Information in this document is provided solely to enable system and software implementers to use Freescale Semiconductor products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document.

Freescale Semiconductor reserves the right to make changes without further notice to any products herein. Freescale Semiconductor makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Freescale Semiconductor assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. “Typical” parameters that may be provided in Freescale Semiconductor data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including “Typicals”, must be validated for each customer application by customer’s technical experts. Freescale Semiconductor does not convey any license under its patent rights nor the rights of others. Freescale Semiconductor products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Freescale Semiconductor product could create a situation where personal injury or death may occur. Should Buyer purchase or use Freescale Semiconductor products for any such unintended or unauthorized application, Buyer shall indemnify and hold Freescale Semiconductor and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Freescale Semiconductor was negligent regarding the design or manufacture of the part.

**Index** 645
Introduction

This reference contains a description of the ANSI library and extended libraries bundled with Main Standard Library for C.

Organization of Files

The C header files are organized alphabetically. Items within a header file are also listed in alphabetical order. Whenever possible, sample code has been included to demonstrate the use of each function.

“Overview of alloca.h” on page 25 covers the non-ANSI alloca() function for dynamic allocation from the stack.
“Overview of assert.h” on page 27 covers the ANSI C exception handling macro assert().
“Overview of conio.h” on page 29 covers the Windows console input and output routines.
“Overview of console.h” on page 41 covers Macintosh console routines.
“Overview of crtl.h” on page 49 covers Win32 console routines.
“Overview of ctype.h” on page 53 covers the ANSI character facilities.
“Overview of direct.h” on page 65 covers Win32x86 directory facilities.
“Overview of dirent.h” on page 69 covers various POSIX directory functions.
“Overview of div_t.h” on page 73 covers two arrays for math routines.
“Overview of errno.h” on page 75 covers ANSI global error variables.
“Overview of extras.h” on page 79 covers additional non standard functions included with the MSL library.
“Overview of fcntl.h” on page 117 covers non-ANSI control of files.
“Overview of fenv.h” on page 125 covers floating-point environment facilities.
“Overview of float.h” on page 139 covers ANSI floating point type limits.
“Overview of FSp_fopen.h” on page 141 contains Macintosh file opening routines.
“Overview of inttypes.h” on page 145 contains greatest-width integer routines and macros.
“Overview of io.h” on page 157, contains common Windows stream input and output routines.

“Overview of iso646.h” on page 161 contains operator symbol alternative words.

“Overview of limits.h” on page 163 covers ANSI integral type limits.

“Overview of locale.h” on page 165 covers ANSI character sets, numeric and monetary formats.

“Overview of malloc.h” on page 169 covers the alloca function for Windows.

“Overview of math.h” on page 171 covers ANSI floating point math facilities.

“Overview of Process.h” on page 239, covers Windows thread process routines.

“Overview of setjmp.h” on page 243 covers ANSI means used for saving and restoring a processor state.

“Overview of signal.h” on page 249 covers ANSI software interrupt specifications.

“Overview of SIOUX” on page 255 covers CodeWarrior™ SIOUX console emulation for Macintosh.

“Overview of stat.h” on page 269 covers non-ANSI file statistics and facilities.

“Overview of stdarg.h” on page 279 covers ANSI custom variable argument facilities.

“Overview of stddef.h” on page 287 covers the ANSI Standard Definitions.

“Overview of stdint.h” on page 289 covers the latest integer types macros.

“Overview of stdio.h” on page 297 covers ANSI standard input and output routines.

“Overview of stdlib.h” on page 403 covers common ANSI library facilities.

“Overview of string.h” on page 453 covers ANSI null terminated character array facilities.

“Overview of tgmath.h” on page 483 lists type-generic math macros.

“Overview of time.h” on page 485 covers ANSI clock, date and time conversion and formatting facilities.

“Overview of timeb.h” on page 507 allows for programmer allocation of a buffer to store time information.

“Overview of unistd.h” on page 511 covers many of the common non-ANSI facilities.

“Overview of unix.h” on page 539 covers some CodeWarrior non-ANSI facilities.

“Overview of utime.h” on page 543 covers non-ANSI file access time facilities.

“Overview of utsname.h” on page 549 covers the non-ANSI equipment naming facilities.

“Overview of wchar.h” on page 553 covers the wide character set for single and array facilities.

“Overview of wctype.h” on page 615 covers the wide character set type comparison facilities.
Introduction
ANSI C Standard

“Overview of WinSIOUX” on page 627 covers CodeWarrior SIOUX console emulation for Windows.

“Overview of the MSL Switches, Flags and Defines” on page 633 covers the various switches and flags, and defines used to customize the MSL C library.

ANSI C Standard

The ANSI C Standard Library included with Freescale CodeWarrior follows the specifications in the ANSI: Programming Language C / X3.159.1989 document together with extensions according to ISO/IEC 9899:1999 (known for some time as “C99”). The functions, variables and macros available in this library can be used transparently by both C and C++ programs.

The Main Standard Library implements internal macros, _MSL_C99, that separate those parts of the C library that were added to the first version of the ANSI Standard for the C programming language (ANSI/ISO 9899-1990) by the second version (ISO/IEC 9899-1999(E)). If _MSL_C99 is defined in a prefix file to have the value 0 before building the MSL C library, only those parts of the library that were defined in ANSI/ISO 9899-1990 are compiled, yielding a smaller library. If _MSL_C99 is defined to have a non-zero value before building the library the full MSL C library is compiled in accord with ISO/IEC 9899-1999(E).

The ANSI C Library and Apple Macintosh

Some functions in the ANSI C Library are not fully operational on the Macintosh environment because they are meant to be used in a character-based user interface instead of the Macintosh computer’s graphical user interface. While these functions are available, they may not work as you expect them to. Such inconsistencies between the ANSI C Standard and the MSL C implementation are noted in a function’s description.

Except where noted, ANSI C Library functions use C character strings, not Pascal character strings.

MSL Extras Library

The MSL Extras Library contains functions macros and types that are not included in the ANSI/ISO C Standard as well as POSIX functions. These are included for Windows and UNIX compatibility. See the description of "_MSL_NEEDS_EXTRAS" on page 635, for access of these functions when including a C standard header.
Introduction

MSL Extras Library

The functions, procedures and types in the headers listed in Table 1.1 are included in the MSL Extras Library.

</tbody>
</table>

Windows Only

On Windows, the MSL extras functions are enabled using the same name with a leading underscore.

POSIX Functionality

The Main Standard Libraries include some, but not all, POSIX functions and types.

Console I/O and the Macintosh

The ANSI Standard Library assumes interactive console I/O (the stdin, stderr, and stdout streams) is always open. Many of the functions in this library were originally designed to be used on a character-oriented user interface, not the graphical user interface of a Macintosh computer. These header files contain functions that help you run character-oriented programs on a Macintosh:

- `console.h` declares `ccommand()`, which displays a dialog that lets you enter command-line arguments
- `SIOUX.h` is part of the SIOUX package, which creates a window that’s much like a dumb terminal or TTY. Your program uses that window whenever your program refers to stdin, stdout, stderr, cin, cout, or cerr.
Console I/O and Windows

The ANSI Standard Library assumes interactive console I/O (the stdin, stderr, and stdout streams) is always open. This command line interface is provided by the Windows console applications. You may want to check the headers io.h, crtl.h and process.h for specific Windows console routines. In addition, WinSIOUX.h and the WinSIOUX libraries provide a Graphic User Interface consisting of a window that is much like a dumb terminal or TTY but with scrolling and cut and paste facilities.

Using Mac OS X and the Extras Library

On OS X, the functions which would previously have come from MSL_Extras are available from the System.framework using headers from the {OS X Volume}:usr:include:access path. Therefore Mach-O on Mac OS X requires access path settings so as to not use the MSL Extras library.

Do not use an access path to the top level {Compiler}:MSL: directory as that will bring in files from the new MSL_Extras.

Compatibility

Parts of the Main Standard Library, including both the ISO Standard C library and POSIX conforming procedures and definitions, as well as MSL library extensions, may not be implemented on all platforms. Furthermore, information about your target may not appear in this version of the printed documentation. You should consult the electronic documentation or release notes for your product to determine whether a particular function is compatible with your target platform.

Intrinsic Functions

Intrinsic functions generate in-line assembly code to perform the library routine. Generally these exist to allow direct access to machine functions which are not easily expressed directly in C. In some cases these map to single assembler instructions.

Some examples of intrinsics are as follows:

```c
long __labs(long);
double __fabs(double);
```

and
Introduction

Intrinsic Functions

__memcpy__ provides access to the block move in the code generator to do the block move inline.

```c
void *__memcpy(void *, const void *, size_t);
```

where `__memcpy()` provides access to the block move in the code generator to do the block move inline.
This reference contains a description of multi-threading and thread safety in the Main C library.

Introduction to Multi-Threading

In programming, the term thread is used to refer to the smallest amount of processor context state necessary to encapsulate a computation. A thread consists of a register set and a stack, together with the address space where data is stored. Some parts of this address space are private to the thread while other parts may be shared with other threads. Variables that belong to the storage class auto and that are instantiated by the thread are private to the thread and cannot be accessed by other threads. This is in contrast to variables that belong to the storage class static, which may be accessed by other threads in the same process. All threads also have access to the standard files, stdin, stdout, and stderr. In addition, a multi-threading implementation may provide for data with the same kind of lifetime as data in the static storage class but where access is restricted to the thread that owns it. Such data is known as thread-local data.

Most current operating systems are said to be multi-threaded because they allow the creation of additional threads within a process beyond the one that begins the execution of the process. Thus, in a multi-threaded operating system, a process may consist of more than one thread, all of them executing simultaneously.

Unless there is more than one processor, the threads are not really executing simultaneously; the operating system is giving the impression of simultaneity by multiplexing between the threads. The operating system determines which thread is to have control of the processor at any particular time. There are two models for operating a multi-threaded process — the cooperative model and the preemptive model. In the cooperative model, the threads signal their willingness to relinquish their control of the processor through a system call and the operating system then decides which thread will gain control. Thus, in this model, the execution of a thread can only be interrupted at points that are convenient to the algorithm.

In the preemptive model, the operating system switches between the threads at arbitrary and unpredictable times and points in the code being executed. Such a thread switch may occur between any two machine instructions and not coincide with a boundary between two C statements; it may even be part-way through the evaluation of an expression. One important result of this is that, since switching between threads happens unpredictably, if more than one thread is changing the value of a shared variable, the results of an execution...
are likely to differ from one run to another. This lack of repeatability makes debugging and validation difficult. In what follows, we shall be assuming a preemptive model of multi-threading.

Multi-threading calls for mechanisms to protect against such uncertainty. Various methods exist for protecting segments of code from being executed by two threads at the same time. A program that is suitably protected against errors in the presence of multi-threading is said to be thread-safe.

Definitions

Essentially, there are no standards for implementing multi-threading. In particular, neither the C99 Standard nor the POSIX Standard makes reference to threads. For the MSL C library, an MSL C Library function is said to be “thread-safe” if a single invocation of the function can be viewed as a single uninterruptable (i.e., atomic) operation. That is, it is possible to have two simultaneously executing threads in a single process, both using the function without danger of mutual interference.

For most functions in the library, the meaning of this is fairly clear. Some functions, such as `rand()` or `strtok()` are defined in C99 to maintain internal state variables and would appear, by definition, to be not thread-safe. However, in MSL on Windows, functions make use of thread-local data to ensure their thread-safety.

Figure 2.1 is a model for a test program that demonstrates the mutual thread safety of two library functions.

Figure 2.1 Thread Safety Test
• Function 1 and function 2 can be the same or different library functions.

• Each loop has to iterate many times.

For these two functions are said to be mutually threadsafe, the results produced by thread 1 must be exactly the same as they would be if thread 2 did not exist.

Thread safety problems only arise if the two threads are sharing data, for example, if function 1 and function 2 are both writing to the same file or if they both use a function that maintains its own internal state without protecting it in thread-local data, as is done in `strtok()`.

The MSL C library functions listed in Table 2.1 have special precautions to make them thread-safe:

<table>
<thead>
<tr>
<th>Table 2.1 Functions with Special Thread Precautions</th>
</tr>
</thead>
<tbody>
<tr>
<td>asctime</td>
</tr>
<tr>
<td>fgetpos</td>
</tr>
<tr>
<td>fputc</td>
</tr>
<tr>
<td>fscanf</td>
</tr>
<tr>
<td>fscanf</td>
</tr>
<tr>
<td>gmtime</td>
</tr>
<tr>
<td>putchar</td>
</tr>
<tr>
<td>realloc</td>
</tr>
<tr>
<td>srand</td>
</tr>
<tr>
<td>vfprintf</td>
</tr>
<tr>
<td>vfprintf</td>
</tr>
</tbody>
</table>

The remaining MSL C functions are intrinsically thread-safe.

Reentrancy Functions

In the most recent versions of MSL C, great pains have been taken to make sure that every function works properly in a multi-threaded environment. The ANSI C standard makes no provisions at all for thread safety. Unlike some other library vendors, MSL C takes the
standpoint that all functions should be thread safe, providing that the
_MSL_THREADSAFE macro is defined to 1.
When the _MSL_THREADSAFE macro is 0, many of the MSL C library functions lose
their thread safe attributes. However, it may be useful to leave the _MSL_THREADSAFE
macro as 0 even on a multi-threaded system for the reasons of speed. The library functions
will be faster if they do not have to wait for thread synchronization. Since many programs
are written using only a single thread, it is often advantageous to provide an efficient
single-threaded library.

GCC and other library vendors provide an assortment of helper functions, all with a _r
suffix, to indicate they are naturally thread safe.

Table 2.2 is a list of enhanced header files and the new “_r” functions they implement:

</table>
Configuring MSL C

This chapter describes how to configure the Main Standard Library for C programming on your system. The topics are as follows:

- “Configuring Memory Management” on page 11
- “Configuring Time and Clock” on page 16
- “Configuring File I/O” on page 17
- “Configuring Console I/O” on page 20
- “Configuring Threads” on page 21

Configuring Memory Management

MSL has a flexible memory management system. In most cases, the default configuration should be sufficient. If the platform operating system has its own memory management, simply complete the __sys_alloc(), __sys_free(), and __sys_pointer_size() routines in the pool_alloc_xxx.c file, where xxx represents the operating system, such as Mac or Win.

The __sys_alloc() routine is called with the size of a desired memory block whenever MSL needs more memory from the system to satisfy malloc(). If the request succeeds, a pointer is returned to the requested memory. The __sys_free() routine is called with a pointer to a previously allocated memory block obtained from __sys_alloc() when MSL no longer needs system memory. The memory should be returned to the operating system.

The __sys_pointer_size() routine is called with a pointer to a previously allocated memory block obtained from __sys_alloc() when MSL needs to determine the size of the memory block (the value of size passed to the __sys_alloc() call that obtained the memory).

If the platform does not have an operating system, or the OS does not support its own memory management, MSL can still accommodate malloc() by using a block of RAM in the program heap as a memory pool. The __MSL_OS_ALLOC_SUPPORT macro must be turned off in the platform prefix file. The __MSL_HEAP_EXTERN_PROTOTYPES, __MSL_HEAP_START, and __MSL_HEAP_SIZE macros must also be defined in order for MSL to find the heap block to use as a memory pool. Generally the pool is provided from the linker, or it could also be provided in the user program in the form of a large array.
The macros listed in (Table 3.1) are used to configure the MSL memory management system:

**Table 3.1 MSL Memory Management Macros**

<table>
<thead>
<tr>
<th>Macro</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>_MSL_MALLOC_IS_ALTIVEC_ALIGNED</code></td>
<td>Defined to 1 if MSL returns a 16 byte aligned memory block for malloc() requests. Defined to 0 if MSL returns less than a 16 byte aligned memory block for malloc() requests. Having <code>_MSL_MALLOC_IS_ALTIVEC_ALIGNED</code> may decrease code size on Altivec machines because it does not have to have a separate implementation of vec_malloc(), but instead the existing malloc() is sufficient to satisfy all memory allocations.</td>
</tr>
<tr>
<td><code>_MSL_MALLOC_0_RETURNS_NON_NULL</code></td>
<td>Defined to 1 if MSL returns a non-NULL value for zero sized malloc() requests. Defined to 0 if MSL returns NULL for zero sized malloc() requests.</td>
</tr>
<tr>
<td><code>_MSL_OS_DIRECT_MALLOC</code></td>
<td>Defined to 1 if MSL is to ignore its own memory pools and make direct OS requests for memory every time malloc() is called. Defined to 0 if MSL uses its internal memory pools to satisfy malloc() requests. Generally it is preferred for MSL to use its own memory pooling, however using <code>_MSL_OS_DIRECT_MALLOC</code> can sometimes provide some help for debugging. <code>_MSL_OS_ALLOC_SUPPORT</code> must be on in order for <code>_MSL_OS_DIRECT_MALLOC</code> to work.</td>
</tr>
<tr>
<td><code>_MSL_CLASSIC_MALLOC</code> (old name: <code>_MSL_PRO4_MALLOC</code>)</td>
<td>Defined if MSL is to use the Pro 4 memory pool scheme. Left undefined if MSL uses its more modern pooling scheme.</td>
</tr>
<tr>
<td><code>_MSL_ALLOCATE_SIZE</code></td>
<td>Defined to the routine name that returns the size of an allocated memory block. Default routine name is __allocate_size</td>
</tr>
<tr>
<td><code>_MSL_ALLOCATE</code></td>
<td>Defined to the internal MSL routine name that allocates a memory block, used only with the modern memory pooling scheme. Default routine name is __allocate</td>
</tr>
</tbody>
</table>

Configuring Memory Management

Table 3.1 MSL Memory Management Macros (continued)

<table>
<thead>
<tr>
<th>Macro</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MSL_ALLOCATE_RESIZE</td>
<td>Defined to the internal MSL routine name that changes the size of an allocated memory block, used only with the modern memory pooling scheme. Default routine name is __allocate_resize.</td>
</tr>
<tr>
<td>_MSL_ALLOCATE_EXPAND</td>
<td>Defined to the internal MSL routine name that tries to expand the size of an allocated memory block, used only with the modern memory pooling scheme. Default routine name is __allocate_resize.</td>
</tr>
<tr>
<td>_MSL_OS_ALLOC_SUPPORT(old name: _No_Alloc_OS_Support)</td>
<td>Defined to 1 if the MSL platform supports memory allocation. Defined to 0 if the MSL platform does not support memory allocation. When defined to 1, the MSL platform must supply both __sys_alloc(), __sys_free(), and __sys_pointer_size() functions in its pool_alloc_XXX.c file. When defined to 0, the MSL platform must define the _MSL_HEAP_EXTERN_PROTOTYPES, _MSL_HEAP_START, and _MSL_HEAP_SIZE macros, and there must be writable space provided at link time for MSL to use as a memory pool.</td>
</tr>
<tr>
<td>_MSL_HEAP_EXTERN_PROTOTYPES</td>
<td>When _MSL_OS_ALLOC_SUPPORT is off, the MSL alloc.c file must be able to access external symbols in order to get access to the start of the writable memory pool area and determine the memory pool size. The platform prefix file must define _MSL_HEAP_EXTERN_PROTOTYPES so it expands to appropriate external prototypes.</td>
</tr>
<tr>
<td>_MSL_POOL_ALIGNMENT</td>
<td>Specifies the alignment requirements of malloc/ free only when using the “Classic” allocator. The ‘alignment’ is a mask used to ensure that blocks allocated always have sizes that are multiples of a given power-of-two, in this case: four. Other values are possible, but for internal reasons the alignment factor must be a multiple of four and must also be a multiple of sizeof(long).</td>
</tr>
</tbody>
</table>
### Configuring Memory Management

#### _MSL_USE_FIX_MALLOC_POOLS_

For tiny allocations, fixed sized pools help significantly speed allocation/deallocation, used only with the modern memory pooling scheme. You can reserve a pool for a small range of sizes. The use of fixed sized pools can be disabled by setting `_MSL_USE_FIX_MALLOC_POOLS` to 0. The default value is 1. Use of fixed size pools requires further configuration. The current shipping configuration is:

1. Each pool will handle approximately 4000 bytes worth of requests before asking for more memory.
2. There are 4 pool types. Each type is responsible for a different range of requests:
   a. 0 - 12 bytes
   b. 13 - 20 bytes
   c. 21 - 36 bytes
   d. 37 - 68 bytes

Requests for greater than 68 bytes go to the variable size pools. The number of types of pools is configurable below. The range of requests for each type is also configurable.

#### _MSL_HEAP_EXTERN_PROTOTYPES_

When `_MSL_OS_ALLOC_SUPPORT` is off, the MSL alloc.c file must be able to access external symbols in order to get access to the start of the writable memory pool area and determine the memory pool size. The platform prefix file must define `_MSL_HEAP_EXTERN_PROTOTYPES` so it expands to appropriate external prototypes.

#### _MSL_HEAP_START_

When `_MSL_OS_ALLOC_SUPPORT` is off, the MSL alloc.c file must be able to find the start of the writable memory pool area. The `_MSL_HEAP_START` macro must be defined in the platform prefix file to expand to a memory location signifying the start of the writable memory pool area.

</tr>
</tbody>
</table>
MSL comes configured by default to support a platform having the ability to determine the time of day and also the ability to return an internal clock tick. The support does not come for free. Each platform must define four simple functions to provide MSL with low-level information from the platform hardware or operating system. Time and clock stub functions are in the time_xxx.c platform file, where xxx is the platform, such as Mac or Win.

For systems that support an internal clock tick, the __get_clock() function must obtain the current clock tick and return its value to MSL. If the clock tick information is not obtainable, return the value -1.

For systems that support the ability to determine the time of day, the __get_time() function must obtain the current time of day and return its time_t equivalent value to MSL. Depending on the value of _MSL_TIME_T_IS_LOCALTIME, the current time is either the “local time” time of day, or it is “Universal Time Coordinated” (UTC), which was formerly called “Greenwich Mean Time” (GMT).

If the current time of day is not obtainable, return the value -1. The __to_gm_time() function must take a “local time” time of day time_t value and convert it into a “global mean” time_t value. If the conversion takes place properly, return 1 to MSL. If the conversion fails, return 0 to MSL.

