transmitted, it is scheduled and transmitted even when the backpressure is activated. If the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur), the remote stations abort the transmission because of excessive collisions.

Following table describes the flow control in the Tx path for Queue 0 based on the setting of the following bits:

- EHFC bit of MTL_RxQ0_Operation_Mode register
- TFE bit of MAC_Q0_Tx_Flow_Ctrl register
- DM bit of MAC_Configuration register

Flow control is similar for all queues.

Table 346. Tx MAC Flow Control

EHFC	TFE	DM	Description
x	0	x	The MAC transmitter does not perform the flow control or backpressure operation.
0	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.
1	1	0	The MAC transmitter performs back-pressure when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx performs back-pressure when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.
0	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1.

Table continues on the next page...

Table 346. Tx MAC Flow Control (continued)

EHFC	TFE	DM	Description
1	1	1	The MAC transmitter sends the Pause packet when Bit 0 of MAC_Q0_Tx_Flow_Ctrl register is set or the sideband signal sbd_flowctrl_i is 1. In addition, the MAC Tx sends a Pause packet when Rx Queue level crosses the threshold set by Bits[10:8] of MTL_RxQ0_Operation_Mode register.

34.4.9.1.4 Enabling Transmit Flow Control

To independently enable Transmit Flow Control for each Tx queue, set the TFE bit in the MAC_Q#_Tx_Flow_Ctrl register.

34.4.9.2 Receive Flow Control

In the Receive path, the Flow Control is functional only in the full-duplex mode. If any Pause packet is received in the half-duplex mode, the packet is considered as a normal control packet.

NOTE

Receive pause packets should have a frame size of 64 bytes.

The Receive Flow Control is implemented by the MAC based on the bit value of the respective register, and the destination address and different fields of the received packet.

Following table describes the flow control in the Rx path based on the setting of the following bits:

- RFE bit of MAC_RX_FLOW_CTRL register
- DM bit of MAC_CONFIGURATION register

Table 347. Rx MAC Flow Control

RFE	DM	Description
0	x	The MAC receiver does not detect the received Pause packets.
1	0	The MAC receiver does not detect the received Pause packets but recognizes such packets as Control packets.
1	1	The MAC receiver detects or processes the Pause packets and responds to such packets by stopping the MAC transmitter.

34.4.9.2.1 Enabling Receive Flow Control

To enable Pause Flow Control, set the RFE bit in the MAC_Rx_Flow_Ctrl register.

34.4.10 Loopback Mode

The MAC supports Loopback of transmitted packets to its receiver.

The following are some guidelines for using the loopback mode:

- Enable loopback only with the full-duplex mode. In half-duplex mode, the carrier sense signal (crs) or collision (col) signal inputs get sampled which may result into issues such as packet dropping.
- If the loopback mode is enabled without connecting a PHY chip (for example, in FPGA setup), you should externally generate the Tx and Rx clocks and provide these clocks to the MAC.
- Do not loop back big packets. Big packets (>1522 bytes) may get corrupted in the loopback FIFO.

To enable this feature, program the LM bit of the MAC_Configuration register.

You can enable loopback for all PHY interfaces. The data is always looped back through internal asynchronous FIFO on to the internal Receive GMII interface, irrespective of which PHY interface is selected. The loopback data is also passed through the corresponding transmit PHY interface block, on to the Ethernet line.

34.4.11 Descriptors

34.4.11.1 Overview

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors. The application creates the descriptors in the system memory. The module supports the following two types of descriptors:

- Normal Descriptor: Normal descriptors are used for packet data and to provide control information applicable to the packets to be transmitted.
- Context Descriptor: Context descriptors are used to provide control information applicable to the packet to be transmitted.

Each normal descriptor contains two buffers and two address pointers. These buffers enable the adapter port to be compatible with various types of memory management schemes.

NOTE

There is no limit for the number of descriptors that can be used for a single packet.

34.4.11.2 Descriptor Structure

The module supports the ring structure for DMA descriptor as shown in the following figure.

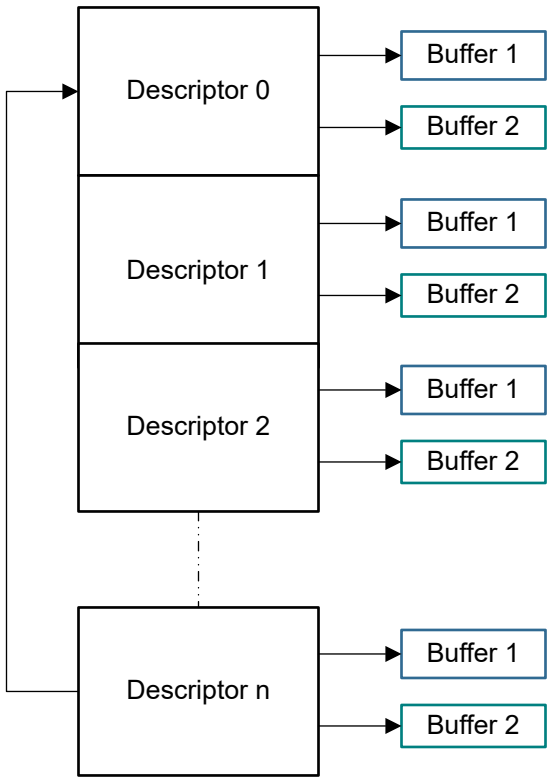

Figure 178. Descriptor Ring Structure

In Ring structure, descriptors are separated by the Word, DWord, or LWord number programmed in the DSL field of the DMA_CH#_Control register. The application needs to program the total ring length, that is, the total number of descriptors in ring span in the following registers of a DMA channel:

- Transmit Descriptor Ring Length Register (DMA_CH#_TxDesc_Ring_Length)
- Channel n Receive Control 2 register (DMA_CH#_RX_CONTROL2)

The Descriptor Tail Pointer Register contains the pointer to the descriptor address (N). The base address and the current descriptor pointer decide the address of the current descriptor that the DMA can process. The descriptors up to one location less than the one indicated by the descriptor tail pointer (N – 1) are owned by the DMA. The DMA continues to process the descriptors until the following condition occurs:

Current Descriptor Pointer == Descriptor Tail Pointer;

The DMA goes into the Suspend mode when this condition occurs. The application must perform a write to the Descriptor Tail pointer register and update the tail pointer so that the following condition is true:

Current Descriptor Pointer < Descriptor Tail Pointer;

The DMA automatically wraps around the base address when the end of ring is reached, as shown in the following figure.

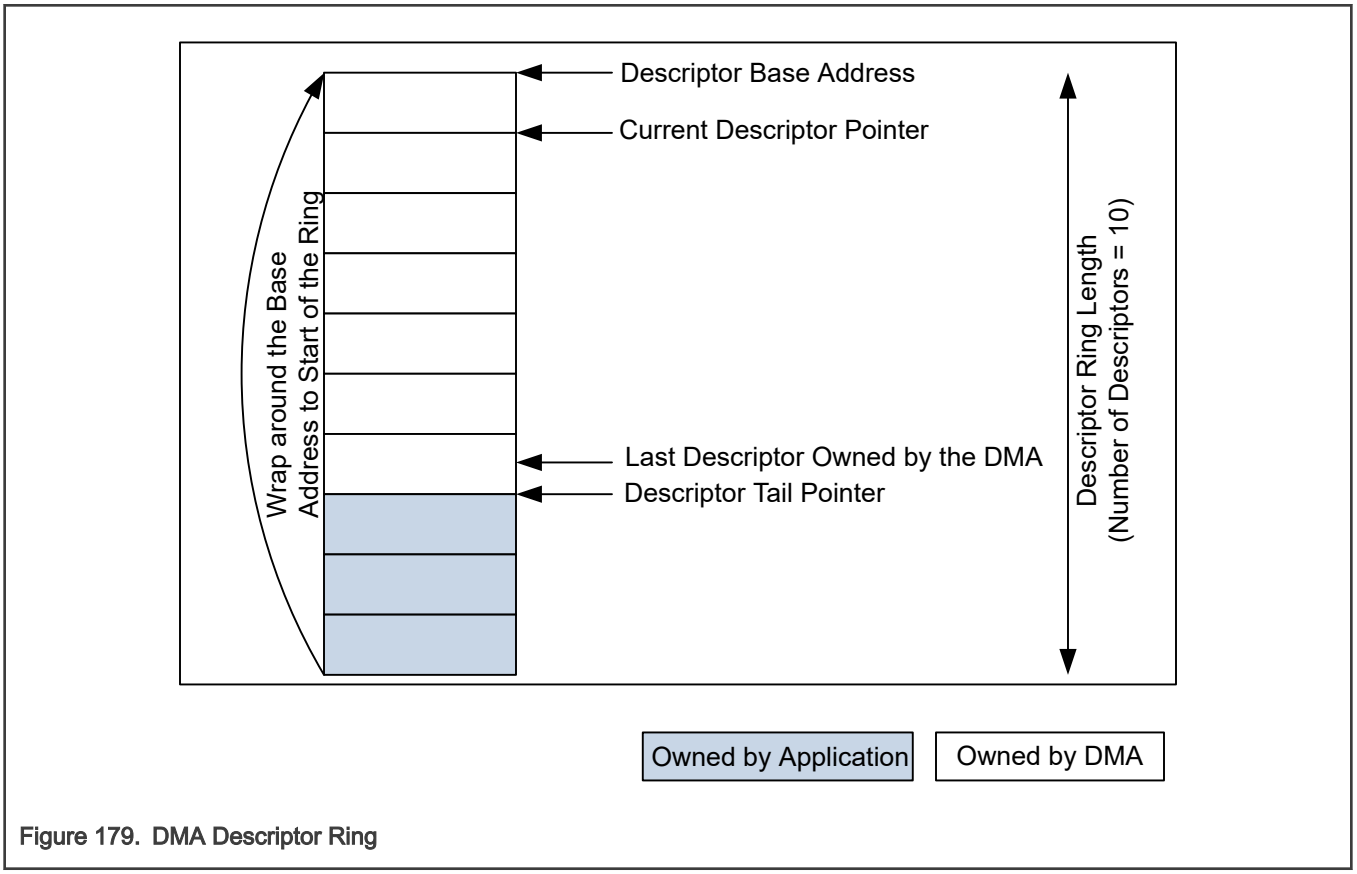

Figure 179. DMA Descriptor Ring

For descriptors owned by the application, the OWN bit of DES3 is reset to 0. For descriptors owned by the DMA, the OWN bit is set to 1. If the application has only one descriptor in the beginning, the application sets the last descriptor address (tail pointer) to Descriptor Base Address + 1. The DMA processes the first descriptor and then waits for the application to advance the tail pointer.

34.4.11.3 Transmit Descriptor

The DMA in the module requires at least one descriptor for a transmit packet. In addition to two buffers, two byte-count buffers, and two address pointers, the transmit descriptor has control fields which can be used to control the MAC operation on per-transmit packet basis. The Transmit Normal descriptor has two formats: Read format and Write-Back format

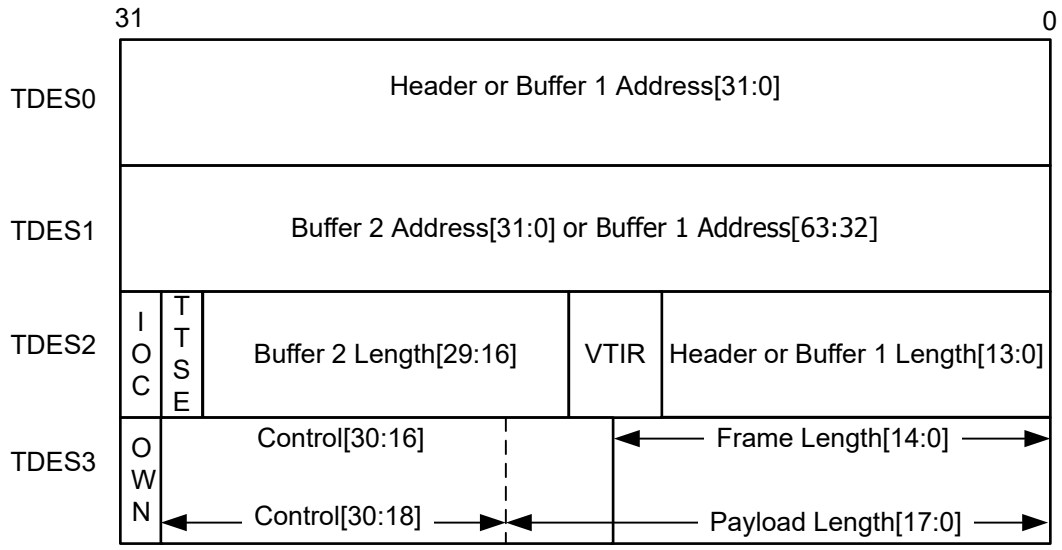
NOTE

TSO Split header is not supported.

34.4.11.3.1 Transmit Normal Descriptor (Read Format)

Following figure shows the Read Format for a Transmit normal descriptor. Table: 'TDES0 Normal Descriptor (Read Format)' through Table: 'TDES3 Normal Descriptor (Read Format)' describe the read format for the Transmit Normal Descriptors: TDES0, TDES1, TDES2, and TDES3.

Figure 180. Transmit Descriptor Read Format



34.4.11.3.1.1 TDES0 Normal Descriptor (Read Format)

Table 348. TDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Buffer 1 Address Pointer or TSO Header Address Pointer These bits indicate the physical address of Buffer 1. These bits indicate the TSO Header Address pointer when the following bits are set: • TSE bit of TDES3 • FD bit of TDES3

34.4.11.3.1.2 TDES1 Normal Descriptor (Read Format)

Table 349. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 or Buffer 1 Address Pointer

Table continues on the next page...

Table 349. TDES1 Normal Descriptor (Read Format)

Bit	Name	Description
		This bit indicates the physical address of Buffer 2 when a descriptor ring structure is used. There is no limitation for the buffer address alignment. In 40- or 48-bit addressing mode, these bits indicate the most-significant 8- or 16- bits of the Buffer 1 Address Pointer.

34.4.11.3.1.3 TDES2 Normal Descriptor (Read Format)

Table 350. TDES2 Normal Descriptor (Read Format)

31	30	29-16	15:14	13:0
IOC	TTSE/ TMWD	B2L	VTIR	HL or B1L

Table 351. TDES2 Normal Descriptor (Read Format)

Bits	Name	Description
31	IOC	Interrupt on Completion This bit controls the setting of TI and ETI status bits in the DMA_CH#_Status register. When ETIC = 1 and TDES2[LD] = 0, this bit sets the ETI bit. When TDES3[LD] = 1, this bit sets the TI status bit.
30	TTSE/ TMWD	Transmit Timestamp Enable or External TSO Memory Write Enable This bit enables the IEEE1588 time stamping for Transmit packet referenced by the descriptor, if TSE bit is not set. If TSE bit is set and external TSO memory is enabled, setting this bit disables external TSO memory writing for this packet.
29:16	B2L	Buffer 2 Length The driver sets this field. When set, this field indicates Buffer 2 length.
15:14	VTIR	VLAN Tag Insertion or Replacement These bits request the MAC to perform VLAN tagging or untagging before transmitting the packets. The application must set the CRC Pad Control bits appropriately when VLAN Tag Insertion, Replacement, or Deletion is enabled for the packet. The following list describes the values of these bits: • 2'b00: Do not add a VLAN tag. • 2'b01: Remove the VLAN tag from the packets before transmission. This option should be used only with the VLAN packets. • 2'b10: Insert a VLAN tag with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. • 2'b11: Replace the VLAN tag in packets with the tag value programmed in the MAC_VLAN_Incl register or context descriptor. This option should be used only with the VLAN packets. These bits are valid when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core.

Table continues on the next page...

Table 351. TDES2 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
13:0	HL or B1L	Header Length or Buffer 1 Length For Header length only bits [9:0] are taken. The size 13:0 is applicable only when interpreting buffer 1 length. If the TCP Segmentation Offload feature is enabled through the TSE bit of TDES3, this field is equal to the header length. When the TSE bit is set in TDES3, the header length includes the length in bytes from Ethernet Source address till the end of the TCP header. The maximum header length supported for TSO feature is 1023 bytes. The maximum header length supported for TSO feature is 1023 bytes. If the TCP Segmentation Offload feature is not enabled, this field is equal to Buffer 1 length.

34.4.11.3.1.4 TDES3 Normal Descriptor (Read Format)

Table 352. TDES3 Normal Descriptor (Read Format)

31	30	29	28	27:26	25:23	22:19	18	17:16	15	14:0
OWN	CTXT	FD	LD	CPC	SAIC	SLOTNUM or THL	TSE	CIC/TPL	TPL	FL/TPL

Table 353. TDES3 Normal Descriptor (Read Format)

Bits	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit after it completes the transfer of data given in the associated buffer(s).
30	CTXT	Context Type This bit should be set to 1'b0 for normal descriptor.
29	FD	First Descriptor When this bit is set, it indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor When this bit is set, it indicates that the buffer contains the last segment of the packet. When this bit is set, the B1L or B2L field should have a non-zero value.
27:26	CPC	CRC Pad Control This field controls the CRC and Pad Insertion for Tx packet. This field is valid only when the first descriptor bit (TDES3[29]) is set. The following list describes the values of Bits[27:26]: • 2'b00: CRC and Pad Insertion The MAC appends the cyclic redundancy check (CRC) at the end of the transmitted packet of length greater than or equal to 60 bytes. The MAC automatically appends padding and CRC to a packet with length less than 60 bytes. • 2'b01: CRC Insertion (Disable Pad Insertion)

Table continues on the next page...

Table 353. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		The MAC appends the CRC at the end of the transmitted packet but it does not append padding. The application should ensure that the padding bytes are present in the packet being transferred from the Transmit Buffer, that is, the packet being transferred from the Transmit Buffer is of length greater than or equal to 60 bytes. • 2'b10: Disable CRC Insertion The MAC does not append the CRC at the end of the transmitted packet. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. • 2'b11: CRC Replacement The MAC replaces the last four bytes of the transmitted packet with recalculated CRC bytes. The application should ensure that the padding and CRC bytes are present in the packet being transferred from the Transmit Buffer. This field is valid only for the first descriptor. Note: When the TSE bit is set, the MAC ignores this field because the CRC and pad insertion is always done for segmentation.
25:23	SAIC	SA Insertion Control These bits request the MAC to add or replace the Source Address field in the Ethernet packet with the value given in the MAC Address 0 or 1 register. The application must set the CRC Pad Control bits appropriately when SA Insertion Control is enabled for the packet. Bit 25 specifies the MAC Address Register (1 or 0) value that is used for Source Address insertion or replacement. The following list describes the values of Bits[24:23]: • 2'b00: Do not include the source address • 2'b01: Include the source address. For reliable transmission, the application must provide frames without source addresses. • 2'b10: Replace the source address. For reliable transmission, the application must provide frames with source addresses. • 2'b11: Reserved These bits are valid in the EQOS-DMA, EQOS-AXI, and EQOS-AHB configurations when the Enable SA and VLAN Insertion on Tx option is selected while configuring the core and when the First Segment control bit (TDES3 [29]) is set. This field is valid only for the first descriptor.
22:19	SLOTNUM or THL	SLOTNUM: Slot Number Control Bits in AV Mode These bits indicate the slot interval in which the data should be fetched from the corresponding buffers addressed by TDES0 or TDES1. When the Transmit descriptor is fetched, the DMA compares the slot number value in this field with the slot interval maintained in the RSN field DMA_CH#_Slot_Function_Control_Status. It fetches the data from the buffers only if a value matches. These bits are valid only for the AV channels. THL: TCP/UDP Header Length

Table continues on the next page...

Table 353. TDES3 Normal Descriptor (Read Format) (continued)

Bits	Name	Description
		If the TSE bit is set, this field contains the length of the TCP/UDP header. The minimum value of this field must be 5 for TCP header. The value must be equal to 2 for UDP header. This field is valid only for the first descriptor.
18	TSE	TSO Split header is not supported. The value of this bit is always zero.
17:16	CIC/TPL	Checksum Insertion Control or TCP Payload Length These bits control the checksum calculation and insertion. The following list describes the bit encoding: • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. This field is valid when the Enable Transmit TCP/IP Checksum Offload option is selected and the TSE bit is reset. When the TSE bit is set, this field contains the upper bits [17:16] of the TCP Payload (or IP Payload for UDP fragmentation). This allows the TCP/UDP packet length field to be spanned across TDES3[17:0] to provide 256 KB packet length support. This field is valid only for the first descriptor.
15	TPL	Reserved or TCP Payload Length When the TSE bit is reset, this bit is reserved. When the TSE bit is set, this is Bit 15 of the TCP payload length [17:0]. This field is valid only when the Enable TCP Segmentation Offloading for TCP/IP Packets option is selected while configuring the core.
14:0	FL/TPL	Frame Length or TCP Payload Length This field is equal to the length of the packet to be transmitted in bytes. When the TSE bit is not set, this field is equal to the total length of the packet to be transmitted: Ethernet Header Length + TCP /IP Header Length – Preamble Length – SFD Length + Ethernet Payload Length When the TSE bit is set, this field is equal to the lower 15 bits of the TCP payload length in case of segmentation and IP payload in case of UDP fragmentation. In case of segmentation, this length does not include Ethernet header or TCP/UDP/IP header length. In case of fragmentation, this length does not include Ethernet header and IP header. When DWRR/WFQ algorithm is NOT enabled, value written into this field is not used when TSE = 0.

34.4.11.3.2 Transmit Normal Descriptor (Write-Back Format)

The write-back format of the Transmit Descriptor includes timestamp low, timestamp high, OWN, and Status bits.

The write-back format is applicable only for the last descriptor of the corresponding packet. The LD bit (TDES3[28]) is set in the descriptor where the DMA writes back the status and timestamp information for the corresponding Transmit packet.

Following figure illustrates the write-back format of the Transmit Descriptor.

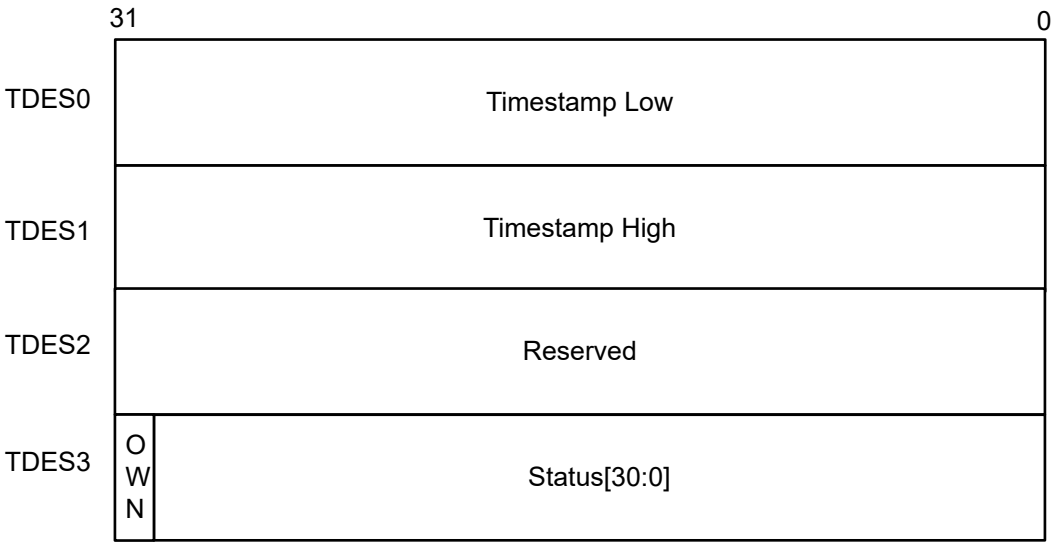


Figure 181. Transmit Descriptor Write-Back Format

TDES0 Normal Descriptor (Write-Back Format)

As described in following table, this format is only applicable to the last descriptor of a packet.

Table 354. TDES0 Normal Descriptor (Write-Back Format)TDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for the corresponding Transmit packet. The DMA writes the timestamp only if TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and the Timestamp status (TTSS) bit is set.

TDES1 Normal Descriptor (Write-Back Format)

As mentioned in the following table, this format is only applicable to the last descriptor of a packet.

Table 355. TDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High The DMA updates this field with the most significant 32 bits of the timestamp captured for corresponding transmit packet. The DMA writes the timestamp only if the TTSE bit of TDES2 is set in the first descriptor of the packet. This field has the timestamp only if the Last Descriptor bit (LD) in the descriptor is set and Timestamp status (TTSS) bit is set.

TDES2 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 356. TDES2 Normal Descriptor (Write-Back Format)

Bit	Description
31:0	Reserved

TDES3 Normal Descriptor (Write-Back Format)

This format is applicable only to the last descriptor of a packet.

Table 357. TDES3 Normal Descriptor (Write-Back Format)

31	30	29	28	27:24	23	22:18	17	16	15	14	13	12	11	10	9	8	7:4	3	2	1	0
OWN	CTXT	FD	LD	Rsvd	DE	Rsvd	TTSS	EUE	ES	JT	FF	PCE	LoC	NC	LC	EC	CC	ED	UF	DB	IHE

Table 358. TDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the the module DMA owns the descriptor. The DMA clears this bit when it completes the packet transmission. After the write-back is complete, this bit is set to 'b0.
30	CTXT	Context Type This bit should be set to 'b0 for Normal descriptor.
29	FD	First Descriptor This bit indicates that the buffer contains the first segment of a packet.
28	LD	Last Descriptor This bit is set 'b1 for last descriptor of a packet. The DMA writes the status fields only in the last descriptor of the packet.
27:24	Rsvd	Reserved
23	DE	Descriptor Error When this bit is set, it indicates that the descriptor content is incorrect. The DMA sets this bit during write-back while closing the descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location after the first descriptor for a packet. • All 1s • CTXT, LD, and FD bits set to 1.

Table continues on the next page...

Table 358. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:18	Rsvd	Reserved
17	TTSS	Tx Timestamp Status This status bit indicates that a timestamp has been captured for the corresponding transmit packet. When this bit is set, TDES0 and TDES1 have timestamp values that were captured for the Transmit packet. This field is valid only when the Last Segment control bit (TDES3 [28]) in a descriptor is set. This bit is valid only when IEEE1588 timestamping feature is enabled; otherwise, it is reserved.
16	EUE	ECC Uncorrectable Error Status Indicates the ECC uncorrectable error in the TSO memory. Note: Uncorrectable error in Transmit FIFO memory is reported with (Bit 13) FF = 1. This is because, all such packets are flushed by the module.
15	ES	Error Summary This bit indicates the logical OR of the following bits: • TDES3[0]: IP Header Error • TDES3[14]: Jabber Timeout • TDES3[13]: Packet Flush • TDES3[12]: Payload Checksum Error • TDES3[11]: Loss of Carrier • TDES3[10]: No Carrier • TDES3[9]: Late Collision • TDES3[8]: Excessive Collision • TDES3[3]: Excessive Deferral • TDES3[2]: Underflow Error This bit is also set when EUE (bit 16) is set.
14	JT	Jabber Timeout This bit indicates that the MAC transmitter has experienced a jabber time-out. This bit is set only when the JD bit of the MAC_Configuration register is not set.
13	FF	Packet Flushed This bit indicates that the DMA or MTL flushed the packet because of a software flush command given by the CPU.