The __to_local_time() function must take a UTC time of day time_t value and convert it into a “local time” time_t value. If the conversion takes place properly, return 1 to MSL. If the conversion fails, return 0 to MSL. The __to_local_time() function is only used when _MSL_TIME_T_IS_LOCALTIME is off.

Finally, the __isdst() function must try to determine whether or not daylight savings time is in effect. If daylight savings time is not in effect, return 0. If daylight savings time is in effect, return 1. If daylight savings time information is not obtainable, return -1.

The macros listed in Table 3.2 are used to configure the time and clock support:
Configuring File I/O

Setting up MSL to handle file I/O is a fairly intensive task. It requires many platform-specific routines to be written. The easiest way to configure file I/O is to simply have MSL not know about it by defining \_MSL\_OS\_DISK\_FILE\_SUPPORT to 0. In that mode,

<table>
<thead>
<tr>
<th>Macros</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MSL_OS_TIME_SUPPORT</td>
<td>Defined to 1 if the MSL platform supports retrieving the time. Defined to 0 if the MSL platform does not support retrieving the time.</td>
</tr>
<tr>
<td>_MSL_CLOCK_T_AVAILABLE</td>
<td>Defined to 1 if the MSL platform supports the \texttt{clock_t} type. Defined to 0 if the MSL platform does not support the \texttt{clock_t} type. The _MSL_OS_TIME_SUPPORT macro must be on before the _MSL_CLOCK_T_AVAILABLE macro is recognized.</td>
</tr>
<tr>
<td>_MSL_CLOCK_T_DEFINED</td>
<td>Defined to 1 if the MSL platform defined the \texttt{clock_t} type. Defined to 0 if the MSL platform does not define the \texttt{clock_t} type.</td>
</tr>
<tr>
<td>_MSL_CLOCK_T</td>
<td>Set to the \texttt{clock_t} type. Default value is unsigned long.</td>
</tr>
<tr>
<td>_MSL_TIME_T_AVAILABLE</td>
<td>Defined to 1 if the MSL platform supports the \texttt{time_t} type. Defined to 0 if the MSL platform does not support the \texttt{time_t} type. The _MSL_OS_TIME_SUPPORT macro must be on before the _MSL_TIME_T_AVAILABLE macro is recognized.</td>
</tr>
<tr>
<td>_MSL_TIME_T_DEFINED</td>
<td>Defined to 1 if the MSL platform defined the \texttt{time_t} type. Defined to 0 if the MSL platform does not define the \texttt{time_t} type.</td>
</tr>
<tr>
<td>_MSL_TIME_T_IS_LOCALTIME</td>
<td>Defined to 1 if the MSL platform value for \texttt{time_t} represents local time, preadjusted for any time zone and offset from UTC (GMT). Defined to 0 if the MSL platform value for \texttt{time_t} represents Universal Time Coordinated. The default value is 1.</td>
</tr>
<tr>
<td>_MSL_CLOCKS_PER_SEC</td>
<td>Set to the number of clock ticks per second. The default value is 60.</td>
</tr>
</tbody>
</table>
MSL does not know about any routines requiring file manipulation such as fopen(), fread(), fwrite(), fclose(), etc.

When _MSL_OS_DISK_FILE_SUPPORT is defined to 1, many low-level file routines need to be written, and several supporting macros also need to be defined properly. First, make sure that _MSL_FILENAME_MAX properly reflects the maximum size of a filename. Also, if the default internal MSL file buffer size is not appropriate, choose a new value for _MSL_BUFSIZE. Once all the macros are properly defined, the following routines in file_io_xxx.c (where xxx represents platform, such as Mac or Win) must be completed.

### Routines

The __open_file routine is perhaps the most complicated of all the low level file I/O routines. It takes a filename and a bunch of mode flags, opens the file, and returns a handle to the file. A file handle is a platform-specific identifier uniquely identifying the open file. The mode flags specify if the file is to be opened in read-only, write-only, or read-write mode. The flags also specify if the file must previously exist for an open to be successful, if the file can be opened whether or not it previously existed, or if the file is truncated (position and end of file marker set to 0) once it is open. If the file is opened successfully, return __no_io_error. If there was an error opening the file, return __io_error.

The __open_temp_file routine in the file_io_Starter.c file is mostly platform independent. It may be customized if there are more efficient ways to perform the task. The __open_temp_file routine is called by tmpfile() to perform the low level work of creating a new temporary file (which is automatically deleted when closed).

The __read_file routine takes a file handle, a buffer, and the size of the buffer and should read information from the file described by the file handle into the buffer. The buffer does not have to be completely filled, but at least one character should be read. The number of characters successfully read is returned in the *count parameter. If an end of file is reached after more than one character has been read, simply return the number of characters read. The subsequent read call should then return zero characters read and a result code of __io_EOF. If the read was successful, return __no_io_error. If the read failed, return __io_error.

The __write_file routine takes a file handle, a buffer, and the size of the buffer. It should then write information to the file described by the file handle from the buffer. The number of characters successfully written is returned in the *count parameter. If the write was successful, return __no_io_error. If the write failed, return __io_error.

The __position_file routine takes a file handle, a position displacement, and a positioning mode and should set the current position in the file described by the file handle based on the displacement and mode. The displacement value is passed as an unsigned long due to certain internal constraints of MSL. The value should actually be treated as signed long. The mode specifies if displacement is an absolute position in the file (treat as position of 0 + displacement), a change from the current position (treat as current position...
+ displacement), or an offset from the end of file mark (treat as EOF position +
displacement). If the positioning was successful, return __no_io_error. If the
positioning failed, return __io_error.

The __close_file routine closes the specified file. If the file was created by
__open_temp_file, it should additionally be deleted. If the close was successful,
return __no_io_error. If the close failed, return __io_error.

The __temp_file_name routine creates a new unique filename suitable for a
temporary file. It is called by tmpnam() to perform the low-level work.

The __delete_file routine deletes an existing file, given its filename. If the delete
was successful, return __no_io_error. If the delete failed, return __io_error.

The __rename_file routine renames an existing file, given its existing filename and a
desired new filename. If the rename was successful, return __no_io_error. If the
rename failed, return __io_error.

Finally, if the platform wants to provide some additional nonstandard file I/O routines that
are common to the Windows operating system, make sure __MSL_WIDE_CHAR is on, then
also define __MSL_WFILEIO_AVAILABLE to 1. The following stub routines must also
be completed in the file_io_xxx.c source file. All routines take wchar_t*
parameters instead of char*: __wopen_file (same function as __open_file),
__wtemp_file_name (same function as __temp_file_name),
__wdelete_file (same function as __delete_file), and __wrename_file
(same function as __rename_file).

The macros listed in Table 3.3 are used to configure the MSL file I/O system:

<table>
<thead>
<tr>
<th>Macros</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>__MSL_OS_DISK_FILE_SUPPORT</td>
<td>Defined to 1 if the MSL platform supports disk file I/O. Defined to 0 if the MSL platform does not support disk file I/O.</td>
</tr>
<tr>
<td>__MSL_FILENAME_MAX</td>
<td>Set to the maximum number of characters allowed in a filename. The default value is 256.</td>
</tr>
</tbody>
</table>
Configuring Console I/O

Console I/O for stdin, stdout, and stderr can be configured in many different ways. The easiest way to configure console I/O is to have it turned off completely. When 
\_MSL\_CONSOLE\_SUPPORT is off, MSL does not know about stdin, stdout, or stderr. Calls such as printf() are not placed in the standard C library.

When \_MSL\_CONSOLE\_SUPPORT is on, there are essentially three ways in which to provide console access.

- The first way is to have MSL automatically throw away all items read and written to the console by turning on \_MSL\_NULL\_CONSOLE\_ROUTINES.
- The second way is to have MSL treat all console I/O as if it were file I/O by turning on \_MSL\_FILE\_CONSOLE\_ROUTINES. Treating the console as file I/O requires configuring the file I/O portion of MSL as described in the previous section. Input and output go through the \_read\_file, \_write\_file, \_close\_file bottlenecks instead of \_read\_console, \_write\_console, and \_close\_console.
- The third way to provide console access is to simply turn on \_MSL\_CONSOLE\_SUPPORT and leave the remainder of the \_MSL\_CONSOLE\_FILE\_IS\_DISK\_FILE and \_MSL\_FILE\_CONSOLE\_ROUTINES flags in their default (off) state. MSL will then call \_read\_console when it needs input (for example from scanf()), \_write\_console when it wants to send output (for example from printf()), and \_close\_console when the console is no longer needed. The three routines should be provided in the \_console\_io\_xxx\_c file.

The macros listed in Table 3.4 are used to configure the MSL console I/O:

<table>
<thead>
<tr>
<th>Macros</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MSL_BUFSIZ</td>
<td>Set to the file I/O buffer size in bytes used to set the BUFSIZ macro. The default value is 4096.</td>
</tr>
<tr>
<td>_MSL_WFILEIO_AVAILABLE</td>
<td>Defined to 1 if MSL has wchar_t extensions for file I/O calls needing filenames, such as _wfopen(). Defined to 0 if MSL only has traditional C file I/O calls. It is an error to have _MSL_WIDE_CHAR off and _MSL_WFILEIO_AVAILABLE on.</td>
</tr>
</tbody>
</table>
Configuring MSL C

Configuring Threads

MSL is highly adaptive when it comes to multi-threading. The C standard makes no mention of threading, and it even has points where global data is accessed directly, for example `errno, asctime()`, etc. MSL can be configured to know about multithreaded

### Table 3.4 MSL Console I/O Macros

<td>Defined to 1 if the MSL platform has console I/O, but it is really in a file. Defined to 0 if the MSL platform has traditional console I/O. Default value is 0.</td>
</tr>
<tr>
<td>_MSL_NULL_CONSOLE_ROUTINES</td>
<td>Defined to 1 if the MSL platform does not perform console I/O. Defined to 0 if the MSL platform performs console I/O. This flag may be set independently of _MSL_CONSOLE_SUPPORT; however, when _MSL_CONSOLE_SUPPORT is off, _MSL_NULL_CONSOLE_ROUTINES must always be on. When _MSL_CONSOLE_SUPPORT is on and _MSL_NULL_CONSOLE_ROUTINES is also on, all console I/O is essentially ignored. Default value is 0.</td>
</tr>
<tr>
<td>_MSL_FILE_CONSOLE_ROUTINES</td>
<td>Defined to 1 if the MSL platform uses the file I/O read/write/close routines for console I/O instead of using the special console read/write/close routines. Define to 0 if the MSL platform uses the special console read/write/close routines. When _MSL_CONSOLE_FILE_IS_DISK_FILE is on, _MSL_FILE_CONSOLE_ROUTINES must always be on. Default value is 0.</td>
</tr>
</tbody>
</table>
Configuring MSL C
Configuring Threads

There are essentially three ways to configure the MSL thread support:

- single thread (not reentrant at all)
- multithreaded with global data (mostly reentrant)
- and multithreaded with thread local data (completely reentrant).

With _MSL_THREADSAFE off, MSL is setup to operate in a single thread environment. There are no critical regions to synchronize operations between threads. It is sometimes advantageous to configure MSL for a single threaded environment. Operations such as file I/O and memory allocations will be quicker, since there is no need to ask for or wait for critical regions. Many simple programs do not make use of threads, thus there may be no need for the additional overhead.

With _MSL_THREADSAFE on, MSL is setup to synchronize operations between threads properly by the use of critical regions. Critical regions are supplied either by POSIX pthread functions or by the use of platform specific calls. If the platform has an underlying POSIX layer supporting pthreads, simply turning on _MSL_THREADSAFE and _MSL_PTHREADS is enough for MSL to fully operate. No other custom code is necessary.

With _MSL_THREADSAFE on and _MSL_PTHREADS off, the platform must provide its own critical region code. This is generally done by first providing an array of critical region identifiers in the critical_regions_xxx.c file, and then by completing the four critical region functions in the critical_regions_xxx.h header file (where xxx represents operating system, such as Mac or Win). The compiler runtime library must make a call to __init_critical_regions() before calling main().

With _MSL_THREADSAFE on, the _MSL_LOCALDATA_AVAILABLE flag controls whether or not the MSL library is completely reentrant or not. When _MSL_LOCALDATA_AVAILABLE is off, the MSL library uses global and static variables, and is therefore not completely reentrant for such items as errno, the random number seed used by rand(), strtok() state information, etc. When _MSL_LOCALDATA_AVAILABLE is on, the MSL library uses thread local storage to maintain state information. Each thread has its own copy of some dynamic memory that gets used.

With _MSL_LOCALDATA_AVAILABLE on and _MSL_PTHREADS on, simply adding the following line to the platform prefix file is enough to fully support complete reentrancy:

```c
#define _MSL_LOCALDATA(_a) __msl_GetThreadLocalData()->_a
```

With _MSL_LOCALDATA_AVAILABLE on and _MSL_PTHREADS off, the platform must completely supply its own routines to maintain and access thread local storage. The thread_local_data_xxx.h and thread_local_data_xxx.c files are used to provide the necessary functionality. Also, the common MSL header (msl_thread_local_data.h) must be modified to include the platform header...
(thread_local_data_xxx.h) based on its __dest_os value. The _MSL_LOCALDATA macro is used to access items in thread local storage. So, for example, if the random number seed needs to be obtained, the MSL code will say _MSL_LOCALDATA(random_next) to get the random number seed. The macro must expand to an l-value expression.

At times, it may be easier to turn on _MSL_PTHREADS even if the underlying platform does not have built-in pthread support. Instead of writing custom code to support the MSL threading model, it may be easier to turn on _MSL_PTHREADS and then write comparable pthread routines. When _MSL_PTHREADS is on and _MSL_THREADSAFE is on, four pthread routines in the pthread_xxx.c file are used by MSL to implement critical regions.

**pthread Routines**

The pthread_mutex_init routine creates a single mutex. MSL will always pass NULL as the second attr argument, which means to use default mutex attributes. Return zero upon success, return an error code upon failure.

The pthread_mutex_destroy routine disposes of a single mutex. Return zero upon success, return an error code upon failure.

The pthread_mutex_lock routine acquires a lock on a single mutex. If the mutex is already locked when pthread_mutex_lock is called, the routine blocks execution of the current thread until the mutex is available. Return zero upon success, return an error code upon failure.

The pthread_mutex_unlock routine releases a lock on a single mutex. Return zero upon success, return an error code upon failure.

Additionally, when _MSL_LOCALDATA_AVAILABLE is on, four more pthread routines in the pthread_xxx.c file are used by MSL to implement thread local data:

- The pthread_key_create routine creates a new thread local data identifier. Each thread can then access its own individual data elements through the identifier. When a thread terminates, the destructor routine is called with the single argument of pthread_getspecific() to clean up any necessary thread local data. Return zero upon success, return an error code upon failure.

- The pthread_key_delete routine disposes of a thread local data identifier. Return zero upon success, return an error code upon failure.

- The pthread_setspecific routine associates a value to a previously created thread local data identifier. The value is specific to the currently executing thread. Return zero upon success, return an error code upon failure.

- The pthread_getspecific routine retrieves a value associated with a thread local data identifier. The value is specific to the currently executing thread. If no
value has been associated with the thread local data identifier, return NULL.
Otherwise, return the previously associated value.

The macros listed in Table 3.5 are used to configure and use the MSL threading support:

**Table 3.5 MSL Thread Support Macros**

<table>
<thead>
<tr>
<th>Macros</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>_MSL_THREADSAFE</td>
<td>Defined to 0 if there is no multi-thread support in MSL. Defined to 1 if there should be multi-thread support in MSL. When defined to 1, many internal aspects of MSL are guarded by critical regions. Having critical regions inside MSL will slow down the execution time for the trade-off of working correctly on a multi-threaded system. Also, many MSL functions will use thread local storage for maintaining state information.</td>
</tr>
<tr>
<td>_MSL_PTHREADS</td>
<td>Defined to 1 if the MSL platform supports the POSIX threading model. Defined to 0 if the MSL platform does not support the POSIX threading model. It is an error to define _MSL_PTHREADS to 1 and _MSL_THREADSAFE to 0. MSL has generic support for the POSIX thread model, so turning on _MSL_THREADSAFE and _MSL_THREADS is enough to properly support a multithreaded system without the need to write any additional support code.</td>
</tr>
<tr>
<td>_MSL_LOCALDATA</td>
<td>Internal MSL flag for accessing thread local data when _MSL_THREADSAFE is 1. Accesses static global data when _MSL_THREADSAFE is 0.</td>
</tr>
<tr>
<td>_MSL_LOCALDATA_AVAILABLE</td>
<td>Defined to 1 if the MSL platform supports thread local data, accessible using the _MSL_LOCALDATA macro. Defined to 0 if the MSL platform does not support thread local data.</td>
</tr>
</tbody>
</table>
alloca.h

This header defines one function, `alloca`, which lets you allocate memory quickly using the stack.

Overview of alloca.h

The alloca.h header file consists of “alloca”, which allocates memory from the stack.

alloca

Allocates memory quickly on the stack.

```c
#include <alloca.h>
void *alloca(size_t nbytes);
```

<table>
<thead>
<tr>
<th>nbytes</th>
<th>size_t</th>
<th>number of bytes of allocation</th>
</tr>
</thead>
</table>

Remarks

This function returns a pointer to a block of memory that is `nbytes` long. The block is on the function’s stack. This function works quickly since it decrements the current stack pointer. When your function exits, it automatically releases the storage.

**NOTE** The AltiVec version of `alloca()` allocates memory on a 16 byte alignment.

- If you use `alloca()` to allocate a lot of storage, be sure to increase the Stack Size for your project in the Project preferences panel.
- If it is successful, `alloca()` returns a pointer to a block of memory. If it encounters an error, `alloca()` returns NULL.
- This function may not be implemented on all platforms.

assert.h

The assert.h header file provides a debugging macro, `assert`, that outputs a diagnostic message and stops the program if a test fails.

Overview of assert.h

The assert.h header file provides a debugging macro, “assert”, which outputs a diagnostic message and stops the program if a test fails.

assert

Abort a program if a test is false.
#include <assert.h>
void assert(int expression);

Table 5.1 assert

<table>
<thead>
<tr>
<th>expression</th>
<th>int</th>
<th>A boolean expression being evaluated</th>
</tr>
</thead>
</table>

Remarks

If `expression` is false the `assert()` macro outputs a diagnostic message to `stderr` and calls `abort()`. The diagnostic message has the form

file: line test -- assertion failed
abort -- terminating

where file is the source file, line is the line number, and test is the failed expression.

To turn off the `assert()` macros, place a `#define NDEBUG` (no debugging) directive before the `#include <assert.h>` directive.

This macro may not be implemented on all platforms.
assert.h
Overview of assert.h

See Also
“abort” on page 405

Listing 5.1 Example of assert() Usage

```c
#define NDEBUG
/* Make sure that assert() is enabled */
#include <assert.h>
#include <stdio.h>

int main(void)
{
    int x = 100, y = 5;
    printf("assert test.\n");

    /*This assert will output a message and abort the program */
    assert(x > 1000);
    printf("This will not execute if NDEBUG is undefined\n");
    return 0;
}
```

Output:
assert test.
foo.c:12 x > 1000 -- assertion failed
abort -- terminating
conio.h

The `conio.h` header file consist of various runtime declarations that pertain to the Win32 x86 targets for console input and output.

Overview of conio.h

This header file defines the facilities as follows:

- `clrscr` on page 30 clears the console window.
- `getch` on page 30 reads a char from the input screen.
- `getche` on page 31 reads a char and echoes to the screen.
- `gotoxy` on page 31 places the cursor on a console window.
- `initcr` on page 32 sets up a console in a GUI application.
- “inp” on page 32 reads a byte from an input port.
- “inpd” on page 33 reads a double word from and input port.
- “inpw” on page 33 reads a word from an input port.
- “kbhit” on page 34 returns true if a key is pressed.
- “outp” on page 34 outputs a byte to a port.
- “outpd” on page 35 outputs a double word to a port.
- “outpw” on page 36 outputs a word to a port.
- “textattr” on page 36 sets the text attributes.
- “textbackground” on page 37 sets the text background color.
- “textcolor” on page 37 sets the text color.
- “wherex” on page 38 returns the horizontal coordinate.
- “wherey” on page 38 returns the vertical coordinate.
_clrscr

Clears the standard output screen.
#include <conio.h>
void _clrscr(void);

Remarks
This facility has no parameters.
No value is returned in this implementation.
This function is Windows only when declared from this header.

getch

This function reads a single char from the standard input device and does not echo it to the output.
#include <conio.h>
int getch(void);
int _getch(void);

Remarks
This facility has no parameters.
The function `getch` returns the char read.
This function is Windows only when declared from this header.

See Also
“getc” on page 348
“getchar” on page 349
getche

This function reads a single char from the standard input device and echoes it to the output without the need of pressing the enter key.

```c
#include <conio.h>
int getche(void);
int _getche(void);
```

Remarks

This facility has no parameters.

The function `getche` returns the char read.

This function is Windows only when declared from this header.

See Also

“`getc`” on page 348
“`getchar`” on page 349

_ggotoxy

Moves the cursor to the horizontal and vertical coordinates in a standard output device.

```c
#include <conio.h>
void _gotoxy(int x, int y);
```

Table 6.1 _gotoxy

<table>
<thead>
<tr>
<th>x</th>
<th>int</th>
<th>vertical screen coordinate</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>int</td>
<td>horizontal screen coordinate</td>
</tr>
</tbody>
</table>

Remarks

No value is returned in this implementation.

This function is Windows only when declared from this header.
conio.h
Overview of conio.h

See Also

“_wherex” on page 38
“_wherey” on page 38

_initscr

Sets up standard 80x25 console with no scrolling region.

#include <conio.h>
void _initscr(void);

Remarks

This facility has no parameters.

There is no need to call _initscr() unless you have a GUI application
(subsystem Windows GUI), where no console is available at runtime.

No value is returned in this implementation.

This function is Windows only when declared from this header.

inp

Reads a byte from the specified port

#include <conio.h>
unsigned char inp(unsigned short port);
unsigned char _inp(unsigned short port);

Table 6.2  inp

<table>
<thead>
<tr>
<th>port</th>
<th>unsigned short</th>
<th>a port specified by number</th>
</tr>
</thead>
</table>

Remarks

The value as a byte read is returned.

This function is Windows only when declared from this header.

See Also

“inpd” on page 33
**Overview of conio.h**

```
#include <conio.h>
unsigned long inpd(unsigned short port);
unsigned long _inpd(unsigned short port);
```

**Remarks**

The value as a long read is returned.

This function is Windows only when declared from this header.

**See Also**

“inp” on page 32
“inpw” on page 33

---

### inpd

**inpd**

Reads a double word from the specified port

```c
#include <conio.h>
unsigned long inpd(unsigned short port);
unsigned long _inpd(unsigned short port);
```

**Table 6.3 inpd**

<table>
<thead>
<tr>
<th>port</th>
<th>unsigned short</th>
<th>a port specified by number</th>
</tr>
</thead>
</table>

**Remarks**

The value as a word read is returned.

**See Also**

“inp” on page 32
“inpw” on page 33

---

### inpw

**inpw**

Reads a word from the specified port

```c
#include <conio.h>
unsigned short inpw(unsigned short port);
unsigned short _inpw(unsigned short port);
```

**Table 6.4 inpw**

<table>
<thead>
<tr>
<th>port</th>
<th>unsigned short</th>
<th>a port specified by number</th>
</tr>
</thead>
</table>

**Remarks**

The value as a word read is returned.
conio.h
Overview of conio.h

This function is Windows only when declared from this header.

See Also
“inp” on page 32
“inpd” on page 33

kbhit

This function is used in a loop to detect an immediate keyboard key press.

#include <conio.h>
int kbhit(void);
int _kbhit(void);
This facility has no parameters.

Remarks
The kbhit function has the side effect of discarding any non-keyboard input records in the console input queue
If the keyboard is pressed kbhit() returns a non zero value otherwise it return zero.
This function is Windows only when declared from this header.

See Also
“getch” on page 30
“getche” on page 31

outp

Outputs a byte to a specified port.

#include <conio.h>
void outp(unsigned short pt, unsigned char out);
void _outp(unsigned short pt, unsigned char out);
**conio.h**

*Overview of conio.h*

**Remarks**

No value is returned in this implementation.
This function is Windows only when declared from this header.

**See Also**

“outp” on page 34
“outpw” on page 36

### Table 6.5  outp

<table>
<thead>
<tr>
<th>pt</th>
<th>unsigned short</th>
<th>a port specified by number</th>
</tr>
</thead>
<tbody>
<tr>
<td>out</td>
<td>unsigned char</td>
<td>a byte value sent to the output</td>
</tr>
</tbody>
</table>

### outpd

Sends a double word to the output port specified.

```c
#include <conio.h>
void outpd(unsigned short pt, unsigned long out);
void _outpd(unsigned short pt, unsigned long out);
```

**See Also**

“outp” on page 34
“outpw” on page 36

<th>unsigned short</th>
<th>a port specified by number</th>
</tr>
</thead>
<tbody>
<tr>
<td>out</td>
<td>unsigned short</td>
<td>a word value sent to the output</td>
</tr>
</tbody>
</table>

**Remarks**

No value is returned in this implementation.

This function is Windows only when declared from this header.

**See Also**

“outp” on page 34

“outpd” on page 35

---

**_textattr**

This function sets the attributes of the console text.

```
#include <conio.h>
void _textattr(int newattr);
```

**Table 6.8 _textattr**

| newattr | int | the text attributes to be set |

**Remarks**

The function _textattr allows you to set both the foreground and background attributes with the variable newattr. The attributes available for this function are defined in the header file wincon.h.
No value is returned in this implementation.
This function is Windows only when declared from this header.

**See Also**

"_textbackground" on page 37
"_textcolor" on page 37

### _textbackground

This function sets the console’s background color.

```c
#include <conio.h>
void _textbackground(int newcolor);
```

**Table 6.9 _textbackground**

<table>
<thead>
<tr>
<th>newcolor</th>
<th>int</th>
<th>the background color to be set</th>
</tr>
</thead>
</table>

### Remarks

The attributes available for this function are defined in the header file `wincon.h`.
No value is returned in this implementation.
This function is Windows only when declared from this header.

**See Also**

"_textattr" on page 36
"_textcolor" on page 37

### _textcolor

This function sets the console’s text color.

```c
#include <conio.h>
void _textcolor(int newcolor);
```
conio.h
Overview of conio.h

Table 6.10 _textcolor

<table>
<thead>
<tr>
<th>newcolor</th>
<th>int</th>
<th>the text color to be set</th>
</tr>
</thead>
</table>

Remarks
The attributes available for this function are defined in the header file wincon.h.
No value is returned in this implementation.
This function is Windows only when declared from this header.

See Also
“textattr” on page 36
“textbackground” on page 37

_wherex

Determines the horizontal coordinate of the cursor in a console window.
#include <conio.h>
int _wherex(void);

Remarks
This facility has no parameters.
Returns the horizontal coordinate.
This function is Windows only when declared from this header.

See Also
“wherey” on page 38
“gotoxy” on page 31

_wherey

Determines the vertical coordinate of the cursor in a console window.
#include <conio.h>
int _wherey(void);
Remarks

This facility has no parameters.
Returns the vertical coordinate.
This function is Windows only when declared from this header.

See Also

"gotoxy" on page 31
"wherex" on page 38
console.h

This header file contains procedures and types, which help you port a program that was written for a command-line/console interface to the Macintosh operating system.

The console.h header file consist of various runtime declarations that pertain to the Classic and Carbon Macintosh interfaces.

Overview of console.h

This header file defines the facilities as follows:

- "ccommand" on page 41 helps you port a program that relies on command-line arguments.
- "clrscr" on page 43 clears the SIOUX window and flushes the buffer.
- "getch" on page 43 returns the keyboard character pressed when an ascii key is pressed.
- "InstallConsole" on page 44 installs the Console package.
- "kbhit" on page 44 returns true if any keyboard key is pressed without retrieving the key.
- "ReadCharsFromConsole" on page 45 reads from the Console into a buffer.
- "RemoveConsole" on page 45 removes the console package.
- "__ttyname" on page 46 returns the name of the terminal associated with the file id. The unix.h function ttyname calls this function.
- "WriteCharsToConsole" on page 46 writes a stream of output to the Console window.

ccommand

Lets you enter command-line arguments for a SIOUX program.

```
#include <console.h>

int ccommand(char ***argv);
```
### Overview of console.h

#### Table 7.1  ccommand

<table>
<thead>
<tr>
<th>argv</th>
<th>char ***</th>
<th>The address of the second parameter of your command line</th>
</tr>
</thead>
</table>

### Remarks

The function `ccommand()` must be the first code generated in your program. It must directly follow any variable declarations in the main function.

This function displays a dialog that lets you enter arguments and redirect standard input and output. Please refer to “Overview of SIOUX” on page 255, for information on customizing SIOUX, or setting console options.

Only `stdin`, `stdout`, `cin`, and `cout` are redirected. Standard error reporting methods `stderr`, `cerr`, and `clog` are not redirected.

The maximum number of arguments that can be entered is determined by the value of `MAX_ARGS` defined in `ccommand.c` and is set to 25. Any arguments in excess of this number are ignored.

Enter the command-line arguments in the Argument field. Choose where your program directs standard input and output with the buttons below the field: the buttons on the left are for standard input and the buttons on the right are for standard output. If you choose Console, the program reads from or write to a SIOUX window. If you choose File, `ccommand()` displays a standard file dialog which lets you choose a file to read from or write to. After you choose a file, its name replaces the word `File`.

The function `ccommand()` returns an integer and takes one parameter which is a pointer to an array of strings. It fills the array with the arguments you entered in the dialog and returns the number of arguments you entered. As in UNIX or DOS, the first argument, the argument in element 0, is the name of the program. Listing 7.1 has an example of command line usage.

This function returns the number of arguments you entered.

Macintosh only—this function may not be implemented on all Mac OS versions.

### See Also

“Customizing SIOUX” on page 258

### Listing 7.1  Example of ccommand() Usage

```c
#include <stdio.h>
#include <console.h>
```

---

42  

MSL C Reference Version 10
int main(int argc, char *argv[]) {  
  int i;  
  argc = ccommand(&argv);  
  for (i = 0; i < argc; i++)  
    printf("%d. %s\n", i, argv[i]);  
  return 0;  
}

clrscr

Clears the console window and flushes the buffers;
#include <console.h>
void clrscr(void);

Remarks
This function is used to select all and clear the screen and buffer by calling
SIOUXclrscr from SIOUX.h.
Macintosh only—this function may not be implemented on all Mac OS versions.

getch

Returns the keyboard character pressed when an ascii key is pressed
#include <console.h>
int getch(void);

Remarks
This function is used for console style menu selections for immediate actions.
Returns the keyboard character pressed when an ascii key is pressed.
Macintosh only—this function may not be implemented on all Mac OS versions.

See Also
"kbhit" on page 44
console.h
Overview of console.h

InstallConsole

Installs the Console package.

```c
#include <console.h>
extern short InstallConsole(short fd);
```

### Remarks

Installs the Console package, this function will be called right before any read or write to one of the standard streams.

This function returns any error.

Macintosh only—this function may not be implemented on all Mac OS versions.

**See Also**

“RemoveConsole” on page 45

---

kbhit

Returns true if any keyboard key is pressed.

```c
#include <console.h>
int kbhit(void);
```

### Remarks

Returns true if any keyboard key is pressed without retrieving the key used for stopping a loop by pressing any key

This function returns non zero when any keyboard key is pressed.

Macintosh only—this function may not be implemented on all Mac OS versions.

**See Also**

“getch” on page 43
Overview of console.h

ReadCharsFromConsole

Reads from the Console into a buffer.

```
#include <console.h>
extern long ReadCharsFromConsole
  (char *buffer, long n);
```

Remarks

Reads from the Console into a buffer. This function is called by read.
Any errors encountered are returned.
Macintosh only—this function may not be implemented on all Mac OS versions.

See Also

“WriteCharsToConsole” on page 46

RemoveConsole

Removes the console package.

```
#include <console.h>
extern void RemoveConsole(void);
```

Remarks

Removes the console package. It is called after all other streams are closed and exit
functions (installed by either atexit or __atexit) have been called.
Since there is no way to recover from an error, this function doesn’t need to
return any.
Macintosh only—this function may not be implemented on all Mac OS versions.
__ttyname

Returns the name of the terminal associated with the file id.
#include <console.h>
extern char *__ttyname(long fildes);

Table 7.4 __ttyname

<table>
<thead>
<tr>
<th>fildes</th>
<th>long</th>
<th>The file descriptor</th>
</tr>
</thead>
</table>

Remarks

Returns the name of the terminal associated with the file id. The unix.h function ttyname calls this function (we need to map the int to a long for size of int variance).

Returns the name of the terminal associated with the file id.

Macintosh only—this function may not be implemented on all Mac OS versions.

See Also

“ttyname” on page 534

WriteCharsToConsole

Writes a stream of output to the Console window.
#include <console.h>
extern long WriteCharsToConsole(char *buffer, long n);

Table 7.5 WriteCharsToConsole

<table>
<thead>
<tr>
<th>buffer</th>
<th>char *</th>
<th>A stream buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>long</td>
<td>Number of char to write</td>
</tr>
</tbody>
</table>
Remarks

Writes a stream of output to the Console window. This function is called by write. Any errors encountered are returned.

Macintosh only—this function may not be implemented on all Mac OS versions.

“ReadCharsFromConsole” on page 45
console.h
Overview of console.h
crtl.h

The crtl.h header file consist of various runtime declarations that pertain to the Win32 x86 targets.

Overview of crtl.h

This header file defines the facilities as follows:

- “Argc” on page 49 is the argument list count.
- “Argv” on page 50 is the argument list variables.
- “_DllTerminate” on page 50 shows when a DLL is running terminate code.
- “_environ” on page 50 is the environment pointers.
- “_HandleTable” on page 51 is a structure allocated for each ed file handle.
- “_CRTStartup” on page 51 initializes the C Runtime start-up routines.
- “_RunInit” on page 52 initializes the runtime, static classes and variables.
- “_SetupArgs” on page 52 sets up the command line arguments.

Argc

The argument count variable

#include <crtl.h>
extern int __argc;

Remarks

Used for command line argument count.
This function may not be implemented on all platforms.
Argv

The argument command variables.

```c
#include <crtl.h>
extern char **__argv;
```

Remarks

- The command line arguments.
- This function may not be implemented on all platforms.

_DllTerminate

A flag to determine when a DLL is running terminate code.

```c
#include <crtl.h>
extern int _DllTerminate;
```

Remarks

- This flag is set when a DLL is running terminate code.
- This function may not be implemented on all platforms.

environ

The environment pointers

```c
#include <crtl.h>
extern char *(*environ);
```

Remarks

- This is a pointer to the environment.
- This function may not be implemented on all platforms.
_HandleTable

FileStruct is a structure allocated for each file handle
#include <crtl.h>
typedef struct
{
    void *handle;
    char translate;
    char append;
} FileStruct;

extern FileStruct * _HandleTable[NUM_HANDLES];
extern int _HandPtr;

Remarks

The variable _HandPtr is a pointer to a table of handles.
The variable NUM_HANDLES lists the number of possible handles.
This function may not be implemented on all platforms.

_CRTStartup

The function _CRTStartup is the C Runtime start-up routine.
#include <crtl.h>
extern void _CRTStartup();

Remarks

This function may not be implemented on all platforms.
crtl.h
Overview of crtl.h

_RunInit
The function _RunInit initializes the runtime, all static classes and variables.
#include <crtl.h>
extern void _RunInit();

Remarks
This function may not be implemented on all platforms.

_SetupArgs
The function _SetupArgs sets up the command line arguments.
#include <crtl.h>
extern void _SetupArgs();

Remarks
This function may not be implemented on all platforms.
The `ctype.h` header file supplies macros and functions for testing and manipulation of character type.

**Overview of ctype.h**

**Character Testing and Case Conversion**

The `ctype.h` header file supplies macros for testing character type and for converting alphabetic characters to uppercase or lowercase. The `ctype.h` macros support ASCII characters (0x00 to 0x7F), and the EOF value. These macros are not defined for the Apple Macintosh Extended character set (0x80 to 0xFF).

This header file defines the facilities as follows:

- “isalnum” on page 55 tests for alphabetical and numerical characters.
- “isalpha” on page 57 tests for alphabetical characters.
- “isblank” on page 57 tests for a space between words and is dependent upon the locale usage.
- “iscntrl” on page 58 tests for control characters.
- “isdigit” on page 58 tests for digit characters.
- “isgraph” on page 59 tests for graphical characters.
- “islower” on page 59 tests for lower case characters.
- “isprint” on page 60 tests for printable characters.
- “ispunct” on page 60 tests for punctuation characters.
- “isspace” on page 61 tests for white space characters.
- “isupper” on page 61 tests for upper case characters.
- “isxdigit” on page 62 tests for hexadecimal characters.
- “tolower” on page 62 changes from uppercase to lowercase.
- “toupper” on page 63 changes from lower case to uppercase.
Character Sets Supported

A Main Standard Library character tests the ASCII character set. Testing of extended character sets is undefined and may or may not work for any specific system. See Table 9.1 for return values.

Table 9.1 Character Testing Functions

<table>
<thead>
<tr>
<th>This function</th>
<th>Returns true if c is</th>
</tr>
</thead>
<tbody>
<tr>
<td>isalnum(c)</td>
<td>Alphanumeric: [a-z], [A-Z], [0-9]</td>
</tr>
<tr>
<td>isalpha(c)</td>
<td>Alphabetic: [a-z], [A-Z].</td>
</tr>
<tr>
<td>isblank(c)</td>
<td>A blankspace between words based on locale</td>
</tr>
<tr>
<td>iscntrl(c)</td>
<td>The delete character (0x7F) or an ordinary control character from 0x00 to 0x1F.</td>
</tr>
<tr>
<td>isdigit(c)</td>
<td>A numeric character: [0-9].</td>
</tr>
<tr>
<td>isgraph(c)</td>
<td>A non-space printing character from the exclamation (0x21) to the tilde (0x7E).</td>
</tr>
<tr>
<td>islower(c)</td>
<td>A lowercase letter: [a-z].</td>
</tr>
<tr>
<td>isprint(c)</td>
<td>A printable character from space (0x20) to tilde (0x7E).</td>
</tr>
<tr>
<td>ispunct(c)</td>
<td>A punctuation character. A punctuation character is neither a control nor an alphanumeric character.</td>
</tr>
<tr>
<td>isspace(c)</td>
<td>A space, tab, return, new line, vertical tab, or form feed.</td>
</tr>
<tr>
<td>isupper(c)</td>
<td>An uppercase letter: [A-Z].</td>
</tr>
<tr>
<td>isxdigit(c)</td>
<td>A hexadecimal digit [0-9], [A-F], or [a-f].</td>
</tr>
</tbody>
</table>
### isalnum

Determine character type.

```c
#include <ctype.h>
int isalnum(int c);
```

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>a-z</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>0-9</td>
<td>1</td>
<td></td>
</tr>
</tbody>
</table>

**Remarks**

This macro returns nonzero for true, zero for false, depending on the integer value of `c`. For example usage, see Listing 9.1.

In the “C” locale, isalnum returns true only for alphabetical or numerical characters.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.

**See Also**

“tolower” on page 62
“toupper” on page 63

**Listing 9.1 Example of Character Testing Functions Usage**

```c
#include <stdio.h>
#include <ctype.h>
int main(void)
{
    char *test = "Fb6# 9,"
    isalnum(test[0]) ?
        printf("%c is alpha numberical\n", test[0]) :
        printf("%c is not alpha numberical\n", test[0]);
    isalpha(test[0]) ?
        printf("%c is alphabetical\n", test[0]) :
        printf("%c is not alphabetical\n", test[0]);
    isblank(test[4]) ?
        printf("%c is a blank space\n", test[4]) :
        printf("%c is not a blank space\n", test[4]);
    iscntrl(test[0]) ?
```
ctype.h
Overview of ctype.h

```c
printf("%c is a control character\n", test[0]) :
printf("%c is not a control character\n", test[0]);
isdigit(test[2]) ?
printf("%c is a digit\n", test[2]) :
printf("%c is not a digit\n", test[2]) ;
isgraph(test[0]) ?
printf("%c is graphical \n", test[0]) :
printf("%c is not graphical\n", test[0]);
islower(test[1]) ?
printf("%c is lower case \n", test[1]) :
printf("%c is not lower case\n", test[1]);
isprint(test[3]) ?
printf("%c is printable\n", test[3]) :
printf("%c is not printable\n", test[3]);
ispunct(test[6]) ?
printf("%c is a punctuation mark\n", test[6]) :
printf("%c is not punctuation mark\n", test[6]);
isspace(test[4]) ?
printf("%c is a space\n", test[4]) :
printf("%c is not a space\n", test[4]);
isupper(test[0]) ?
printf("%c is upper case \n", test[1]) :
printf("%c is not upper case\n", test[1]);
isdigit(test[5]) ?
printf("%c is a hex digit\n", test[5]) :
printf("%c is not a hex digit\n", test[5]);
return 0;
```

Output:
F is alpha numerical
F is alphabetical
   is a blank sapce
F is not a control character
6 is a digit
F is graphical
b is lower case
# is printable
   is a punctuation mark
   is a space
b is upper case
9 is a hex digit
isalpha

Determine character type.

```c
#include <ctype.h>
int isalpha(int c);
```

**Table 9.3 isalpha**

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

**Remarks**

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.

isblank

Tests for a blank space or a word separator dependent upon the locale usage.

```c
#include <ctype.h>
int isblank(int c);
```

**Table 9.4 isblank**

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

**Remarks**

This function determines if a character is a blank space or tab or if the character is in a locale specific set of characters for which isspace is true and is used to separate words in text.

In the “C” locale, isblank returns true only for the space and tab characters.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.
ctype.h
Overview of ctype.h

See Also

“isspace” on page 61

iscntrl

Determine character type.
#include <ctype.h>
int iscntrl(int c);

Table 9.5 iscntrl

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.
Table 9.1 describes what the character testing functions return.
This function may not be implemented on all platforms.

isdigit

Determine character type.
#include <ctype.h>
int isdigit(int c);

Table 9.6 isdigit

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.
Table 9.1 describes what the character testing functions return.
This function may not be implemented on all platforms.
isgraph

Determine character type.

```c
#include <ctype.h>
int isgraph(int c);
```

Table 9.7 isgraph

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.

islower

Determine character type.

```c
#include <ctype.h>
int islower(int c);
```

Table 9.8 islower

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.

In the “C” locale, islower returns true only for the lowercase characters. Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.
**ctype.h**

*Overview of ctype.h*

---

**isprint**

Determine character type.

```c
#include <ctype.h>
int isprint(int c);
```

**Table 9.9  isprint**

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

**Remarks**

This macro returns nonzero for true, zero for false, depending on the integer value of `c`. For example usage, see Listing 9.1.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.

---

**ispunct**

Determine character type.

```c
#include <ctype.h>
int ispunct(int c);
```

**Table 9.10  ispunct**

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

**Remarks**

This macro returns nonzero for true, zero for false, depending on the integer value of `c`. For example usage, see Listing 9.1.

In the “C” locale, `ispunct` returns true for every printing character for which neither `isspace` nor `isalnum` is true.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.
iscase

Determine character type.

#include <ctype.h>
int isspace(int c);

Table 9.11 isspace

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.

In the "C" locale, isspace returns true only for the standard white-space characters.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.

isupper

Determine character type.

#include <ctype.h>
int isupper(int c);

Table 9.12 isupper

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.

In the "C" locale, isupper returns true only for the uppercase characters.

Table 9.1 describes what the character testing functions return.