Table continues on the next page...

Table 358. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
12	PCE	Payload Checksum Error This bit indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either because of insufficient bytes, as indicated by the Payload Length field of the IP Header or the MTL starting to forward the packet to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet packet being transmitted to avoid deadlock, the MTL starts forwarding the packet when the FIFO is full, even in the store-and-forward mode. This error can also occur when Bus Error is detected during packet transfer. When the Full Checksum Offload engine is not enabled, this bit is reserved.
11	LoC	Loss of Carrier This bit indicates that Loss of Carrier occurred during packet transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during packet transmission). This is valid only for the packets transmitted without collision and when the MAC operates in the half-duplex mode.
10	NC	No Carrier This bit indicates that the carrier sense signal form the PHY was not asserted during transmission.
9	LC	Late Collision This bit indicates that packet transmission was aborted because a collision occurred after the collision window (512 byte times including Preamble and Carrier Extension in GMII mode). This bit is not valid if Underflow Error is set.
8	EC	Excessive Collision This bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the MAC_Configuration register, this bit is set after first collision and the transmission of the packet is aborted.
7:4	CC	Collision Count This 4-bit counter value indicates the number of collisions occurred before the packet was transmitted. The count is not valid when the EC bit is set.
3	ED	Excessive Deferral This bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbps mode or Jumbo Packet enabled mode) if DC bit is set in the MAC_Configuration register. When TBS is enabled in full duplex mode and this bit is set, it indicates that the frame has been dropped after the expiry time has reached.
2	UF	Underflow Error This bit indicates that the MAC aborted the packet because the data arrived late from the system memory. The underflow error can occur because of either of the following conditions:

Table continues on the next page...

Table 358. TDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• The DMA encountered an empty Transmit Buffer while transmitting the packet • The application filled the MTL Tx FIFO slower than the MAC transmit rate The transmission process enters the suspended state and sets the underflow bit corresponding to a queue in the MTL_Interrupt_Status register.
1	DB	Deferred Bit This bit indicates that the MAC deferred before transmitting because of presence of carrier. This bit is valid only in the half-duplex mode.
0	IHE	IP Header Error When IP Header Error is set, this bit indicates that the Checksum Offload engine detected an IP header error. This bit is valid only when Tx Checksum Offload is enabled. Otherwise, it is reserved. If COE detects an IP header error, it still inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload. In full duplex mode, when EST/Qbv is enabled and this bit is set, it indicates the frame drop status due to Frame Size error or Schedule Error.

34.4.11.3.3 Transmit Context Descriptor

The context descriptor is used to provide the timestamps for one-step timestamp correction, VLAN Tag ID for VLAN insertion feature.

The Transmit Context descriptor can be provided any time before a packet descriptor. The context is valid for the current packet and subsequent packets. The context descriptor is used to provide the timestamps for one-step timestamp correction and VLAN Tag ID for VLAN insertion feature. Write back is done on a context descriptor only to reset the OWN bit.

NOTE

The VLAN Tag IDs and MSS values, provided by the application in a context descriptor with their corresponding Valid bits set, are stored internally by the DMA. When the outer or inner VLAN tag is provided with the Valid bit set, the DMA always passes the last valid VLAN tag to the MTL. The application cannot invalidate the valid VLAN tag stored by the DMA. The VLAN tag is inserted or replaced based on the control inputs provided for the packet.

The Inner VLAN Tag Control input is used only for the next packet that immediately follows the context descriptor. The application must provide a context descriptor before the normal descriptor of each packet for which the DMA should use the inner VLAN Tag control input.

The following figure shows the format of the Transmit Context descriptor.

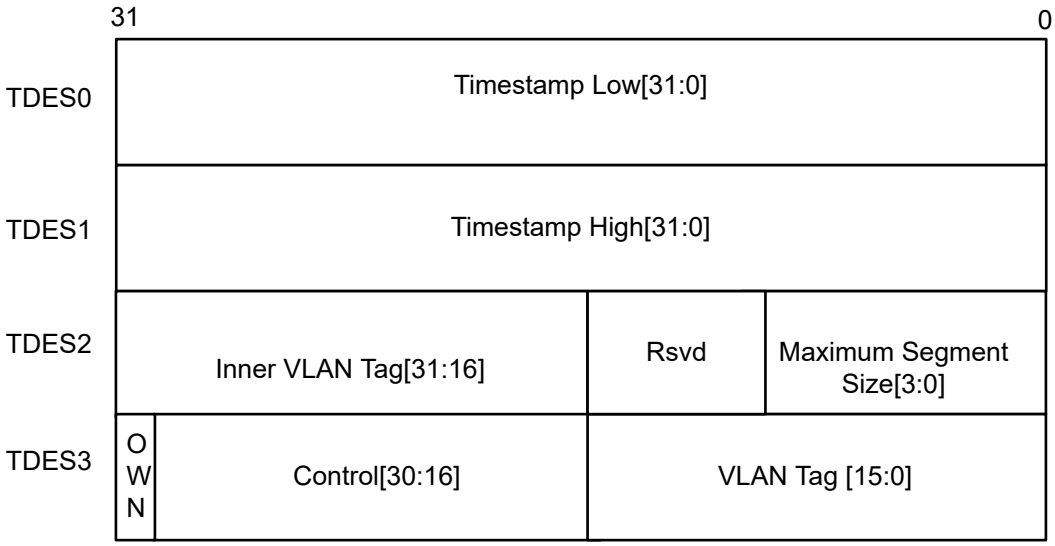

Figure 182. Transmit Context Descriptor Format

34.4.11.3.3.1 TDES0 Context Descriptor

Following table describes the format of the TDES0 Context descriptor.

Table 359. TDES0 Context Descriptor

Bit	Name	Description
31:0	TTSL	Transmit Packet Timestamp Low For one-step correction, the driver can provide the lower 32 bits of timestamp in this descriptor word. The DMA uses this value as the low word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

34.4.11.3.3.2 TDES1 Context Descriptor

Following table describes the format of the TDES1 Context descriptor.

Table 360. TDES1 Context Descriptor

Bit	Name	Description
31:0	TTSH	Transmit Packet Timestamp High For one-step correction, the driver can provide the upper 32 bits of timestamp in this descriptor. The DMA uses this value as the high word for doing one-step timestamp correction. This field is valid only if the OSTC and TCMSSV bits of TDES3 context descriptor are set.

34.4.11.3.3.3 TDES2 Context Descriptor

Following table explains the format of the TDES2 Context descriptor.

Table 361. TDES2 Context Descriptor

Bit	Name	Description
31:16	IVT	Inner VLAN Tag When the IVLTV bit of TDES3 context descriptor is set and the TCMSSV and OSTC bits of TDES3 context descriptor are reset, TDES2[31:16] contains the inner VLAN Tag to be inserted in the subsequent Transmit packets.
15:14	Rsvd	Reserved
13:0	MSS	TSO Split header is not supported. The value of this bit is always zero.

34.4.11.3.3.4 TDES3 Context Descriptor

Table 362. TDES3 Context Descriptor

31	30	29:28	27	26	25:24	23	22:18	17	16	15:0
OWN	CTXT	Rsvd	OSTC	TCMSSV	Rsvd	CDE	Rsvd	IVLTV	VLTV	VT

Follwoing table details the format of the TDES3 Context descriptor.

Table 363. TDES3 Context Descriptor

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit immediately after the read.
30	CTXT	Context Type This bit should be set to 1'b1 for Context descriptor.
29:28	Rsvd	Reserved
27	OSTC	One-Step Timestamp Correction Enable When this bit is set, the DMA performs a one-step timestamp correction with reference to the timestamp values provided in TDES0 and TDES1.
26	TCMSSV	One-Step Timestamp Correction Input or MSS Valid When this bit and the OSTC bit are set, it indicates that the Timestamp Correction input provided in TDES0 and TDES1 is valid. When the OSTC bit is reset and this bit and the TSE bit of TDES3 are set in subsequent normal descriptor, it indicates that the MSS input in TDES2 is valid.
25:24	Rsvd	Reserved
23	CDE	Context Descriptor Error

Table continues on the next page...

Table 363. TDES3 Context Descriptor (continued)

Bit	Name	Description
		When this bit is set, it indicates that the descriptor content is incorrect.The DMA sets this bit during write-back while closing the context descriptor. Descriptor Errors can be: • Incorrect sequence from the context descriptor. For example, a location before the first descriptor for a packet. • All 1s. • CD, LD, and FD bits set to 1. Note 1: When Descriptor Error occurs due to All 1s or CTXT, LD, and FD bits set to 1, the Transmit DMA closes the transmit descriptor with DE and LD bits set to 1. When IOC bit in TDES2 of corresponding first descriptor is set to 1, Transmit DMA will set the TI bit in the DMA_CH#_Status register Note 2: Based on CTXT, LD, and FD bits of the transmit descriptor, the subsequent descriptor might be considered as the First Descriptor (even if FD bit is not set) and partial packet is sent.
22:20	Rsvd	Reserved
19:18	IVTIR	Inner VLAN Tag Insert or Replace When this bit is set, these bits request the MAC to perform Inner VLAN tagging or un-tagging before transmitting the packets. If the packet is modified for VLAN tags, the MAC automatically recalculates and replaces the CRC bytes. The following list describes the values of these bits: • 2'b00: Do not add the inner VLAN tag. • 2'b01: Remove the inner VLAN tag from the packets before transmission. This option should be used only with the VLAN frames. • 2'b10: Insert an inner VLAN tag with the tag value programmed in the MAC_In-ner_VLAN_Incl register or context descriptor. • 2'b11: Replace the inner VLAN tag in packets with the tag value programmed in the MAC_Inner_VLAN_Incl register or context descriptor. This option should be used only with the VLAN frames. These bits are valid when the Enable SA and VLAN Insertion on Tx and Enable Double VLAN Processing options are selected.
17	IVLTV	Inner VLAN Tag Valid When this bit is set, it indicates that the IVT field of TDES2 is valid.
16	VLTV	VLAN Tag Valid When this bit is set, it indicates that the VT field of TDES3 is valid.
15:0	VT	VLAN Tag This field contains the VLAN Tag to be inserted or replaced in the packet. This field is used as VLAN Tag only when the VLTI bit of the MAC_VLAN_Incl register is reset.

34.4.11.4 Receive Descriptor

The DMA in the module attempts to read a descriptor only if the Tail Pointer is different from the Base Pointer or current pointer. It is recommended to have a descriptor ring with a length that can accommodate at least two complete packets received by the MAC.

Otherwise, the performance of the DMA is impacted greatly because of the unavailability of the descriptors. In such situations, the RxFIFO in MTL becomes full and starts dropping packets.

The following Receive Descriptors are present:

- Normal descriptors
- Context descriptors

All RX descriptors are prepared by the software and given to the DMA as "Normal" Descriptors with the content as shown in Receive Normal Descriptor (Read Format). The DMA reads this descriptor and after transferring a received packet (or part of) to the buffers indicated by the descriptor, the Rx DMA will close the descriptor with the corresponding packet status. The format of this status is given in the "Receive Normal Descriptor (Write-Back Format)".

For some packets, the normal descriptor bits are not enough to write the complete status. For such packets, the RX DMA writes the extended status to the next descriptor (without processing or using the Buffers/ Pointers embedded in that descriptor). The format and content of the descriptor write back is described in "Receive Context Descriptor".

34.4.11.4.1 Receive Normal Descriptor (Read Format)

The read format for a Receive Normal descriptor is made up of a header or Buffer 1 address, reserved field, payload or Buffer 2 or Next Descriptor address, a 30-bit reserved filed, OWN bit, and an interrupt bit.

Following figure shows the Read Format for a Receive Normal Descriptor.

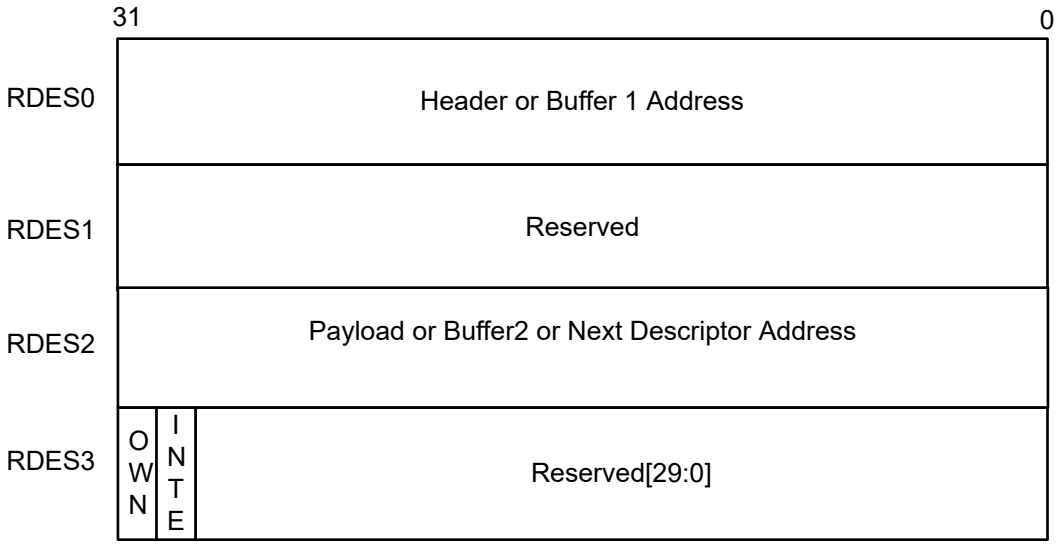

Figure 183. Receive Normal Descriptor Read Format

NOTE

In the Receive Descriptor (Read Format), if the Buffer Address field is all 0s, the module does not transfer data to that buffer and skips to the next buffer or next descriptor.

34.4.11.4.1.1 RDES0 Normal Descriptor (Read Format)

Following table explains the read format of the RDES0 Normal Descriptor.

Table 364. RDES0 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF1AP	Header or Buffer 1 Address Pointer When the SPH bit of Control register of a channel is reset, these bits indicate the physical address of Buffer 1. When the SPH bit is set, these bits indicate the physical address of Header Buffer where the Rx DMA writes the L2/L3/L4 header bytes of the received packet. The application can program a byte-aligned address for this buffer which means that the LS bits of this field can be non-zero. However, while transferring the start of packet, the DMA performs a Write operation with RDES0[1:0] (or RDES0[2:0]/[3:0] in case of 64-/128-bit configuration) as zero. However, the packet data is shifted as per actual offset as given by buffer address pointer. If the address pointer points to a buffer where the middle or last part of the packet is stored, the DMA ignores the offset address and writes to the full location as indicated by the data-width.

34.4.11.4.1.2 RDES1 Normal Descriptor (Read Format)

Following table describes the read format of the RDES1 Normal Descriptor.

Table 365. RDES1 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	Reserved or BUF1AP	In 64-bit addressing mode, this field contains the most-significant 32 bits of the Buffer 1 Address Pointer. Otherwise, this field is reserved.

34.4.11.4.1.3 RDES2 Normal Descriptor (Read Format)

Following table provides the read format of the RDES2 Normal Descriptor.

Table 366. RDES2 Normal Descriptor (Read Format)

Bit	Name	Description
31:0	BUF2AP	Buffer 2 Address Pointer These bits indicate the physical address of Buffer 2. When the SPH bit of the DMA_CH#_Control register is set, the buffer address pointer must be bus width-aligned, that is, RDES2[3:0, 2:0, or 1:0] = 0 corresponding to 128, 64, or 32 bus width. LSBs are ignored internally. When the SPH bit of the DMA_CH#_Control register is reset, there is no limitations on the RDES2 value. However, the RxDMA uses the LS Bits of the pointer address only while transferring the start bytes of a packet. If the BUF2AP is giving the address of a buffer in which the middle or last part of a packet is stored, the DMA ignores BUF2AP[3:0 or 2:0 or 1:0] (corresponding to 128- or 64- or 32-bit data-bus) and writes to the complete location.

34.4.11.4.1.4 RDES3 Normal Descriptor (Read Format)

Following table describes the read format of the RDES3 Normal Descriptor.

31	30	19-26	25	24	23:0
OWN	IOC	Rsvd	BUF2V	BUF1V	Rsvd

Table 367. RDES3 Normal Descriptor (Read Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	IOC	Interrupt Enabled on Completion When this bit is set, an interrupt is issued to the application when the DMA closes this descriptor.
29:26	Rsvd	Reserved
25	BUF2V	Buffer 2 Address Valid When this bit is set, it indicates to the DMA that the buffer 2 address specified in RDES2 is valid. The application must set this bit so that the DMA can use the address, to which the Buffer 2 address in RDES2 is pointing, to write received packet data.
24	BUF1V	Buffer 1 Address Valid When set, this indicates to the DMA that the buffer 1 address specified in RDES1 is valid. The application must set this value if the address pointed to by Buffer 1 address in RDES1 can be used by the DMA to write received packet data.
23:0	Rsvd	Reserved

34.4.11.4.2 Receive Normal Descriptor (Write-Back Format)

The following figure illustrates the write-back format for a Receive Normal descriptor.

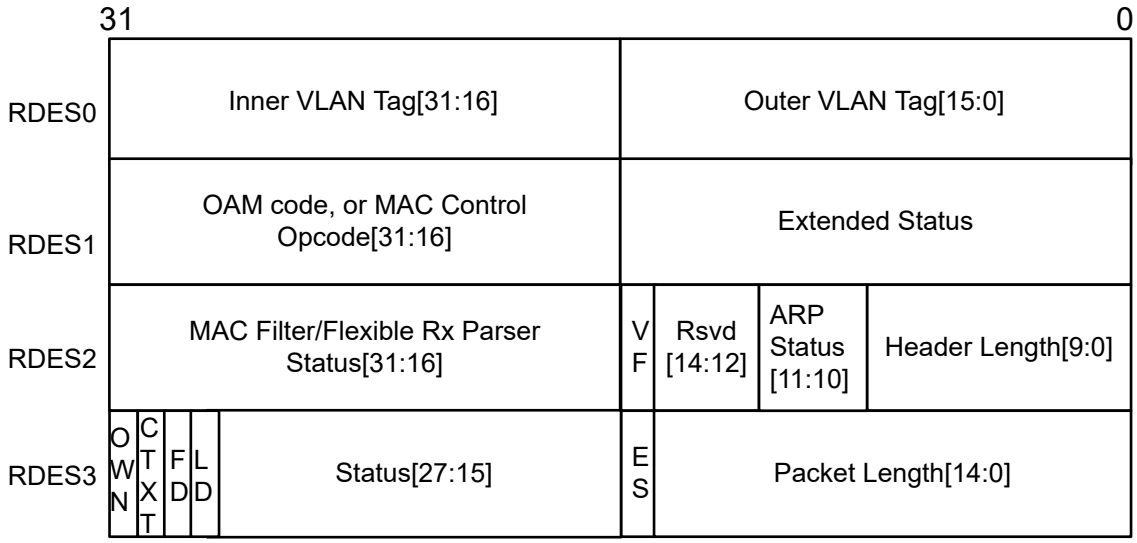

Figure 184. Receive Normal Descriptor (Write-Back Format)

NOTE

When Flexible RX Parser is enabled, RDES2[31:16] indicates Parser status, and not the MAC filter status. MAC filter status is not available when Flexible RX parser is enabled.

34.4.11.4.2.1 RDES0 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES0 Normal Descriptor.

Table 368. RDES0 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	IVT	Inner VLAN Tag This field contains the Inner VLAN tag of the received packet if the RS0V bit of RDES3 is set. This is valid only when Double VLAN tag processing and VLAN tag stripping are enabled.
15:0	OVT	Outer VLAN Tag This field contains the Outer VLAN tag of the received packet if the RS0V bit of RDES3 is set.

34.4.11.4.2.2 RDES1 Normal Descriptor (Write-Back Format)

The Status fields in write-back format are valid only for the last descriptor (RDES3[28] is set). Following table provides the details of the write-back format for RDES1 Normal Descriptor.

31:16	15	14	13	12	11:8	7	6	5	4	3	2:0
OPC	TD	TSA	PV	PFT	PMT	IPCE	IPCB	IPV6	IPV4	IPHE	PT

Table 369. RDES1 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:16	OPC	OAM Sub-Type Code, or MAC Control Packet opcode OAM Sub-Type Code If Bits[18:16] of RDES3 are set to 3'b111, this field contains the OAM sub-type and code fields. MAC Control Packet opcode The bits[15:8] of RDES3 contains the subtype and bits [7:0] contains the code.
15	TD	Timestamp Dropped This bit indicates that the timestamp was captured for this packet but it got dropped in the MTL Rx FIFO because of overflow. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
14	TSA	Timestamp Available When Timestamp is present, this bit indicates that the timestamp value is available in a context descriptor word 2 (RDES2) and word 1(RDES1). This is valid only when the Last Descriptor bit (RDES3 [28]) is set. The context descriptor is written in the next descriptor just after the last normal descriptor for a packet.
13	PV	PTP Version This bit indicates that the received PTP message has the IEEE 1588 version 2 format. When this bit is reset, it indicates the IEEE 1588 version 1 format. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
12	PFT	PTP Packet Type This bit indicates that the PTP message is sent directly over Ethernet. This bit is available only when you select the Timestamp feature. Otherwise, this bit is reserved.
11:8	PMT	PTP Message Type These bits are encoded to give the type of the message received: • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling

Table continues on the next page...

Table 369. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 1011–1110: Reserved • 1111: PTP packet with Reserved message type These bits are available only when you select the Timestamp feature.
7	IPCE	IP Payload Error When this bit is set, it indicates either of the following: • The 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) calculated by the MAC does not match the corresponding checksum field in the received segment. • The TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. • The TCP, UDP, or ICMP segment length is less than minimum allowed segment length for TCP, UDP, or ICMP. Bit 15 (ES) of RDES3 is not set when this bit is set.
6	IPCB	IP Checksum Bypassed This bit indicates that the checksum offload engine is bypassed. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
5	IPV6	IPv6 header Present This bit indicates that an IPV6 header is detected. When the Enable Split Header Feature option is selected and the SPH bit of Control Register of a channel is set, the IPV6 header is available in the header buffer area to which RDES0 is pointing.
4	IPV4	IPV4 Header Present This bit indicates that an IPV4 header is detected. When the SPH bit of RDES3 is set, the IPV4 header is available in the header buffer area to which RDES0 is pointing.
3	IPHE	IP Header Error When this bit is set, it indicates either of the following: • The 16-bit IPv4 header checksum calculated by the MAC does not match the received checksum bytes. • The IP datagram version is not consistent with the Ethernet Type value. • Ethernet packet does not have the expected number of IP header bytes. This bit is valid when either Bit 5 or Bit 4 is set. This bit is available when you select the Enable Receive TCP/IP Checksum Check feature.
2:0	PT	Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE): • 3'b000: Unknown type or IP/AV payload not processed • 3'b001: UDP • 3'b010: TCP

Table continues on the next page...

Table 369. RDES1 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 3'b011: ICMP • 3'b110: AV Tagged Data Packet • 3'b111: AV Tagged Control Packet • 3'b101: AV Untagged Control Packet • 3'b100: IGMP if IPV4 Header Present bit is set else DCB (LLDP) Control Packet If the COE does not process the payload of an IP datagram because there is an IP header error or fragmented IP, it sets these bits to 3'b000.

34.4.11.4.2.3 RDES2 Normal Descriptor (Write-Back Format)

31:29	28	27	26:19	18	17	16	15	14	13:11	10	9:0
L3L4FM	L4FM	L3FM	MADRM	HF	DAF	SAF	OTS	ITS	Rsvd	ARPNR	HL

Table 370. RDES2 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31:29	L3L4FM	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received packet: • 000: Filter 0 • 001: Filter 1 • 010: Filter 2 • 011: Filter 3 • 100: Filter 4 • 101: Filter 5 • 110: Filter 6 • 111: Filter 7 This field is valid only when Bit 28 or Bit 27 is set high. When more than one filter matches, these bits give the number of lowest filter. Note: This status is not available when Flexible RX Parser is enabled.
28	L4FM	Layer 4 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match • All enabled Layer 3 and Layer 4 filter fields match When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits[31:29].

Table continues on the next page...

Table 370. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		Note: This status is not available when Flexible RX Parser is enabled.
27	L3FM	Layer 3 Filter Match When this bit is set, it indicates that the received packet matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed • All enabled filter fields match When more than one filter matches, this bit gives the layer 3 filter status of filter indicated by Bits[31:29]. Note: This status is not available when Flexible RX Parser is enabled.
26:19	MADRM	MAC Address Match or Hash Value When the HF bit is reset, this field contains the MAC address register number that matched the Destination address of the received packet. This field is valid only if the DAF bit is reset. When the HF bit is set, this field contains the hash value computed by the MAC. A packet passes the hash filter when the bit corresponding to the hash value is set in the hash filter register. Note: This status is not available when Flexible RX Parser is enabled.
18	HF	Hash Filter Status When this bit is set, it indicates that the packet passed the MAC address hash filter. Bits[26:19] indicate the hash value. Note: This status is not available when Flexible RX Parser is enabled.
17	DAF/RXPI	Destination Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the DA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet parsing is incomplete (RXPI) due to ECC error. Note: When this bit is set, ES bit of RDES3 is also set.
16	SAF/RXPD	SA Address Filter Fail When Flexible RX Parser is disabled, and this bit is set, it indicates that the packet failed the SA Filter in the MAC. When Flexible RX Parser is enabled, this bit is set to indicate that the packet is dropped (RXPD) by the parser. Note: When this bit is set, ES bit of RDES3 is also set.
15	OTS	VLAN Filter Status When set, this bit indicates that the VLAN Tag of the received packed passed the VLAN filter. This bit is redefined as Outer VLAN Tag Filter Status (OTS). This bit is valid for both Single and Double VLAN Tagged frames

Table continues on the next page...

Table 370. RDES2 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
14	ITS	Inner VLAN Tag Filter Status (ITS) This bit is valid only for Double VLAN Tagged frames, when Double VLAN Processing is enabled. For more information, see Filter Status.
13:11	Rsvd	Reserved
10	ARPNR	ARP Reply Not Generated When this bit is set, it indicates that the MAC did not generate the ARP Reply for received ARP Request packet. This bit is set when the MAC is busy transmitting ARP reply to earlier ARP request (only one ARP request is processed at a time). This bit is reserved when the Enable IPv4 ARP Offload option is not selected.
9:0	HL	L3/L4 Header Length This field contains the length of the header of the packet split by the MAC at L3 or L4 header boundary as identified by the MAC receiver. This field is valid only when the first descriptor bit is set (FD = 1). The header data is written to the Buffer 1 address of corresponding descriptor. If header length is zero, this field is not valid. It implies that the MAC did not identify and split the header. This field is valid when the Enable Split Header Feature option is selected.