This function may not be implemented on all platforms.
ctype.h
Overview of ctype.h

isxdigit

Determine hexadecimal type.
#include <ctype.h>
int isxdigit(int c);

Table 9.13 isxdigit

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks
This macro returns nonzero for true, zero for false, depending on the integer value of c. For example usage, see Listing 9.1.
Table 9.1 describes what the character testing functions return.
This function may not be implemented on all platforms.

tolower

Character conversion macro. For example usage see Listing 9.2.
#include <ctype.h>
int tolower(int c);

Table 9.14 tolower

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

tolower() returns the lowercase equivalent of uppercase letters and returns all other characters unchanged.
This function may not be implemented on all platforms.

See Also

“isalpha” on page 57
“toupper” on page 63.
Listing 9.2 Example of tolower(), toupper() Usage

```c
#include <ctype.h>
#include <stdio.h>

int main(void)
{
    static char s[] =
        "** DELICIOUS! lovely? delightful **";
    int i;

    for (i = 0; s[i]; i++)
        putchar(tolower(s[i]));
    putchar('
');

    for (i = 0; s[i]; i++)
        putchar(toupper(s[i]));
    putchar('
');

    return 0;
}
```

Output:
** delicious! lovely? delightful **
** DELICIOUS! LOVELY? DELIGHTFUL **

toupper

Character conversion macro.
```
#include <ctype.h>

int toupper(int c);
```

Table 9.15 toupper

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

Remarks

The function toupper() returns the uppercase equivalent of a lowercase letter and returns all other characters unchanged. For example usage, see Listing 9.1.
This function may not be implemented on all platforms.

See Also

“isalpha” on page 57
“tolower” on page 62
direct.h

The `direct.h` header file consists of various runtime declarations that pertain to the Win32 x86 targets for reading and manipulation of directories/folders.

Overview of direct.h

This header file defines the facilities as follows:
- `_getdcwd` on page 65 gets the current working directory.
- `_getdiskfree` on page 66 gets the amount of free disk space.
- `_getdrives` on page 66 gets drives available.

__getdcwd

Determines the current working directory information.

```c
#include <direct.h>
char * _getdcwd(int drive, char *path, int len);
```

<table>
<thead>
<tr>
<th>drive</th>
<th>int</th>
<th>The current drive as a number</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>char *</td>
<td>The current working directory path</td>
</tr>
<tr>
<td>len</td>
<td>int</td>
<td>The buffer size</td>
</tr>
</tbody>
</table>

Remarks

If the full path exceeds the buffers length unexpected results may occur.

The current working directory is returned if successful or NULL if failure occurs.

This function is Windows only when declared from this header.
direct.h
Overview of direct.h

See Also
"_chdrive" on page 81

__getdiskfree

Determines the free disk space.
#include <direct.h>
unsigned __getdiskfree(unsigned int drive, struct _diskfree_t *
dfree);

Table 10.2 __getdiskfree

<table>
<thead>
<tr>
<th>drive</th>
<th>unsigned int</th>
<th>The current drive as a number</th>
</tr>
</thead>
<tbody>
<tr>
<td>dfree</td>
<td>_diskfree_t *</td>
<td>A structure that holds the disk information</td>
</tr>
</tbody>
</table>

Remarks

The structure _diskfree_t holds the disk attributes.
Zero is returned on success, true value is returned on failure.
This function is Windows only when declared from this header.

See Also
"__getdrive" on page 85

__getdrives

Determines the logical drive information.
#include <direct.h>
unsigned long __getdrives(void);

Remarks

There is no parameter for this function.
Returns the logical drives as a long integer value. Bit 0 is drive A, bit 1 is drive B, bit 2 is drive C and so forth.
This function is Windows only when declared from this header.

See Also

"_getdrive" on page 85
dirent.h

The header `dirent.h` defines several file directory functions for reading directories.

Overview of dirent.h

This header file defines the facilities as follows:

- “opendir” on page 69 opens a directory stream.
- “readdir” on page 70 reads a directory stream.
- “readdir r” on page 70 reentrant read a directory stream.
- “rewinddir” on page 71 rewinds a directory stream.
- “closedir” on page 72 closes a directory stream.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also

Table 1.1 for information on POSIX naming conventions.

opendir

This function opens the directory named as an argument and returns a stream pointer of type `DIR`.

```c
#include <dirent.h>

DIR * opendir(const char *path);
```

Table 11.1 opendir

<table>
<thead>
<tr>
<th>path</th>
<th>const char *</th>
<th>The path of the directory to be opened</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
dirent.h
Overview of dirent.h

Remarks
This function returns NULL if the directory can not be opened. If successful a
directory stream pointer of type DIR * is returned.
This function may not be implemented on all platforms.

See Also
"closedir" on page 72

readdir
This function is used read the next directory entry.
#include <dirent.h>
struct dirent * readdir(DIR *dp);

Table 11.2 readdir

<table>
<thead>
<tr>
<th>dp</th>
<th>DIR *</th>
<th>The stream being read</th>
</tr>
</thead>
</table>

Remarks
The data pointed to by readdir() may be overwritten by another call to
readdir().
The function readdir returns the next directory entry from the stream dp as a
pointer of struct dirent.
This function may not be implemented on all platforms.

See Also
"rewinddir" on page 71

readdir_r
This function is the reentrant version to read the next directory entry.
#include <dirent.h>
int readdir_r(DIR *ref, struct dirent *entry, 
struct dirent ** result);
The `readdir_r()` function provides the same service as "readdir" on page 70. The difference is that `readdir()` would return a pointer to the next directory entry, and that pointer was internal to the library implementation. For `readdir_r()`, the caller provides the storage for the `dirent` struct.

On a successful call to `readdir_r()`, the function result is zero, the storage for entry is filled with the next directory entry, and the result pointer contains a pointer to entry. If the end of the directory is reached, the function result is zero and the result pointer is `NULL`. If any error occurs, the function result is an error code.

This function may require extra library support.
This function may not be implemented on all platforms.

**See Also**

"rewinddir" on page 71
"readdir" on page 70

### rewinddir

This function `rewinddir` resets the directory stream to the original position.

```c
#include <dirent.h>
void rewinddir(DIR * dp);
```

**Remarks**

There is no return.
This function may not be implemented on all platforms.

See Also

“opendir” on page 69

closedir

The function closedir() ends the directory reading process. It deallocates the directory stream pointer and frees it for future use.

```c
#include <dirent.h>
int closedir(DIR * dp);
```

Table 11.5 closedir

<table>
<thead>
<tr>
<th>dp</th>
<th>DIR *</th>
<th>The directory stream pointer to be closed</th>
</tr>
</thead>
</table>

Remarks

The function closedir() returns zero on success and the value of -1 on failure.

This function may not be implemented on all platforms.

See Also

“opendir” on page 69
The div.h header defines two structures used for math computations.

Overview of div_t.h

This header file defines the facilities as follows:
- “div_t” on page 73 stores remainder and quotient variables.
- “ldiv_t” on page 74 stores remainder and quotient variables.
- “lldiv_t” on page 74 stores remainder and quotient variables.

div_t
Stores the remainder and quotient from the div function.

```
#include <div_t.h>
typedef struct {
    int quot;
    int rem;
} div_t;
```

Remarks
This function may not be implemented on all platforms.

See Also
“div” on page 419
**div_t.h**

*Overview of div_t.h*

---

**ldiv_t**

Stores the remainder and quotient from the `ldiv` function.

```c
#include <div_t.h>
typedef struct {
    int    quot;
    int    rem;
} ldiv_t;
```

**Remarks**

This function may not be implemented on all platforms.

**See Also**

“`ldiv` on page 425”

---

**lldiv_t**

Stores the remainder and quotient from the `lldiv` function.

```c
#include <div_t.h>
typedef struct {
    long long    quot;
    long long    rem;
} lldiv_t;
```

**Remarks**

This function may not be implemented on all platforms.

**See Also**

“`ldiv` on page 425”

---
errno.h

The `errno.h` header file provides the global error code variable `extern errno`.

Overview of `errno.h`

There is one global declared in `errno.h`: “`errno` on page 75

---

`errno`

The `errno.h` header file provides the global error code variable `errno`.

```
#include <errno.h>
extern int errno;
```

The math library used for Mac OS and Windows (when optimized) is not fully compliant with the 1990 ANSI C standard in that none of the math functions set `errno`. The MSL math libraries provide better means of error detection. Using `fpclassify` (which is C99 portable) provides a better error reporting mechanism. The setting of `errno` is considered an obsolete mechanism because it is inefficient as well as uninformative.

Most functions in the standard library return a special value when an error occurs. Often the programmer needs to know about the nature of the error. Some functions provide detailed error information by assigning a value to the global variable `errno`. The `errno` variable is declared in the `errno.h` header file. See Table 13.1

The `errno` variable is not cleared when a function call is successful; its value is changed only when a function that uses `errno` returns its own error value. It is the programmer’s responsibility to assign 0 to `errno` before calling a function that uses it. For example:

Table 13.1 lists the error number macros defined in MSL. Not all these values are used in MSL but are defined in POSIX and other systems and are therefore defined in MSL to facilitate the compilation of codes being ported from other platforms.

This macro may not be implemented on all platforms.
### Table 13.1 Error Number Definitions

<tr>
<td>ENOMEM</td>
<td>Win32 assigned only, No error detected</td>
</tr>
<tr>
<td>EMACOSERR</td>
<td>Mac OS assigned only, the value is assigned to the global variable __MacOSErrNo</td>
</tr>
</tbody>
</table>
#include <errno.h>
#include <stdio.h>
#include <extras.h>

int main(void)
{
    char *num = "5000000000";
    long result;
    result = strtol(num, 0, 10);

    if (errno == ERANGE)
        printf("Range error!\n");
    else
        printf("The string as a long is %ld", result);

    return 0;
}

Output:
Range error!
The header extras.h defines several CodeWarrior provided non standard console functions.

Overview of extras.h

The extras.h header file consists of several functions which may be indirectly included by other headers or included for use directly through extras.h. This header file defines the facilities as follows:

- "chdrive" on page 81 changes the working drive.
- "chsize" on page 82 changes a file size.
- "filelength" on page 82 gets the file length.
- "fileno" on page 83 gets the file number.
- "fullpath" on page 84 gets the full pathname.
- "gcvt" on page 85 converts a floating point value to a string.
- "getdrive" on page 85 gets the drive as a number.
- "GetHandle" on page 86 (Windows only) gets console handle.
- "get_osfhandle" on page 86 get an operating system handle.
- "heapmin" on page 87 releases unused heap to the system.
- "itoa" on page 87 converts int to string.
- "itow" on page 88 converts int to wide character string.
- "ltoa" on page 88 converts long to string.
- "ltow" on page 89 converts long to wide character string.
- "makepath" on page 90 creates a path.
- "open_osfhandle" on page 90 opens an operating system handle.
- "putenv" on page 91 puts an environment variable.
- "searchenv" on page 92 searches the environment variable.
- "splitpath" on page 92 splits a path into components.
- "strcasecmp" on page 93 converts both strings to lower case before comparing them.
extras.h
Overview of extras.h

- “strcmpi” on page 94 performs case-insensitive string compare.
- “strdate” on page 94 stores a date in a string.
- “strdup” on page 95 duplicates a string.
- “stricmp” on page 96 performs string comparison ignoring case.
- “stricoll” on page 96 performs case-insensitive locale collating string comparison.
- “strlwr” on page 97 converts string to lower case.
- “strncasecmp” on page 97 converts both strings to lower case before comparing them.
- “strncmpi” on page 98 performs case-insensitive string compare.
- “strnicmp” on page 100 performs string comparison ignoring case but specifying the comparison length.
- “strncoll” on page 99 performs length-limited locale collating string comparison.
- “strncoll” on page 100 performs case-insensitive locale collating string comparison with a length limitation.
- “strnset” on page 101 sets a number of characters in a string.
- “strrev” on page 102 reverses characters in a string.
- “strset” on page 102 sets characters in a set.
- “strspnp” on page 103 finds a string in another string.
- “strupr” on page 104 converts string to upper case.
- “tell” on page 104 gets the file indicator position.
- “ultoa” on page 105 converts unsigned long to string.
- “ultow” on page 106 converts unsigned long to wide character string.
- “wcsdup” on page 107 creates a wide character string duplicate.
- “wcsicoll” on page 108 performs case-insensitive string comparison collated by locale setting.
- “wcsicmp” on page 108 performs wide character string comparison ignoring case.
- “wcsicoll” on page 109 converts wide character string to lower case.
- “wcsncoll” on page 110 performs length-limited locale collating wide string comparison.
- “wcsnicmp” on page 110 performs wide character string comparison ignoring case but specifying the comparison length.
- “wcsnicoll” on page 110 performs length-limited locale collating wide string case insensitive comparison.
- “wcsnset” on page 112 sets a number of characters in a wide character string.
extras.h
Overview of extras.h

- "wcsrev" on page 113 reverses a wide character string.
- "wcset" on page 113 sets characters in a wide character string.
- "wcspnp" on page 114 finds a wide character string in another wide character string.
- "wstrrev" on page 115 reverses wide character string.
- "wcsupr" on page 114 converts wide string to upper case.
- "wtoi" on page 115 converts wide string to integer.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also
"MSL Extras Library Headers” on page 4 for information on POSIX naming conventions.

_chdrive

Changes the current drive by number.

```c
#include <extras.h>
_chdrive(int drive);
```

Table 14.1 _chdrive

<table>
<thead>
<tr>
<th>drive</th>
<th>int</th>
<th>The drive as a number</th>
</tr>
</thead>
</table>

Remarks

The drive is listed as a number, 1 for A, 2 for B, 3 for C, and so forth.
Zero is returned on success and negative one on failure.
This function may not be implemented on all platforms.

See Also
"_getdrive" on page 85
extras.h
Overview of extras.h

chsize

This function is used to change a file's size.

#include <extras.h>

int chsize(int handle, long size);
int _chsize(int handle, long size);

<table>
<thead>
<tr>
<th>Table 14.2 chsize</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
</tr>
<tr>
<td>size</td>
</tr>
</tbody>
</table>

Remarks

If a file is truncated all data beyond the new end of file is lost.
This function returns zero on success and a negative one if a failure occurs.

See Also

"GetHandle" on page 86

filelength

Retrieves the file length based on a file handle.

#include <extras.h>

int filelength(int fileno);
int _filelength(int fileno);

<table>
<thead>
<tr>
<th>Table 14.3 filelength</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileno</td>
</tr>
</tbody>
</table>

The filelength as an int value is returned on success. A negative one is returned on failure.
This function may not be implemented on all platforms.
Overview of extras.h

See Also

“GetHandle” on page 86

fileno

Obtains the file descriptor associated with a stream.

#include <extras.h>

int fileno(FILE *stream);

Remarks

This function obtains the file descriptor for the stream. You can use the file descriptor with other functions in unix.h, such as read() and write().

For the standard I/O streams stdin, stdout, and stderr, fileno() returns the values listed in Table 14.5.

Table 14.5 Fileno Return Value for Standard Streams

<table>
<thead>
<tr>
<th>This function call...</th>
<th>Returns this file descriptor...</th>
</tr>
</thead>
<tbody>
<tr>
<td>fileno(stdin)</td>
<td>0</td>
</tr>
<tr>
<td>fileno(stdout)</td>
<td>1</td>
</tr>
<tr>
<td>fileno(stderr)</td>
<td>2</td>
</tr>
</tbody>
</table>

If it is successful, fileno() returns a file descriptor. If it encounters an error, it returns -1 and sets errno.

This function may not be implemented on all platforms.

See Also

“fdopen” on page 306

“open, _wopen” on page 121
extras.h
Overview of extras.h

Figure 14.1 Example of fileno() usage.

```c
#include <extras.h>
#include <stdio.h>

int main(void)
{
    printf("The handle for the standard input device is: \%d",
           fileno(stdin));

    return 0;
}
```

Result
The handle for the standard input device is: 0

__fullpath

Converts a relative path name to a full path name.

```c
#include <extras.h>
char *__fullpath(char * absPath,
                 const char * relPath, size_t maxLength);
```

<table>
<thead>
<tr>
<th>absPath</th>
<th>char *</th>
<th>The full absolute path</th>
</tr>
</thead>
<tbody>
<tr>
<td>relPath</td>
<td>const char *</td>
<td>The relative path</td>
</tr>
<tr>
<td>maxLength</td>
<td>size_t</td>
<td>The maximum path length</td>
</tr>
</tbody>
</table>

Remarks
If the maxLength is NULL a path of up to MAX_PATH is used.
A pointer to the absPath is returned on success. On failure NULL is returned.
This function may not be implemented on all platforms.
gcvt

This function converts a floating point value to a null terminated char string.

```c
#include <extras.h>
char *gcvt(double value, int digits, char *buffer);
char *_gcvt(double value, int digits, char *buffer);
```

### Remarks

The resultant string includes the decimal point and sign of the original value.
This function returns a pointer to the `buffer` argument.
This function may not be implemented on all platforms.

### See Also

“`atof` on page 410

---

_getdrive

Finds the current drive as a number.

```c
#include <extras.h>
int _getdrive();
```

This facility has no parameters.
The current drive number is returned.
This function may not be implemented on all platforms.
extras.h
Overview of extras.h

See Also
"_chdrive" on page 81
"GetHandle" on page 86

GetHandle

GetHandle retrieves the current objects handle.
#include <extras.h>
int GetHandle();
This facility has no parameters.
The device handle is returned on success. A negative one is returned on failure.
This function may not be implemented on all platforms.

See Also
"fileno" on page 83

__get_osfhandle

Retrieve an operating system file handle.
#include <extras.h>
long __get_osfhandle(int filehandle);

<table>
<thead>
<tr>
<th>filehandle</th>
<th>int</th>
<th>An operating system file handle</th>
</tr>
</thead>
</table>

An operating system file handle as opposed to C file handle is returned if successful
otherwise sets errno and returns NULL.
This function may not be implemented on all platforms.

See Also
"GetHandle" on page 86
"_open_osfhandle" on page 90.
heapmin

This function releases the heap memory back to the system.

```c
#include <extras.h>
int heapmin(void);

int _heapmin(void);
```

This facility has no parameters.

Heapmin returns zero if successful otherwise sets errno to ENOSYS and returns -1;

itoa

This function converts an int value to a null terminated char array.

```c
#include <extras.h>
char * itoa(int val, char *str, int radix);

char * _itoa(int val, char *str, int radix);
```

### Table 14.9 itoa

<table>
<thead>
<tr>
<th>val</th>
<th>int</th>
<th>The integer value to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>char *</td>
<td>The string to store the converted value</td>
</tr>
<tr>
<td>radix</td>
<td>int</td>
<td>The numeric base of the number to be converted</td>
</tr>
</tbody>
</table>

#### Remarks

The radix is the base of the number in a range of 2 to 36.

A pointer to the converted string is returned.

This function may not be implemented on all platforms.

#### See Also

“atoi” on page 411

“ltoa” on page 88
### itow

This function converts an int value to a null terminated wide char array.

```c
#include <extras.h>
wchar_t* itow(int val, wchar_t *str, int radix);
wchar_t* _itow(int val, wchar_t *str, int radix);
```

<table>
<thead>
<tr>
<th>val</th>
<th>int</th>
<th>The integer value to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>wchar_t*</td>
<td>The string to store the converted value</td>
</tr>
<tr>
<td>radix</td>
<td>int</td>
<td>The numeric base of the number to be converted</td>
</tr>
</tbody>
</table>

**Remarks**
- The radix is the base of the number in a range of 2 to 36.
- A pointer to the converted wide character string is returned.
- This function may not be implemented on all platforms.

**See Also**
- “itoa” on page 87

### ltoa

This function converts a long int value to a null terminated char array.

```c
#define ltoa(x, y, z) _itoa(x, y, z);
#define _ltoa(x, y, z) _itoa(x, y, z);
```

**Remarks**
- This function simply redefines _itoa for 32 bit systems.
- A pointer to the converted wide character string is returned.
This function may not be implemented on all platforms.

**See Also**

“itoa” on page 87
“atol” on page 412

## _ltow

This function converts an long value to a null terminated wide char array.

```
#include <extras.h>
wchar_t *ltow(unsigned long val, wchar_t *str, int radix);
```

<table>
<thead>
<tr>
<th>Table 14.11 _ltow</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
</tr>
<tr>
<td>val</td>
</tr>
<tr>
<td>radix</td>
</tr>
</tbody>
</table>

**Remarks**

The radix is the base of the number in a range of 2 to 36.
A pointer to the converted wide character string is returned.
This function may not be implemented on all platforms.

**See Also**

“itow” on page 88,
“ltoh” on page 88.
makepath

Makepath is used to create a path.

```c
#include <extras.h>
void makepath(char *path, const char *drive,
              const char *dir, const char *fname, const char *ext);
void _makepath(char *path, const char *drive,
               const char *dir, const char *fname, const char *ext);
```

<table>
<thead>
<tr>
<th>Table 14.12 makepath</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
</tr>
<tr>
<td>drive</td>
</tr>
<tr>
<td>dir</td>
</tr>
<tr>
<td>fname</td>
</tr>
<tr>
<td>ext</td>
</tr>
</tbody>
</table>

There is no return value.

This function may not be implemented on all platforms.

See Also

"_chdrive" on page 81

__open_osfhandle

Opens an operating system handle.

```c
#include <extras.h>
int _open_osfhandle(long ofshandle, int flags);
```
### extras.h

**Overview of extras.h**

<table>
<thead>
<tr>
<th>Remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>This function opens an operating system handle as a C file handle.</td>
</tr>
<tr>
<td>The file handle value is returned on success. A negative one is returned on failure.</td>
</tr>
<tr>
<td>This function may not be implemented on all platforms.</td>
</tr>
</tbody>
</table>

**See Also**

“`get_osfhandle`” on page 86.

---

### putenv

**Remarks**

May also be used to modify or delete an existing string. The string must be a global value.

The environment is restored at the program termination.

Zero is returned on success or negative one on failure.

This function may not be implemented on all platforms.