34.4.11.4.2.4 RDES3 Normal Descriptor (Write-Back Format)

Following table describes the write-back format for the RDES3 Normal Descriptor.

31	30	29	28	27	26	25	24	23	22	21	20	19	18:16	15	14:0
OWN	CTXT	FD	LD	RS2V	RS1V	RS0V	CE	GP	RWT	OE	RE	DE	LT	ES	PL

Table 371. RDES3 Normal Descriptor (Write-Back Format)

Bit	Name	Description
31	OWN	Own Bit When this bit is set, it indicates that the module DMA owns the descriptor. When this bit is reset, it indicates that the application owns the descriptor. The DMA clears this bit when either of the following conditions is true: • The DMA completes the packet reception • The buffers associated with the descriptor are full
30	CTXT	Receive Context Descriptor When this bit is set, it indicates that the current descriptor is a context type descriptor. The DMA writes 1'b0 to this bit for normal receive descriptor. When CTXT and FD bits are used together, {CTXT, FD}

Table continues on the next page...

Table 371. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• 2'b00: Intermediate Descriptor • 2'b01: First Descriptor • 2'b10: Reserved • 2'b11: Descriptor Error (due to all 1s) Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	FD	First Descriptor When this bit is set, it indicates that this descriptor contains the first buffer of the packet. If the size of the first buffer is 0, the second buffer contains the beginning of the packet. If the size of the second buffer is also 0, the next descriptor contains the beginning of the packet. See the CTXT bit description for details of using the CTXT bit and FD bit together.
28	LD	Last Descriptor When this bit is set, it indicates that the buffers to which this descriptor is pointing are the last buffers of the packet.
27	RS2V	Receive Status RDES2 Valid When this bit is set, it indicates that the status in RDES2 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
26	RS1V	Receive Status RDES1 Valid When this bit is set, it indicates that the status in RDES1 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
25	RS0V	Receive Status RDES0 Valid When this bit is set, it indicates that the status in RDES0 is valid and it is written by the DMA. This bit is valid only when the LD bit of RDES3 is set.
24	CE	CRC Error When this bit is set, it indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received packet. This field is valid only when the LD bit of RDES3 is set.
23	GP	Giant Packet When this bit is set, it indicates that the packet length exceeds the specified maximum Ethernet size of 1518, 1522, or 2000 bytes (9018 or 9022 bytes if jumbo packet enable is set). Note: Giant packet indicates only the packet length. It does not cause any packet truncation.
22	RWT	Receive Watchdog Timeout

Table continues on the next page...

Table 371. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		When this bit is set, it indicates that the Receive Watchdog Timer has expired while receiving the current packet. The current packet is truncated after watchdog timeout.
21	OE	Overflow Error When this bit is set, it indicates that the received packet is damaged because of buffer overflow in Rx FIFO. Note: This bit is set only when the DMA transfers a partial packet to the application. This happens only when the Rx FIFO is operating in the threshold mode. In the store-and-forward mode, all partial packets are dropped completely in Rx FIFO.
20	RE	Receive Error When this bit is set, it indicates that the gmii_rxer_i signal is asserted while the gmii_rxdv_i signal is asserted during packet reception. This error also includes carrier extension error in the GMII and half-duplex mode. Error can be of less or no extension, or error (rxd!= 0f) during extension.
19	DE	Dribble Bit Error When this bit is set, it indicates that the received packet has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode.
18:16	LT	Length/Type Field This field indicates if the packet received is a length packet or a type packet. The encoding of the 3 bits is as follows: • 3'b000: The packet is a length packet • 3'b001: The packet is a type packet. • 3'b011: The packet is a ARP Request packet type • 3'b100: The packet is a type packet with VLAN Tag • 3'b101: The packet is a type packet with Double VLAN Tag • 3'b110: The packet is a MAC Control packet type • 3'b111: The packet is a OAM packet type • 3'b010: Reserved
15	ES	Error Summary When this bit is set, it indicates the logical OR of the following bits: • RDES3[24]: CRC Error • RDES3[19]: Dribble Error • RDES3[20]: Receive Error • RDES3[22]: Watchdog Timeout • RDES3[21]: Overflow Error • RDES3[23]: Giant Packet • RDES2[17]: Destination Address Filter Fail, when Flexible RX Parser is enabled

Table continues on the next page...

Table 371. RDES3 Normal Descriptor (Write-Back Format) (continued)

Bit	Name	Description
		• RDES2[16]: SA Address Filter Fail, when Flexible RX Parser is enabled This field is valid only when the LD bit of RDES3 is set.
14:0	PL	Packet Length These bits indicate the byte length of the received packet that was transferred to system memory (including CRC). This field is valid when the LD bit of RDES3 is set and Overflow Error bits are reset. The packet length also includes the two bytes appended to the Ethernet packet when IP checksum calculation is enabled and the received packet is not a MAC control packet. This field is valid when the LD bit of RDES3 is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current packet.

34.4.11.4.3 Receive Context Descriptor

This descriptor is read-only for the application. Only the DMA can write to this descriptor. The context descriptor provides information about the extended status related to the last received packet. The Bit 30 of RDES3 indicates the context type descriptor.

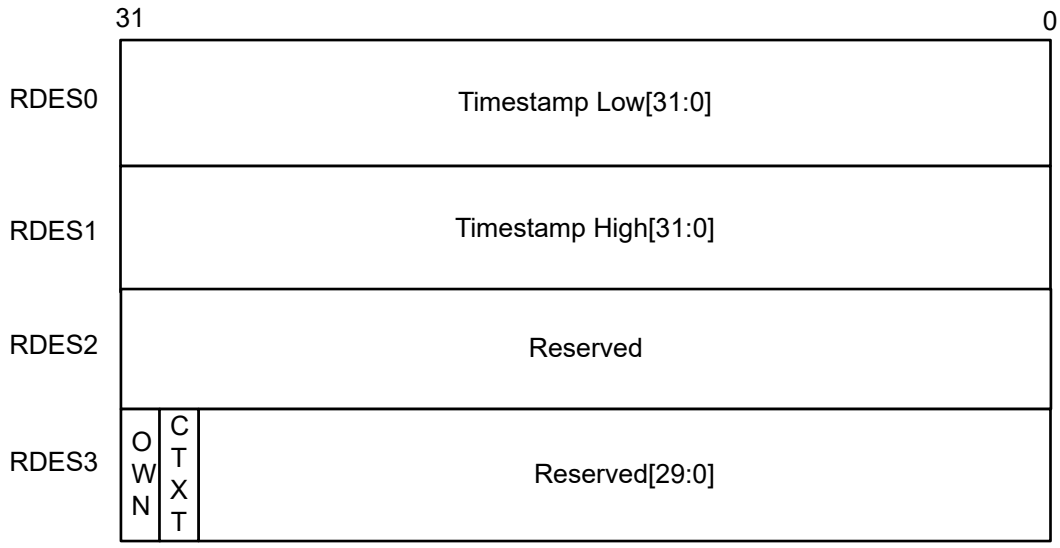

Figure 185. Receive Context Descriptor Format

34.4.11.4.3.1 RDES0 Context Descriptor

Table 372. RDES0 Context Descriptor

Bit	Name	Description
31:0	RTSL	Receive Packet Timestamp Low The DMA updates this field with least significant 32 bits of the timestamp captured for corresponding Receive packet. When this field and the RTSH field of RDES1 show all-ones value, the timestamp must be considered as corrupt.

34.4.11.4.3.2 RDES1 Context Descriptor

Table 373. RDES1 Context Descriptor

Bit	Field	Description
31:0	RTSH	Receive Packet Timestamp High The DMA updates this field with most significant 32 bits of the timestamp captured for corresponding receive packet. When this field and the RTSL field of RDES0 show all-ones value, the timestamp must be considered as corrupt.

Table 375. RDES3 Context Descriptor (continued)

Bit	Name	Description
		When this bit is set, it indicates that the current descriptor is a context descriptor. The DMA writes 1'b1 to this bit for context descriptor. DMA writes 2’b11 to indicate a descriptor error due to all 1s. When CTXT and DE bits are used together, {CTXT, DE} • 2’b00: Reserved • 2’b01: Reserved • 2’b10: Context Descriptor • 2’b11: Descriptor Error Note: When Descriptor Error occurs, the Receive DMA closes the receive descriptor indicating Descriptor Error. This receive descriptor is skipped and the buffer addresses are not used to write the packet data Receive DMA will set the CDE bit in DMA_CH#_Status register but not the RI bit even when IOC is set, as this is not marked as last receive descriptor for the packet. The subsequent valid receive descriptor is used to write the packet data.
29	DE	Descriptor Error See the CTXT bit description for details of using theDE bit along with CTXT bit.
28:0	Rsvd	Reserved

34.4.11.5 Enhanced Descriptor for Time-Based Scheduling

The time-based scheduling feature needs 32 bytes Enhanced Descriptors to be enabled on all the DMA channels that intend to use the feature (by setting the EDSE bit of DMA_CH(#i)_TX_Control register).

The structure of 32-byte Descriptor for the Context and the Normal Descriptor in Read and Write formats are described in the following sections.

34.4.11.5.1 Enhanced Normal Descriptor - Read (32-Bit Mode)

The fields present in the first 16 bytes of the Enhanced Descriptor format of normal descriptor are as follows:

- LTV

  Launch Time Valid indicates the Launch Time (LT) and GSN fields present in the descriptor are valid. The LTV must be set only if the FD bit of the descriptor is not.

- GSN

  This field indicates the GCL slot number associated with the packet.

- Launch Time (LT)

  This field indicates the Launch Time associated with the packet.

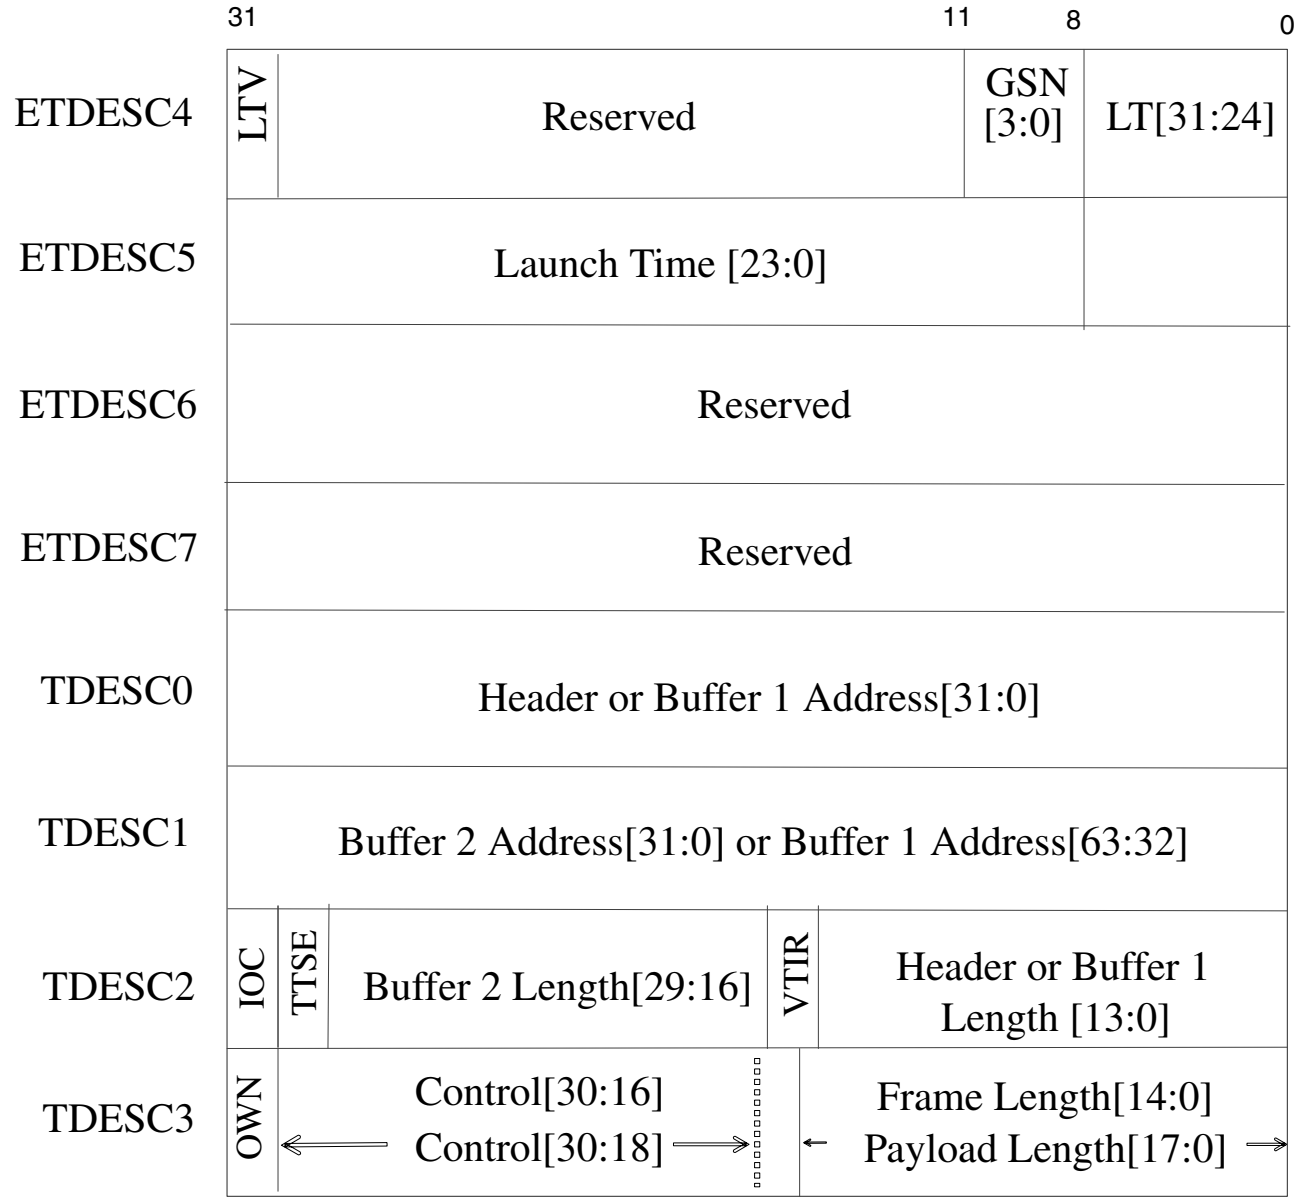

Figure 186. Enhanced Normal Descriptor - Read (32-Bit Mode)

34.4.11.5.2 Enhanced Normal Descriptor (Write, 32-Bit Mode)

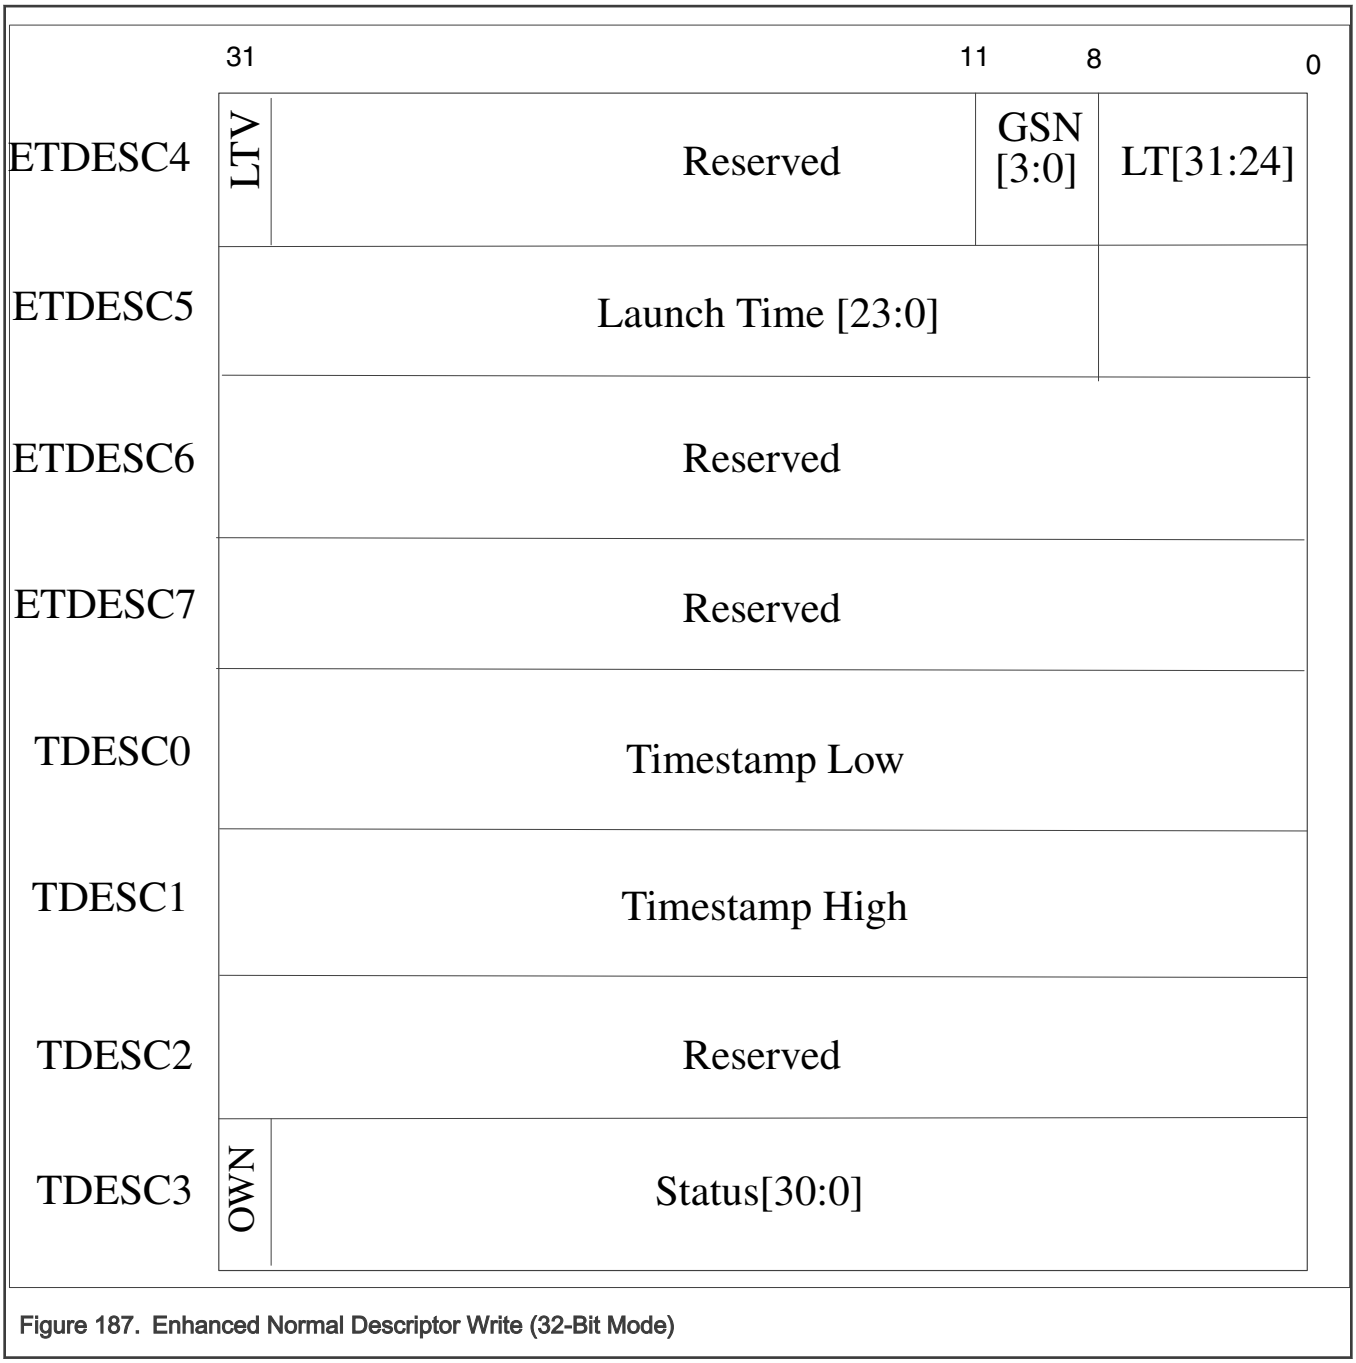

Figure 187. Enhanced Normal Descriptor Write (32-Bit Mode)

NOTE

- All the enhanced descriptor examples, assumes a 32-bit data width configurations. However, the same definitions are valid in 64 and 128 bit configurations.
- In both the write back formats, no modifications can be done to the extended 16 bytes. The rest of the 16 bytes (TDESC0 to TDESC3) are written back as per the previous 16 bytes Descriptor format.
- Fetch time when enabled overrides the AV slot function
- When an unaligned new GCL list (with a different CTR) is installed it is recommended not to have traffic during the installation of the new list. Any traffic during the switching of the lists might have unpredictable behavior regarding Fetch, Launch, and Launch expiry as the CTR and BTR values get updated while the frame is being processed

34.4.11.5.3 Enhanced Context Descriptor (Read, 32-bit Mode)

The first 16 bytes of the Enhanced context descriptor (ETDESC4 to ETDESC7) are reserved and must be zeros. The fields present in last bytes of the Descriptor (TDESC0 to TDESC3) are same as the context descriptor (TDESC0 to TDESC3) in 16 byte format.

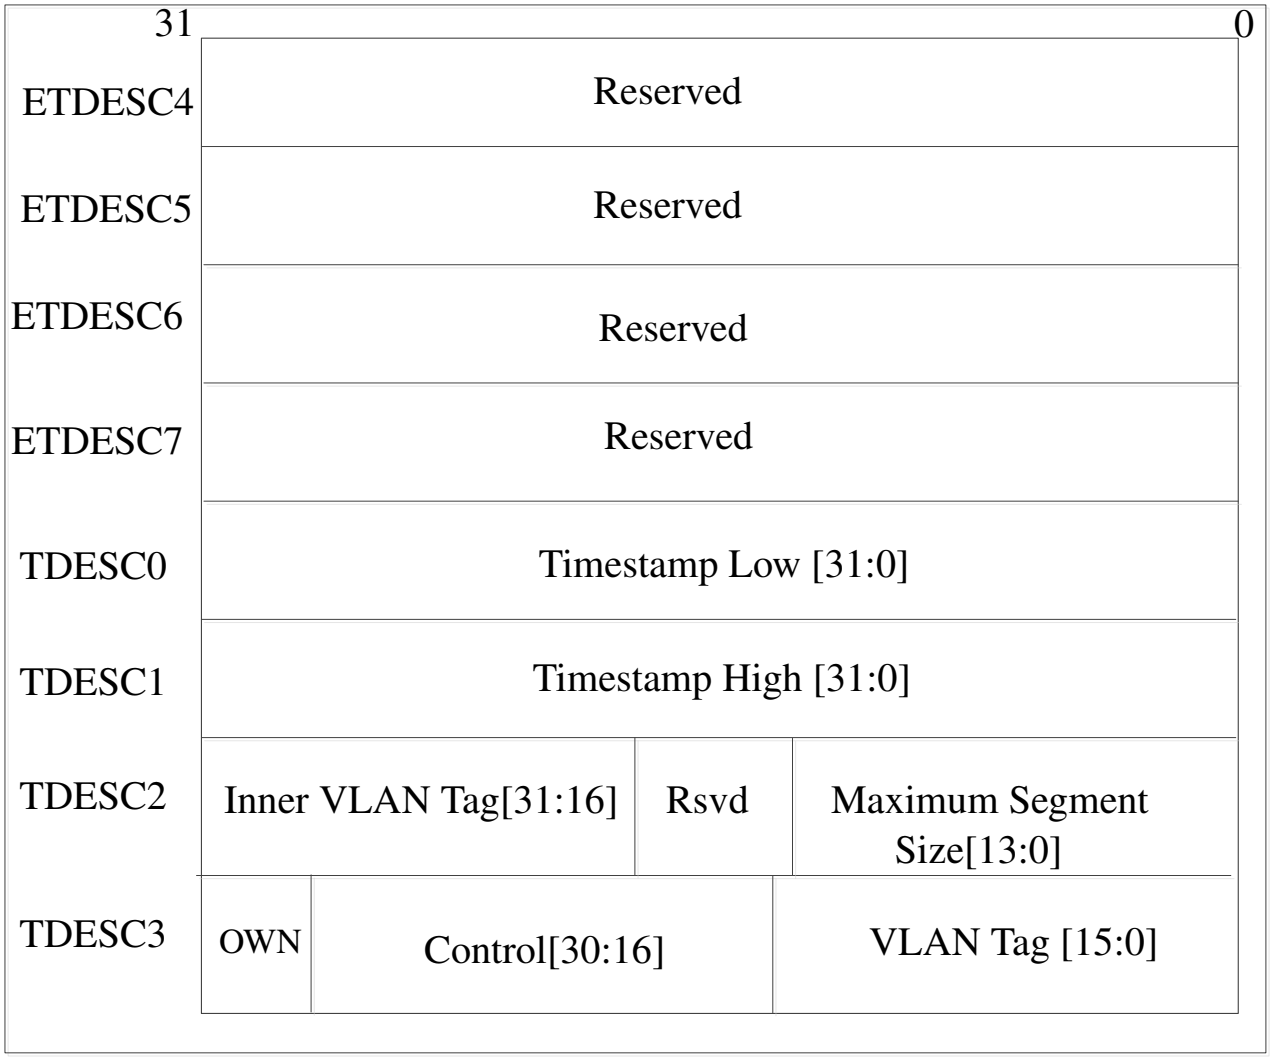

Figure 188. Enhanced Context Descriptor - Read

34.4.11.5.4 Enhanced Context Descriptor (Write, 32 Bit Mode)

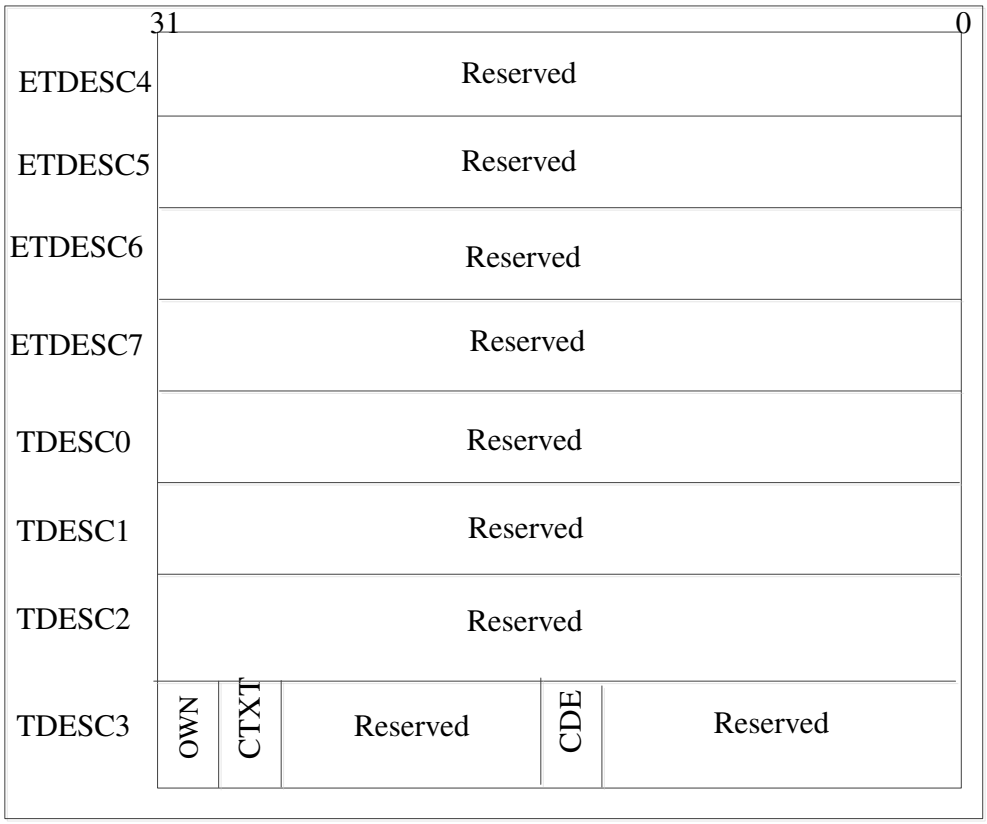

Figure 189. Enhanced Context Descriptor - Write

34.4.12 Power management and low power modes

This section describes the power management (PMT) mechanisms supported by the MAC. PMT supports the reception of network (remote) wake-up frames and magic packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and magic packets received by the MAC. The PMT block sits on the receiver path of the MAC and is enabled with remote wake-up frame enable and magic packet enable. These enables are in the PMT control and status register and are programmed by the application.

When the power-down mode is enabled in the PMT, then all received frames are dropped by the Ethernet core and they are not forwarded to the application. The Ethernet comes out of the power-down mode only when either a magic packet or a remote wake-up frame is received and the corresponding detection is enabled.

34.4.12.1 Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) is an operational mode that enables the IEEE 802.3 MAC sublayer along with a family of physical layers to operate in the Low-Power Idle (LPI) mode. The EEE operational mode supports the IEEE 802.3 MAC operation at 100 Mbps. The Ethernet module supports the IEEE 802.3az-2010 for EEE. The LPI mode allows power saving by switching off the parts of the communication device functionality when there is no data to be transmitted and received. The systems on both sides

of the link can disable some functionality to save power during periods of low-link utilization. The MAC controls whether the system should enter or exit the LPI mode and communicates this to the PHY. The EEE specifies the capabilities negotiation methods that the link partners can use to determine whether EEE is supported, and then select the set of parameters that are common to both devices.

34.4.12.1.1 Transmit path functions

In the transmit path, the software must set the LPIEN bit of the MAC LPI control status register to indicate to the MAC to stop transmission and initiate the LPI protocol. The MAC completes the transmission in progress, generates its transmission status, and starts transmitting the LPI pattern instead of the IDLE pattern if the link status has been up continuously for a period specified in the LPI LS TIMER(LST) field of MAC LPI timers control register. The PHY link status bit of the LPI control and status register indicates the link status of the PHY.

According to the Energy Efficient Ethernet standard (IEEE 802.3az-2010), the PHY must not stop the transmit clock during the LPI state in the MII (10 or 100) mode.

To make the PHY enter the LPI state, the MAC performs the following tasks:

1. De-asserts transmit enable (TX_EN).
2. Asserts transmit error (TX_ER). Sets TXD[3:0] to 0x1 The MAC maintains the same state of the TX_EN, TX_ER, and TXD signals for the entire duration during which the PHY remains in the LPI state.
3. Updates the status (TLPIEN bit of MAC LPI control status register and generates an interrupt. To bring the PHY out of the LPI state, that is, when the software resets the LPIEN bit, the MAC performs the following tasks:
4. Stops transmitting the LPI pattern and start transmitting the IDLE pattern
5. Starts the LPI TW TIMER
6. Updates the LPI exit status (TLPIEX bit of the MAC LPI control status register and generates an interrupt

The MAC cannot start the transmission until the wake-up time specified for the PHY expires. The auto-negotiated wake-up interval is programmed in the TWT field of the MAC LPI Timers control register.

34.4.12.1.2 Automated entry/exit of LPI mode in TX path

The MAC transmitter can be programmed to enter and exit LPI IDLE mode automatically based on whether it is IDLE for a specific period or has a packet to transfer. These modes are enabled and controlled by the MAC LPI control status register.

When the LPITXA (bit 19) and LPITXEN (bit 16) of the MAC LPI control status register are set, the MAC transmitter enters the LPI IDLE state when the MAC transmit path (including the MTL layers and DMA layers) are idle. The MAC transmitter exits the LPI IDLE state and clears the LPITXEN bit as soon as any of the functions in the TX path (DMA, MTL, or MAC) becomes non-idle due to initiation of a packet transfer. In addition to the above, when bit 20 (LPIATE) is also set, the MAC transmitter enters LPI IDLE state only when the transmit path remains in an idle state (no activity) for the time indicated by the value in MAC LPI Entry Timer. In this mode also, the MAC transmitter exits the LPI IDLE state as soon as any of the functions becomes non-idle. However, the LPITXEN bit is not cleared but remains active so that reentry to LPI IDLE state is possible without any software intervention when the MAC becomes idle again.

When both LPIATE and LPITXA bits are cleared, you can directly control the entry and exit of the LPI IDLE state by programming the LPITXEN bit.

34.4.12.1.3 Receive path functions

In the receive path, when the PHY receives the signals from the link partner to enter into the LPI state, the PHY and MAC perform the following tasks:

1. The PHY asserts RX_ER.
2. The PHY sets RXD[7:0] to 0x01.
3. The PHY de-asserts RX_DV. The PHY maintains the same state of the RX_ER, RXD, and RX_DV signals for the entire duration during which it remains in the LPI state.

4. The MAC updates the RLPIEN bit of the MAC LPI control status register and immediately generates an interrupt.

When the PHY receives signals from the link partner to exit the LPI state, the PHY and MAC perform the following tasks:

1. The PHY de-asserts RX_ER and returns to a normal inter-packet state.
2. The MAC updates the RLPIEX bit of the MAC LPI control status register and generates an interrupt immediately. The sideband signal (synchronous to Rx clock) is also asserted.

34.4.12.1.4 LPI timers

The transmitter maintains the following two timers that are loaded with the respective values from the MAC_LPI_Timers_Control register:

- LPI LS Timer
  - The LPI LS TIMER counts, in milliseconds, the time expired since the link status is up. You can enable the monitoring of the LUD bit of the MAC_PHYIF_Control_Status register by setting the PLSEN bit of the MAC_LPI_Control_Status register. The link status is indicated to the MAC by the LNKSTS bit of the MAC_PHYIF_Control_Status register or the value programmed by the software in the PLS bit of the MAC_LPI_Control_Status register. If the link status is not available in the MAC_PHYIF_Control_Status, the software should get the PHY link status by reading the PHY register and accordingly update the PLS bit. This timer is cleared every time the link goes down. It starts to increment when the link is up again and continues to increment until the value of the timer becomes equal to the terminal count. Once the terminal count is reached, the timer remains at the same value as long as the link is up. The terminal count is the value programmed in bits 25:16 of the MAC_LPI_Timers_Control register. The GMII interface does not assert the LPI pattern unless the terminal count is reached. This ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as 1 second in the IEEE 802.3-az-2010. The LPI LS TIMER is 10-bit wide. Therefore, the software can program up to 1,023 ms.
- LPI TW Timer
  - The LPI TW TIMER counts, in microseconds, the time expired since the de-assertion of LPI. The terminal count should be programmed in bits 15:0 of MAC register 53 (LPI timers control register). The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. After exiting the LPI mode, the MAC resumes its normal operation after the TW timer reaches the terminal count. The MAC supports the LPI TW TIMER in units of a microsecond. The LPI TW TIMER is 16-bits wide. Therefore, the software can program up to 65,535 µs.

34.4.12.1.5 LPI interrupt

The MAC generates the LPI interrupt when the Tx or Rx side enters or exits the LPI state. The low-power interrupt is asserted when the LPI interrupt status is set. The LPI interrupt can be cleared by reading the MAC LPI control status register.

34.4.12.2 Power management and wake-up

The power management (PMT) block supports the reception of magic packets as wake up packets, as well as the reception of network (remote) wake-up packets as wake up packets.

34.4.12.2.1 Magic packet detection

The magic packet frame is based on a method that uses Advanced Micro Device’s magic packet technology to power up the sleeping device on the network. The MAC receives a specific packet of information, called a magic packet, addressed to the node on the network.

Only magic packets that are addressed to the device or a broadcast address are checked to determine whether they meet the wake-up requirements. Magic packets that pass the address filtering (unicast or broadcast)are checked to determine whether they meet the remote wake-on-LAN data format of 6 bytes of all ones followed by a MAC address appearing 16 times.

The application enables magic packet wake-up by writing a 1 to bit 1 of the PMT control and status register. The PMT block constantly monitors each frame addressed to the node for a specific magic packet pattern. Each frame received is checked for

a 0xFFFF FFFF FFFF pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the MAC address without any breaks or interruptions. In case of a break in the 16 repetitions of the address, the 0xFFFF FFFF FFFF pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame but must be preceded by the synchronization stream (0xFFFF FFFF FFFF). The device also accepts a multicast frame, as long as the 16 duplications of the MAC address are detected.

If the MAC address of a node is 0x0011 2233 4455, then the MAC scans for the data sequence:

- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55
- ...CRC

Magic packet detection is updated in the PMT control and status register for magic packet received. A PMT interrupt to the application triggers a read to the PMT CSR to determine whether a magic packet frame is received. When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a magic packet is received and the corresponding detection is enabled.

34.4.12.2.2 Remote wake-up detection

The PMT block supports the reception of network (remote) wake-up packets as wake-up packets.

When the MAC is in sleep mode and the remote wake-up bit is enabled in PMT control and status register (0x00C0), normal operation is resumed after receiving a remote wake-up frame. The application writes all eight wake-up filter registers by performing a sequential write to address (0x00C4). The application enables remote wake-up by writing a 1 to bit 2 of the PMT control and status register.

PMT supports 16 programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of filter command, and if filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter byte mask determines which bytes of the frame must be examined. The 31st bit of the byte mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT control and status register for every remote wake-up frame received. A PMT interrupt to the application triggers a read to the PMT control and status register to determine the reception of a wake-up frame.

34.4.12.3 System considerations during power-down

MAC neither gates nor stops clocks when power-down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked with ENET_RX_CLK during power-down mode because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during deep-sleep mode.

The PMT interrupt is asserted when a valid wake-up frame is received. This signal is generated in the receive clock domain.

The recommended power-down and wake-up sequences are as follows.

1. Disable the transmit DMA and wait for any previous frame transmissions to complete. These transmissions can be detected when transmit interrupt (see DMA channel status register bit TI) is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the MAC configuration register.

3. Wait until the receive DMA empties all the frames from the Rx FIFO. This can be done by reading the appropriate bits of Debug registers in the DMA and MTL CSR space.
4. Enable power-down mode by appropriately configuring the PMT registers.
5. Enable the MAC receiver and enter power-down mode.
6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter sleep mode.
7. On receiving a valid wake-up frame, the MAC asserts the PMT interrupt signal and exits the power-down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the PMT status register to clear the interrupt, then enable the other modules in the system and resume normal operation.

34.4.13 Clocks

The table found here describes the clock sources for ENET_QOS. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 376. ENET_QOS Clocks

Clock name	Description
aclk_i	Bus clock
clk_csr_i	CSR clock, same source as aclk_i
ptp_ref_i	PTP clock

34.4.14 Interrupts

This module supports interrupt coalescing which reduces the number of interrupts generated by IP and reduces the CPU load. Various interrupt event gets captured in status register. If interrupt enable bit of an interrupt is set then corresponding interrupt will be generated based on event status in status registers. INTM (interrupt mode) bit decides that interrupt signal is a level signal or pulse signal.

Interrupt output signals are shown below which are synchronous to control and Status register (CSR) clock.

- Sbd_intr_o – common interrupt
- Sbd_perch_tx_intr_o[max_dma_ch] – Interrupt per Tx channel
- Sbd_perch_rx_intr_o [max_dma_ch] – Interrupt per Rx channel

NOTE

max_dma_ch is equal to number of Tx/Rx queues which is 2.

The sbd_intr_o common interrupt is level signal. When sbd_intr_o interrupt is asserted, then corresponding interrupt event source can be found in DMA_Interrupt status register. DMA_Interrupt status register is read only register which contains the interrupt event source bits corresponding to each DMA channel (Tx and Rx queue pair), MAC transaction layer and MAC blocks. Software must then read the following registers corresponding to the bits that are set.

- MAC_Interrupt_Status register
- MTL_Interrupt_Status register
- DMA_CH(n)_Status register

sbd_intr_o interrupt gets de-asserted only when all the enabled interrupt events are cleared in their respective status registers and correspondingly all the bits in the DMA_Interrupt_Status register are cleared.

The DMA_CH[n]_Status register captures all the interrupt events of that Tx DMA and Rx DMA channel pair. The DMA_CH[n]_Interrupt_Enable register contains the corresponding enable bits for each of the interrupt event. There are two groups of interrupts in the DMA channel namely Normal and Abnormal interrupts. They are indicated by bits[15:14] of DMA_CH[n]_Status register respectively. The normal group is for events that happen during the normal transfer of packets (TI, RI, TBU) while the abnormal interrupt events are for error events

Interrupts are not queued. If the same interrupt event occurs again before the driver responds to the previous one, no additional interrupts are generated.

The common sbd_intr_o output signal is asserted for the transfer complete interrupts only when the corresponding interrupts are enabled in DMA_CH[n]_Interrupt_Enable register.

This module also supports the following per Channel Transfer Complete interrupt signals.

- sbd_perch_tx_intr_o[max_dma_ch] (Transmit Per Channel Interrupts)
- sbd_perch_rx_intr_o[max_dma_ch] (Receive Per Channel Interrupts)

The behavior of the RI/TI/ sbd_perch_tx_intr_o[]/sbd_perch_rx_intr_o[] changes depending on the settings of INTM field bit[17:16] in DMA_Mode. Following table explains the Transfer Complete Interrupt behavior.

Table 377. Transfer Complete Interrupt Behavior

Interrupt Mode	Behavior of the sbd_perch_tx_intr_o[] and sbd_perch_rx_intr_o[]	Behavior of TI/RI and sbd_intr_o
INTM=1	These signals reflect the value of corresponding TI/RI bits in DMA_CH[n]_Status register when the corresponding interrupt enable is set. Hence they are level signals and are cleared by the application by writing 1'b1 to the RI/TI status bits. This signal will not be asserted when the corresponding interrupt enable bit is not set.	The TI/RI is set as explained above. However, the sbd_intr_o signal and NIS status bit are not asserted for any RI/TI events.
INTM=2	In this mode, RI/TI interrupts are queued. These signals reflect the value of corresponding TI/RI bits inDMA_CH[n]_Status register when the corresponding interrupt enable is set. They are level signals and cleared by software by writing 1'b1 to the RI/TI status bits. However, it is set again if another TI/RI event(s) is detected before the TI/RI bits are cleared for the previous event.	The RI/TI status bits are set whenever the Transfer Complete event is detected and gets reset whenever software driver clears those bits by writing 1. However, if another Transfer Complete event is detected before it is cleared (serviced) by the software, then the module automatically set these status bits again. However, the sbd_intr_o signal is not generated based on TI/RI

34.4.14.1 PMT interrupts

The PMT interrupt signal is asserted when a valid remote wake-up packet is received. When software resets the PWRDWN bit in the remote wake-Up packet detection register, the MAC comes out of the power-down mode, but this event does not generate the PMT interrupt.

When you enable the power-down mode in the PMT block, the MAC drops all received packets and does not forward any packet to the MTL Rx FIFO or the application. The MAC comes out of the power-down mode only when a remote wake-up packet is received and the corresponding detection is enabled. The PMT block is available in the receive path of MAC.

34.5 External signals

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

Table 378. External signals

Port name	Interface	I/O	Description
1588_EVENT_AUX_IN	RMII	I	
1588_EVENT_IN	RMII	I	
1588_EVENT_OUT	RMII	O	
TX_CLK	RGMII	O for (RGMII)	RGMII: The transmit clock signal is always provided by the MAC on the TX_CLK line. Source-synchronous clocking is used: the clock signal that is output (by either the PHY or the MAC) is synchronous with the data signals.
RX_CLK	RGMII	I	RGMII: Received clock signal (recovered from incoming received data)
REF_CLK1	RMII	I/O	This 50Mhz clock used by the RMII interface. When RMII mode is selected, RX_CLK (25Mhz or 2.5Mhz) should be derived from this clock.
TX_EN	RMII, RGMII	O	The MAC drives this signal. This signal has multiple functions depending on the selected PHY interface. • RMII: When high, indicates that valid data is being transmitted on the phy_txd_o bus. Synchronous to REF_CLK.

Table continues on the next page...

Table 378. External signals (continued)

Port name	Interface	I/O	Description
			• RGMII: Contains TX_EN on the rising edge of TX_CLK, and a logical derivative of TX_EN and TX_ER (TX_EN XOR TX_ER) on the falling edge of TX_CLK.
TX_DATA	RMII, RGMII	O	This is a group of transmit data signals driven by the MAC. It has multiple functions depending on the selected PHY interface. • RMII: Bits[1:0] provide the RMII transmit data. The data is valid only when the TX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits[3:0] provide serial output Ethernet data
RX_DATA	RMII, RGMII	I	This is a group of data signals received from the PHY. It has multiple functions depending on the selected PHY interface. • RMII: Bits [1:0] provide the RMII receive data. The data is valid only when the RX_EN signal is high. Synchronous to REF_CLK. • RGMII: Bits [3:0] contains the Ethernet input data transferred from the PHY to the media-access controller.
MDC	RMII, RGMII	O	Management Data Clock. The MAC provides timing reference for the MDIO or MII through this periodic clock. This clock is generated from the application clock through a clock divider controlled by MAC_MDIO_ADDRESS[CR].

Table continues on the next page...

Table 378. External signals (continued)

Port name	Interface	I/O	Description
MDIO	RMII, RGMII	I/O	Transfers control information between the external PHY and the MAC. Data is synchronous to MDC. This signal is an input after reset.
RX_EN	RGMII	I	The PHY drives this signal. It has multiple functions depending on the selected PHY interface. • RMII: Contains the crs and data valid information of the Receive interface. Synchronous to REF_CLK. In RGMII mode, contains receive data valid on the rising edge of RX_CLK, and a logical derivative of receive data valid and RX_ER (receive data valid XOR RX_ER) on the falling edge of RX_CLK.

34.6 Initialization

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section provides the instructions for initializing the DMA or MAC registers in the proper sequence.

34.6.1 Initializing DMA

Complete the following steps to initialize the DMA:

1. Provide a software reset. This resets all of the MAC internal registers and logic (bit-0 of DMA_Mode).
2. Wait for the completion of the reset process (poll bit 0 of the DMA_MODE, which is only cleared after the reset operation is completed).
3. Program the following fields to initialize the DMA_SYSBUS_MODE register:
    a. AAL
    b. Fixed burst or undefined burst
    c. Burst mode values in case of AHB bus interface, OSR_LMT in case of AXI bus interface.
    d. If fixed length value is enabled, select the maximum burst length possible on the AXI Bus (bits [7:1])
4. Create a descriptor list for transmit and receive. In addition, ensure that the descriptors are owned by DMA (set bit 31 of descriptor TDES3/RDES3). For more information about descriptors, see Descriptors
5. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= 1) and DMA_CH#_RX_CONTROL2 (for i = 0; i <= 1)). The ring length programmed must be at least 4.

NOTE

The descriptor address from the start to the end of the ring must not cross the 4GB boundary.

6. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_RXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). Also, program transmit and receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1))

   NOTE

   For 40-bit or 48-bit addressing mode, program the higher address List registers (DMA_CH[n]_TXDESC_LIST_HADDRESS, DMA_CH[n]_RXDESC_LIST_HADDRESS).

   The tailpointer registers must be advanced to the location immediately after the descriptors that are set, for the DMA to know that additional descriptors are available.

7. Program the settings of the following registers for the parameters like maximum burst-length (PBL) initiated by DMA, descriptor skip lengths, OSP in case of TxDMA, RBSZ in case of RxDMA, and so on:
   - DMA_CH(#i)_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_TX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)
   - DMA_CH(#i)_RX_Control (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)
8. Enable the interrupts by programming the DMA_CH(#i)_Interrupt_Enable (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
9. Start the Receive and Transmit DMAs by setting SR (bit 0) of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) and ST (bit 0) of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 to 9 for all the Tx DMA and Rx DMA channels selected in the hardware.

34.6.2 Initializing MTL Registers

The Transaction Layer (MTL) registers must be initialized to establish the transmit and receive operating modes and commands.

Complete the following steps to initialize the MTL registers:

1. Program the Tx Scheduling (SCHALG) and Receive Arbitration Algorithm (RAA) fields in MTL_Operation_Mode to initialize the MTL operation in case of multiple Tx and Rx queues.
2. Program the Receive Queue to DMA mapping in MTL_RxQ_DMA_Map0 and MTL_RxQ_DMA_Map1 registers.
3. Program the following fields to initialize the mode of operation in the MTL_TxQ0_Operation_Mode register.
   a. Transmit Store And Forward (TSF) or Transmit Threshold Control (TTC) in case of threshold mode
   b. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
   c. Transmit Queue Size (TQS)
4. Program the following fields to initialize the mode of operation in the MTL_RxQ0_Operation_Mode register:
   a. Receive Store and Forward (RSF) or RTC in case of Threshold mode
   b. Flow Control Activation and De-activation thresholds for MTL Receive FIFO (RFA and RFD)
   c. Error Packet and undersized good Packet forwarding enable (FEP and FUP)
   d. Receive Queue Size (RQS)
5. Repeat previous two steps for all MTL Tx and Rx queues selected in the configuration.

34.6.3 Initializing MAC

The MAC configuration registers establish the operating mode of the MAC. These registers must be initialized before initializing the DMA.

The following MAC Initialization operations can be performed after DMA initialization. If the MAC initialization is completed before the DMA is configured, enable the MAC receiver (last step in the following sequence) only after the DMA is active. Otherwise, received frames fill the Rx FIFO and overflow.

1. Provide the MAC address registers: MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. If more than one MAC address is enabled in your configuration, program the MAC addresses appropriately.
2. Program the following fields to set the appropriate filters for the incoming frames in the MAC_PACKET_FILTER register:
    a. Receive All
    b. Promiscuous mode
    c. Hash or Perfect Filter
    d. Unicast, multicast, broadcast, and control frames filter settings
3. Program the following fields for proper flow control in the MAC_Q0_TX_FLOW_CTRL register:
    a. Pause time and other Pause frame control bits
    b. Transmit Flow control bits
    c. Flow Control Busy
4. Program the MAC_INTERRUPT_ENABLE register, as required, and if applicable, for your configuration.
5. Program the appropriate fields in the MAC_CONFIGURATION register. For ex: Inter-packet gap while transmission and jabber disable.
6. Set bit 0 and 1 in MAC_CONFIGURATION register to start the MAC transmitter and receiver.

34.7 Application Information

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

34.7.1 Performing Normal Receive and Transmit Operation

During normal operation of the module, normal and transmit interrupts are read, descriptors polled, the DMA is suspended (if it does not own descriptors), and values of current host transmitter or receiver descriptor pointers are read for debugging.

For normal operation, complete the following steps:

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive).
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data.
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and writing the descriptor tail pointer to Tx/Rx tail pointer register (DMA_CH[n]_TXDESC_TAIL_POINTER and DMA_CH[n]_RXDESC_TAIL_POINTER).
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (DMA_CH[n]_CURRENT_APP_TXDESC and DMA_CH[n]_CURRENT_APP_RXDESC).
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register DMA_CH[n]_CURRENT_APP_TXBUFFER and DMA_CH[n]_CURRENT_APP_RXBUFFER).

34.7.2 Stopping and Starting Transmission

Complete the following steps to pause the transmission.

NOTE

The steps are provided for Channel 0.

1. Disable the Transmit DMA (if applicable) by clearing Bit 0 (ST) of DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) Register.
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of MTL_TXQ0_DEBUG Register (TRCSTS is not 01 and TXQSTS=0).
3. Disable the MAC transmitter and MAC receiver by clearing Bit (RE) and Bit 1(TE) of the MAC_Config-uration Register.
4. Disable the Receive DMA (if applicable), after making sure that the data in the Rx FIFO is transferred to the system memory (by reading the appropriate bits of MTL_TXQ0_DEBUG Register, PRXQ=0 and RXQSTS=00).
5. Make sure that both Tx Queue and Rx Queue are empty (TXQSTS is 0 in MTL_TXQ0_DEBUG Register and RXQSTS is 0 in MTL_RXQ0_DEBUG Register).
6. To restart the operation, first start the DMAs, and then enable the MAC Transmitter and Receiver.

NOTE

- Do not change the configuration (such as duplex mode, speed, port, or loop back) when the MAC is actively transmitting or receiving. These parameters are changed by software only when the MAC transmitter and receiver are not active.
- Similarly, do not change the DMA-related configuration when Transmit and Receive DMA are active.

34.7.3 Programming Guidelines for Switching to New Descriptor List in RxDMA

Switching to a new descriptor list is different in the Rx DMA compared to the Tx DMA. Switching to a new descriptor list is permitted when the RxDMA is in SUSPEND state, as clarified by the following points:

- Generally, RxDMA prepares the descriptors in advance.
- If the RxDMA goes to SUSPEND due to descriptors not being available, a major failure occurs (software is not able to free the filled-up descriptors/buffers). If this issue is not rectified immediately, frames will be lost because of an RxFIFO Overflow. Therefore, the software is allowed to create a new descriptor list and program the RxDMA to start using it immediately, without going into STOP state.

34.7.4 Programming Guidelines for Multi-Channel Multi-Queuing

34.7.4.1 Transmit

1. Program the Transmit queue size in the TQS field of MTL_TXQ[n]_OPERATION_MODE register. Based on the value programmed in the TQS field, the size of the queue is determined.