---

**Table 14.13 _open_osfhandle**

<table>
<thead>
<tr>
<th>ofhandle</th>
<th>long</th>
<th>The file as an operating system handle</th>
</tr>
</thead>
<tbody>
<tr>
<td>flags</td>
<td>int</td>
<td>file opening flags</td>
</tr>
</tbody>
</table>

**Table 14.14 putenv**

<table>
<thead>
<tr>
<th>inVarName</th>
<th>char *</th>
<th>The string to add to the environmental variable</th>
</tr>
</thead>
</table>

---

**putenv**

Adds a string to the environmental variable.

```c
#include <extras.h>
int putenv(const char * inVarName)
int _putenv(const char * inVarName)
```
extras.h
Overview of extras.h

_searchenv

Searches the environmental path for a file.
#include <extras.h>
void _searchenv(const char *filename,
    const char *varname, char *pathname);

<table>
<thead>
<tr>
<th>filename</th>
<th>const char *</th>
<th>The file to search for</th>
</tr>
</thead>
<tbody>
<tr>
<td>varname</td>
<td>const char *</td>
<td>The environmental variable name</td>
</tr>
<tr>
<td>pathname</td>
<td>char *</td>
<td>The path name of the file</td>
</tr>
</tbody>
</table>

Remarks
The current drive is searched first then a specified environmental variable path is searched.
There is no return value.
This function may not be implemented on all platforms.

splitpath

This function takes a path and returns pointers to each of the components of the path.
#include <extras.h>
void splitpath(const char *path, char *drive,
    char *dir, char *fname, char *ext)
void _splitpath(const char *path, char *drive,
    char *dir, char *fname, char *ext)
The programmer must provide arrays large enough to hold the various components. This function may not be implemented on all platforms.

See Also

“chdir” on page 513

### strcasecmp

A function for ignore case string comparison

```c
#include <extras.h>
int strcasecmp(const char *str1, const char *str2);
```

#### Table 14.17 strcasecmp

<table>
<thead>
<tr>
<th>str1</th>
<th>const char *</th>
<th>String being compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>str2</td>
<td>const char *</td>
<td>Comparison string</td>
</tr>
</tbody>
</table>

**Remarks**

The function converts both strings to lower case before comparing them.

Strcasecmp returns greater than zero if str1 is larger than str2 and less than zero if str2 is larger than str1. If they are equal returns zero.
This function may not be implemented on all platforms.

See Also

“strncasecmp” on page 97
“stricmp” on page 96.

stricmp

A case insensitive string compare.

#include <extras.h>
int stricmp(const char *s1, const char *s2);
int _stricmp(const char *s1, const char *s2);

Table 14.18  stricmp

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The first string to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const char *</td>
<td>The comparison string</td>
</tr>
</tbody>
</table>

An integer value of less than zero if the first argument is less than the second in a case insensitive string comparison. A positive value if the first argument is greater than the second argument in a case insensitive string comparison. Zero is returned if both case insensitive strings are the same.

This function may not be implemented on all platforms.

See Also

“strcasecmp” on page 93
“strnicmp” on page 100

strdate

The strdate function stores a date in a buffer provided.

#include <extras.h>
char * strdate(char *str);
char * _strdate(char *str);
The function returns a pointer to the `str` argument.

**Remarks**

This function stores a date in the buffer in the string format of mm/dd/yy where the buffer must be at least 9 characters.

This function may not be implemented on all platforms.

**See Also**

“strftime” on page 499

---

### strdup

Creates a duplicate string in memory.

```c
#include <extras.h>
char * strdup(const char *str);
char * _strdup(const char *str);
```

<table>
<thead>
<tr>
<th>str</th>
<th>const char *</th>
<th>The string to be copied</th>
</tr>
</thead>
<tbody>
<tr>
<td>A pointer to the storage location or NULL if unsuccessful.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>This function may not be implemented on all platforms.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**See Also**

“memcpy” on page 457
**stricmp**

A function for string comparison ignoring case.

```c
#include <extras.h>

int stricmp(const char *s1, const char *s2);
int _stricmp(const char *s1, const char *s2);
```

<table>
<thead>
<tr>
<th>s1</th>
<th>s2</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char *</td>
<td>const char *</td>
<td>The string being compared</td>
</tr>
</tbody>
</table>

Stricmp returns greater than zero if str1 is larger than str2 and less than zero if str2 is larger than str1. If they are equal returns zero.

This function may not be implemented on all platforms.

**See Also**

“strcmp” on page 461
“strncmp” on page 470

---

**stricoll**

A case insensitive locale collating string comparison.

```c
#include <extras.h>

int stricoll(const char *s1, const char *s2);
int _stricoll(const char *s1, const char *s2);
```

<table>
<thead>
<tr>
<th>s1</th>
<th>s2</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char *</td>
<td>const char *</td>
<td>The string to compare</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>s1</th>
<th>s2</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char *</td>
<td>const char *</td>
<td>A comparison string</td>
</tr>
</tbody>
</table>

Remarks

The comparison is done according to a collating sequence specified by the LC_COLLATE component of the current locale.

If the first string is less than the second a negative number is returned. If the first string is greater than the second then a positive number is returned. If both strings are equal then zero is returned.

This function may not be implemented on all platforms.

See Also

“strncoll” on page 99
“wcsicoll” on page 108

---

strlwr

This function converts a string to lowercase.

```c
#include <extras.h>
char * strlwr(char *str);
char * _strlwr(char *str);
```

Table 14.23 strlwr

<table>
<thead>
<tr>
<th>str</th>
<th>char</th>
<th>The string being converted</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>char</td>
<td>The string being converted</td>
</tr>
</tbody>
</table>

A pointer to the converted string is returned.

This function may not be implemented on all platforms.

See Also

“strupr” on page 104
“tolower” on page 62

---

strncasecmp

Ignore case string comparison function with length specified.

```c
#include <string.h>
int strncasecmp(const char *s1, const char *s2, unsigned n);
```
### `strncasecmp`

A length limited case insensitive comparison of one string to another string.

```c
#include <extras.h>

int strncasecmp(const char *s1, const char *s2, size_t n);
int _strncasecmp(const char *s1, const char *s2, size_t n);
```

<table>
<thead>
<tr>
<th>s1</th>
<th>A string to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>A comparison string</td>
</tr>
<tr>
<td>n</td>
<td>number of characters to compare</td>
</tr>
</tbody>
</table>

**Remarks**

Starting at the beginning of the string characters of the strings are compared until a difference is found or until \( n \) characters have been compared.
If the first argument is less than the second argument in a case insensitive comparison a negative integer is returned. If the first argument is greater than the second argument in a case insensitive comparison then a positive integer is returned. If they are equal then zero is returned.

This function may not be implemented on all platforms.

See Also

“stricmp” on page 96
“strncasecmp” on page 97
“wcsicmp” on page 108

strncoll

A length limited locale collating string comparison.

```
#include <extras.h>

int strncoll(const char *s1, const char *s2, size_t n);
int _strncoll(const char *s1, const char *s2, size_t sz);
```

Table 14.26  strncoll

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The string to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const char *</td>
<td>A comparison string</td>
</tr>
<tr>
<td>sz</td>
<td>size_t</td>
<td>Number of characters to collate</td>
</tr>
</tbody>
</table>

Remarks

The comparison is done according to a collating sequence specified by the LC_COLLATE component of the current locale.

If the first string is less than the second a negative number is returned. If the first string is greater than the second then a positive number is returned. If both strings are equal then zero is returned.

This function may not be implemented on all platforms.

See Also

“strncoll” on page 100
“wcsncoll” on page 110
#strnicmp

A function for string comparison ignoring case but specifying the comparison length.

```c
#include <extras.h>

int strnicmp(const char *s1, const char *s2, int n);
nt _strnicmp(const char *s1, const char *s2, int n);
```

The function `strnicmp` returns greater than zero if `s1` is larger than `s2` and less than zero if `s2` is larger than `s1`. If they are equal returns zero.

This function may not be implemented on all platforms.

**See Also**

“`strcmp` on page 461”
“`strncmp` on page 470”

##strnicoll

A case insensitive locale collating string comparison with a length limitation.

```c
#include <extras.h>

int strnicoll(const char *s1, const char *s2, size_t sz);
nt _strnicoll(const char *s1, const char *s2, size_t sz);
```

**Table 14.27 strnicmp**

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The string being compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const char *</td>
<td>The comparison string</td>
</tr>
<tr>
<td>n</td>
<td>int</td>
<td>Maximum comparison length</td>
</tr>
</tbody>
</table>

The function `strnicoll` returns greater than zero if `s1` is larger than `s2` and less than zero if `s2` is larger than `s1`. If they are equal returns zero.

This function may not be implemented on all platforms.

**See Also**

“`strcoll` on page 464”
“`strncoll` on page 471”
Overview of extras.h

### Remarks

The comparison is done according to a collating sequence specified by the \texttt{LC_COLLATE} component of the current locale.

If the first string is less than the second a negative number is returned. If the first string is greater than the second then a positive number is returned. If both strings are equal then zero is returned.

### See Also

- "\texttt{stricoll}" on page \pageref{stricoll}
- "\texttt{wcsicoll}" on page \pageref{wcsicoll}

---

**strnset**

This function sets the first \( n \) characters of string to a character.

```c
#include <extras.h>

char * strnset(char *str, int c, size_t n)
char * _strnset(char *str, int c, size_t n)
```

### Table 14.29 strnset

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
</tr>
</thead>
<tbody>
<tr>
<td>sz</td>
<td>size_t</td>
</tr>
</tbody>
</table>

### Remarks

If the number of characters exceeds the length of the string all characters are set except for the terminating character.

A pointer to the altered string is returned.

---

MSL C Reference Version 10

101
This function may not be implemented on all platforms.

See Also

“strset” on page 102

---

### strrev

This function reverses a string.

```c
#include <extras.h>
char * _strrev(char *str);
```

Table 14.30 _strrev

<table>
<thead>
<tr>
<th>str</th>
<th>char *</th>
<th>The string to be reversed</th>
</tr>
</thead>
</table>

A pointer to the reversed string.

This function may not be implemented on all platforms.

See Also

“strcpy” on page 464

---

### strset

This function sets characters of string to a character

```c
#include <extras.h>
char * strset(char *str, int c)
```

Table 14.31 strset

<table>
<thead>
<tr>
<th>str</th>
<th>char *</th>
<th>The string to be modified</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>int</td>
<td>The char to be set</td>
</tr>
</tbody>
</table>

A pointer to the altered string is returned.
This function may not be implemented on all platforms.

See Also

“strnset” on page 101

**strspnp**

This function returns pointer to first character in s1 that isn't in s2

```c
#include <extras.h>
char * strspnp(char *s1, const char *s2)
char * _strspnp(char *s1, const char *s2)
```

<table>
<thead>
<tr>
<th>Table 14.32 strspnp</th>
</tr>
</thead>
<tbody>
<tr>
<td>s1</td>
</tr>
<tr>
<td>s2</td>
</tr>
</tbody>
</table>

Remarks

This function determines the position in the string being searched is not one of the chars in the string set.

A pointer to the first character in s1 that is not in s2 or NULL is returned if all the characters of s1 are in s2.

This function may not be implemented on all platforms.

See Also

“strcspn” on page 465
“strspn” on page 475
**extras.h**

*Overview of extras.h*

---

**strupr**

The function `strupr` converts a string to uppercase.

```c
#include <extras.h>
char * strupr(char *str);
char * _strupr(char *str);
```

<table>
<thead>
<tr>
<th>Table 14.33  strupr</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
</tr>
</tbody>
</table>

A pointer to the converted string is returned.

This function may not be implemented on all platforms.

**See Also**

- "toupper" on page 63
- "strlwr" on page 97

---

**tell**

Returns the current offset for a file.

```c
#include <extras.h>
long tell(int fildes);
```

<table>
<thead>
<tr>
<th>Table 14.34  tell</th>
</tr>
</thead>
<tbody>
<tr>
<td>fildes</td>
</tr>
</tbody>
</table>

**Remarks**

This function returns the current offset for the file associated with the file descriptor `fildes`. The value is the number of bytes from the file's beginning.

If it is successful, `tell()` returns the offset. If it encounters an error, `tell()` returns `-1L`.

This function may not be implemented on all platforms.
### extras.h

**Overview of extras.h**

See Also

- “ftell” on page 344
- “lseek” on page 527

#### Listing 14.1 Example of tell() Usage

```c
#include <stdio.h>
#include <extras.h>

int main(void)
{
    int fd;
    long int pos;

    fd = open("mytest", O_RDWR | O_CREAT | O_TRUNC);
    write(fd, "Hello world!\n", 13);
    write(fd, "How are you doing?\n", 19);

    pos = tell(fd);
    printf("You're at position %ld.", pos);
    close(fd);
    return 0;
}
```

**Result**

This program prints the following to standard output:

You're at position 32.

---

**ultoa**

This function converts an unsigned long value to a null terminated char array.

```c
#include <extras.h>
char * ultoa(unsigned long val, char *str, int radix);
char * _ultoa(unsigned long val, char *str, int radix);
```
The radix is the base of the number in a range of 2 to 36. This function is the converse of `strtoul()` and uses the number representation described there. A pointer to the converted string is returned. This function may not be implemented on all platforms.

**See Also**

- "itoa" on page 87
- "ltos" on page 88

### _ultow

This function converts an unsigned long value to a null terminated wide character array.

```c
#include <extras.h>
wchar_t *_ultow(unsigned long val, wchar_t *str, int radix);
```

**Table 14.36  _ultow**

<table>
<thead>
<tr>
<th>val</th>
<th>unsigned long</th>
<th>The value to be converted</th>
</tr>
</thead>
<tbody>
<tr>
<td>str</td>
<td>wchar_t *</td>
<td>A buffer large enough to hold the converted value</td>
</tr>
<tr>
<td>radix</td>
<td>int</td>
<td>The base of the number being converted</td>
</tr>
</tbody>
</table>
Remarks

The radix is the base of the number in a range of 2 to 36. This function is the wide character equivalent of `strtoul()` and uses the number representation described there.

A pointer to the converted wide character string is returned.

This function may not be implemented on all platforms.

See Also

“strtoul” on page 443
“itow” on page 88
“_ltow” on page 89

wcsdup

Creates a duplicate wide character string in memory.

```c
#include <extras.h>

wchar_t * wcsdup(const wchar_t *str)
wchar_t * _wcsdup(const wchar_t *str)
```

Table 14.37 wcsdup

<table>
<thead>
<tr>
<th>str</th>
<th>const wchar_t *</th>
<th>The string to be copied</th>
</tr>
</thead>
</table>

A pointer to the storage location is returned upon success or NULL is returned if unsuccessful.

This function may not be implemented on all platforms.

See Also

“strdup” on page 95
**extras.h**

*Overview of extras.h*

---

**wcsicmp**

A function for wide character string comparison ignoring case.

```c
#include <extras.h>

int wcsicmp(const wchar_t *s1, const wchar_t *s2);
int _wcsicmp(const wchar_t *s1, const wchar_t *s2);
```

Table 14.38  **wcsicmp**

<table>
<thead>
<tr>
<th>s1</th>
<th>const wchar_t *</th>
<th>The string being compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const wchar_t *</td>
<td>The comparison string</td>
</tr>
</tbody>
</table>

The function _wcsicmp returns greater than zero if str1 is larger than str2 and less than zero if str2 is larger than str1. If they are equal returns zero.

This function may not be implemented on all platforms.

**See Also**

“`strcmp` on page 461”

“`strncmp` on page 470”

---

**wcsicoll**

A case insensitive locale collating wide character string comparison.

```c
#include <extras.h>

int wcsicoll(const wchar_t *s1, const wchar_t *s2);
int _wcsicoll(const wchar_t *s1, const wchar_t *s2);
```

Table 14.39  **wcsicoll**

<table>
<thead>
<tr>
<th>s1</th>
<th>const wchar_t *</th>
<th>The wide string to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const wchar_t *</td>
<td>A comparison wide character string</td>
</tr>
</tbody>
</table>

---

108  

*MSL C Reference Version 10*
**Remarks**

The comparison is done according to a collating sequence specified by the LC_COLLATE component of the current locale.

If the first string is less than the second a negative number is returned. If the first string is greater than the second then a positive number is returned. If both strings are equal then zero is returned.

This function may not be implemented on all platforms.

**See Also**

“wcsncoll” on page 110

“stricoll” on page 96

### wcslwr

This function converts a string to lowercase.

```c
#include <extras.h>

wchar_t *wcslwr(wchar_t *str);

wchar_t *wcslwr(wchar_t *str);
```

**See Also**

“strupr” on page 104

“strlwr” on page 97
extras.h
Overview of extras.h

wcsncoll

A length limited locale collating wide string comparison.

```
#include <extras.h>
int wcsncoll(const wchar_t *s1, const wchar_t *s2, size_t sz);
int _wcsncoll(const wchar_t *s1, const wchar_t *s2, size_t sz);
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>s1</strong></td>
<td>const wchar_t *</td>
</tr>
<tr>
<td><strong>s2</strong></td>
<td>const wchar_t *</td>
</tr>
<tr>
<td><strong>sz</strong></td>
<td>size_t</td>
</tr>
</tbody>
</table>

**Remarks**

The comparison is done according to a collating sequence specified by the LC_COLLATE component of the current locale.

If the first string is less than the second a negative number is returned. If the first string is greater than the second then a positive number is returned. If both strings are equal then zero is returned.

This function may not be implemented on all platforms.

**See Also**

“stricoll” on page 96
“wcsnicoll” on page 110

wcsnicoll

A length limited locale collating wide string case insensitive comparison.

```
#include <extras.h>
int wcsnicoll(const wchar_t *s1, const wchar_t *s2, size_t sz);
```
```c
int _wcsnicoll(const wchar_t *s1, const wchar_t *s2, size_t sz);
```

### Remarks

The comparison is done according to a collating sequence specified by the `LC_COLLATE` component of the current locale.

If the first string is less than the second a negative number is returned. If the first string is greater than the second then a positive number is returned. If both strings are equal then zero is returned.

This function may not be implemented on all platforms.

### See Also

- “wcsncoll” on page 110
- “strnicoll” on page 100

---

### wcsnicmp

A function for a wide character string comparison ignoring case but specifying the comparison length.

```c
#include <extras.h>
iint wcsnicmp(const wchar_t *s1, const wchar_t *s2, size_t n);
iint _wcsnicmp(const wchar_t *s1, const wchar_t *s2, size_t n);
```

#### Table 14.43 wcsnicmp

<table>
<thead>
<tr>
<th>s1</th>
<th>const wchar_t *</th>
<th>The string being compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const wchar_t *</td>
<td>A comparison wide character string</td>
</tr>
<tr>
<td>sz</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The function `_wcsnicmp` returns greater than zero if str1 is larger than str2 and less than zero if str2 is larger than str1. If they are equal returns zero.

This function may not be implemented on all platforms.

See Also

“stricmp” on page 96
“strncmp” on page 470

wcsnset

This function sets the first n characters of wide character string to a character.

```c
#include <extras.h>

wchar_t *wcsnset(wchar_t *str, wchar_t wc, size_t n);
wchar_t *wcsnset(wchar_t *str, wchar_t wc, size_t n);
```

**Table 14.44 wcsnset**

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t *</th>
<th>The string to be modified</th>
</tr>
</thead>
<tbody>
<tr>
<td>wc</td>
<td>wchar_t</td>
<td>The char to be set</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The number of characters in the string to set.</td>
</tr>
</tbody>
</table>

Remarks

If the number of characters exceeds the length of the string all characters are set except for the terminating character.
A pointer to the altered string is returned.
This function may not be implemented on all platforms.
see also

"strset" on page 102

wcsrev

This function reverses a wide character string.
#include <extras.h>
wchar_t * wcsrev(wchar_t *str);
wchar_t * _wcsrev(wchar_t *str);

Table 14.45 wcsrev

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t *</th>
<th>The string to be reversed</th>
</tr>
</thead>
</table>

A pointer to the reversed string is returned.
This function may not be implemented on all platforms.

See Also

"wstrrev" on page 115

wcsset

This function sets characters of a wide character string to a wide character.
#include <extras.h>
wchar_t * wcsset(wchar_t *str, wchar_t wc);
wchar_t * _wcsset(wchar_t *str, wchar_t wc);

Table 14.46 wcsset

<th>wchar_t *</th>
<th>The string to be modified</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>wchar_t</td>
<td>The char to be set</td>
</tr>
</tbody>
</table>

A pointer to the altered string is returned.
extras.h
Overview of extras.h

See Also
“strnset” on page 101

wcsspnp

This function returns pointer to first character in s1 that isn't in s2
#include <extras.h>
wchar_t * wcsspnp(const wchar_t *s1, const wchar_t *s2);
wchar_t * _wcsspnp(const wchar_t *s1, const wchar_t *s2);

Table 14.47  wcsspnp

<table>
<thead>
<tr>
<th>s1</th>
<th>const wchar_t *</th>
<th>The string being checked</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const wchar_t *</td>
<td>The search string as a char set.</td>
</tr>
</tbody>
</table>

Remarks
This function determines the position in the string being searched is not one of the chars in the string set.
A pointer to the first character in s1 that is not in s2 or NULL if all the characters of s1 are in s2.
This function may not be implemented on all platforms.

See Also
“strspnp” on page 103
“strspn” on page 475

wcsupr

The function _wcsupr  converts a wide character string to uppercase.
#include <extras.h>
wchar_t * wcsupr(wchar_t *str);
wchar_t * _wcsupr(wchar_t *str);
**wcsupr**

Table 14.48  wcsupr

| str | wchar_t * | The string being converted |

A pointer to the converted string is returned.
This function may not be implemented on all platforms.

**See Also**

“strupr” on page 104
“strlwr” on page 97

**wstrrev**

This function reverses a wide character string.

```c
#include <string.h>
wchar_t * _wstrrev(wchar_t * str);
```

`Table 14.49  _wstrrev`

| str | wchar_t * | The string to be reversed |

A pointer to the reversed string is returned.
This function may not be implemented on all platforms.

**See Also**

“strrev” on page 102

**wtoi**

This function converts a null terminated wide char array to an int value.