   In the Transmit operation, the number of channels is equal to the number of the queues. Due to this reason, the Channel-to-Queue mapping is fixed.
2. For a queue to be used, the queue must be enabled in TXQEN in the corresponding MTL_TXQ[n]_OPERATION_MODE Register. In DMA configurations, the ST bit of DMA_CH[n]_TX_CONTROL Register and corresponding TXQEN in MTL_TXQ[n]_OPERATION_MODE Register needs to be enabled.
3. The scheduling method needs to be programmed in SCHALG of MTL_OPERATION_MODE register.
4. Program the MTL_TXQ[n]_Quantum_Weight for DCB queue as per the selected algorithm. In case of CBS algorithm in AVB queues, the MTL_TXQ[n]_ETS_CONTROL, MTL_TXQ[n]_SENDSLOPECREDIT, MTL_TXQ[n]_HICREDIT and MTL_TXQ[n]_LOCREDIT registers also need to be programmed as required.

5. If DCB is enabled and PFC function is required, program MAC_TXQ_PRTY_MAP0 Register to assign a fixed priority to the queue. This priority assigned is used for determining if the corresponding queue should stop transmitting packet based on the received PFC packet.

34.7.4.2 Receive

1. Program the Receive queue size in the RQS field of MTL_RXQ[n]_OPERATION_MODE Register. Based on the value programmed in RQS field, the size of the queue is determined.
2. Enable the Receive Queues 0 to 4 in the fields RXQ0EN to RXQ4EN in MAC_RXQ_CTRL0 Register for AV or DCB. In DMA configurations, SR bit of statically or dynamically mapped DMA_CH[n]_RX_CONTROL Register and corresponding RXQ[n]_EN in MAC_RXQ_CTRL0 Register needs to be enabled.
3. The MAC routes the Rx packets to the Rx Queues based on following packet types:
    a. AV PTP Packets: Based on the programming of AVPTPQ in MAC_RXQ_CTRL1 Register.
    b. AV Untagged Control packets: Based on the programming of AVCPQ in MAC_RXQ_CTRL1 Register.
    c. Data Center Bridging (DCB) related Link Layer Discovery Protocol (LLDP) packets. Program DCBCPQ in MAC_RXQ_CTRL1 Register to indicate to MAC which queue should get the DCB packets.
    d. VLAN Tag Priority field in VLAN Tagged packets: Program PSRQ4-0 of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 Register for the routing of tagged packets based on the USP (user Priority) field of the received packets to the Rx Queues 0 to 4.
    e. The AV tagged control and data packets are also routed based on PSRQ field of the MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers.

NOTE

The priorities set in PSRQ4-0 should be unique.

4. If multiple RX DMA channels are enabled, the following programming should be done for proper arbitration and mapping:
    a. Program the RAA field of MTL_OPERATION_MODE register to select the arbitration algorithm to decide which RxQ is read out from the RxFIFO memory.
    b. Program the MTL_RXQ[n]_CONTROL to decide the weights and the packet arbitration for each RxQ.
    c. If static mapping is programmed in MTL_RXQ_DMA_MAP[n] register (RXQ[n]DADMACH is reset to 0), bits RXQx2DMA and others need to be programmed to select the channel for which each queue is mapped.
    d. Set RXQ[n]DADMACH bit in MTL_RXQ_DMA_MAP0 Register to select dynamic mapping of packets in each RxQueue.
    e. In dynamic channel mapping, the routing of a packet to a specific RxDMA channel is decided by the value of DCS field in the lowest MAC Address Register.

34.7.4.2.1 Programming Guidelines for Recovering from DMA Channel Failure

When the DMA channel issues a bus error, follow these steps to recover from the failure.

Recovering from the Receive DMA Channel Failure

1. Set the RPF bit to 1. This flushes all the packets one after the other.

    This step is optional. However, setting this bit prevents HOL (head-of-line) blocking in the Rx queues when packets sent to the RXDMA are stopped due to bus error.
2. Reprogram the specific Registers of the DMA channel.
3. Start the DMA channel.

Recovering from the Transmit DMA Channel Failure

1. Stop the specific DMA channel, even if it is in active state.
2. Flush the corresponding MTL queue.
3. Reprogram the specific Registers of the DMA channel.
4. Start the DMA channel.

NOTE

Due to the known limitations in the design, reprogramming the DMA channel registers might not always be successful in recovering from a Bus Error. If the module is not fully functional after reprogramming the DMA, as a workaround, issue a Soft Reset to recover from the Bus Error.

34.7.5 Programming Guidelines for IEEE 1588 Timestamping

34.7.5.1 Initialization Guidelines for System Time Generation

You can enable the timestamp feature by setting Bit 0 of the MAC_TIMESTAMP_CONTROL Register. However, it is essential that the timestamp counter be initialized after this bit is set. Complete the following steps during the module initialization:

1. Mask the Timestamp Trigger interrupt by clearing the bit 16 of MAC_INTERRUPT_ENABLE Register.
2. Set Bit 0 of MAC_TIMESTAMP_CONTROL Register to enable timestamping.
3. Program MAC_SUB_SECOND_INCREMENT Register based on the PTP clock frequency.
4. If you are using the Fine Correction approach, program MAC_Timestamp_Addend and set Bit 5 of MAC_TIMESTAMP_CONTROL Register.
5. Poll the MAC_TIMESTAMP_CONTROL Register until Bit 5 is cleared.
6. Program Bit 1 of MAC_TIMESTAMP_CONTROL Register to select the Fine Update method (if required).
7. Program MAC_SYSTEM_TIME_SECONDS_UPDATE Register and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE Register with the appropriate time value.
8. Set Bit 2 in MAC_TIMESTAMP_CONTROL Register.
9. The timestamp counter starts operation as soon as it is initialized with the value written in the Timestamp Update registers. If one-step timestamping is enabled
    a. To enable one-step timestamping, program Bit 27 of the TDES3 Context Descriptor.
    b. Program registers MAC_TIMESTAMP_INGRESS_ASYM_CORR and MAC_TIMESTAMP_EGRESS_ASYM_CORR to update the correction field in PDelay_Req PTP messages.
10. Enable the MAC receiver and transmitter for proper timestamping.

NOTE

If timestamp operation is disabled by clearing Bit 0 of MAC_TIMESTAMP_CONTROL Register, repeat all these steps to restart the timestamp operation.

34.7.5.2 System Time Correction

34.7.5.2.1 Coarse Correction Method

To synchronize or update the system time in one process (coarse correction method):

1. Set the offset (positive or negative) in the Timestamp Update registers(MAC_SYSTEM_TIME_SECONDS_UPDATE and MAC_SYSTEM_TIME_NANOSECONDS_UPDATE).
2. Set Bit 3 (TSUPDT) of MAC_TIMESTAMP_CONTROL REGISTER.

The value in the Timestamp Update registers is added to or subtracted from the system time when the TSUPDT bit is cleared.

34.7.5.2.2 Fine Correction Method

To synchronize or update the system time to reduce system-time jitter (fine correction method):

1. With the help of the algorithm, calculate the rate by which you want to make the system time increments slower or faster.
2. Update the MAC_TIMESTAMP_ADDEND with the new value and set Bit 5 of the MAC_TIMESTAMP_CONTROL Register.
3. Wait for the time for which you want the new value of the Addend register to be active. You can do this by enabling the Timestamp Trigger interrupt after the system time reaches the target value.
4. Program the required target time in MAC_PPS[n]_TARGET_TIME_SECONDS Register and MAC_PPS[n]_TARGET_TIME_NANOSECONDS Register.
5. Enable the Timestamp interrupt in bit 12 of MAC_INTERRUPT_ENABLE register.
6. Set bit 4 in Register MAC_Timestamp_Control.
7. When this trigger causes an interrupt, read MAC_INTERRUPT_STATUS Register.
8. Reprogram MAC_TIMESTAMP_ADDEND Register with the old value and set bit 5 again.

34.7.6 Programming Guidelines for AV Feature

After you enable the AV feature in the module controller, there are several programming tasks to be followed:

- Initializing the DMA for QOS-AHB configurations only
- Enabling slot number checking
- Enabling average bits per slot reporting
- Disabling flow control for AV-enabled queues (transmit and receive flow control)

34.7.6.1 Initializing the DMA in Audio Video Feature

The first step in programming the AV feature in a QOS-AHB configuration is to initialize the DMA.

Use this initialization sequence for QOS-AHB/QOS-AXI configurations with AV feature.

1. Provide a software reset to reset all QOS internal registers and logic (bit 0 in DMA_MODE register).
2. Wait for the completion of the reset process. Poll bit 0 of the DMA_MODE register), which is cleared only after the reset operation is completed.
3. Program the fields to initialize the DMA register by setting the values in DMA_MODE register.
4. Create a proper descriptor list for transmit and receive. In addition, ensure that the DMA owns the Transmit and Receive descriptors. When OSF mode is used, at least two TX descriptors are required.

   For more information about descriptors, see Descriptors .
5. Make sure that your software creates three or more different transmit or receive descriptors in the list before reusing any of the descriptors.
6. Program the Transmit and Receive Ring length registers (DMA_CH(#i)_TXDESC_RING_LENGTH (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) and DMA_CH#_RX_CONTROL2 (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1)). The ring length programmed must be at least 4.
7. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1), DMA_CH(#i)_TXDESC_LIST_ADDRESS (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1)). In addition, you must program the Transmit and Receive tail pointer registers indicating to the DMA about the available descriptors (DMA_CH(#i)_TXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_TX_CH-1) and DMA_CH(#i)_RXDESC_TAIL_POINTER (for i = 0; i <= DWC_EQOS_NUM_D-MA_RX_CH-1)).

8. Program the following fields to initialize the mode of operation in the MTL_TXQ0_OPERATION_MODE register:
    a. Transmit Store And Forward (TSF)
    b. Transmit Threshold Control (TTC)
    c. Transmit Queue Enable (TXQEN) to value 2'b10 to enable Transmit Queue0
    d. Transmit Queue Size (TQS)
9. Enable the interrupts by programming the DMA_CH(#i)_INTERRUPT_ENABLE (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register.
10. Repeat steps 4 through 9 for all additional channels of AV feature.
11. Program the CBS control register, idleSlope, sendSlope, hiCredit, and loCredit registers of the AV Queues.
12. Start the Receive and Transmit DMA by setting bit 0 of the DMA_CH(#i)_TX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1) register and bit 0 of the DMA_CH(#i)_RX_CONTROL (for i = 0; i <= DWC_EQOS_NUM_DMA_RX_CH-1) register.

34.7.6.2 Enabling Slot Number Checking

You can enable slot number checking to specify the intervals at which the DMA channels mapped to AV Queues fetch the frames from the AHB/AXI system bus.

These steps should be completed after step 11 and before step 12 of "Initializing DMA".

You can use the slot number check feature to specify the intervals at which the DMA Channels mapped to AV Queues fetch the frames from the AHB/AXI system bus. This feature is useful for a uniform and periodic transfer of the AV traffic from the host memory. The feature is available only when you enable timestamping and program the MAC_SUB_SECOND_INCREMENT register. To enable the slot number checking:

1. Enable timestamping by following the steps described in "Initialization Guidelines for System Time Generation".
2. Make sure that the SLOTNUM field (bits 22:19) of TDES3 Normal Descriptor (Read Format) contains a valid slot number. You can read the current reference slot number from the DMA_CH(#i)_Slot_Function_Control_Status (for i = 0; i <= DWC_EQOS_NUM_DMA_TX_CH-1).
3. Set Bit 0 (ESC) of the Slot Function Control and Status register of a channel to enable the slot number checking.

34.7.6.3 Enabling Average Bits Per Slot Reporting

You can enable the reporting of the average bits that are transmitted in a slot.

The CBS Status register of the additional AV channels provides information about the average bits that are transmitted in a slot. The software can asynchronously read this register to retrieve information about the average bits transmitted per slot. To enable average bits per slot reporting:

1. Enable timestamping by following the steps described in the Initialization Guidelines for System Time Generation .
2. Program Bits [6:4], SLC, of the MTL_TXQ[n]_ETS_CONTROL register of a channel with the number of slots over which the average transmitted bits per slot need to be computed.
3. Enable Bit 9(ABPSSIE) of the MTL_Q[n]_INTERRUPT_CONTROL_STATUS register of a channel to generate the average bits per slot interrupt.

NOTE

- The frequency of this interrupt depends on the value programmed in step 2. For example, when you program value 0 in the SLC field, the interrupt is generated at every 125 microsecond.
- When not required, you can disable this interrupt to stop the interrupt flooding.

4. Read Bits [16:0], ABS, from the MTL_TXQ[n]_ETS_STATUS register of a channel on each interrupt.

NOTE

The software can read the ABS bits in polling mode even if the ABPSIE bit is not enabled. When high, bit 1 (ABPSIS) of the MTL_TXQ[n]_ETS_STATUS register indicates that a new value is updated in the ABS field.

34.7.6.4 Disabling Flow Control for AV Enabled Queues

34.7.6.4.1 Transmit Flow

Program the EHFC (Enable Hardware Flow Control) bit of corresponding Rx Queue's MTL_RXQ[n]_OPERATION_MODE register to 0.

34.7.6.4.2 Receive Flow Control

Program the PSTQ[n] field corresponding to AV enabled Tx Queue in MAC_TXQ_PRTY_MAP0/1 register to 0.

34.7.6.5 Programming Guidelines for Flexible Pulse-Per-Second Output

After you enable the Flexible Pulse-Per-Second Output feature in the module controller, you can perform the following tasks:

- Generating Single Pulse on PPS
- Generating Next Pulse on PPS
- Generating a Pulse Train on PPS
- Generating an Interrupt without Affecting the PPS

34.7.6.5.1 Generating Single Pulse on PPS

To generate single pulse on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS) for start time of PPS signal output.
2. Program the start time value in the Target Time registers (MAC_PPS0_TARGET_TIME_SECONDS and MAC_PPS0_TARGET_TIME_NANOSECONDS).
3. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= 3) Register.
4. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to 0001. This instructs the MAC to generate single pulse on the PPS signal output at the time programmed in the Target Time registers.

34.7.6.5.2 Generating Next Pulse on PPS

When the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance.

To program the next pulse:

1. Program the start time for the next pulse in the Target Time registers. This time should be more than the time at which the falling edge occurs for the previous pulse.
2. Program the width of the next PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1).
3. Program Bits [3:0], PPSCMD, of MAC_PPS_CONTROL to generate a single pulse after the time at which the previous pulse is de-asserted. This instructs the MAC to generate single pulse on the PPS signal output, at the time programmed in Target Time registers.

   If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the QOS may generate only 1 extended pulse.

34.7.6.5.3 Generating a Pulse Train on PPS

To generate a pulse train on PPS:

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_Control Register. This instructs the MAC to use the Target Time registers for start time of the PPS signal output.
2. Program the start time value in the Target Time registers.
3. Program the interval value between the train of pulses on the PPS signal output in MAC_PPS(#i)_INTERVAL (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
4. Program the width of the PPS signal output in MAC_PPS(#i)_WIDTH (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register.
5. Program Bits[3:0], PPSCMD, of MAC_PPS_CONTROL Register to 0010. This instructs the MAC to generate train of pulses on the PPS signal output with start time programmed in Target Time registers.

   By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands.
6. Program the stop value in the Target Time registers. Ensure that Bit 31 (TSTRBUSY) of MAC_PPS(#i)_TARGET_TIME_NANOSECONDS (for i = 0; i <= DWC_EQOS_PPS_OUT_NUM-1) Register is reset before programming the Target Time registers again.
7. Program the PPSCMD field (bit 3:0) of MAC_PPS_CONTROL to 0100. This stops the train of pulses on PPS signal output after the programmed stop time specified in Step 6 elapses.

   You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in Step 7) by programming 0110 in the PPSCMD field before the time (programmed in Step 6) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in Step 2) elapses.

34.7.6.5.4 Generating an Interrupt without Affecting the PPS

You can use bits[6:5], TRGTMODSEL, of the MAC_PPS_CONTROL Register to program the Target Time registers to do any one of the following:

- Generate only interrupts.
- Generate interrupts and the PPS start and stop time.
- Generate only PPS start and stop time.

To program the Target Time registers to generate only interrupt events:

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of MAC_PPS_CONTROL Register. This instructs the MAC to use the Target Time registers for target time interrupt.
2. Program a target time value in the Target Time registers. This instructs the MAC to generate an interrupt when the target time elapses.

   If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

34.7.6.6 Programming Guidelines for VLAN Filtering on Receive

To program VLAN filtering on receive:

1. Program MAC_VLAN_TAG register for the following bit to select the filtering method:
   a. ETV: Enable 12-Bit VLAN Tag Comparison or 16-bit VLAN Tag comparison.
   b. VTHM: VLAN Tag Hash Table Match Enable.
   c. ERIVLT: Enable inner VLAN Tag or outer VLAN Tag (to enable the inner or outer VLAN Tag filtering, Double VLAN Processing should enabled by setting EDVLP)

d. ERSVLM: Enable Receive S-VLAN Match or C-VLAN match (for S-VLAN processing to be enabled, set ESVL)

e. DOVLTC: Ignores VLAN Type for Tag Match

f. VTIM: to enable VLAN Tag Inverse Match instead of the normal VLAN Tag matching

2. Program VL of MAC_VLAN_Tag Register for the 12-bit or 16-bit VLAN tag.
3. If Hash filtering of VLAN tag is enabled, program MAC_VLAN_HASH_TABLE Register. When ETV bit is reset, upper 4 bits of the calculated CRC-32 of VLAN Tag are inverted and used to index the content of MAC_VLAN_Hash_Table register. When ETV bit is set, upper 4 bits of calculated CRC-32 of VLAN Tag are used to index the content of MAC_VLAN_HASH_TABLE register. For example, when ETV bit is set, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. When ETV bit is reset a hash value of 4'b1000 selects Bit 7 of the VLAN Hash table.

34.7.6.7 Programming Guidelines for Extended VLAN Filtering and Routing on Receive

For the indirect access of the per VLAN Tag registers, follow these steps.

- Write
  1. Write the required data into the MAC VLAN Tag Data register.
  2. Program the VLAN Tag Control Register's OFS field with the required Filter Register's offset and command type to the CT field. For a write command, set this bit to 0.
  3. Write 1 to the OB field and wait till the OB bit is reset to do the next write. This will guarantee that the appropriate VLAN Tag Filter Register has been programmed.
- Read
  1. Program the VLAN Tag Control Register's OFS Field with the required register's offset and command type to the CT field. For a read command, set this bit to 1.
  2. Write 1 to the OB field and wait till the OB bit is reset. The appropriate VLAN Tag Filter register's value is available in the MAC VLAN Tag Data Register.

34.7.6.8 Programming Sequence for Queue/Channel Based VLAN Inclusion Register

To program the queue/channel-based VLAN inclusion register:

NOTE

Indirect VLAN include registers are not accessed while setting the CBTI bit.

1. Set the CBTI bit of MAC_VLAN_INCL register to 1, to enable queue/channel based VLAN Tag insertion on all transmitted packets. This bit must be set before any indirect access to the queue/channel specific MAC_VLAN_INCL(#i) register.
2. Program the VLAN Tag and VLAN Type to be inserted in packets from a particular queue/channel in VLT and CSVL fields of MAC_VLAN_INCL register; corresponding offset address in ADDR field (0 for queue/channel 0, 1 for queue/channel 1, and so on) must be set. Set the RDWR bit to 0 to indicate write access. The write to byte 0 (byte 3 in Big Endian mode) of MAC_VLAN_INCL register initiates access to indirect access MAC_VLAN_INCL(#i) register.
3. The BUSY bit of MAC_VLAN_INCL register is set by the module to indicate the progress of access to indirect access MAC_VLAN_INCL(#i) register. On completion of the access, the BUSY bit is cleared. The application must not attempt subsequent access to MAC_VLAN_INCL(#i) register when the BUSY bit is 1.
4. Repeat step 2 and step 3 to program VLAN Tag and VLAN Type to be inserted in packets from the remaining queues/channels. The application must ensure that the required VLAN Tag and VLAN Type for all the queues/channels are programmed; otherwise unintended VLAN Tag and VLAN Type might be inserted.

34.7.7 Programming Guidelines for EST

Program the gate control values and time intervals in the Software Owned Gate Control List (SWOL) along with the other EST related registers that are described in ENET_QOS register descriptions to appropriate values. The following sub-sections provide step by step details for programming the GCL and the other EST related registers.

34.7.7.1 Programming the GCL and GCL Linked Registers

To program the Gate Control List (GCL) and the four other registers implemented per GCL:

1. The GCL and the four other GCL-linked registers should be accessed via indirect addressing using the MTL_EST_GCL_CONTROL and MTL_EST_GCL_DATA registers. The SWOL bit of the MTL_EST_STATUS register indicates if GCL0 or GCL1 is owned by software.
2. To program the GCL, write the 32-bit write data to MTL_EST_GCL_DATA register. Then program TL_EST_GCL_CONTROL register to write the write address and other control information.
3. In the MTL_EST_GCL_DATA register, Write Data consists of up to 8 bits (5 configurable, 3 reserved) of Gate Controls and up to 24 bits (configurable) of Time Interval. Gate Close is indicated by programming a '0' and Gate Open is indicated by programming a '1'. For a 4-TC and 20-bit Time Interval Configuration, the data width is 24-bits and the remaining 8-bits are reserved/read-only. The data should be written in the following format.

   {8'h0, TC3, TC2, TC1, TC0, 20-bit Time Interval} where TCx = 0 or 1.
4. MTL_EST_GCL_CONTROL register: Program the SRWO bit to 1 (to start a Write Op) and program the address and R/W fields appropriately.
5. Poll and check for the SRWO bit to be cleared by hardware to indicate the completion of the previous operation before initiating a new R/W operation via the same indirect addressing mode.
6. Repeat steps 3, 4, 5 until the programming of the GCL is completed.
7. Using the same indirect addressing method described above, program the BTR, CTR, TER and LLR registers. Set the GCRR bit in the MTL_EST_GCL_CONTROL register appropriately. The GCRR bit interprets the address field as belonging to these registers (instead of the GCL).

After programming of the GCL and the related registers, program the MTL_EST_CONTROL register to allow hardware to own and process the GCL.When the List Length (as indicated in LLR) is 1, the associated Time Interval should be smaller than the value of the Cycle Time Register. Otherwise, an error is reported (as detailed in the Error handling section) as a single set of gate controls add no value in the TSN context.

NOTE

The time unit in all the GCL related registers is seconds and nanoseconds. In cases where internally generated PTP System Time is used, the nanoseconds field must be programmed to use the Digital Rollover mode. (TSCTRLSSR field of MAC_TIMESTAMP_CONTROL must be set to value '1')

34.7.7.2 Programming the EST Registers

After completing the steps mentioned in "Programming the GCL and GCL Linked Registers" , program the MTL_EST_CONTROL register.

1. Set the Current Time Offset Value and Time Internal Left Shift fields of the MTL_EST_CONTROL register appropriately. Also, set the Enable EST (EEST) and Switch to SWOL (SWOL) bits.

NOTE

The CTOV recommendations for GMII for SPRAM configurations are:

- 96 * Tx clock period, for 32 and 64 bit data width configurations.
- 128 * Tx clock period for 128 bit data width configurations.

The CTOV recommendations for GMII for non-SPRAM configurations are:

- 30 * Tx clock period, when SA/VLAN insertion is enabled.
- 22 * Tx clock period, when SA/VLAN insertion is not enabled.

2. This will enable the hardware to own and process the new GCL and make a switch to the new GCL at the BTR value. The hardware provides an interrupt (if enabled) when the switch to the new list happens.
3. Appropriate action has to be taken by software to address any other interrupts (explained in the Inter-rupts section) received during the hardware execution of the GCL.

Set the SSWL (Switch to Software Owned List) bit in the MTL_EST_CONTROL register to handoff to hardware. Software is not allowed to write to the GCL and GCL linked registers when the SSWL bit is set, because the new GCL might be in use by the hardware.

The SSWL is reset/cleared by the hardware when it successfully switches to the new list. The hardware also flips the SWOL bit to indicate the new GCL that the software owns.

To install a new GCL, program the GCL it owns (indicated by SWOL bit) as described in "Programming the GCL and GCL Linked Registers" and then program the MTL_EST_CONTROL register as described above. Ensure that the new BTR is set to an appropriate value to avoid BTRError that might need software intervention in some cases.

To avoid transmission overruns, the packet length (frame size) information should be available at all times. Therefore, in the DMA configurations, program the packet length in the first descriptor of every Tx frame. Similarly, in the MTL configuration, provide the packet length in the control word.

NOTE

To avoid transmission overruns, the Packet Length provided in the Transmit Descriptor should account for the SA and VLAN insertion, if applicable, that is, Packet Length should represent the actual packet length on the Ethernet line.

34.7.8 Programming the Launch Time in Time-Based Scheduling

The Launch Time is programmed in the Enhanced Normal Transmit Descriptors in DMA configurations and is driven as a control word in MTL configurations as follows:

The OSTC and Launch Time features are mutually exclusive and should not be used together; in case of a conflict (if OSTC = LTV = 1 in MTL configuration), priority is given to OSTC and the Launch Time is ignored.

In DMA configuration, if a context descriptor is received with a valid OSTC values immediately before receiving a first normal descriptor with LTV bit set, then the LTV is ignored.

34.7.9 Programming Guidelines for Media Clock Generation and Recovery

34.7.9.1 Programming Guidelines for Media Clock Generation

1. To set the PPS instance in Media Clock generation mode, program the appropriate Presentation Time Control (supported generation modes "1001-1011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_CONTROL register.
2. Based on the selected PPS instance, application must drive the appropriate trigger signal to the corresponding mcg_pst_trig_i[#i].
3. Based on the programmed mode, DUT captures the timestamp and programs it in the MAC_PPS(#i)_TARGET_TIME_SECONDS register. Then, mcgr_dma_req_o[#i] is set.

4. For every request generated by the DUT, the module reads the corresponding MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the read request by asserting the corresponding mcgr_dma_ack_i[#i].

34.7.9.2 Programming Guidelines for Media Clock Recovery

1. Enable the Current Presentation Time (CPT) Counter by setting the PTGE field of MAC_TIMESTAMP_CONTROL register. In addition to programming the initialization values for the System Time, update the MAC_PRESN_TIME_UPDT register with the equivalent Presentation Time init value. Only then the TSINIT field of MAC_TIMESTAMP_CONTROL register is set.
2. The Increment values used for the System time is also used for the Current Presentation time. This is because, the increment value is in Sub-seconds and Sub-nanoseconds.
3. When an update is needed, along with programming the update values for the System Time, the MAC_PRESN_TIME_UPDT register should be updated with the equivalent Presentation Time update value (32-bit ns). Finally, TSUPDT field of MAC_TIMESTAMP_CONTROL register must be set for the update to happen.
4. Program the MCGREN#i of MAC_PPS_CONTROL register to enable the PPS instance to operate in MCGR mode.
5. To set the PPS instance in Media Clock recovery mode, program the appropriate Presentation Time Control (supported recovery modes "0001 - 0011") to PPSCTRL_PPSCMD (for 0th instance)/PPSCMD#i (for 1,2,3 instances) of MAC_PPS_Control register.
6. After PPS instance is set in recovery mode, corresponding mcgr_dma_req_o[#i] is set by the DUT. For every request generated by the DUT, program the target presentation time into the MAC_PPS(#i)_TARGET_TIME_SECONDS register and acknowledge the request by asserting the corresponding mcgr_d-ma_ack_i[#i]. Acknowledgment can be given before/after programming the Target presentation time.
7. Observe the recovered media clock on the corresponding ptp_pps_o[#i].

34.7.10 Programming Guidelines for ECC Protection for Memories

1. Enable the ECC feature for the respective memory by setting the appropriate bit in MTL_ECC_CONTROL register.
2. A correctable interrupt (sbd_sfty_ce_intr_o) or an uncorrectable interrupt (sbd_sfty_ue_intr_o) are generated to indicate to the application if any correctable/uncorrectable/address errors are detected. Appropriate status is indicated in the DMA/MTL_ECC_INTERRUPT_STATUS register.
3. Debug mode is provided for each memory to specify errors.

NOTE

Enable the ECC feature before the traffic is online (or after the reset), otherwise false interrupts might be triggered.

34.7.10.1 Programming Guidelines for ECC Hardware Error Injection (Debug Mode)

1. Enable the ECC error injection feature for MTL TX/RX and DMA TSO, by setting the appropriate bit in the MTL_DBG_CTL register.
2. Enable the ECC error injection feature for the EST memory by setting the appropriate bit in the EST_GCL_CONTROL register.
3. Enable the ECC error injection for RX Parser memory by setting the appropriate bit in the MTL_RXP_INDIRECT_ACC_CONTROL_STATUS register. To access Rx Parser memory in debug mode, disable the Rx Parser feature by setting the FRPE bit of MTL_OPERATION_MODE register to 0.
4. Where multiple CSR writes are required, for writing single data word into the memory, the application should ensure that all the CSR writes corresponding to one memory write should have the same value for the error injection control word.

34.7.11 Programming Guidelines for On-Chip Datapath Parity Protection

Follow the below steps for on-chip datapath parity protection:

1. Set the EDPP bit of MTL_DPP_CONTROL register to enable the generation of parity and detection of parity Mismatch on datapath.
2. An uncorrectable interrupt (sbd_sfty_ue_intr_o) is generated to indicate to the application whether any parity Mismatches are detected and the appropriate status will be indicated in DMA/MTL_SAFETY_INTERRUPT_STATUS and MAC_DPP_FSM_INTERRUPT_STATUS register.
3. Debug mode is supported for each parity generator, to insert error.

NOTE

To avoid false safety interrupts, enable the datapath parity protection before the start of Rx or Tx traffic.

34.7.12 Programming Guidelines for FSM Parity and Timeout

To program the FSM parity and timeout:

1. Set the PRTYEN and TMOUTEN fields of MAC_FSM_CONTROL register to enable the FSM parity and timeout feature respectively.
2. For parity error detection, force the FSMs to enter into a state with even number of 1s and wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
3. For Error Injection mode in FSM parity, select the appropriate clock domain for which parity error injection should be set using the [23:16] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt to be set with FSMPES of MAC_DPP_FSM_INTERRUPT_STATUS.
4. For FSM Timeouts, program the large and normal mode values indicated by LTMRMD and NTMRMD of MAC_FSM_ACT_TIMER register.
5. Select large or normal mode tic generation per clock domain by using the [31:24] bits of MAC_FSM_CONTROL Register.
6. Set the TMR field of the MAC_ACT_TIMER field with the appropriate number of CSR clock cycles used to generate 1-microsecond tic.
7. Force the FSM in a particular clock domain to be in an active state for Timeout duration (for example, T-2T). Check for the safety interrupt and the status bit for the corresponding clock domain getting set in [15:8] bits of MAC_DPP_FSM_INTERRUPT_STATUS register.
8. For Error Injection mode in FSM timeout, select the appropriate clock domain for which timeout error injection must be set using the [15:8] bits of MAC_FSM_CONTROL register. Wait for the safety uncorrectable interrupt along with the corresponding error status set in MAC_DPP_FSM_INTERRUPT_STATUS.
9. For application/CSR interface timeout, only normal mode tic generation is used. Based on the timeouts of the configured interface, appropriate fields (MSTTES, SLVTES) of MAC_DPP_FSM_INTERRUPT_STATUS are set along with the safety interrupt.

34.8 Memory Map and register definition

NOTE

This section and all its sub-sections are Synopsys Proprietary. Used with permission.

This section includes the ENET module memory map and detailed descriptions of all registers.

34.8.1 ENET_QOS register descriptions

34.8.1.1 ENET_QOS memory map

ENET_QOS_TSN base address: 428A_0000h

Fields

Field	Description
31 —	Reserved
30-28 SARC	Source Address Insertion or Replacement Control This field controls the source address insertion or replacement for all transmitted packets. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits[29:28]: 2'b0x: - The mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation. 2'b10: - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected while configuring the core, the MAC inserts the content of the MAC Address 1 registers in the SA field of all transmitted packets. 2'b11: - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers in the SA field of all transmitted packets. - If Bit 30 is set to 1 and the MAC Address Register 1 is enabled, the MAC replaces the content of the MAC Address 1 registers in the SA field of all transmitted packets. Note: - Changes to this field take effect only on the start of a packet. If you write to this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 000 - mti_sa_ctrl_i and ati_sa_ctrl_i input signals control the SA field generation 010 - Contents of MAC Addr-0 inserted in SA field 011 - Contents of MAC Addr-0 replaces SA field 110 - Contents of MAC Addr-1 inserted in SA field

Table continues on the next page...

Table continued from the previous page...

Field	Description
	111 - Contents of MAC Addr-1 replaces SA field
27 IPC	Checksum Offload When set, this bit enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled. The Layer 3 and Layer 4 Packet Filter and Enable Split Header features automatically selects the IPC Full Checksum Offload Engine on the Receive side. When any of these features are enabled, you must set the IPC bit. 0 - IP header/payload checksum checking is disabled 1 - IP header/payload checksum checking is enabled
26-24 IPG	Inter-Packet Gap These bits control the minimum IPG between packets during transmission. Inter-Packet Gap These bits control the minimum IPG between packets during transmission. This range of minimum IPG is valid in full-duplex mode. In the half-duplex mode, the minimum IPG can be configured only for 64-bit times (IPG = 100). Lower values are not considered. When a JAM pattern is being transmitted because of backpressure activation, the MAC does not consider the minimum IPG. The above function (IPG less than 96 bit times) is valid only when EIPGEN bit in MAC_EXT_CONFIGURATION register is reset. When EIPGEN is set, then the minimum IPG (greater than 96 bit times) is controlled as per the description given in EIPG field in MAC_EXT_CONFIGURATION register. 000 - 96 bit times IPG 001 - 88 bit times IPG 010 - 80 bit times IPG 011 - 72 bit times IPG 100 - 64 bit times IPG 101 - 56 bit times IPG 110 - 48 bit times IPG 111 - 40 bit times IPG
23 GPSLCE	Giant Packet Size Limit Control Enable When this bit is set, the MAC considers the value in GPSL field in MAC_EXT_CONFIGURATION register to declare a received packet as Giant packet. This field must be programmed to more than 1,518 bytes. Otherwise, the MAC considers 1,518 bytes as giant packet limit. When this bit is reset, the MAC considers a received packet as Giant packet when its size is greater than 1,518 bytes (1522 bytes for tagged packet).

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The watchdog timeout limit, Jumbo Packet Enable and 2K Packet Enable have higher precedence over this bit, that is the MAC considers a received packet as Giant packet when its size is greater than 9,018 bytes (9,022 bytes for tagged packet) with Jumbo Packet Enabled and greater than 2,000 bytes with 2K Packet Enabled. The watchdog timeout, if enabled, terminates the received packet when watchdog limit is reached. Therefore, the programmed giant packet limit should be less than the watchdog limit to get the giant packet status. 0 - Giant Packet Size Limit Control is disabled 1 - Giant Packet Size Limit Control is enabled
22 S2KP	IEEE 802. IEEE 802.3as Support for 2K Packets When this bit is set, the MAC considers all packets with up to 2,000 bytes length as normal packets. When the JE bit is not set, the MAC considers all received packets of size more than 2K bytes as Giant packets. When this bit is reset and the JE bit is not set, the MAC considers all received packets of size more than 1,518 bytes (1,522 bytes for tagged) as giant packets. For more information about how the setting of this bit and the JE bit impact the Giant packet status, see the Table, Gaint Packet Status based on S2KP and JE Bits. Note: When the JE bit is set, setting this bit has no effect on the giant packet status. 0 - Support upto 2K packet is disabled 1 - Support upto 2K packet is Enabled
21 CST	CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. CRC stripping for Type packets When this bit is set, the last four bytes (FCS) of all packets of Ether type (type field greater than 1,536) are stripped and dropped before forwarding the packet to the application. Note: For information about how the settings of the ACS bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bits. 0 - CRC stripping for Type packets is disabled 1 - CRC stripping for Type packets is enabled
20 ACS	Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming packets only if the value of the length field is less than 1,536 bytes. All received packets with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming packets to the application, without any modification. Note: For information about how the settings of CST bit and this bit impact the packet length, see the Table, Packet Length based on the CST and ACS Bit . 0 - Automatic Pad or CRC Stripping is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - Automatic Pad or CRC Stripping is enabled
19 WD	Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive packets of up to 16,383 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the packet being received. The MAC cuts off any bytes received after 2,048 bytes. 0 - Watchdog is enabled 1 - Watchdog is disabled
18 BE	Packet Burst Enable When this bit is set, the MAC allows packet bursting during transmission in the GMII half-duplex mode. 0 - Packet Burst is disabled 1 - Packet Burst is enabled
17 JD	Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer packets of up to 16,383 bytes. When this bit is reset, if the application sends more than 2,048 bytes of data (10,240 if JE is set high) during transmission, the MAC does not send rest of the bytes in that packet. 0 - Jabber is enabled 1 - Jabber is disabled
16 JE	Jumbo Packet Enable When this bit is set, the MAC allows jumbo packets of 9,018 bytes (9,022 bytes for VLAN tagged packets) without reporting a giant packet error in the Rx packet status. 0 - Jumbo packet is disabled 1 - Jumbo packet is enabled
15 PS	Port Select This bit selects the Ethernet line speed. This bit, along with Bit 14, selects the exact line speed. In the 10/100 Mbps-only (always 1) or 1000 Mbps-only (always 0) configurations, this bit is read-only (RO) with appropriate value. In default 10/100/1000 Mbps configurations, this bit is read-write (R/W). The mac_speed_o[1] signal reflects the value of this bit. 0 - For 1000 or 2500 Mbps operations 1 - For 10 or 100 Mbps operations
14 FES	Speed This bit selects the speed mode. The mac_speed_o[0] signal reflects the value of this bit. 0 - 10 Mbps when PS bit is 1 and 1 Gbps when PS bit is 0

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - 100 Mbps when PS bit is 1 and 2.5 Gbps when PS bit is 0
13 DM	Duplex Mode When this bit is set, the MAC operates in the full-duplex mode in which it can transmit and receive simultaneously. This bit is RO with default value of 1'b1 in the full-duplex-only configurations. 0 - Half-duplex mode 1 - Full-duplex mode
12 LM	Loopback Mode When this bit is set, the MAC operates in the loopback mode at GMII. The (G)MII Rx clock input (clk_rx_i) is required for the loopback to work properly. This is because the Tx clock is not internally looped back. 0 - Loopback is disabled 1 - Loopback is enabled
11 ECRSFD	Enable Carrier Sense Before Transmission in Full-Duplex Mode When this bit is set, the MAC transmitter checks the CRS signal before packet transmission in the full-duplex mode. The MAC starts the transmission only when the CRS signal is low. When this bit is reset, the MAC transmitter ignores the status of the CRS signal. 0 - ECRSFD is disabled 1 - ECRSFD is enabled
10 DO	Disable Receive Own When this bit is set, the MAC disables the reception of packets when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets given by the PHY. This bit is not applicable in the full-duplex mode. 0 - Enable Receive Own 1 - Disable Receive Own
9 DCRS	Disable Carrier Sense During Transmission When this bit is set, the MAC transmitter ignores the (G)MII CRS signal during packet transmission in the half-duplex mode. As a result, no errors are generated because of Loss of Carrier or No Carrier during transmission. When this bit is reset, the MAC transmitter generates errors because of Carrier Sense. The MAC can even abort the transmission. 0 - Enable Carrier Sense During Transmission 1 - Disable Carrier Sense During Transmission
8 DR	Disable Retry

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII interface, the MAC ignores the current packet transmission and reports a Packet Abort with excessive collision error in the Tx packet status. When this bit is reset, the MAC retries based on the settings of the BL field. This bit is applicable only in the half-duplex mode. 0 - Enable Retry 1 - Disable Retry
7 —	Reserved
6-5 BL	Back-Off Limit The back-off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000/2500 Mbps; 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. n = retransmission attempt. The random integer r takes the value in the range 0 <= r < 2^k This bit is applicable only in the half-duplex mode. 00 - k = min(n,10) 01 - k = min(n,8) 10 - k = min(n,4) 11 - k = min(n,1)
4 DC	Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Packet Abort status, along with the excessive deferral error bit set in the Tx packet status, when the Tx state machine is deferred for more than 24,288 bit times in 10 or 100 Mbps mode. If the MAC is configured for 1000/2500 Mbps operation, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but it is prevented because of an active carrier sense signal (CRS) on GMII. The defer time is not cumulative. For example, if the transmitter defers for 10,000 bit times because the CRS signal is active and the CRS signal becomes inactive, the transmitter transmits and collision happens. Because of collision, the transmitter needs to back off and then defer again after back off completion. In such a scenario, the deferral timer is reset to 0, and it is restarted. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. 0 - Deferral check function is disabled 1 - Deferral check function is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
3-2 PRELEN	Preamble Length for Transmit packets These bits control the number of preamble bytes that are added to the beginning of every Tx packet. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. 00 - 7 bytes of preamble 01 - 5 bytes of preamble 10 - 3 bytes of preamble 11 - Reserved
1 TE	Transmitter Enable When this bit is set, the Tx state machine of the MAC is enabled for transmission on the GMII interface. When this bit is reset, the MAC Tx state machine is disabled after it completes the transmission of the current packet. The Tx state machine does not transmit any more packets. 0 - Transmitter is disabled 1 - Transmitter is enabled
0 RE	Receiver Enable When this bit is set, the Rx state machine of the MAC is enabled for receiving packets from the GMII interface. When this bit is reset, the MAC Rx state machine is disabled after it completes the reception of the current packet. The Rx state machine does not receive any more packets from the GMII interface. 0 - Receiver is disabled 1 - Receiver is enabled

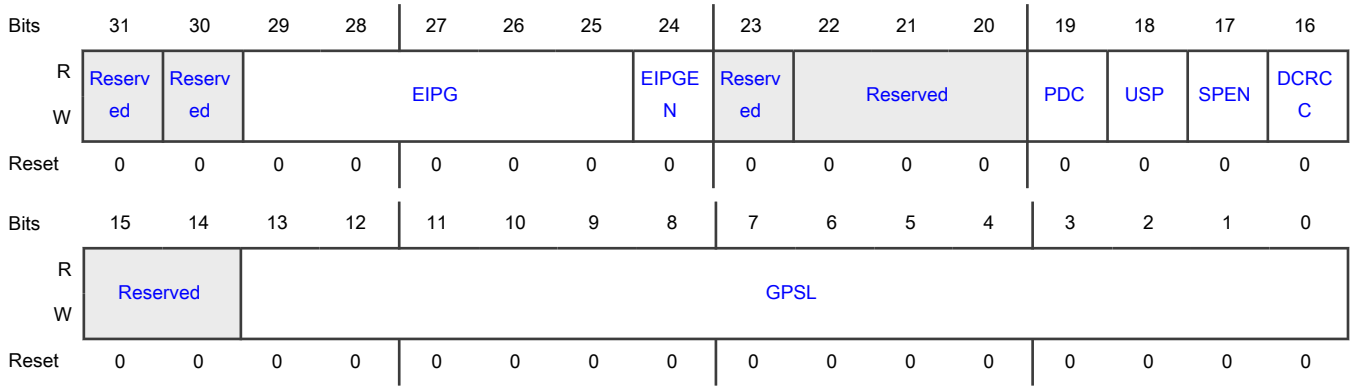
34.8.1.3 MAC Extended Configuration Register (MAC_EXT_CONFIGURATION)

The MAC Extended Configuration Register establishes the operating mode of the MAC.

Offset

Register	Offset
MAC_EXT_CONFIGURATION	4h

Diagram



Fields

Field	Description
31 —	Reserved
30 —	Reserved
29-25 EIPG	Extended Inter-Packet Gap The value in this field is applicable when the EIPGEN bit is set. This field (as Most Significant bits), along with IPG field in CONFIGURATION register, gives the minimum IPG greater than 96 bit times in steps of 8 bit times: {EIPG, IPG} 8'h00 - 104 bit times 8'h01 - 112 bit times 8'h02 - 120 bit times ---------- 8'hFF - 2144 bit times
24 EIPGEN	Extended Inter-Packet Gap Enable When this bit is set, the MAC interprets EIPG field and IPG field in CONFIGURATION register together as minimum IPG greater than 96 bit times in steps of 8 bit times. When this bit is reset, the MAC ignores EIPG field and interprets IPG field in CONFIGURATION register as minimum IPG less than or equal to 96 bit times in steps of 8 bit times. Note: The extended Inter-Packet Gap feature must be enabled when operating in Full-Duplex mode only. There may be undesirable effects on back-pressure function and frame transmission if it is enabled in Half-Duplex mode. 0 - Extended Inter-Packet Gap is disabled 1 - Extended Inter-Packet Gap is enabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
23 —	Reserved
22-20 —	Reserved
19 PDC	Packet Duplication Control When this bit is set, the received packet with Multicast/Broadcast Destination address is routed to multiple Receive DMA Channels. The Receive DMA Channels is identified by the DCS field of MAC_ADDRESS(#i)_HIGH register corresponding to the MAC Address register that matches the Multicast/Broadcast Destination address in the received packet. The DCS field is interpreted to be a one-hot value, each bit corresponding to the Receive DMA Channel. When this bit is reset, the received packet is routed to single Receive DMA Channel. The Receive DMA Channel is identified by the DCS field of ADDRESS(#i)_High register corresponding to the MAC Address register that matches the Destination address in the received packet. The DCS field is interpreted as a binary value. 0 - Packet Duplication Control is disabled 1 - Packet Duplication Control is enabled
18 USP	Unicast Slow Protocol Packet Detect When this bit is set, the MAC detects the Slow Protocol packets with unicast address of the station specified in the MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW registers. The MAC also detects the Slow Protocol packets with the Slow Protocols multicast address (01-80-C2-00-00-02). When this bit is reset, the MAC detects only Slow Protocol packets with the Slow Protocol multicast address specified in the IEEE 802.3-2015, Section 5. 0 - Unicast Slow Protocol Packet Detection is disabled 1 - Unicast Slow Protocol Packet Detection is enabled
17 SPEN	Slow Protocol Detection Enable When this bit is set, MAC processes the Slow Protocol packets (Ether Type 0x8809) and provides the Rx status. The MAC discards the Slow Protocol packets with invalid sub-types. When this bit is reset, the MAC forwards all error-free Slow Protocol packets to the application. The MAC considers such packets as normal Type packets. 0 - Slow Protocol Detection is disabled 1 - Slow Protocol Detection is enabled
16 DCRCC	Disable CRC Checking for Received Packets When this bit is set, the MAC receiver does not check the CRC field in the received packets. When this bit is reset, the MAC receiver always checks the CRC field in the received packets. 0 - CRC Checking is enabled 1 - CRC Checking is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
15-14 —	Reserved
13-0 GPSL	Giant Packet Size Limit If the received packet size is greater than the value programmed in this field in units of bytes, the MAC declares the received packet as Giant packet. The value programmed in this field must be greater than or equal to 1,518 bytes. Any other programmed value is considered as 1,518 bytes. For VLAN tagged packets, the MAC adds 4 bytes to the programmed value. When the Enable Double VLAN Processing option is selected, the MAC adds 8 bytes to the programmed value for double VLAN tagged packets. The value in this field is applicable when the GPSLCE bit is set in MAC_CONFIGURATION register.

34.8.1.4 MAC Packet Filter (MAC_PACKET_FILTER)

The MAC Packet Filter register contains the filter controls for receiving packets. Some of the controls from this register go to the address check block of the MAC which performs the first level of address filtering. The second level of filtering is performed on the incoming packet based on other controls such as Pass Bad Packets and Pass Control Packets.

Fields

Field	Description
31 RA	Receive All

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, the MAC Receiver module passes all received packets to the application, irrespective of whether they pass the address filter or not. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bit in the Rx Status Word. When this bit is reset, the Receiver module passes only those packets to the application that pass the SA or DA address filter. 0 - Receive All is disabled 1 - Receive All is enabled
30-22 —	Reserved
21 DNTU	Drop Non-TCP/UDP over IP Packets When this bit is set, the MAC drops the non-TCP or UDP over IP packets. The MAC forward only those packets that are processed by the Layer 4 filter. When this bit is reset, the MAC forwards all non-TCP or UDP over IP packets. 0 - Forward Non-TCP/UDP over IP Packets 1 - Drop Non-TCP/UDP over IP Packets
20 IPFE	Layer 3 and Layer 4 Filter Enable When this bit is set, the MAC drops packets that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When this bit is reset, the MAC forwards all packets irrespective of the match status of the Layer 3 and Layer 4 fields. 0 - Layer 3 and Layer 4 Filters are disabled 1 - Layer 3 and Layer 4 Filters are enabled
19-17 —	Reserved
16 VTFE	VLAN Tag Filter Enable When this bit is set, the MAC drops the VLAN tagged packets that do not match the VLAN Tag. When this bit is reset, the MAC forwards all packets irrespective of the match status of the VLAN Tag. 0 - VLAN Tag Filter is disabled 1 - VLAN Tag Filter is enabled
15-11 —	Reserved
10 HPF	Hash or Perfect Filter When this bit is set, the address filter passes a packet if it matches either the perfect filtering or hash filtering as set by the HMC or HUC bit.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is reset and the HUC or HMC bit is set, the packet is passed only if it matches the Hash filter. 0 - Hash or Perfect Filter is disabled 1 - Hash or Perfect Filter is enabled
9 SAF	Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received packets with the values programmed in the enabled SA registers. If the comparison fails, the MAC drops the packet. When this bit is reset, the MAC forwards the received packet to the application with updated SAF bit of the Rx Status depending on the SA address comparison. Note: According to the IEEE specification, Bit 47 of the SA is reserved. However, in DWC_ether_qos, the MAC compares all 48 bits. The software driver should take this into consideration while programming the MAC address registers for SA. 0 - SA Filtering is disabled 1 - SA Filtering is enabled
8 SAIF	SA Inverse Filtering When this bit is set, the Address Check block operates in the inverse filtering mode for SA address comparison. If the SA of a packet matches the values programmed in the SA registers, it is marked as failing the SA Address filter. When this bit is reset, if the SA of a packet does not match the values programmed in the SA registers, it is marked as failing the SA Address filter. 0 - SA Inverse Filtering is disabled 1 - SA Inverse Filtering is enabled
7-6 PCF	Pass Control Packets These bits control the forwarding of all control packets (including unicast and multicast Pause packets). 00 - MAC filters all control packets from reaching the application 01 - MAC forwards all control packets except Pause packets to the application even if they fail the Address filter 10 - MAC forwards all control packets to the application even if they fail the Address filter 11 - MAC forwards the control packets that pass the Address filter
5 DBF	Disable Broadcast Packets When this bit is set, the AFM module blocks all incoming broadcast packets. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast packets. 0 - Enable Broadcast Packets 1 - Disable Broadcast Packets
4	Pass All Multicast

Table continues on the next page...

Table continued from the previous page...

Field	Description
PM	When this bit is set, it indicates that all received packets with a multicast destination address (first bit in the destination address field is '1') are passed. When this bit is reset, filtering of multicast packet depends on HMC bit. 0 - Pass All Multicast is disabled 1 - Pass All Multicast is enabled
3 DAIF	DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast packets. When this bit is reset, normal filtering of packets is performed. 0 - DA Inverse Filtering is disabled 1 - DA Inverse Filtering is enabled
2 HMC	Hash Multicast When this bit is set, the MAC performs the destination address filtering of received multicast packets according to the hash table. When this bit is reset, the MAC performs the perfect destination address filtering for multicast packets, that is, it compares the DA field with the values programmed in DA registers. 0 - Hash Multicast is disabled 1 - Hash Multicast is enabled
1 HUC	Hash Unicast When this bit is set, the MAC performs the destination address filtering of unicast packets according to the hash table. When this bit is reset, the MAC performs a perfect destination address filtering for unicast packets, that is, it compares the DA field with the values programmed in DA registers. 0 - Hash Unicast is disabled 1 - Hash Unicast is enabled
0 PR	Promiscuous Mode When this bit is set, the Address Filtering module passes all incoming packets irrespective of the destination or source address. The SA or DA Filter Fails status bits of the Rx Status Word are always cleared when PR is set. 0 - Promiscuous Mode is disabled 1 - Promiscuous Mode is enabled

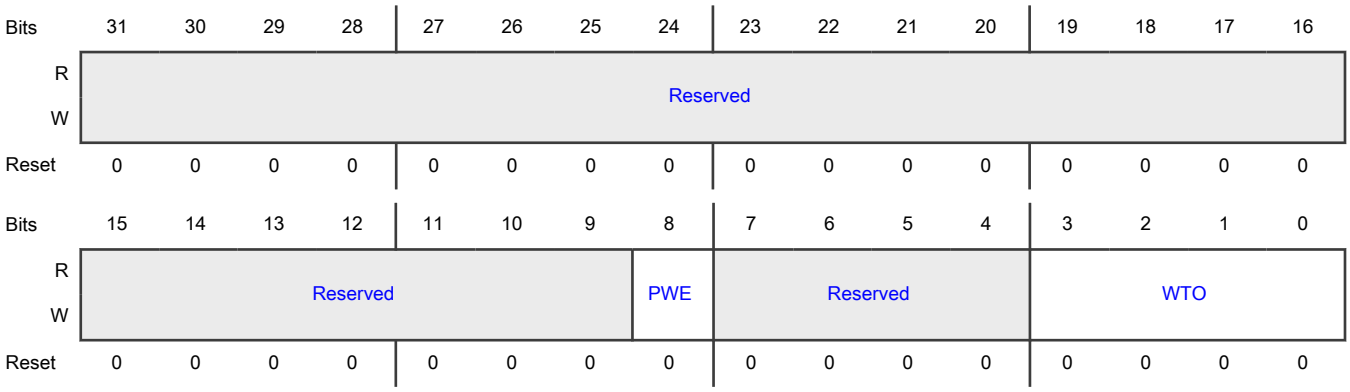
34.8.1.5 Watchdog Timeout (MAC_WATCHDOG_TIMEOUT)

The Watchdog Timeout register controls the watchdog timeout for received packets.