```c
#include <extras.h>
int wtoi(const wchar_t *str);
int _wtoi(const wchar_t *str);
```
The `_wtoi()` function converts the character array pointed to by `str` to an integer value.

This function skips leading white space characters.

This function sets the global variable `errno` to `ERANGE` if the converted value cannot be expressed as a value of type int.

The function `_wtoi()` returns the converted integer value.

This function may not be implemented on all platforms.

**See Also**

“`atoi`” on page 411
The header file `fcntl.h` contains several file control functions that are useful for porting a program from UNIX.

**Overview of fcntl.h**

This header file defines the facilities as follows:

- "`creat, _wcreate` on page 118" creates a file.
- "`fcntl` on page 119" manipulates a file descriptor.
- "`open, _wopen` on page 121" opens a file and returns its ID.

**fcntl.h and UNIX Compatibility**

The header file `fcntl.h.h` contains several functions that are useful for porting a program from UNIX. These functions are similar to the functions in many UNIX libraries. However, since the UNIX and Macintosh operating systems have some fundamental differences, they cannot be identical. The descriptions of the functions tell you what the differences are.

Generally, you don’t want to use these functions in new programs. Instead, use their counterparts in the native API.

**NOTE**

If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

**See Also**

"`MSL Extras Library Headers` on page 4" for information on POSIX naming conventions.
**Overview of fcntl.h**

---

**creat, _wcreate**

Create a new file or overwrite an existing file and a wide character variant.

```c
#include <fcntl.h>
int creat(const char *filename, int mode);
int _creat(const char *filename, int mode);
int _wcreat(const wchar_t *wfilename, int mode);
```

<table>
<thead>
<tr>
<th><strong>filename</strong></th>
<th>char*</th>
<th>The name of the file being created</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>wfilename</strong></td>
<td>wchar_t*</td>
<td>The name of the file being created</td>
</tr>
<tr>
<td><strong>mode</strong></td>
<td>int</td>
<td>The open mode</td>
</tr>
</tbody>
</table>

**Remarks**

This function creates a file named `filename` you can write to. If the file does not exist, `creat()` creates it. If the file already exists, `creat()` overwrites it. The function ignores the argument mode.

This function call:

```c
creat(path, mode);
```

is equivalent to this function call:

```c
open(path, O_WRONLY|O_CREAT|O_TRUNC, mode);
```

If it’s successful, `creat()` returns the file description for the created file. If it encounters an error, it returns -1.

This function may not be implemented on all platforms.

**See Also**

“fopen” on page 317
“fdopen” on page 306
“close” on page 515.
Listing 15.1 Example of creat() Usage

```c
#include <stdio.h>
#include <unix.h>

int main(void)
{
    int fd;

    fd = creat("Jeff:Documents:mytest", 0);
    /* Creates a new file named mytest in the folder Documents on the volume Akbar. */
    write(fd, "Hello world!\n", 13);
    close(fd);
    return 0;
}
```

**fcntl**

Manipulates a file descriptor.

```c
#include <fcntl.h>

int fcntl(int fildes, int cmd, ...);
int _fcntl(int fildes, int cmd, ...);
```

**Table 15.2 fcntl**

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
<th>The file descriptor</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmd</td>
<td>int</td>
<td>A command to the file system</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td>A variable argument list</td>
</tr>
</tbody>
</table>

**Remarks**

This function performs the command specified in cmd on the file descriptor fildes.

In the CodeWarrior ANSI library, fcntl() can perform only one command, F_DUPFD. This command returns a duplicate file descriptor for the file that fildes refers to. You must include a third argument in the function call. The new
fcntl.h

Overview of fcntl.h

file descriptor is the lowest available file descriptor that is greater than or equal to the third argument.

Table 15.3 Floating Point Characteristics

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_DUPFD</td>
<td>Return a duplicate file descriptor.</td>
</tr>
</tbody>
</table>

If it is successful, `fcntl()` returns a file descriptor. If it encounters an error, `fcntl()` returns -1.

This function may not be implemented on all platforms.

See Also

“fileno” on page 83
“open, _wopen” on page 121
“fdopen” on page 306.

Listing 15.2 Example of fcntl() Usage

```c
#include < unix.h >

int main(void)
{
    int fd1, fd2;
    fd1 = open("mytest", O_WRONLY | O_CREAT);
    write(fd1, "Hello world!\n", 13);
    /* Write to the original file descriptor. */
    fd2 = fcntl(fd1, F_DUPFD, 0);
    /* Create a duplicate file descriptor. */
    write(fd2, "How are you doing?\n", 19);
    /* Write to the duplicate file descriptor. */
    close(fd2);
    return 0;
}
```

Result After you run this program,
the file mytest contains the following:
Hello world!
How are you doing?

---

**open, _wopen**

Opens a file and returns its ID and a wide character variant.

```c
#include <fcntl.h>

int open(const char *path, int oflag);
int _open(const char *path, int oflag);
```

| Table 15.4 open |
|-----------------|-----------------|
| path            | char *          |
| oflag           | int             |
|                 | The file path as a string |
|                 | The open mode   |

**Remarks**

The function `open()` opens a file for system level input and output. and is used with the UNIX style functions `read()` and `write()`.

<table>
<thead>
<tr>

    exit( EXIT_FAILURE);
}
In a certain corner of la Mancha, the name of which I do not choose to remember, there lived one of those country gentlemen, who adorn their halls with rusty lance and worm-eaten targets.
fenv.h

The `<fenv.h>` header file prototypes and defines C99 data types, macros and functions that allow interaction with the floating-point environment.

Overview of fenv.h

Using the data types, macros, and functions in `fenv.h`, programmers are able to test and change rounding direction as well as test, set, and clear exception flags. Both the rounding direction and exception flags can be saved and restored as a single entity.

Data Types

There are two data types defined in `fenv.h`:

- "fenv_t" is the floating point environment type.
- "fexcept_t" is the floating point exception type.

fenv_t

This type represents the entire floating-point environment.

fexcept_t

The type represents the floating-point exception flags collectively.

Macros

Each macro correlates to a unique bit position in the floating-point control register and a bitwise OR of any combination of macros results in distinct values. Macro values are platform dependent. There are three distinct macro types.

- "Floating-point exceptions" on page 127.
Floating-Point Exception Flags

</tr>
</tbody>
</table>

Pragmas

The header fenv.h requires one pragma “FENV_ACC” on page 127, which must be set in order for floating point flags to be tested.

FENV_ACC

FENV_ACCESS must be set to the on position in order for the floating-point flags to be tested. Whether this pragma is on or off by default is implementation dependent.

This pragma may not be implemented on all platforms.

#pragma STDC FENV_ACCESS on|off|default

Floating-point exceptions

The header fenv.h includes several floating point exception flags manipulators.

- “feclearexcept” on page 128,
- “fegetexceptflag” on page 129,
- “feraiseexcept” on page 130,
- “fegetexceptflag” on page 131,
- “fetestexcept” on page 132,
feclearexcept

The feclearexcept clears one or more floating-point exception flag indicated by its argument. The argument represents the floating-point exception flags to be cleared.

```c
#include <fenv.h>
void feclearexcept(int excepts);
```

### Table 16.4 feclearexcept

<table>
<thead>
<tr>
<th>excepts</th>
<th>int</th>
<th>Determines which floating-point exception flags to clear</th>
</tr>
</thead>
</table>

### Remarks

The following example illustrates how programmers might want to “overlook” a floating-point exception. In this case two division operations are taking place. The first uses real numbers, the second imaginary. Suppose that even if the first operation fails we would still like to use the results from the second operation and act like no exceptions have occurred.

There is no return value.

This function may not be implemented on all platforms.

### Listing 16.1 Example of feclearexcept Usage

```c
void ie_feclearexcept(void)
{
    float complex1[2] = {0,1};
    float complex2[2] = {0,2};
    float result[2] = {0,0};
    feclearexcept(FE_ALL_EXCEPT);

    /* CALCULATE */
    result[0] = complex1[0] / complex2[0]; /* OOPs 0/0, sets the FE_INVALID flag */
    result[1] = complex1[1] / complex2[1]; /* = some # */
    /* CHECK IF @ LEAST 1 OPERATION WAS SUCCESS */
    if ( (result[0] != 0) || (result[1] != 0) )
        feclearexcept(FE_INVALID);
    /* clear flag */
    else
        cout << "what ever\n";
}
The `fegetexceptflag` function stores a representation of the states of the floating-point exception flags in the object pointed to by the argument `flag`. Which exception flags to save is indicated by a second argument.

```c
#include <fenv.h>
void fegetexceptflag(fexcept_t *flagp, int excepts);
```

### Remarks

The purpose of this function is to save specific floating-point exception flags to memory. In the case of the example below the saved values determine the output of the program.

Which exception flags to save is indicated by the argument `excepts`.

There is no return value.

This function may not be implemented on all platforms.

### Listing 16.2 Example of `fegetexceptflag` Usage

```c
void ie_fegetexceptflag()
{
    int result = 0;
    fexcept_t flag;
    feclearexcept(FE_ALL_EXCEPT);

    /* SOME OPERATION TAKES PLACE */
    result = 1+1;
    /* NEED TO KNOW IF OPERATION WAS SUCCESSFUL */
    fegetexceptflag(&flag, FE_INTEGRAL | FE_OVERFLOW);
    cout <<" Rest of code ... \n";
}
```

---

Table 16.5 `fegetexceptflag`

<table>
<thead>
<tr>
<th>flagp</th>
<th>fexcept_t</th>
<th>Pointer to floating-point exception flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>excepts</td>
<td>int</td>
<td>Determines which floating-point exception flags to save</td>
</tr>
</tbody>
</table>

---
fenv.h
Floating-point exceptions

/* NOW CHECK OBJECT POINTED 2 BY flag */
if (flag == FE_INVALID)
    cout << "The operation was invalid!\n";
if (flag == FE_OVERFLOW)
    cout << "The operation overflowed!\n";
if (flag == FE_INVALID | FE_OVERFLOW)
    cout << "A failure occurred!\n";
else
    cout << "success!\n";
}

feraiseexcept

The feraiseexcept function raises the floating-point exceptions represented by its argument.
#include <fenv.h>
void feraiseexcept(int excepts);

Table 16.6  feraiseexcept

<table>
<thead>
<tr>
<th>excepts int</th>
<th>determines which floating-point exception flags to raise</th>
</tr>
</thead>
</table>

Remarks

The difference between feraiseexcept and fesetexceptflag is what value the floating-point exception is raised to. feraiseexcept simply raises the exception, raise meaning setting to a logical one. On the other hand fesetexceptflag looks at the value of a stored floating-point exception flag and raises the current flag to the level of the stored value. If the stored exception flag is zero, the current exception flag is changed to a zero.

There is no return value.

This function may not be implemented on all platforms.

Listing 16.3  Example of feraiseexcept Usage

void ie_feraiseexcept(void)
{
    feclearexcept(FE_ALL_EXCEPT); /* all exception flags = 0 */
    /* RAISE SPECIFIC FP EXCEPTION FLAGS */
}
fenv.h

Floating-point exceptions

```c
feraiseexcept(FE_INVALID | FE_OVERFLOW);
```

fesetexceptflag

The `fesetexceptflag` function will set the floating-point exception flags indicated by the second argument to the states stored in the object pointed to in the first argument.

```
#include <fenv.h>
void fesetexceptflag(const fexcept_t *flagp, int excepts);
```

Remarks

The example below illustrates how this function can be used to restore floating-point exception flags after a function call.

There is no return value.

This function may not be implemented on all platforms.

**Listing 16.4  Example of fesetexceptflag Usage**

```c
void ie_fesetexceptflag(void)
{
    float result = 0;
    fexcept_t flag = 0;  /* fp exception flags saved here */
    feclearexcept(FE_ALL_EXCEPT);

    fegetexceptflag(&flag, FE_INVALID | FE_OVERFLOW);  /* save some flags */
    /* SOME FUNCTION CALL */
    result = 0/0;  /* OOPS caused an exception */
    for (int i = 0; i < 100; i++)
        cout << i << endl;
}
```

Table 16.7  fesetexceptflag

<table>
<thead>
<tr>
<th>flag</th>
<th>const fexcept_t *</th>
<th>Constant pointer to floating-point exception flags</th>
</tr>
</thead>
<tbody>
<tr>
<td>excepts</td>
<td>int</td>
<td>Determines which floating-point exception flags to raise</td>
</tr>
</tbody>
</table>

Remarks

The example below illustrates how this function can be used to restore floating-point exception flags after a function call.

There is no return value.

This function may not be implemented on all platforms.
/* NOW WE'RE BACK & WANT ORIGINAL VALUES OF FLAGS */
   fesetexceptflag(&flag, FE_INVALID | FE_OVERFLOW); /* restore flags */
}

fetestexcept

Use the fetestexceptflag function to find out if a floating-point exception has occurred.
The argument determines which exceptions to check for.

#include <fenv.h>
int fetestexcept(int excepts);

Table 16.8 fetestexcept

<table>
<thead>
<tr>
<th>excepts</th>
<th>int</th>
<th>Determines which floating-point exception flags to check</th>
</tr>
</thead>
</table>

Remarks

The example below is similar to the fegetexceptflag example. This time though
fetestexcept provides a direct interface to the exception flags so there is no need to
save and then operate on the exception flag values.

Returns true if floating point exception has occurred.
This function may not be implemented on all platforms.

Listing 16.5 Example of fetestexcept Usage

void ie_fetestexcept(void)
{
   int result = 0;
   feclearexcept(FE_ALL_EXCEPT);

   /* SOME OPERATION TAKES PLACE */
   result = 1+1;
   /* NEED TO KNOW IF OPERATION WAS SUCCESSFUL */
   /* but instead of getting flags, check them directly */
   if (fetestexcept(FE_INVALID) == 1)
      cout << "The operation was invalid!\n";
   if (fetestexcept(FE_OVERFLOW) == 1)
      cout << "The operation overflowed!\n";
if (fetestexcept(FE_INVALID | FE_OVERFLOW) == 1)  
    cout << "A failure occurred\n";  
else  
    cout << "success!\n"; 
}

Rounding
The header fenv.h includes two functions for determining the rounding direction.

- "fegetround" on page 133.
- "fesetround" on page 134.

fegetround
The fegetround function returns the value of the rounding direction macro representing the current rounding direction.

#include <fenv.h>
int fegetround(void);

This facility has no parameters.

Remarks
The example that follows changes the rounding direction to compute an upper bound for the expression, then restores the previous rounding direction. This example illustrates the functionality of all the rounding functions.

The function fegetround returns the current rounding direction as an integer value.

This function may not be implemented on all platforms.

Listing 16.6 Example of fegetround Usage

void ie_fegetround(void)  
{
    int direction = 0;
    double x_up = 0.0, a = 5.0, b = 2.0, c = 3.0,
    d = 6.0, f = 2.5, g = 0.5, ubound = 0;
    feclearexcept(FE_ALL_EXCEPT);

    /* CALCULATE DENOMINATOR */
    fesetround(FE_DOWNWARD);
fenv.h
Environment

```c
x_up = f + g;
    /* calculate denominator */
    /* CALCULATE EXPRESSION */
direction = fegetround();
    /* save rounding direction */
fesetround(FE_UPWARD);
    /* change rounding direction */
ubound = (a * b + c * d) / x_up;
    /* result should = 9.3333 */
fesetround(direction);
    /* return original state */
cout << " (a * b + c * d) / (f + g) = " << ubound << endl;
}
```

fesetround

The fesetround function sets the rounding direction specified by its argument, round. If the value of round does not match any of the rounding macros, the function returns 0 and the rounding direction is not changed.

```c
#include <fenv.h>
int fesetround(int round);
```

<table>
<thead>
<tr>
<th>round</th>
<th>int</th>
<th>Determines the direction result are rounded.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 16.9  fesetround

Remarks

For a function to be reentrant the function must save the rounding direction in a local variable with fegetround() and restore with fesetround() upon exit.

Zero is returned if and only if the argument is not equal.

This function may not be implemented on all platforms.

For an example of fesetround, see Listing 16.6.

Environment

The header  fenv.h  includes several functions for determining the floating-point environment information.
fegetenv

The fegetenv stores the current floating-point environment in the object pointed to by the argument.

#include <fenv.h>
void fegetenv(fenv_t *envp);

Table 16.10 fegetenv

<table>
<thead>
<tr>
<th>envp</th>
<th>fenv_t*</th>
<th>Pointer to floating-point environment</th>
</tr>
</thead>
</table>

Remarks

This function is used when a programmer wants to save the current floating-point environment, that is the state of all the floating-point exception flags and rounding direction. In the example that follows the stored environment is used to hide any floating-point exceptions raised during an interim calculation.

There is no return value.

This function may not be implemented on all platforms.

Listing 16.7 Example of fegetenv Usage

```c
long double ie_fegetenv(void)
{
    float x=0, y=0;
    fenv_t env1 =0, env2 = 0;
    feclearexcept(FE_ALL_EXCEPT);

    fesetenv(FE_DFL_ENV); /* set 2 default */
    x = x +y; /* fp op, may raise exception */
    fegetenv(&env1);
    y = y * x; /* fp op, may raise exception */
    fegetenv(&env2);
}```
feholdexcept

Saves the current floating-point environment and then clears all exception flags. This function does not affect the rounding direction and is the same as calling:

fegetenv(envp);
fecelexcept(FE_ALL_EXCEPT);
#include <fenv.h>
int feholdexcept(fenv_t *envp)

There is no return value.
This function may not be implemented on all platforms.

Listing 16.8 Example of feholdexcept Usage

```c
void ie_feholdexcept(void)
{
    /* This function signals underflow if its result is
denormalized, overerflow if its result is infinity,
and inexact always, but hides spurious exceptions
occurring from internal computations. */

    fenv_t local_env;
    int c;
    /* can be FP_NAN, FP_INFINITE , FP_ZERO,
      FP_NORMAL, or FP_SUBNORMAL */
    long double A=4, B=3, result=0;
    fecelexcept(FE_ALL_EXCEPT);

    feholdexcept(&local_env);
    /* save fp environment */
    /* INTERNAL COMPUTATION */
    result = pow(A,B);
    c = fpclassify(result);
    /* inquire about result */
    fecelexcept(FE_ALL_EXCEPT);
    /* hides spurious exceptions */
    feraiseexcept(FE_INEXACT);
    /* always raise */
}```

Table 16.11 feholdexcept

<table>
<thead>
<tr>
<th>envp</th>
<th>fenv_t</th>
<th>Pointer to floating-point environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>envp</td>
<td>fenv_t</td>
<td>Pointer to floating-point environment</td>
</tr>
</tbody>
</table>
if (c==FP_INFINITE)
    feraiseexcept(FE_OVERFLOW);
else if (c==FP_SUBNORMAL)
    feraiseexcept(FE_UNDERFLOW);
/* RESTORE LOCAL ENV W/ CHNGS */
feupdateenv(&local_env);
}

fesetenv

The fesetenv function establishes the floating-point environment represented by the object pointed to by envp. This object will have been set by a previous call to the functions fegetenv, feholdexcept or can use FE_DEFAULT_ENV.

#include <fenv.h>
void fesetenv(const fenv_t *envp);

Table 16.12 fesetenv

<table>
<thead>
<tr>
<th>envp</th>
<th>const fenv_t</th>
<th>Pointer to floating-point environment</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

There is no return value.
This function may not be implemented on all platforms.
For an example of fesetenv, see Listing 16.7.

feupdateenv

This is a multi-step function that takes a saved floating-point environment and does the following:

1. Save the current floating-point environment into temporary storage. This value will be used as a mask to determine which signals to raise.
2. Restore the floating-point environment pointed to by the argument envp.
3. Raise signals in newly restored floating-point environment using values saved in step one.

#include <fenv.h>
void feupdateenv(const fenv_t *envp);
This function may not be implemented on all platforms.
There is no return value.
For an example of feupdateenv, see Listing 16.8.

### Table 16.13 feupdateenv

**fenv.h**
*Environment*

---

138  MSL C Reference Version 10
The float.h header file macros specify the “Floating Point Number Characteristics” on page 139 for float, double, and long double types.

Overview of float.h

The float.h header file consists of macros that specify the characteristics of floating point number representation for float, double, and long double types.

Floating Point Number Characteristics

These macros are listed in Table 17.1. Macros beginning with FLT apply to the float type; DBL, the double type; and LDBL, the long double type.

The FLT_RADIX macro specifies the radix of exponent representation.

The FLT_ROUNDS specifies the rounding mode. CodeWarrior C rounds to nearest.

<table>
<thead>
<tr>

</table>
The FSp_fopen.h header defines functions to open a file based on the Macintosh file system.

Overview of FSp_fopen.h

This header file defines the facilities as follows:

- “FSp_fopen” on page 141 opens a Macintosh file for fopen.
- “FSRef_fopen” on page 142 opens a Macintosh file for fopen when files exist.
- “FSRefParentAndFilename_fopen” on page 143 opens Macintosh files for existing and non-existing files that can be created.

FSp_fopen

The function FSp_fopen opens a file with the Macintosh Toolbox FSpec function and returns a FILE pointer.

```c
#include <Fsp_fopen.h>

FILE * FSp_fopen(ConstFSSpecPtr spec, const char * open_mode);
```

Table 18.1 FSp_fopen

<table>
<thead>
<tr>
<th>spec</th>
<th>ConstFSSpecPtr</th>
<th>A toolbox file pointer</th>
</tr>
</thead>
<tbody>
<tr>
<td>open_mode</td>
<td>char</td>
<td>The open mode</td>
</tr>
</tbody>
</table>

Remarks

This function requires the programmer to include the associated FSp_fopen.c source file in their project. It is not included in the MSL C library.

The FSp_fopen facility opens a file with the Macintosh Toolbox FSRefPtr function and return a FILE pointer.

Macintosh only—this function may not be implemented on all Mac OS versions.
FSRef_fopen

Opens an existing file with FSRef and returns a FILE pointer.

```c
#include <Fsp_fopen.h>
FILE * FSRef_fopen(FSRefPtr spec, const char * open_mode);
```

Table 18.2 FSRef_fopen

<table>
<thead>
<tr>
<th>spec</th>
<th>FSRefPtr</th>
<th>An FSRef pointer for an existing file.</th>
</tr>
</thead>
<tbody>
<tr>
<td>open_mode</td>
<td>char *</td>
<td>The open mode</td>
</tr>
</tbody>
</table>

Remarks

This function requires the programmer to include the associated FSp_fopen.c source file in their project as it is not included in the MSL C library. Also, there are three libraries that may need to be weak linked in a non-Carbon target in order to build when you use the new file system APIs.