Offset

Register	Offset
MAC_WATCHDOG_TIMEOUT	Ch

Diagram



Fields

Field	Description
31-9 —	Reserved
8 PWE	Programmable Watchdog Enable When this bit is set and the WD bit of the MAC_CONFIGURATION register is reset, the WTO field is used as watchdog timeout for a received packet. When this bit is cleared, the watchdog timeout for a received packet is controlled by setting of WD and JE bits in MAC_CONFIGURATION register. 0 - Programmable Watchdog is disabled 1 - Programmable Watchdog is enabled
7-4 —	Reserved
3-0 WTO	Watchdog Timeout When the PWE bit is set and the WD bit of the MAC_CONFIGURATION register is reset, this field is used as watchdog timeout for a received packet. If the length of a received packet exceeds the value of this field, such packet is terminated and declared as an error packet. Note: When the PWE bit is set, the value in this field should be more than 1,522 (0x05F2). Otherwise, the IEEE 802.3-specified valid tagged packets are declared as error packets and then dropped. 0000 - 2 KB 0001 - 3 KB 0010 - 4 KB

34.8.1.6 MAC Hash Table Register 0 (MAC_HASH_TABLE_REG0)

The Hash Table Register 0 contains the first 32 bits of the hash table, when the width of the hash table is 128 or 256 bits.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Description
31-0 HT31T0	MAC Hash Table First 32 Bits This field contains the first 32 Bits [31:0] of the Hash table.

34.8.1.7 MAC Hash Table Register 1 (MAC_HASH_TABLE_REG1)

The Hash Table Register 1 contains the second 32 bits of the hash table.

The Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming packet is passed through the CRC logic and the upper six (seven in 128-bit Hash or eight in 256-bit Hash) bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 6'b100000 (in 64-bit Hash) selects Bit 0 of the Hash Table Register 1, a value of 7b'1110000 (in 128-bit Hash) selects Bit 16 of the Hash Table Register 3 and a value of 8b'10111111 (in 256-bit Hash) selects Bit 31 of the Hash Table Register 5.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).

- Perform bitwise reversal for the value obtained in Step 1.

- Take the upper 6 (or 7 or 8) bits from the value obtained in Step 2.

If the corresponding bit value of the register is 1'b1, the packet is accepted. Otherwise, it is rejected. If the PM bit is set in MAC_Packet_Filter, all multicast packets are accepted regardless of the multicast hash values.

If the Hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written.

If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Description
31 EIVLRXS	Enable Inner VLAN Tag in Rx Status When this bit is set, the MAC provides the inner VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the inner VLAN Tag in Rx status. 0 - Inner VLAN Tag in Rx status is disabled 1 - Inner VLAN Tag in Rx status is enabled
30 —	Reserved
29-28 EIVLS	Enable Inner VLAN Tag Stripping on Receive This field indicates the stripping operation on inner VLAN Tag in received packet. 00 - Do not strip 01 - Strip if VLAN filter passes 10 - Strip if VLAN filter fails 11 - Always strip
27 ERIVLT	ERIVLT 0 - Inner VLAN tag is disabled 1 - Inner VLAN tag is enabled
26 EDVLP	Enable Double VLAN Processing When this bit is set, the MAC enables processing of up to two VLAN Tags on Tx and Rx (if present). When this bit is reset, the MAC enables processing of up to one VLAN Tag on Tx and Rx (if present). 0 - Double VLAN Processing is disabled 1 - Double VLAN Processing is enabled
25 VTHM	VLAN Tag Hash Table Match Enable When this bit is set, the most significant four bits of CRC of VLAN Tag (ones-complement of most significant four bits of CRC of VLAN Tag when ETV bit is reset) are used to index the content of the MAC_VLAN_Hash_Table register. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the packet matched the VLAN hash table. When the ETV bit is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison. When the ETV bit is reset, the ones-complement of the CRC of the 16-bit VLAN tag is used for comparison. When this bit is reset, the VLAN Hash Match operation is not performed. 0 - VLAN Tag Hash Table Match is disabled 1 - VLAN Tag Hash Table Match is enabled
24 EVLRXS	Enable VLAN Tag in Rx status When this bit is set, MAC provides the outer VLAN Tag in the Rx status. When this bit is reset, the MAC does not provide the outer VLAN Tag in Rx status.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	0 - VLAN Tag in Rx status is disabled 1 - VLAN Tag in Rx status is enabled
23 —	Reserved
22-21 EVLS	Enable VLAN Tag Stripping on Receive This field indicates the stripping operation on the outer VLAN Tag in received packet. 00 - Do not strip 01 - Strip if VLAN filter passes 10 - Strip if VLAN filter fails 11 - Always strip
20-19 —	Reserved
18 ESVL	Enable S-VLAN When this bit is set, the MAC transmitter and receiver consider the S-VLAN packets (Type = 0x88A8) as valid VLAN tagged packets. 0 - S-VLAN is disabled 1 - S-VLAN is enabled
17 VTIM	VLAN Tag Inverse Match Enable When this bit is set, this bit enables the VLAN Tag inverse matching. The packets without matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The packets with matched VLAN Tag are marked as matched. 0 - VLAN Tag Inverse Match is disabled 1 - VLAN Tag Inverse Match is enabled
16-7 —	Reserved
6-2 OFS	Offset This field holds the address offset of the MAC VLAN Tag Filter Register which the application is trying to access. The width of the field depends on the number of MAC VLAN Tag Registers enabled.
1 CT	Command Type This bit indicates if the current register access is a read or a write. When set, it indicate a read operation. When reset, it indicates a write operation. 0 - Write operation 1 - Read operation

Table continues on the next page...

Table continued from the previous page...

Field	Description
0 OB	Operation Busy This bit is set along with a read or write command for initiating the indirect access to per VLAN Tag Filter register. This bit is reset when the read or write command to per VLAN Tag Filter indirect access register is complete. The next indirect register access can be initiated only after this bit is reset. During a write operation, the bit is reset only after the data has been written into the Per VLAN Tag register. During a read operation, the data should be read from the VLAN_TAG_DATA register only after this bit is reset. 0 - Operation Busy is disabled 1 - Operation Busy is enabled

34.8.1.9 MAC VLAN Tag Data (MAC_VLAN_TAG_DATA)

This register holds the read/write data for Indirect Access of the Per VLAN Tag registers. During the read access, this field contains valid read data only after the OB bit is reset.

During the write access, this field should be valid prior to setting the OB bit in the MAC_VLAN_Tag_Ctrl Register.

Offset

Register	Offset
MAC_VLAN_TAG_DATA	54h

Fields

Field	Description
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
27-25 DMACHN	DMA Channel Number The DMA Channel number to which the VLAN Tagged Frame is to be routed if it passes this VLAN Tag Filter is programmed in this field. If the Routing based on VLAN Tag Filter is not necessary, this field need not be programmed.
24 DMACHEN	DMA Channel Number Enable This bit is the Enable for the DMA Channel Number value programmed in the field DMACH. When this bit is reset, the Routing does not occur based on VLAN Filter result. The frame is routed based on DA Based DMA Channel Routing. 0 - DMA Channel Number is disabled 1 - DMA Channel Number is enabled
23-21 —	Reserved
20 ERIVLT	Enable Inner VLAN Tag Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit and the EDVLP field are set, the MAC receiver enables operation on the inner VLAN Tag (if present). When this bit is reset, the MAC receiver enables operation on the outer VLAN Tag (if present). 0 - Inner VLAN tag comparison is disabled 1 - Inner VLAN tag comparison is enabled
19 ERSVLM	Enable S-VLAN Match for received Frames This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC receiver enables filtering or matching for S-VLAN (Type = 0x88A8) packets. When this bit is reset, the MAC receiver enables filtering or matching for C-VLAN (Type = 0x8100) packets. 0 - Receive S-VLAN Match is disabled 1 - Receive S-VLAN Match is enabled
18 DOVLTC	Disable VLAN Type Comparison This bit is valid only when VLAN Tag Enable of the Filter is set. When this bit is set, the MAC does not check whether the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit is of type S-VLAN or C-VLAN. When this bit is reset, the MAC filters or matches the VLAN Tag specified by the Enable Inner VLAN Tag Comparison bit only when VLAN Tag type is similar to the one specified by the Enable S-VLAN Match for received Frames bit. 0 - VLAN type comparison is enabled 1 - VLAN type comparison is disabled

Table continues on the next page...

Table continued from the previous page...

Field	Description
17 ETV	12bits or 16bits VLAN comparison This bit is valid only when VEN of the Filter is set. When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged packet. 0 - 16 bit VLAN comparison 1 - 12 bit VLAN comparison
16 VEN	VLAN Tag Enable This bit is used to enable or disable the VLAN Tag. When this bit is set, the MAC compares the VLAN Tag of received packet with the VLAN Tag ID. When this bit is reset, no comparison is performed irrespective of the programming of the other fields. 0 - VLAN Tag is disabled 1 - VLAN Tag is enabled
15-0 VID	VLAN Tag ID This field holds the VLAN Tag value which is used by the MAC for perfect comparison. It is valid when VLAN Tag Enable is set.

34.8.1.10 MAC VLAN Hash Table (MAC_VLAN_HASH_TABLE)

When VTHM bit of the MAC_VLAN_TAG register is set, the 16-bit VLAN Hash Table register is used for group address filtering based on the VLAN tag. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on the ETV bit of MAC_VLAN_TAG Register) in the incoming packet is passed through the CRC logic. When ETV bit of MAC_VLAN_TAG register is set, the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. When ETV bit of MAC_VLAN_TAG register is reset, the ones-complement of upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, when ETV bit is set a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table, whereas when ETV bit is reset a hash value of 4b'1000 selects Bit 7 of the VLAN Hash table.

The hash value of the destination address is calculated in the following way:

- Calculate the 32-bit CRC for the VLAN tag or ID (For steps to calculate CRC32, see Section 3.2.8 of IEEE 802.3).

- Perform bitwise reversal for the value obtained in step 1.

- Take the upper four bits from the value obtained in step 2.

If the VLAN hash Table register is configured to be double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written.

- If double-synchronization is enabled, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Fields

Field	Description
31 BUSY	Busy This bit indicates the status of the read/write operation of indirect access to the queue/channel specific VLAN inclusion register. For write operation write to a register is complete when this bit is reset. For read operation the read data is valid when the bit is reset. The application must make sure that this bit is reset before attempting subsequent access to this register. 0 - Busy status not detected 1 - Busy status detected
30 RDWR	Read write control This bit controls the read or write operation for indirectly accessing the queue/channel specific VLAN Inclusion register. When set indicates write operation and when reset indicates read operation. This does not have any effect when CBTI is reset. 0 - Read operation of indirect access 1 - Write operation of indirect access
29-27 —	Reserved
26-24 ADDR	Address This field selects one of the queue/channel specific VLAN Inclusion register for read/write access. This does not have any effect when CBTI is reset.
23-22 —	Reserved
21	Channel based tag insertion

Table continues on the next page...

Table continued from the previous page...

Field	Description
CBTI	When this bit is set, outer VLAN tag is inserted for every packets transmitted by the MAC. The tag value is taken from the queue/channel specific VLAN tag register. The VLTI, VLP, VLC, and VLT fields of this register are ignored when this bit is set. When this bit is set, a write operation to byte 3 of this register initiates the read/write access to the indirect register. When reset, outer VLAN operation is based on the setting of VLTI, VLP, VLC and VLT fields of this register. 0 - Channel based tag insertion is disabled 1 - Channel based tag insertion is enabled
20 VLTI	VLAN Tag Input When this bit is set, it indicates that the VLAN tag to be inserted or replaced in Tx packet should be taken from: - The Tx descriptor 0 - VLAN Tag Input is disabled 1 - VLAN Tag Input is enabled
19 CSVL	C-VLAN or S-VLAN When this bit is set, S-VLAN type (0x88A8) is inserted or replaced in the 13th and 14th bytes of transmitted packets. When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0 - C-VLAN type (0x8100) is inserted or replaced 1 - S-VLAN type (0x88A8) is inserted or replaced
18 VLP	VLAN Priority Control When this bit is set, the control bits[17:16] are used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and bits[17:16] are ignored. 0 - VLAN Priority Control is disabled 1 - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 13 and 14) and VLAN tag (bytes 15 and 16) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion The MAC inserts VLT in bytes 15 and 16 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 13 and 14. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The MAC replaces VLT in bytes 15 and 16 of all VLAN-type transmitted packets (Bytes 13 and 14 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00 - No VLAN tag deletion, insertion, or replacement 01 - VLAN tag deletion 10 - VLAN tag insertion 11 - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

34.8.1.12 MAC Inner VLAN Tag Inclusion or Replacement (MAC_INNER_VLAN_INCL)

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet.

The Inner VLAN Tag Inclusion or Replacement register contains the inner VLAN tag to be inserted or replaced in the Transmit packet. It also contains the inner VLAN tag insertion controls.

When this bit is reset, C-VLAN type (0x8100) is inserted or replaced in the 13th and 14th bytes of transmitted packets. 0 - C-VLAN type (0x8100) is inserted 1 - S-VLAN type (0x88A8) is inserted
18 VLP	VLAN Priority Control When this bit is set, the VLC field is used for VLAN deletion, insertion, or replacement. When this bit is reset, the mti_vlan_ctrl_i control input is used and the VLC field is ignored. 0 - VLAN Priority Control is disabled 1 - VLAN Priority Control is enabled
17-16 VLC	VLAN Tag Control in Transmit Packets - 2'b00: No VLAN tag deletion, insertion, or replacement - 2'b01: VLAN tag deletion The MAC removes the VLAN type (bytes 17 and 18) and VLAN tag (bytes 19 and 20) of all transmitted packets with VLAN tags. - 2'b10: VLAN tag insertion

Table continues on the next page...

Table continued from the previous page...

Field	Description
	The MAC inserts VLT in bytes 19 and 20 of the packet after inserting the Type value (0x8100 or 0x88a8) in bytes 17 and 18. This operation is performed on all transmitted packets, irrespective of whether they already have a VLAN tag. - 2'b11: VLAN tag replacement The MAC replaces VLT in bytes 19 and 20 of all VLAN-type transmitted packets (Bytes 17 and 18 are 0x8100 or 0x88a8). Note: Changes to this field take effect only on the start of a packet. If you write this register field when a packet is being transmitted, only the subsequent packet can use the updated value, that is, the current packet does not use the updated value. 00 - No VLAN tag deletion, insertion, or replacement 01 - VLAN tag deletion 10 - VLAN tag insertion 11 - VLAN tag replacement
15-0 VLT	VLAN Tag for Transmit Packets This field contains the value of the VLAN tag to be inserted or replaced. The value must only be changed when the transmit lines are inactive or during the initialization phase. Bits[15:13] are the User Priority field, Bit 12 is the CFI/DEI field, and Bits[11:0] are the VID field in the VLAN tag. The following list describes the bits of this field: - Bits[15:13]: User Priority - Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) - Bits[11:0]: VLAN Identifier (VID) field of VLAN tag

34.8.1.13 MAC Q0 Tx Flow Control (MAC_Q0_TX_FLOW_CTRL)

The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC.

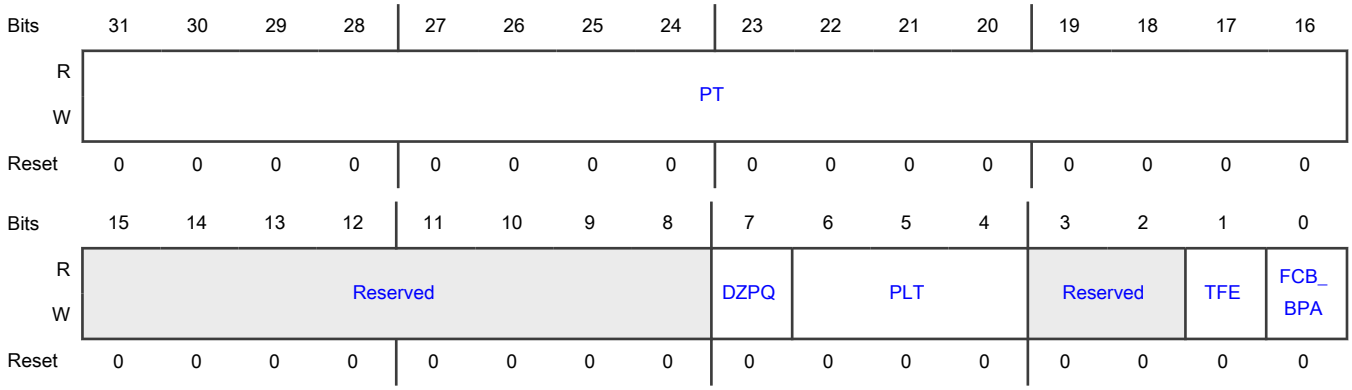
The Flow Control register controls the generation and reception of the Control (Pause Command) packets by the Flow control module of the MAC. A Write to a register with the Busy bit set to 1 triggers the Flow Control block to generate a Pause packet. The fields of the control packet are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control packet. The Busy bit remains set until the control packet is transferred onto the cable. The application must make sure that the Busy bit is cleared before writing to the register.

When the PFCE bit in the MAC_Q0_RX_FLOW_CTRL register is enabled, this register controls the generation of Priority Flow Control (PFC) frames with priorities mapped according to PSRQ0 in the MAC_Q0_RXQ_CTRL2 register.

Offset

Register	Offset
MAC_Q0_TX_FLOW_CTRL	70h

Diagram



Fields

Field	Description
31-16 PT	Pause Time This field holds the value to be used in the Pause Time field in the Tx control packet. If the Pause Time bits are configured to be double-synchronized to the (G)MII clock domain, consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.
15-8 —	Reserved
7 DZPQ	Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the zero-quanta Pause packets on de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i or mti_flowctrl_i). When this bit is reset, normal operation with automatic zero-quanta Pause packet generation is enabled. 0 - Zero-Quanta Pause packet generation is enabled 1 - Zero-Quanta Pause packet generation is disabled
6-4 PLT	Pause Low Threshold This field configures the threshold of the Pause timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of the Pause packet. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot times), and PLT = 001, a second Pause packet is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256-28) slot times after the first Pause packet is transmitted. The following list provides the threshold values for different values. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII interface. This (approximate) computation is based on the packet size (64, 1518, 2000, 9018, 16384, or 32768) + 2 Pause Packet Size + IPG in Slot Times. 000 - Pause Time minus 4 Slot Times (PT -4 slot times) 001 - Pause Time minus 28 Slot Times (PT -28 slot times)

Table continues on the next page...

Table continued from the previous page...

Field	Description
	010 - Pause Time minus 36 Slot Times (PT -36 slot times) 011 - Pause Time minus 144 Slot Times (PT -144 slot times) 100 - Pause Time minus 256 Slot Times (PT -256 slot times) 101 - Pause Time minus 512 Slot Times (PT -512 slot times) 110 - Reserved
3-2 —	Reserved
1 TFE	Transmit Flow Control Enable Full-Duplex Mode: In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to Tx Pause packets. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause packets. Half-Duplex Mode: In the half-duplex mode, when this bit is set, the MAC enables the backpressure operation. When this bit is reset, the backpressure feature is disabled. 0 - Transmit Flow Control is disabled 1 - Transmit Flow Control is enabled
0 FCB_BPA	Flow Control Busy or Backpressure Activate This bit initiates a Pause packet in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. Full-Duplex Mode: In the full-duplex mode, this bit should be read as 1'b0 before writing to this register. To initiate a Pause packet, the application must set this bit to 1'b1. During Control packet transfer, this bit continues to be set to indicate that a packet transmission is in progress. When Pause packet transmission is complete, the MAC resets this bit to 1'b0. You should not write to this register until this bit is cleared. Half-Duplex Mode: When this bit is set (and TFE bit is set) in the half-duplex mode, the MAC asserts the backpressure. During backpressure, when the MAC receives a new packet, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Flow Control Busy or Backpressure Activate is disabled 1 - Flow Control Busy or Backpressure Activate is enabled

34.8.1.14 MAC Q1 Tx Flow Control (MAC_Q1_TX_FLOW_CTRL)

This register controls the generation of PFC Control packets of priorities mapped as per the PSRQi field in the MAC_Q1_RXQ_CTRL2/MAC_Q1_RXQ_CTRL3 registers.

Offset

Register	Offset

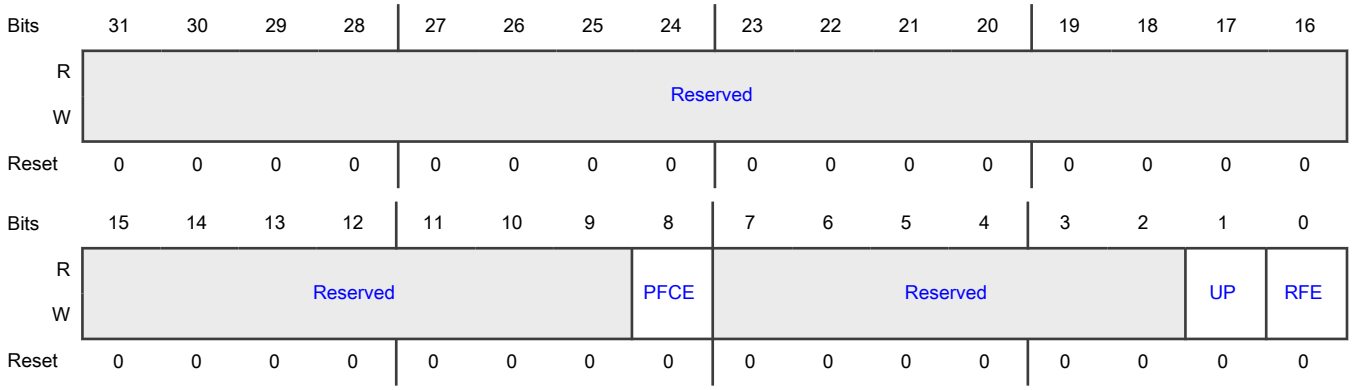
MAC_RX_FLOW_CTRL	90h

Diagram



Fields

Field	Description
31-9 —	Reserved
8 PFCE	Priority Based Flow Control Enable When this bit is set, it enables generation and reception of priority-based flow control (PFC) packets. When this bit is reset, it enables generation and reception of 802.3x Pause control packets. 0 - Priority Based Flow Control is disabled 1 - Priority Based Flow Control is enabled
7-2 —	Reserved
1 UP	Unicast Pause Packet Detect A pause packet is processed when it has the unique multicast address specified in the IEEE 802.3. When this bit is set, the MAC can also detect Pause packets with unicast address of the station. This unicast address should be as specified in MAC_ADDRESS0_HIGH and MAC_ADDRESS0_LOW. When this bit is reset, the MAC only detects Pause packets with unique multicast address. Note: The MAC does not process a Pause packet if the multicast address is different from the unique multicast address. This is also applicable to the received PFC packet when the Priority Flow Control (PFC) is enabled. The unique multicast address (0x01_80_C2_00_00_01) is as specified in IEEE 802.1 Qbb-2011. 0 - Unicast Pause Packet Detect disabled 1 - Unicast Pause Packet Detect enabled
0 RFE	Receive Flow Control Enable When this bit is set and the MAC is operating in full-duplex mode, the MAC decodes the received Pause packet and disables its transmitter for a specified (Pause) time. When this bit is reset or the MAC is operating in half-duplex mode, the decode function of the Pause packet is disabled. When PFC is enabled, flow control is enabled for PFC packets. The MAC decodes the received PFC packet and disables the Transmit queue, with matching priorities, for a duration of received Pause time.

Field	Description
	11 - Reserved
3-2 RXQ1EN	Receive Queue 1 Enable This field is similar to the RXQ0EN field. 00 - Queue not enabled 01 - Queue enabled for AV 10 - Queue enabled for DCB/Generic 11 - Reserved
1-0 RXQ0EN	Receive Queue 0 Enable This field indicates whether Rx Queue 0 is enabled for AV or DCB. 00 - Queue not enabled 01 - Queue enabled for AV 10 - Queue enabled for DCB/Generic 11 - Reserved

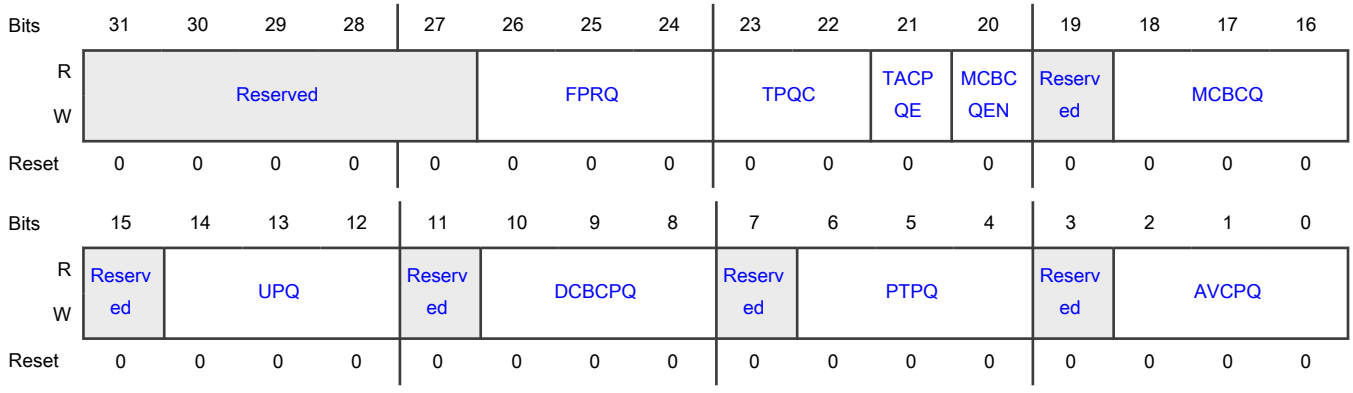
34.8.1.23 Receive Queue Control 1 (MAC_RXQ_CTRL1)

The Receive Queue Control 1 register controls the routing of multicast, broadcast, AV, DCB, and untagged packets to the Rx queues.