- TextCommon
- UnicodeConverter
- UTCUtils

The FSRefPtr facility returns a FILE pointer

Macintosh only—this function may not be implemented on all Mac OS versions.

inttypes.h

The header inttypes.h defines integer type equivalent symbols and keywords.

Overview of inttypes.h

The inttypes.h header file consists of functions for manipulation of greatest-width integers and for converting numeric character string to greatest-width integers. It includes various types and macros to support these manipulations. It also includes formatting symbols for formatted input and output functions.

- “Greatest-Width Integer Types” on page 145, a type used for long long division
- “Greatest-Width Format Specifier Macros” on page 146, formatting specifiers for printf and scanf family functions.
- “Greatest-Width Integer Functions” on page 150, functions for manipulation and conversion

The header inttype.h includes several functions for greatest-width integer manipulation and conversions.

- “imaxabs” on page 150 computes the absolute value of a greatest-width integer.
- “imaxdiv” on page 150 computes the quotient and remainder.
- “strtoimax” on page 151 converts string to greatest-width integer.
- “strtoumax” on page 152 converts string to greatest-width unsigned integer.
- “wsttoimax” on page 153 converts wide character string to greatest-width integer.
- “wsttoumax” on page 155 converts wide character string to greatest-width unsigned integer.

Greatest-Width Integer Types

One type is defined for greatest-width integer types used for long long division manipulation.
inttypes.h
Greatest-Width Format Specifier Macros

imaxdiv_t
A structure type that can store the value returned by the imaxdiv function as described in Table 19.1.

Greatest-Width Integer Functions

The header `inttypes.h` includes several functions for greatest-width integer manipulation and conversions.

**imaxabs**

Computes the absolute value of a greatest-width integer.

```c
#include <inttypes.h>
intmax_t imaxabs(intmax_t j);
```

**Remarks**

The behavior is undefined if the result can not be represented.

The `imaxabs` function returns the absolute value.

This function may not be implemented on all platforms.

**See Also**

“`abs`” on page 406

“`labs`” on page 424

**imaxdiv**

Compute the greatest-width integer quotient and remainder.

```c
#include <inttypes.h>
imaxdiv_t imaxdiv(intmax_t numer, intmax_t denom);
```

**Table 19.5 imaxdiv**

<table>
<thead>
<tr>
<th>numer</th>
<th>intmax_t</th>
<th>The numerator</th>
</tr>
</thead>
<tbody>
<tr>
<td>denom</td>
<td>intmax_t</td>
<td>The denominator</td>
</tr>
</tbody>
</table>
Remarks

The result is undefined behavior when either part of the result cannot be represented.

The imaxdiv function returns a structure of type "imaxdiv_t" on page 146 storing both the quotient and the remainder values.

This function may not be implemented on all platforms.

See Also

"div" on page 419
"ldiv" on page 425

strtoimax

Character array conversion to a greatest-width integral value.

```
#include <inttypes.h>

intmax_t strtoimax(const char * restrict nptr,
        char ** restrict endptr, int base);
```

Table 19.6 strtoimax

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>A character array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>char **</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

Remarks

The strtoimax() function converts a character array, pointed to by nptr, that is expected to represent an integer expressed with the radix base to an integer value of type UINTMAX_MIN, or UINTMAX_MAX. A plus or minus sign (+ or -) prefixing the number string is optional.

The base argument in strtoimax() specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then a strtol family function
converts the character array based on its format. Character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to a long int value.

This function skips leading white space.

The converted value is return upon success. If a failure occurs zero is returned. If the value is outside of a representable range, the appropriate `INTMAX_MAX`, or `INTMAX_MIN` value is returned and `ERANGE` is stored in `errno`.

This function may not be implemented on all platforms.

See Also

“strtoumax” on page 152

“strtoll” on page 442

### strtoumax

Character array conversion to a greatest-width integer value.

```c
#include <inttypes.h>
uintmax_t strtoumax(const char * restrict nptr,
        char ** restrict endptr, int base);
```

#### Table 19.7 strtoumax

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>A character array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>char **</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>
inttypes.h
Greatest-Width Integer Functions

Remarks

The `strtoumax()` function converts a character array, pointed to by `nptr`, to an integer value of type `UINTMAX_MIN`, or `UINTMAX_MAX`, in base. A plus or minus sign prefix is ignored.

The `base` argument in `strtoumax()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If `base` is 0, then a `strtoul` family function converts the character array based on its format. Character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to the functions' respective types.

This function skips leading white space.

The converted value is return upon success. If a failure occurs zero is returned. If the value is outside of a representable range, the appropriate `INTMAX_MIN`, or `UINTMAX_MAX` value is returned and `ERANGE` is stored in `errno`.

This function may not be implemented on all platforms.

See Also

“strtoimax” on page 151
“strtoul” on page 443
“strtoull” on page 444

wcstoimax

Wide character array conversion to a greatest-width integral value.

```c
#include <inttypes.h>

intmax_t wcstoimax(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base);
```
### Remarks

The `wcstoiimax()` function converts a wide character array, pointed to by `nptr`, expected to represent an integer expressed in radix base to an integer value of type `INTMAX_MIN`, or `INTMAX_MAX`. A plus or minus sign (+ or -) prefixing the number string is optional.

The base argument in `wcstoiimax()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then a `wcstoll` family function converts the wide character array based on its format. Numerical strings beginning with ’0’ are assumed to be octal, numerical strings beginning with ’0x’ or ’0X’ are assumed to be hexadecimal. All other numerical strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by `nptr`. This position marks the first wide character that is not convertible to a long int value.

This function skips leading white space.

The converted value is return upon success. If a failure occurs zero is returned. If the value is outside of a representable range, the appropriate `INTMAX_MAX`, or `INTMAX_MIN` value is returned and `ERANGE` is stored in `errno`.

This function may not be implemented on all platforms.

### See Also

“`wcstoumax`” on page 155
Wide character array conversion to a greatest-width integer value.

```
#include <inttypes.h>

uintmax_t wcstoumax(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base);
```

Table 19.9 wcstoumax

<table>
<thead>
<tr>
<th>nptr</th>
<th>const wchar_t *</th>
<th>A wide character array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>wchar_t **</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

Remarks

The `wcstoumax()` function converts a wide character array, pointed to by `nptr`, to an integer value of type `UINTMAX_MIN` or `UINTMAX_MAX`, in base. A plus or minus sign prefix is ignored.

The `base` argument in `wcstoumax()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If `base` is 0, then and a `wcstoul` family function converts the wide character array based on its format. Numerical strings beginning with '0' are assumed to be octal, numerical strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other numerical strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by `nptr`. This position marks the first wide character that is not convertible to the functions' respective types.

This function skips leading white space.

The converted value is return upon success. If a failure occurs zero is returned. If the value is outside of a representable range, the appropriate `UINTMAX_MIN`, or `UINTMAX_MAX` value is returned and `ERANGE` is stored in `errno`.

This function may not be implemented on all platforms.
See Also

“wcstoimax” on page 153
io.h

The header io.h defines several Windows console functions.

Overview of io.h

This header file defines the facilities as follows:

- "findclose" on page 158 closes a directory search.
- "findfirst" on page 158 opens a directory search.
- "findnext" on page 159 searches a directory.
- "setmode" on page 160 sets the translation for unformatted input and output.

NOTE  If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also  
Table 1.1 for information on POSIX naming conventions.

_finddata_t  

The structure _finddata_t is defined to store directory information. This structure is used in the directory searching functions.

Listing 20.1 Example of _finddata_t Usage

```
struct _finddata_t {
  unsigned attrib;
  __std(time_t) time_create; /* -1 for FAT file systems */
  __std(time_t) time_access; /* -1 for FAT file systems */
  __std(time_t) time_write;
  _fsize_t size;
  char name[260];
};
```
_findclose

Closes the handle opened by _findfirst.

```c
#include <io.h>
int _findclose(long fhandle);
```

Remarks

The fhandle is returned by _findfirst.
Zero is returned on success and a negative one on failure.
Windows compatible header yet may also be implemented in other headers.

See Also

“_findfirst” on page 158
“_findnext” on page 159

_table_20_1_ _findclose

<table>
<thead>
<tr>
<th>fhandle</th>
<th>long</th>
<th>The size in bytes of the allocation</th>
</tr>
</thead>
</table>

__findfirst

Searches a directory folder.

```c
#include <io.h>
long _findfirst(const char *pathname,
                struct _finddata_t * fdata);
```

Table 20.2 _findfirst

<table>
<thead>
<tr>
<th>pathname</th>
<th>const char *</th>
<th>The pathname of the file to be found</th>
</tr>
</thead>
<tbody>
<tr>
<td>fdata</td>
<td>_finddata_t *</td>
<td>A pointer to a directory information structure</td>
</tr>
</tbody>
</table>
Remarks
Wildcards are allowed in the directory search.
A file handle is returned.
Windows compatible header yet may also be implemented in other headers.

See Also
"_finddata_t" on page 157
"_findnext" on page 159
"_findclose" on page 158

_table_20.3 _findnext

<table>
<thead>
<tr>
<th>fhandle</th>
<th>long</th>
<th>The handle returned from calling _findfirst</th>
</tr>
</thead>
<tbody>
<tr>
<td>fdata</td>
<td>_finddata_t*</td>
<td>A pointer to a directory information structure</td>
</tr>
</tbody>
</table>

Remarks
Wildcards are allowed in the directory search.
Zero is returned if the file is found, if no file is found then a negative one is returned.
Windows compatible header yet may also be implemented in other headers.

See Also
"_finddata_t" on page 157
"_findfirst" on page 158
"_findclose" on page 158
### _setmode

The `_setmode` function sets the translation mode of the file given by `handle`.

```c
#include <io.h>
int _setmode(int handle, int mode);
```

#### Table 20.4 _setmode

<table>
<thead>
<tr>
<th>int</th>
<th>handle *</th>
<th>handle</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>mode *</td>
<td>The translation mode</td>
</tr>
</tbody>
</table>

#### Remarks

The mode must be one of two manifest constants, `_O_TEXT` or `_O_BINARY`.

The `_O_TEXT` mode sets text (a translated) mode. Carriage return-linefeed (CR-LF) combinations are translated into a single linefeed character on input. Linefeed characters are translated into CR-LF combinations on output.

The `_O_BINARY` mode sets binary (an untranslated) mode, in which linefeed translations are suppressed.

While `_setmode` is typically used to modify the default translation mode of `stdin` and `stdout`, you can use it on any file. If you apply `_setmode` to the file `handle` for a stream, call `_setmode` before performing any input or output operations on the stream.

The previous translation mode is returned or negative one on failure.

Windows compatible header yet may also be implemented in other headers.
iso646.h

The header iso646.h defines keyword alternates for the C operator symbols.

Overview of iso646.h

This header file consists of equivalent “words” for standard C operators as shown in Table 21.1.

Table 21.1 Operator Keyword Equivalents

<table>
<thead>
<tr>
<th>Operator</th>

<td>Maximum value for an object of type unsigned long long int</td>
</tr>
</tbody>
</table>
locale.h

The locale.h header file provides facilities for handling different character sets and numeric and monetary formats.

Overview of locale.h

This header file defines the facilities as follows:

- “localeconv” gets the locale.
- “setlocale” sets the locale.

Locale Specification

The ANSI C Standard specifies that certain aspects of the C compiler are adaptable to different geographic locales. The locale.h header file provides facilities for handling different character sets and numeric and monetary formats. CodeWarrior C supports the “C” locale by default and a vendor implementation.

The lconv structure, defined in locale.h, specifies numeric and monetary formatting characteristics for converting numeric values to character strings. A call to localeconv() will return a pointer to an lconv structure containing the settings for the “C” locale. Listing 23.1. An lconv member is assigned “CHAR_MAX” on page 163 value if it is not applicable to the current locale.

Listing 23.1 Example of lconv Structure and Contents Returned by localeconv() Usage

```c
struct lconv {
    char * decimal_point;
    char * thousands_sep;
    char * grouping;
    char * int_curr_symbol;
    char * currency_symbol;
    char * mon_decimal_point;
    char * mon_thousands_sep;
    char * mon_grouping;
    char * positive_sign;
    char * negative_sign;
    char int_frac_digits;
    char frac_digits;
};
```
locale.h
Overview of locale.h

    char  p_cs_precedes;
    char  p_sep_by_space;
    char  n_cs_precedes;
    char  n_sep_by_space;
    char  p_sign_posn;
    char  n_sign_posn;
    char  *int_curr_symbol;
    char  int_p_cs_precedes;
    char  int_n_cs_precedes;
    char  int_p_sep_by_space;
    char  int_n_sep_by_space;
    char  int_p_sign_posn;
    char  int_n_sign_posn;

);
locale.h
Overview of locale.h

Remarks

The category argument specifies the part of the C compiler to query or set. The argument can have one of six values defined as macros in locale.h:
LC_ALL for all aspects, LC_COLLATE for the collating function strcoll(), LC_CTYPE for ctype.h functions and the multibyte conversion functions in stdlib.h, LC_MONETARY for monetary formatting, LC_NUMERIC for numeric formatting, and LC_TIME for time and date formatting.

If the locale argument is a null pointer, a query is made. The setlocale() function returns a pointer to a character string indicating which locale the specified compiler part is set to. The CodeWarrior C compiler supports the "C" and "" locale.

Attempting to set a part of the CodeWarrior C compiler's locale will have no effect.

This function may not be implemented on all platforms.

See Also

"strcoll" on page 462
malloc.h

The header malloc.h defines one function, alloca, which lets you allocate memory quickly on from the stack.

Overview of malloc.h

This header file consists of alloca, which allocates memory from the stack.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also

“MSL Extras Library Headers” on page 4 for information on POSIX naming conventions.

alloca

Allocates memory quickly on the stack.

#include <malloc.h>

void *alloca(size_t nbytes);

Table 24.1 alloca

<table>
<thead>
<tr>
<th>nbytes</th>
<th>size_t</th>
<th>The size in bytes of the allocation</th>
</tr>
</thead>
</table>

Remarks

This function returns a pointer to a block of memory that is nbytes long. The block is on the function’s stack. This function works quickly since it decrements the current stack pointer. When your function exits, it automatically releases the storage.
malloc.h
Non Standard <malloc.h> Functions

If you use `alloca()` to allocate a lot of storage, be sure to increase the Stack Size for your project in the Project preferences panel.

If it is successful, `alloca()` returns a pointer to a block of memory. If it encounters an error, `alloca()` returns NULL.

This function may not be implemented on all platforms.

See Also

“calloc” on page 417
“free” on page 422
“malloc” on page 427
“realloc” on page 434

Non Standard <malloc.h> Functions

Various non standard functions are included in the header `malloc.h` for legacy source code and compatibility with operating system frameworks and application programming interfaces.

For the function `heapmin` see “heapmin” on page 87 for a full description.
math.h

The `math.h` header file provides floating point mathematical and conversion functions.

Overview of math.h

This header file defines the facilities as follows:

Classification Macros

- "fpclassify" on page 175 classifies floating point numbers.
- "isfinite" on page 176 tests if a value is a finite number.
- "isnan" on page 177 tests if a value is a computable number.
- "isnormal" on page 177 tests for normal numbers.
- "signbit" on page 178 tests for a negative number.

Functions

- "acos" on page 178 determines the arccosine.
- "asin" on page 179 determines the arcsine.
- "atan" on page 180 determines the arctangent.
- "atan2" on page 181 determines the arctangent of two variables.
- "ceil" on page 183 determines the smallest int not less than x.
- "cos" on page 184 determines the cosine.
- "cosh" on page 186 determines the hyperbolic cosine.
- "exp" on page 187 computes the exponential.
- "fabs" on page 188 determines the absolute value.
- "floor" on page 190 determines the largest integer not greater than x.
- "fmod" on page 191 determines the remainder of a division.
- "frexp" on page 193 extracts a value of the mantissa and exponent.
- "ldexp" on page 197 computes a value from a mantissa and exponent.
- "log" on page 198 determines the natural logarithm.
- "log10" on page 200 determines the logarithm to base 10.
- "modf" on page 201 separates integer and fractional parts.
math.h
Overview of math.h

- “pow” on page 202 raises to a power.
- “sin” on page 204 determines the sine.
- “sinh” on page 205 determines the hyperbolic sine.
- “sqrt” on page 207 determines the square root.
- “tan” on page 208 determines the tangent.
- “tanh” on page 209 determines the hyperbolic tangent.

C9X Implementations

- “acosh” on page 211 computes the (non-negative) arc hyperbolic cosine.
- “asin” on page 212 computes the arc hyperbolic sine.
- “atanh” on page 213 computes the arc hyperbolic tangent.
- “cbrt” on page 214 computes the real cube root.
- “copysign” on page 215 gives a value with the magnitude of x and the sign of y.
- “erf” on page 216 computes the error function.
- “erfc” on page 217 complementary error function.
- “exp2” on page 217 computes the base-2 exponential.
- “expm1” on page 218 computes the exponential minus 1.
- “fdim” on page 219 computes the positive difference of its arguments.
- “fma” on page 220 a ternary operation to multiply and add.
- “fmax” on page 221 computes the maximum numeric value of its argument.
- “fmin” on page 222 computes the minimum numeric value of its arguments.
- “gamma” on page 223 computes the gamma function.
- “hypot” on page 224 computes the square root of the sum of the squares of the arguments.
- “isgreater” on page 194 compares two numbers for x greater than y.
- “isgreaterless” on page 195 compares numbers for x not equal to y.
- “isless” on page 195 compares two numbers for x less than y.
- “islessequal” on page 196 compares two numbers for x is less than or equal to y.
- “isunordered” on page 196 compares two numbers for lack of order.
- “ilogb” on page 225 determines the exponent.
- “lgamma” on page 226 computes the log of the absolute value.
- “log1p” on page 227 computes the natural- log of x plus 1.
- “log2” on page 228 computes the base-2 logarithm.
- “logb” on page 229 extracts the exponent of a double value.
• “nan” on page 230 stores floating point information.
• “nan” on page 230 Tests for NaN.
• “nearbyint” on page 230 rounds off the argument to an integral value.
• “nextafter” on page 231 determines the next representable value in the type of the function.
• “remainder” on page 232 computes the remainder x REM y required by IEC 559.
• “remquo” on page 233 computes the same remainder as the remainder function.
• “rint” on page 234 rounds off the argument to an integral value.
• “rinttol” on page 235 rounds its argument to the nearest long integral value.
• “round” on page 236 rounds its argument to an integral value in floating-point format.
• “roundtol” on page 237 rounds its argument to the nearest integral value.
• “scalb” on page 237 computes x * FLT_RADIX^n.
• “trunc” on page 238 rounds its argument to an integral value in floating-point format nearest to but no larger than the argument.

Floating Point Mathematics

The HUGE_VAL macro, defined in math.h, is returned as an error value by the stdcrt() function. See "strtold" on page 441 for information on stdcrt().

Un-optimized x86 math.h functions may use the “errno” on page 75 global variable to indicate an error condition. In particular, many functions set errno to EDOM when an argument is beyond a legal domain. See Table 13.1.

NaN Not a Number

NaN stands for ‘Not a Number’ meaning that it has no relationship with any other number. A NaN is neither greater, less, or equal to a number. Whereas infinity is comparable to a number that is, it is greater than all numbers and negative infinity is less than all numbers.

There are two types of NaN, the signalling NaN and quiet NaN. The difference between a signalling NaN and a quiet NaN is that both have a full exponent and both have at least one non-zero significant bit, but the signalling NaN has its 2 most significant bits as 1 whereas a quiet NaN has only the second most significant bit as 1.
Quiet NaN
A quiet NaN is the result of an indeterminate calculation such as zero divided by zero, infinity minus infinity. The IEEE floating-point standard guarantees that a quiet NaN is detectable by requiring that the invalid exception be raised whenever an NaN appears as an operand to any basic arithmetic(+,-,\times) or non-arithmetic operation (load/store). The Main Standard Library for C follows the IEEE specification.

Signaling NaN
A signalling NaN does not occur as a result of arithmetic. A signalling NaN occurs when you load a bad memory value into a floating-point register that happens to have the same bit pattern as a signalling NaN. IEEE 754 requires that in such a situation the invalid exception be raised and the signalling NaN be converted to a quiet NaN so the lifetime of a signalling NaN may be brief.

Floating point error testing.
The math library used for PowerPC Mac OS and Windows (when optimized) is not fully compliant with the 1990 ANSI C standard. One way it deviates is that none of the math functions set errno.

The setting of errno is considered an obsolete mechanism because it is inefficient as well as un-informative. Further more various math facilities may set errno haphazardly for 68k Mac OS.

The MSL math libraries provide better means of error detection. Using fpclassify (which is fully portable) provides a better error reporting mechanism. Listing 25.1 shows an example code used for error detection that allows you to recover in your algorithm based on the value returned from fpclassify.

Inlined Intrinsics Option
For the Win32 x86 compilers CodeWarrior has an optimization option, “inline intrinsics”. If this option is on the math functions do not set the global variable errno. The debug version of the ANSI C libraries built by CodeWarrior has “inline intrinsics” option off and errno is set. The optimized release version of the library has “inline intrinsics” option on, and errno is not set.

Floating Point Classification Macros
Several facilities are available for floating point error classification.
Enumerated Constants

The Main Standard Library for C includes the following constant types for Floating point evaluation.

- **FP_NAN** represents a quiet NaN
- **FP_INFINITE** represents a positive or negative infinity
- **FP_ZERO** represents a positive or negative zero
- **FP_NORMAL** represents all normal numbers
- **FP_SUBNORMAL** represents denormal numbers

Remarks

This function may not be implemented on all platforms.

See Also

*"NaN Not a Number" on page 173*

fpclassify

Classifies floating point numbers.

```c
#include <math.h>

int __fpclassify(long double x);
int __fpclassifyd(double x);
int __fpclassifyf(float x);
```

Table 25.1 fpclassify

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number evaluated</th>
</tr>
</thead>
</table>

Remarks

An integral value **FP_NAN**, **FP_INFINITE**, **FP_ZERO**, **FP_NORMAL** and **FP_SUBNORMAL**.