Offset

Register	Offset
MAC_RXQ_CTRL1	A4h

Diagram



Fields

Field	Description
31-27 —	Reserved
26-24 FPRQ	Frame Preemption Residue Queue This field holds the Rx queue number to which the residual preemption frames must be forwarded. Preemption frames that are tagged and pass the SA/DA/VLAN filtering are routed based on PSRQ and all other frames are treated as residual frames and is routed to the queue number mentioned in this field. The Queue-0 is used as a default queue for express frames, so this field cannot be programmed to a value 0.
23-22 TPQC	Tagged PTP over Ethernet Packets Queuing Control. This field controls the routing of the VLAN Tagged PTPoE packets. If DWC_EQOS_AV_ENABLE is selected in the configuration, the following programmable options are allowed. - 2'b00: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for only non-AV enabled Rx Queues). - 2'b01: VLAN Tagged PTPoE packets are routed to Rx Queue specified by PTPQ field (That Rx Queue can be enabled for AV or non-AV traffic). - 2'b10: VLAN Tagged PTPoE packets are routed to only AV enabled Rx Queues based on PSRQ. - 2'b11: Reserved If DWC_EQOS_AV_ENABLE is not selected in the configuration, the following programmable options are allowed. - 1'b0: VLAN Tagged PTPoE packets are routed as generic VLAN Tagged packet (based on PSRQ for DCB/Generic enabled Rx Queues). - 1'b1: VLAN Tagged PTPoE packets are routed to Rx Queues specified by PTPQ field.
21 TACPQE	Tagged AV Control Packets Queuing Enable. When set, the MAC routes the received Tagged AV Control packets to the Rx queue specified by AVCPQ field. When reset, the MAC routes the received Tagged AV Control packets based on the tag priority matching the PSRQ fields in MAC_RXQ_CTRL2 and MAC_RXQ_CTRL3 registers. 0 - Tagged AV Control Packets Queuing is disabled 1 - Tagged AV Control Packets Queuing is enabled
20 MCBCQEN	Multicast and Broadcast Queue Enable This bit specifies that Multicast or Broadcast packets routing to the Rx Queue is enabled and the Multicast or Broadcast packets must be routed to Rx Queue specified in MCBCQ field. 0 - Multicast and Broadcast Queue is disabled 1 - Multicast and Broadcast Queue is enabled
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
18-16 MCBCQ	Multicast and Broadcast Queue This field specifies the Rx Queue onto which Multicast or Broadcast Packets are routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Multicast or Broadcast Packets. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
15 —	Reserved
14-12 UPQ	Untagged Packet Queue This field indicates the Rx Queue to which Untagged Packets are to be routed. Any Rx Queue enabled for Generic/DCB/AV traffic can be used to route the Untagged Packets. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
11 —	Reserved
10-8 DCBCPQ	DCB Control Packets Queue This field specifies the Rx queue on which the received DCB control packets are routed. The DCB data packets are routed based on the PSRQ field of the Transmit Flow Control Register of corresponding queue. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2

Table continues on the next page...

Table continued from the previous page...

Field	Description
	011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
7 —	Reserved
6-4 PTPQ	PTP Packets Queue This field specifies the Rx queue on which the PTP packets sent over the Ethernet payload (not over IPv4 or IPv6) are routed. When the AV8021ASMEN bit of MAC_TIMESTAMP_CONTROL register is set, only untagged PTP over Ethernet packets are routed on an Rx Queue. If the bit is not set, then based on programming of TPQC field, both tagged and untagged PTPoE packets can be routed to this Rx Queue. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved 110 - Reserved 111 - Reserved
3 —	Reserved
2-0 AVCPQ	AV Untagged Control Packets Queue This field specifies the Receive queue on which the received AV tagged and untagged control packets are routed. The AV tagged (when TACPQE bit is set) and untagged control packets are routed to Receive queue specified by this field. 000 - Receive Queue 0 001 - Receive Queue 1 010 - Receive Queue 2 011 - Receive Queue 3 100 - Receive Queue 4 101 - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
	110 - Reserved 111 - Reserved

34.8.1.24 Receive Queue Control 2 (MAC_RXQ_CTRL2)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to the RxQueues 0 to 3.

Offset

Register	Offset
MAC_RXQ_CTRL2	A8h

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Description
31-24 PSRQ3	Priorities Selected in the Receive Queue 3 This field decides the priorities assigned to Rx Queue 3. All packets with priorities that match the values set in this field are routed to Rx Queue 3. For example, if PSRQ3[6, 3] are set, packets with USP field equal to 3 or 6 are routed to Rx Queue 3. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 3 crosses the flow control threshold settings.
23-16 PSRQ2	Priorities Selected in the Receive Queue 2 This field decides the priorities assigned to Rx Queue 2. All packets with priorities that match the values set in this field are routed to Rx Queue 2.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	For example, if PSRQ2[1, 0] are set, packets with USP field equal to 1 or 0 are routed to Rx Queue 2. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 2 crosses the flow control threshold settings.
15-8 PSRQ1	Priorities Selected in the Receive Queue 1 This field decides the priorities assigned to Rx Queue 1. All packets with priorities that match the values set in this field are routed to Rx Queue 1. For example, if PSRQ1[4] is set, packets with USP field equal to 4 are routed to Rx Queue 1. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 1 crosses the flow control threshold settings.
7-0 PSRQ0	Priorities Selected in the Receive Queue 0 This field decides the priorities assigned to Rx Queue 0. All packets with priorities that match the values set in this field are routed to Rx Queue 0. For example, if PSRQ0[5] is set, packets with USP field equal to 5 are routed to Rx Queue 0. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. this field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 0 crosses the flow control threshold settings.

34.8.1.25 Receive Queue Control 3 (MAC_RXQ_CTRL3)

This register controls the routing of tagged packets based on the USP (user Priority) field of the received packets to Rx Queue 4.

Offset

Register	Offset
MAC_RXQ_CTRL3	ACh

31-24 —	Reserved
23-16 —	Reserved
15-8 —	Reserved
7-0 PSRQ4	Priorities Selected in the Receive Queue 4 This field decides the priorities assigned to Rx Queue 4. All packets with priorities that match the values set in this field are routed to Rx Queue 4. For example, if PSRQ4[7:4] is set, packets with USP field equal to 7, 6, 5, or 4 are routed to Rx Queue 4. The software must ensure that the content of this field is mutually exclusive to the PSRQ fields for other queues, that is, the same priority is not mapped to multiple Rx queues. This field also determines the priorities to be included in the PFC packet sent to remote station when Rx Queue 4 crosses the flow control threshold settings.

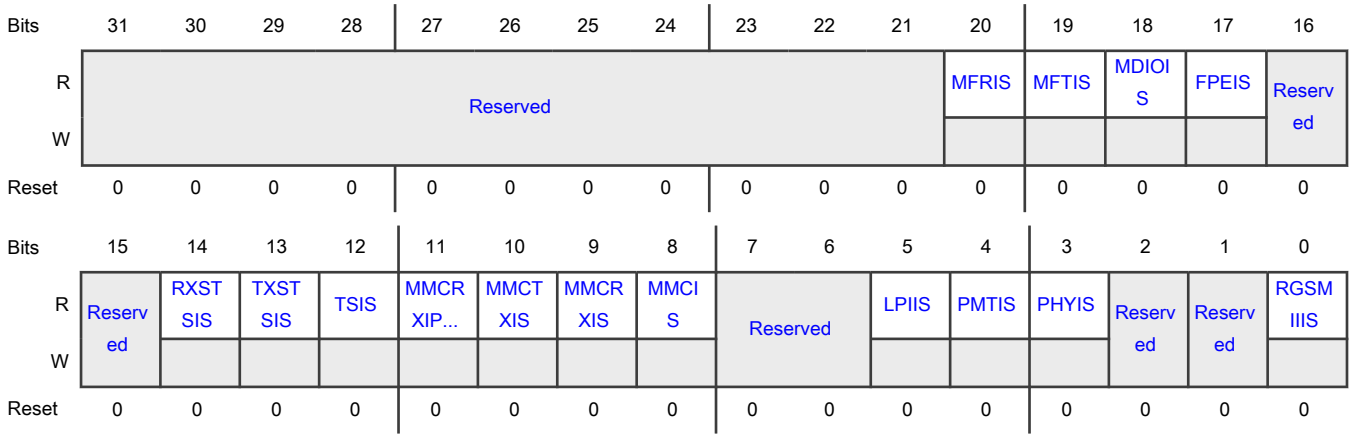
34.8.1.26 Interrupt Status (MAC_INTERRUPT_STATUS)

The Interrupt Status register contains the status of interrupts.

Offset

Register	Offset
MAC_INTERRUPT_STATUS	B0h

Diagram



Fields

Field	Description
31-21 —	Reserved
20 MFRIS	MMC FPE Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0 - MMC FPE Receive Interrupt status not active 1 - MMC FPE Receive Interrupt status active
19 MFTIS	MMC FPE Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC FPE Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option along with FPE support. 0 - MMC FPE Transmit Interrupt status not active 1 - MMC FPE Transmit Interrupt status active
18 MDIOIS	MDIO Interrupt Status This bit indicates an interrupt event after the completion of MDIO operation. To reset this bit, the application has to read this bit/Write 1 to this bit when RCWE bit of CSR_SW_CTRL register is set. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - MDIO Interrupt status not active 1 - MDIO Interrupt status active
17 FPEIS	Frame Preemption Interrupt Status

Table continues on the next page...

Table continued from the previous page...

Field	Description
	This bit indicates an interrupt event during the operation of Frame Preemption (Bits[19:16] of MAC_FPE_CTRL_STS register is set). To reset this bit, the application must clear the event in MAC_FPE_CTRL_STS that has caused the Interrupt. 0 - Frame Preemption Interrupt status not active 1 - Frame Preemption Interrupt status active
16 —	Reserved
15 —	Reserved
14 RXSTSIS	Receive Status Interrupt This bit indicates the status of received packets. This bit is set when the RWT bit is set in the MAC_RX_TX_STATUS register. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0 - Receive Interrupt status not active 1 - Receive Interrupt status active
13 TXSTSIS	Transmit Status Interrupt This bit indicates the status of transmitted packets. This bit is set when any of the following bits is set in the MAC_RX_TX_STATUS register: - Excessive Collision (EXCOL) - Late Collision (LCOL) - Excessive Deferral (EXDEF) - Loss of Carrier (LCARR) - No Carrier (NCARR) - Jabber Timeout (TJT) This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_RX_TX_STATUS register. 0 - Transmit Interrupt status not active 1 - Transmit Interrupt status active
12 TSIS	Timestamp Interrupt Status If the Timestamp feature is enabled, this bit is set when any of the following conditions is true: - The system time value is equal to or exceeds the value specified in the Target Time High and Low registers. - There is an overflow in the Seconds register. - The Target Time Error occurred, that is, programmed target time already elapsed.

Table continues on the next page...

Table continued from the previous page...

Field	Description
	If the Auxiliary Snapshot feature is enabled, this bit is set when the auxiliary snapshot trigger is asserted. In configurations other than EQOS_CORE, when drop transmit status is enabled in MTL, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TXTIMESTAMP_STATUS_SECONDS registers. When PTP offload feature is enabled, this bit is set when the captured transmit timestamp is updated in the MAC_TX_TIMESTAMP_STATUS_NANOSECONDS and MAC_TX_TIMESTAMP_STATUS_SECONDS registers, for PTO generated Delay Request and Pdelay request packets. This bit is cleared when the corresponding interrupt source bit is read (or corresponding interrupt source bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set) in the MAC_TIMESTAMP_STATUS register. 0 - Timestamp Interrupt status not active 1 - Timestamp Interrupt status active
11 MMCRXIPIS	MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) and Enable Receive TCP/IP Checksum Check options. 0 - MMC Receive Checksum Offload Interrupt status not active 1 - MMC Receive Checksum Offload Interrupt status active
10 MMCTXIS	MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Transmit Interrupt status not active 1 - MMC Transmit Interrupt status active
9 MMCRXIS	MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all bits in this interrupt register are cleared. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Receive Interrupt status not active 1 - MMC Receive Interrupt status active
8 MMCIS	MMC Interrupt Status This bit is set high when Bit 11, Bit 10, or Bit 9 is set high. This bit is cleared only when all these bits are low. This bit is valid only when you select the Enable MAC Management Counters (MMC) option. 0 - MMC Interrupt status not active 1 - MMC Interrupt status active

Table continues on the next page...

Table continued from the previous page...

Field	Description
7-6 —	Reserved
5 LPIIS	LPI Interrupt Status When the Energy Efficient Ethernet feature is enabled, this bit is set for any LPI state entry or exit in the MAC Transmitter or Receiver. This bit is cleared when the corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is read (or corresponding interrupt source bit of MAC_LPI_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). 0 - LPI Interrupt status not active 1 - LPI Interrupt status active
4 PMTIS	PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN packet is received in the power-down mode (RWKPRCVD and MGKPRCVD bits in MAC_PMT_CONTROL_STATUS register). This bit is cleared when corresponding interrupt source bit are cleared because of a Read operation to the MAC_PMT_CONTROL_STATUS register (or corresponding interrupt source bit of MAC_PMT_CONTROL_STATUS register is written to 1 when RCWE bit of CSR_SW_CTRL register is set). This bit is valid only when you select the Enable Power Management option. 0 - PMT Interrupt status not active 1 - PMT Interrupt status active
3 PHYIS	PHY Interrupt This bit is set when rising edge is detected on the phy_intr_i input. This bit is cleared when this register is read (or this bit is written to 1 when RCWE bit of CSR_SW_CTRL register is set). 0 - PHY Interrupt not detected 1 - PHY Interrupt detected
2 —	Reserved
1 —	Reserved
0 RGSMIIIS	RGMII or SMII Interrupt Status This bit is set because of any change in value of the Link Status of RGMII or SMII interface (LNKSTS bit in MAC_PHYIF_CONTROL_STATUS register). This bit is cleared when the PHYIF_CONTROL_STATUS register is read (or LNKSTS bit of MAC_PHYIF_CONTROL_STATUS register is written to 1 when RCWE bit of MAC_CSR_SW_CTRL register is set). This bit is valid only when you select the optional RGMII or SMII PHY interface. 0 - RGMII or SMII Interrupt Status is not active

Table continues on the next page...

Table continued from the previous page...

Field	Description
	1 - RGMII or SMII Interrupt Status is active

34.8.1.27 Interrupt Enable (MAC_INTERRUPT_ENABLE)

The Interrupt Enable register contains the masks for generating the interrupts.

Offset

Register	Offset
MAC_INTERRUPT_ENABLE	B4h

8 RWT	Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. Receive Watchdog Timeout This bit is set when a packet with length greater than 2,048 bytes is received (10, 240 bytes when Jumbo Packet mode is enabled) and the WD bit is reset in the MAC_CONFIGURATION register. This

Table continues on the next page...

Table continued from the previous page...

Field	Description
	bit is set when a packet with length greater than 16,383 bytes is received and the WD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No receive watchdog timeout 1 - Receive watchdog timed out
7-6 —	Reserved
5 EXCOL	Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. Excessive Collisions When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the transmission aborted after 16 successive collisions while attempting to transmit the current packet. If the DR bit is set in the CONFIGURATION register, this bit is set after the first collision and the packet transmission is aborted. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No collision 1 - Excessive collision is sensed
4 LCOL	Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (512 bytes including Preamble and Carrier Extension in GMII mode). Late Collision When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the packet transmission aborted because a collision occurred after the collision window (512 bytes including Preamble and Carrier Extension in GMII mode). This bit is not valid if the Underflow error occurs. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No collision 1 - Late collision is sensed
3 EXDEF	Excessive Deferral When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Excessive Deferral

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When the DTXSTS bit is set in the MAC_OPERATION_MODE register and the DC bit is set in the MAC_CONFIGURATION register, this bit indicates that the transmission ended because of excessive deferral of over 24,288 bit times (155,680 in 1000/2500 Mbps mode or when Jumbo packet is enabled). Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Excessive deferral 1 - Excessive deferral
2 LCARR	Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. Loss of Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the loss of carrier occurred during packet transmission, that is, the phy_crs_i signal was inactive for one or more transmission clock periods during packet transmission. This bit is valid only for packets transmitted without collision. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Carrier is present 1 - Loss of carrier
1 NCARR	No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. No Carrier When the DTXSTS bit is set in the MAC_OPERATION_MODE register, this bit indicates that the carrier signal from the PHY is not present at the end of preamble transmission. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Carrier is present 1 - No carrier
0 TJT	Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_CONFIGURATION register. Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired which happens when the packet size exceeds 2,048 bytes (10,240 bytes when the Jumbo packet is enabled) and JD bit is reset in the MAC_CONFIGURATION register. This bit is set when the packet size exceeds 16,383 bytes and the JD bit is set in the MAC_CONFIGURATION register. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event.

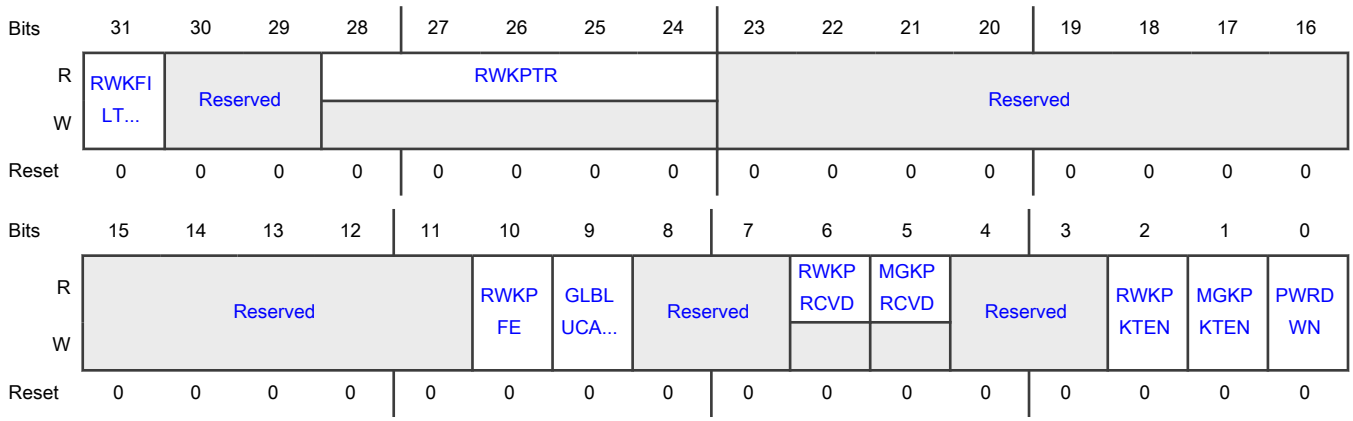
34.8.1.29 PMT Control and Status (MAC_PMT_CONTROL_STATUS)

The PMT Control and Status Register.

Offset

Register	Offset
MAC_PMT_CONTROL_STATUS	C0h

Diagram



Fields

Field	Description
31 RWKFILTRST	Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. Remote Wake-Up Packet Filter Register Pointer Reset When this bit is set, the remote wake-up packet filter register pointer is reset to 3'b000. It is automatically cleared after 1 clock cycle. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Remote Wake-Up Packet Filter Register Pointer is not Reset 1 - Remote Wake-Up Packet Filter Register Pointer is Reset
30-29	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Description
—	
28-24 RWKPTR	Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. Remote Wake-up FIFO Pointer This field gives the current value (0 to 7, 15, or 31 when 4, 8, or 16 Remote Wake-up Packet Filters are selected) of the Remote Wake-up Packet Filter register pointer. When the value of this pointer is equal to maximum for the selected number of Remote Wake-up Packet Filters, the contents of the Remote Wake-up Packet Filter Register are transferred to the clk_rx_i domain when a Write occurs to that register.
23-11 —	Reserved
10 RWKPFE	Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. Remote Wake-up Packet Forwarding Enable When this bit is set along with RWKPKTEN, the MAC receiver drops all received frames until it receives the expected Wake-up frame. All frames after that event including the received wake-up frame are forwarded to application. This bit is then self-cleared on receiving the wake-up packet. The application can also clear this bit before the expected wake-up frame is received. In such cases, the MAC reverts to the default behavior where packets received are forwarded to the application. This bit must only be set when RWKPKTEN is set high and PWRDWN is set low. The setting of this bit has no effect when PWRDWN is set high. Note: If Magic Packet Enable and Wake-Up Frame Enable are both set along with setting of this bit and Magic Packet is received prior to wake-up frame, this bit is self-cleared on receiving Magic Packet, the received Magic packet is dropped, and all frames after received Magic Packet are forwarded to application. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect. 0 - Remote Wake-up Packet Forwarding is disabled 1 - Remote Wake-up Packet Forwarding is enabled
9 GLBLUCAST	Global Unicast When this bit set, any unicast packet filtered by the MAC (DAF) address recognition is detected as a remote wake-up packet. 0 - Global unicast is disabled 1 - Global unicast is enabled
8-7 —	Reserved
6 RWKPRCVD	Remote Wake-Up Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. Remote Wake-Up Packet Received

Table continues on the next page...

Table continued from the previous page...

Field	Description
	When this bit is set, it indicates that the power management event is generated because of the reception of a remote wake-up packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - Remote wake-up packet is received 1 - Remote wake-up packet is received
5 MGKPRCVD	Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. Magic Packet Received When this bit is set, it indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared when this register is read. Access restriction applies. Clears on read (or write of 1 when RCWE bit in CSR_SW_CTRL register is set). Self-set to 1 on internal event. 0 - No Magic packet is received 1 - Magic packet is received
4-3 —	Reserved
2 RWKPKTEN	Remote Wake-Up Packet Enable When this bit is set, a power management event is generated when the MAC receives a remote wake-up packet. 0 - Remote wake-up packet is disabled 1 - Remote wake-up packet is enabled
1 MGKPKTEN	Magic Packet Enable When this bit is set, a power management event is generated when the MAC receives a magic packet. 0 - Magic Packet is disabled 1 - Magic Packet is enabled
0 PWRDWN	Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. Power Down When this bit is set, the MAC receiver drops all received packets until it receives the expected magic packet or remote wake-up packet. This bit is then self-cleared and the power-down mode is disabled. The software can clear this bit before the expected magic packet or remote wake-up packet is received. The packets received by the MAC after this bit is cleared are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Remote Wake-Up Packet Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. Access restriction applies. Setting 1 sets. Self-cleared. Setting 0 has no effect.

	0 - Power down is disabled 1 - Power down is enabled

34.8.1.30 Remote Wakeup Filter (MAC_RWK_PACKET_FILTER)

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register.

The Remote Wakeup Filter registers are implemented as 8, 16, or 32 indirect access registers (wkuppktfilter_reg#i) based on whether 4, 8, or 16 Remote Wakeup Filters are selected in the configuration and accessed by application through MAC_RWK_PACKET_FILTER register. When the Remote Wakeup Filters are to be programmed, the entire set of wkuppktfilter_reg registers must be written. The wkuppktfilter_reg register is programmed by sequentially writing the eight, sixteen or thirty-two register values in MAC_RWK_PACKET_FILTER register for wkuppktfilter_REG0, wkuppktfilter_REG1, ..., wkuppktfilter_REG31 respectively. The wkuppktfilter_reg register is read in a similar way. The MAC updates the wkuppktfilter_reg register current pointer value in RWKPTR field of MAC_PMT_CONTROL_STATUS register.

The Remote Wakeup Filters are arranged in blocks of 4 filters each and each such block have eight 32-bit wide registers, viz. wkuppktfilter_REG0-7, wkuppktfilter_reg8-15, wkuppktfilter_REG16-23 and wkuppktfilter_REG24-31. The fields of Remote Wakeup Filter are described as follows:

Filter i Byte Mask: The filter i byte mask register defines the bytes of the packet that are examined by filter i (0, 1, 2, 3, .., 15) to determine whether or not a packet is a wake-up packet.

- The MSB (31st bit) must be zero.

- Bit j[30:0] is the byte mask.

- If Bit j (byte number) of the byte mask is set, the CRC block processes the Filter i Offset + j of the incoming packet; otherwise Filter i Offset + j is ignored.

Filter i Command: The 4-bit filter i command controls the filter i operation.

- Bit 3 specifies the address type, defining the destination address type of the pattern. When the bit is set, the pattern applies to only multicast packets; when the bit is reset, the pattern applies only to unicast packet.

- Bit 2 (Inverse Mode), when set, reverses the logic of the CRC16 hash function signal, to reject a packet with matching CRC-16 value. Bit 2, along with Bit 1, allows a MAC to reject a subset of remote wake-up packets by creating filter logic such as "Pattern 1 AND NOT Pattern 2".

- Bit 1 (And_Previous) implements the Boolean logic. When set, the result of the current entry is logically ANDed with the result of the previous filter. This AND logic allows a filter pattern longer than 32 bytes by splitting the mask among two, three, or four filters. This depends on the number of filters that have the And_Previous bit set. The details are provided below:

-- The And_Previous bit setting is applicable within a set of 4 filters.

-- Setting of And_Previous bit of filter that is not enabled has no effect, that is setting And_Previous bit of lowest number filter in the set of 4 filters has no effect. For example, setting of And_Previous bit of Filter 0 has no effect.

-- If And_Previous bit is set for filter to form AND chained filter, the AND chain breaks at the point any filter is not enabled. For example: If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set) but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 1 is not enabled (bit 0 in Filter 1 command is reset), then only Filter 2 result ANDed with Filter 3 result is considered. If Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 3 And_Previous bit is set (bit 1 in Filter 3 command is set), but Filter 2 is not enabled (bit 0 in Filter 2 command is reset), then since setting of Filter 2 And_Previous bit has no effect only Filter 1 result ORed with Filter 3 result is considered.

-- If filters chained by And_Previous bit setting have complementary programming, then a frame may never pass the AND chained filter. For example, if Filter 2 And_Previous bit is set (bit 1 in Filter 2 command is set), Filter 1 Address_Type bit is set (bit 3 in Filter 1 command is set) indicating multicast detection and Filter 2 Address_Type bit is reset (bit 3 in Filter 2 command is reset) indicating unicast detection or vice versa, a remote wakeup frame does not pass the AND chained filter as a remote wakeup frame cannot be of both unicast and multicast address type.

- Bit 0 is the enable for filter i. If Bit 0 is not set, filter i is disabled.

Filter i Offset: The filter i offset register defines the offset (within the packet) from which the filter i examines the packets.

- This 8-bit pattern-offset is the offset for the filter i first byte to be examined.

- The minimum allowed offset is 12, which refers to the 13th byte of the packet.

- The offset value 0 refers to the first byte of the packet.

Filter i CRC-16: The filter i CRC-16 register contains the CRC-16 value calculated from the pattern and the byte mask programmed in the Remote Wakeup filter register.

- The 16-bit CRC calculation uses the following polynomial: G(x) = x^16 + x^15 + x^2 + 1

- Each mask, used in the hash function calculation, is compared with a 16-bit value associated with that mask. Each filter has the following:

-- 32-bit Mask: Each bit in this mask corresponds to one byte in the detected packet. If the bit is 1, the corresponding byte is taken into the CRC-16 calculation.

-- 8-bit Offset Pointer: Specifies the byte to start the CRC-16 computation. The pointer and the mask are used together to locate the bytes to be used in the CRC-16 calculations.

The structure of the RWK Filter registers is shown in "Figure 10-11 Remote Wake-Up Packet Filter Register".