This function may not be implemented on all platforms.
See Also

“isfinite” on page 176
“isnan” on page 177
“isnormal” on page 177
“signbit” on page 178
“NaN Not a Number” on page 173

Listing 25.1  Example of Error Detection Usage

```c
switch(fpclassify(pow(x,y))
{
 case FP_NAN: // we know y is not an int and <0
 case FP_INFINITY: // we know y is an int <0
 case FP_NORMAL: // given x=0 we know y=0
 case FP_ZERO:// given x<0 we know y >0
}
```

isfinite

The facility isfinite tests if a value is a finite number.

```c
#include <math.h>
int isfinite(double x);
```

Table 25.2  isfinite

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number evaluated</th>
</tr>
</thead>
</table>

Remarks

The facility returns true if the value tested is finite otherwise it returns false.

This function may not be implemented on all platforms.

See Also

“fpclassify” on page 175
isnan

The facility `isnan` test if a value is a computable number.

```c
#include <math.h>
int isnan(double x);
```

**Table 25.3 isnan**

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number evaluated</th>
</tr>
</thead>
</table>

**Remarks**

This facility is true if the argument is not a number.
This function may not be implemented on all platforms.

**See Also**

“fpclassify” on page 175
“NaN Not a Number” on page 173

isnormal

A test of a normal number.

```c
#include <math.h>
int isnormal(double x);
```

**Table 25.4 isnormal**

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number evaluated</th>
</tr>
</thead>
</table>

**Remarks**

This facility is true if the argument is a normal number.
This function may not be implemented on all platforms.

**See Also**

“fpclassify” on page 175
math.h
Floating Point Math Facilities

signbit

A test for a number that includes a signed bit
#include <math.h>
int __signbit(long double x);
int __signbitd(double x);
int __signbitf(float x);

Table 25.5 signbit

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number evaluated</th>
</tr>
</thead>
</table>

Remarks
This facility is true if the sign of the argument value is negative.
This function may not be implemented on all platforms.

See Also
“fpclassify” on page 175

Floating Point Math Facilities

Several facilities are available for floating point manipulations.

acos

This function computes the arc values of cosine, sine, and tangent.
#include <math.h>
double acos(double x);
float acosf(float);
long double acosl(long double);

Table 25.6 acos

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to be computed</th>
</tr>
</thead>
</table>
Remarks

The function `acos()` may set `errno` to EDOM if the argument is not in the range of -1 to +1. See “Floating point error testing.” on page 174, for information on newer error testing procedures. For example usage, see Listing 25.2.

The function `acos()` returns the arccosine of the argument `x` in radians. If the argument to `acos()` is not in the range of -1 to +1, the global variable `errno` may be set to EDOM and returns 0. See “Floating point error testing.” on page 174, for information on newer error testing procedures.

This function may not be implemented on all platforms.

See Also

“Inlined Intrinsics Option” on page 174
“cos” on page 184
“errno” on page 75

acosf

Implements the `acos()` function for float type values. See “acos” on page 178.

acosl

Implements the `acos()` function for long double type values. See “acos” on page 178.

asin

Arcsine function.

```c
#include <math.h>

double asin(double x);
float asinf(float);
long double asinl(long double);
```

Table 25.7 asin

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to be computed</th>
</tr>
</thead>
</table>
Remarks

This function computes the arc values of sine. For example usage, see Listing 25.2.

The function asin() may set errno to EDOM if the argument is not in the range of -1 to +1. See “Floating point error testing.” on page 174, for information on newer error testing procedures.

The function asin() returns the arcsine of x in radians. If the argument to asin() is not in the range of -1 to +1, the global variable errno may be set to EDOM and returns 0. See “Floating point error testing.” on page 174, for information on newer error testing procedures.

This function may not be implemented on all platforms.

See Also

“Inlined Intrinsics Option” on page 174
“sin” on page 204
“errno” on page 75

asinf

Implements the asin() function for float type values. See “asin” on page 179.

asinl

Implements the asin() function for long double type values. See “asin” on page 179.

atan

Arctangent function. This function computes the value of the arc tangent of the argument.

```c
#include <math.h>
double atan(double x);
float atanf(float);
long double atanl(long double);
```
Remarks

The function `atan()` returns the arc tangent of the argument `x` in the range `[-\pi/2, +\pi/2]` radians. For example usage, see Listing 25.2.

This function may not be implemented on all platforms.

See Also

“tan” on page 208
“errno” on page 75
math.h
Floating Point Math Facilities

Table 25.9  atan2

<table>
<thead>
<tr>
<th></th>
<th>double, float or long double</th>
<th>Value one</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td></td>
<td></td>
</tr>
<tr>
<td>x</td>
<td></td>
<td>Value two</td>
</tr>
</tbody>
</table>

Remarks

A domain error occurs if both x and y are zero. For example usage, see Listing 25.2.

The function atan2() returns the arc tangent of \( \frac{y}{x} \) in the range \([-\frac{\pi}{2}, \frac{\pi}{2}]\) radians.

This function may not be implemented on all platforms.

See Also

“Inlined Intrinsics Option” on page 174
“tan” on page 208
“errno” on page 75

Listing 25.2  Example of acos(), asin(), atan(), atan2() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 0.5, y = -1.0;

    printf("arccos (%f) = %f\n", x, acos(x));
    printf("arcsin (%f) = %f\n", x, asin(x));
    printf("arctan (%f) = %f\n", x, atan(x));
    printf("arctan (%f / %f) = %f\n", y, x, atan2(y, x));

    return 0;
}
```

Output:
arccos (0.500000) = 1.047198
arcsin (0.500000) = 0.523599
arctan (0.500000) = 0.463648
arctan (-1.000000 / 0.500000) = -1.107149
atan2f

Implements the atan2() function for float type values. See “atan2” on page 181.

atan2l

Implements the atan2() function for long double type values. See “atan2” on page 181.

ceil

Compute the smallest floating point number not less than \( x \).

```c
#include <math.h>
double ceil(double x);
float ceilf(float);
long double ceill(long double);
```

Remarks

ceil() returns the smallest integer not less than \( x \).

This function may not be implemented on all platforms.

See Also

“floor” on page 190
“fmod” on page 191
“round” on page 236

Listing 25.3 Example of ceil() Usage

```c
#include <math.h>
#include <stdio.h>
```
math.h
Floating Point Math Facilities

int main(void)
{
    double x = 100.001, y = 9.99;

    printf("The ceiling of %f is %f.\n", x, ceil(x));
    printf("The ceiling of %f is %f.\n", y, ceil(y));

    return 0;
}

Output:
The ceiling of 100.001000 is 101.000000.
The ceiling of 9.990000 is 10.000000.

ceilf

Implements the ceil() function for float type values. See “ceil” on page 183.

ceill

Implements the ceil() function for long double type values. See “ceil” on page 183.

cos

Compute cosine.
#include <math.h>

double cos(double x);
float cosf(float);
long double cosl(long double);

<table>
<thead>
<tr>
<th>Table 25.11 cos</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
</tr>
</tbody>
</table>
Remarks

\( \cos() \) returns the cosine of \( x \). \( x \) is measured in radians.

This function may not be implemented on all platforms.

See Also

“sin” on page 204
“tan” on page 208

Listing 25.4 Example of cos() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 0.0;
    printf("The cosine of \%f is \%f.\n", x, cos(x));
    return 0;
}
```

Output:
The cosine of 0.000000 is 1.000000.

cosf

Implements the \( \cos() \) function for float type values. See “cos” on page 184.

cosl

Implements the \( \cos() \) function for long double type values. See “cos” on page 184.
cosh

Compute the hyperbolic cosine.

double cosh(double x);
float coshf(float);
long double coshl(long double);

 Remarks

cosh() returns the hyperbolic cosine of x.
This function may not be implemented on all platforms.

See Also

“Inlined Intrinsics Option” on page 174
“sinh” on page 205
“tanh” on page 209

Listing 25.5 Example of cosh() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 0.0;
    printf("Hyperbolic cosine of %f is %f.\n",x,cosh(x));
    return 0;
}
```

Output:
Hyperbolic cosine of 0.000000 is 1.000000.
coshf

Implements the cosh() function for float type values. See “cosh” on page 186.

coshl

Implements the cosh() function for long double type values. See “cosh” on page 186.

exp

Computes the exponent of the function’s argument

```c
#include <math.h>
double exp(double x);
float expf(float);
long double expl(long double);
```

Table 25.13  exp

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to be computed</th>
</tr>
</thead>
</table>

Remarks

A range error may occur for larger numbers.
exp() returns $e^x$, where $e$ is the natural logarithm base value.
This function may not be implemented on all platforms.

See Also

“Inlined Intrinsics Option” on page 174
“log” on page 198
“expm1” on page 218
“exp2” on page 217
“pow” on page 202
math.h
Floating Point Math Facilities

Listing 25.6 Example of exp() Usage

#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 4.0;
    printf("The natural logarithm base e raised to the\n");
    printf("power of %f is %f.\n", x, exp(x));

    return 0;
}

Output:
The natural logarithm base e raised to the
power of 4.000000 is 54.598150.

expf
Implements the exp() function for float type values. See “exp” on page 187.

expl
Implements the exp() function for long double type values. See “exp” on page 187.

fabs
Compute the floating point absolute value.
#include <math.h>
double fabs(double x);
float fabsf(float);
long double fabsl(long double);

MSL C Reference Version 10
Remarks

The `fabs()` function returns the absolute value of `x`.
This function may not be implemented on all platforms.

See Also

“`floor`” on page 190
“`ceil`” on page 183
“`fmod`” on page 191

Listing 25.7 Example of fabs() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double s = -5.0, t = 5.0;
    printf("Absolute value of \%f is \%f.\n", s, fabs(s));
    printf("Absolute value of \%f is \%f.\n", t, fabs(t));

    return 0;
}
```

Output:
Absolute value of -5.000000 is 5.000000.
Absolute value of 5.000000 is 5.000000.

### fabsf

Implements the `fabs()` function for float type values. See “`fabs`” on page 188.
math.h
Floating Point Math Facilities

fabsl

Implements the fabs() function for long double type values. See “fabs” on page 188.

floor

Compute the largest floating point not greater than x.
#include <math.h>
double floor(double x);
float floorf(float);
long double floorl(long double);

Remarks
The function floor() returns the largest integer not greater than x.
This function may not be implemented on all platforms.

See Also
“ceil” on page 183
“fmod” on page 191
“fabs” on page 188

Listing 25.8 Example of floor() Usage

#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 12.03, y = 10.999;
    printf("Floor value of \%f is \%f.\n", x, floor(x));
    printf("Floor value of \%f is \%f.\n", y, floor(y));

    return 0;
}
return 0;
}

Output:
Floor value of 12.030000 is 12.000000.
Floor value of 10.999000 is 10.000000.

floorf

Implements the floor() function for float type values. See “floor” on page 190.

floorl

Implements the floor() function for long double type values. See "Floor" on page 190.

fmod

Return the floating point remainder of \( \frac{x}{y} \).

```c
#include <math.h>

double fmod(double x, double y);
float fmodf(float, float);
long double fmodl(long double, long double);
```

Table 25.16 fmod

<table>
<thead>
<tr>
<th></th>
<th>double, float or long double</th>
<th>The value to compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td></td>
<td></td>
</tr>
<tr>
<td>y</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Remarks

\( \text{fmod}(x) \) returns, when possible, the value \( f \) such that \( x = i y + f \) for some integer \( i \), and \( |f| < |y| \). The sign of \( f \) matches the sign of \( x \).

This function may not be implemented on all platforms.
math.h
Floating Point Math Facilities

See Also
“floor” on page 190
“ceil” on page 183
“fmod” on page 191
“fabs” on page 188

Listing 25.9 Example of fmod() Usage

#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = -54.4, y = 10.0;
    printf("Remainder of \%f / \%f = \%f.\n", x, y, fmod(x, y));

    return 0;
}

Output:
Remainder of -54.400000 / 10.000000 = -4.400000.

fmodf

Implements the fmod() function for float type values. See “fmod” on page 191.

fmodl

Implements the fmod() function for long double type values. See “fmod” on page 191.
frexp

Extract the mantissa and exponent. The frexp() function extracts the mantissa and exponent of value based on the formula \( x \cdot 2^n \), where the mantissa is \( 0.5 < |x| < 1.0 \) and \( n \) is an integer exponent.

```
#include <math.h>
double frexp(double value, int *exp);
float frexpf(float, int *);
long double frexpl(long double, int *);
```

### Remarks
frexp() returns the double mantissa of value. It stores the integer exponent value at the address referenced by exp.

This function may not be implemented on all platforms.

### See Also
- “ldexp” on page 197
- “fmod” on page 191

### Listing 25.10 Example of frexp() Usage
```
#include <math.h>
#include <stdio.h>

int main(void)
{
    double m, value = 12.0;
    int e;

    m = frexp(value, &e);

    printf("%f = %f \times 2 \text{ to the power of } \%d.\n", value, m, e);
    return 0;
}
```
Output:
12.000000 = 0.750000 \times 2 \text{ to the power of } 4.

frexpf

Implements the frexp() function for float type values. See “frexp” on page 193.

frexpl

Implements the frexp() function for long double type values. See “frexp” on page 193.

isgreater

The facility determine the greater of two doubles. Unlike \texttt{x>y isgreater} does not raise an invalid exception when \texttt{x} and \texttt{y} are unordered.

\begin{verbatim}
#include <math.h>
int isgreater(x, y);
\end{verbatim}

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{x} & float, double or long double \\
\hline
\textbf{y} & float, double or long double \\
\hline
\end{tabular}
\caption{isgreater}
\end{table}

Remarks

This facility is true if \texttt{x} is greater than \texttt{y}.

This function may not be implemented on all platforms.
isgreaterless

The facility determines if two numbers are unequal. Unlike \( x > y \) \( \| \) \( x < y \)
\isgreaterless\ does not raise an invalid exception when \( x \) and \( y \) are unordered.

\#include <math.h>

int isgreaterless(x, y)

Table 25.19 isgreaterless

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>float, double or long double</td>
<td>number compared</td>
</tr>
</tbody>
</table>

Remarks

This facility returns true if \( x \) is greater than or less than \( y \).

This function may not be implemented on all platforms.

isless

The facility determines the lesser of two numbers.

\#include <math.h>

int isless(x, y);

Table 25.20 isless

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number compared</th>

</thead>
<tbody>
<tr>
<td>y</td>
<td>float, double or long double</td>
<td>number compared</td>
</tr>
</tbody>
</table>

Remarks

This facility is true if \( x \) is less than \( y \).

This function may not be implemented on all platforms.
**math.h**

*Floating Point Math Facilities*

---

**islessequal**

The facility test for less than or equal to comparison. Unlike \( x < y \) \| \( x == y \)

islessequal does not raise an invalid exception when \( x \) and \( y \) are unordered.

#include <math.h>
int islessequal(x, y);

**Table 25.21** islessequal

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>float, double or long double</td>
<td>number compared</td>
</tr>
</tbody>
</table>

**Remarks**

This facility is true if \( x \) is less than or equal to \( y \).

This function may not be implemented on all platforms.

---

**isunordered**

The facility compares the order of the arguments.

#include <math.h>
int isunordered(x, y);

**Table 25.22** isunordered

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>number compared</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>float, double or long double</td>
<td>number compared</td>
</tr>
</tbody>
</table>

**Remarks**

This facility is true if the arguments are unordered false otherwise.

This function may not be implemented on all platforms.
**ldexp**

Compute a value from a mantissa and exponent. The `ldexp()` function computes \( x \times 2^{\text{exp}} \). This function can be used to construct a double value from the values returned by the `frexp()` function.

```c
#include <math.h>
double ldexp(double x, int exp);
float ldexpf(float, int);
long double ldexpl(long double, int);
```

**Remarks**

The function `ldexp()` returns \( x \times 2^{\text{exp}} \).

This function may not be implemented on all platforms.

**See Also**

“frexp” on page 193
“modf” on page 201

**Listing 25.11 Example of ldexp() Usage**

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double value, x = 0.75;
    int e = 4;
    
    value = ldexp(x, e);
    printf("%.f * 2 to the power of %.d is %.f.\n", x, e, value);
    return 0;
}
```
math.h
Floating Point Math Facilities

Output:
0.750000 * 2 to the power of 4 is 12.000000.

ldexpf
Implements the ldexp() function for float type values. See “ldexp” on page 197.

ldexpl
Implements the ldexp() function for long double type values. See “ldexp” on page 197.

log
Compute the natural logarithms.
#include <math.h>
double log(double x);
float logf(float);
long double logl(long double);

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to be computed</th>
</tr>
</thead>
</table>

Remarks
log() returns log_ex. If x < 0 the log() may assign EDOM to errno
See “Floating point error testing.” on page 174, for information on newer error testing procedures.
This function may not be implemented on all platforms.

See Also
“Inlined Intrinsics Option” on page 174
Listing 25.12  Example of log(), log10() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 100.0;

    printf("The natural logarithm of %f is %f\n",x, log(x));
    printf("The base 10 logarithm of %f is %f\n",x, log10(x));

    return 0;
}
```

Output:
The natural logarithm of 100.000000 is 4.605170
The base 10 logarithm of 100.000000 is 2.000000

---

**logf**

Implements the log() function for float type values. See “log” on page 198.

---

**logl**

Implements the log() function for long double type values. See “log” on page 198.
math.h
Floating Point Math Facilities

log10

Compute the base 10 logarithms.
#include <math.h>
double log10(double x);
float log10f(float);
long double log10l(long double);

Table 25.25 log10

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to be computed</th>
</tr>
</thead>
</table>

Remarks

log10() returns log_{10}x. If x < 0 log10() may assign EDOM to *errno*. See “Floating point error testing.” on page 174, for information on newer error testing procedures. For example usage, see Listing 25.12.

This function may not be implemented on all platforms.

See Also

“Inlined Intrinsics Option” on page 174
“exp” on page 187
“errno” on page 75

log10f

Implements the log10() function for float type values. See “log10” on page 200.

log10l

Implements the log10() function for long double type values. See “log10” on page 200.
modf

Separates integer and fractional parts.

#include <math.h>

double modf(double value, double *iptr);
float fmodf(float value, float *iptr);
long double modfl(long double value, long double *iptr);

<table>
<thead>
<tr>
<th>Table 25.26 modf</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
</tr>
<tr>
<td>iptr</td>
</tr>
</tbody>
</table>

Remarks

The modf() function separates value into its integer and fractional parts. In other words, modf() separates value such that value = f + i where 0 ≤ f < 1, and i is the largest integer that is not greater than value.

modf() returns the signed fractional part of value, and stores the integer part in the integer pointed to by iptr.

This function may not be implemented on all platforms.

See Also

“frexp” on page 193
“ldexp” on page 197

Listing 25.13 Example of modf() Usage

#include <math.h>
#include <stdio.h>

int main(void)
{
    double i, f, value = 27.04;

    f = modf(value, &i);
    printf("The fractional part of %f is %f\n", value, f);
```c
#include <math.h>

double pow(double x, double y);
float powf(float, float x);
long double powl(long double, long double x);
```

**Remarks**

The `pow()` function may assign `EDOM` to `errno` if `x` is 0.0 and `y` is less than or equal to zero or if `x` is less than zero and `y` is not an integer. For example of error detection usage, see Listing 25.1.
See “Floating point error testing.” on page 174, for information on newer error testing procedures.

The function `pow()` returns \( x^y \).

This function may not be implemented on all platforms.

**See Also**

“**Inlined Intrinsics Option**” on page 174

“sqrt” on page 207

### Listing 25.14 Example of pow() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x;

    printf("Powers of 2:\n");
    for (x = 1.0; x <= 10.0; x += 1.0)
        printf("2 to the %4.0f is %4.0f.\n", x, pow(2, x));

    return 0;
}
```

**Output:**

Powers of 2:
2 to the 1 is 2.
2 to the 2 is 4.
2 to the 3 is 8.
2 to the 4 is 16.
2 to the 5 is 32.
2 to the 6 is 64.
2 to the 7 is 128.
2 to the 8 is 256.
2 to the 9 is 512.
2 to the 10 is 1024.

---

**powf**

Implements the pow() function for float type values. See “**pow**” on page 202.
math.h
Floating Point Math Facilities

powl

Implements the pow() function for long double type values. See “pow” on page 202.

sin

Compute sine.
#include <math.h>
double sin(double x);
float sinf(float x);
long double sinl(long double x);

Table 25.28  sin

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to be computed</th>
</tr>
</thead>
</table>

Remarks

The argument for the sin() function should be in radians. One radian is equal to 360/2\pi degrees.
The function sin() returns the sine of x. x is measured in radians.
This function may not be implemented on all platforms.

See Also

“cos” on page 184
“tan” on page 208

Listing 25.15  Example of sin() Usage

#include <math.h>
#include <stdio.h>

#define DtoR 2*pi/360

int main(void)
{
    double x = 57.0;
    double xRad = x*DtoR;
```c
#include <math.h>

double sinh(double x);
float sinhf(float x);
long double sinhl(long double x);
```

### Remarks

A range error can occur if the absolute value of the argument is too large.

- `sinh()` returns the hyperbolic sine of `x`.
- This function may not be implemented on all platforms.

**See Also**

- “Inlined Intrinsics Option” on page 174
- “cosh” on page 186
- “tanh” on page 209

**Listing 25.16 Example of sinh() Usage**

```c
#include <stdio.h>
#include <math.h>

int main(void)
{
    double x = 0.5;
    printf("Hyperbolic sine of \%f is \%f.\n", x, sinh(x));
    return 0;
}
```

Output:
Hyperbolic sine of 0.500000 is 0.521095.

---

**sinhf**

Implements the sinh() function for float type values. See “sinh” on page 205.

---

**sinhl**

Implements the sinh() function for long double type values. See “sinh” on page 205.
sqrt

Calculate the square root.
#include <math.h>
double sqrt(double x);
float sqrtf(float x);
long double sqrtl(long double x);

Table 25.30  sqrt

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to compute</th>
</tr>
</thead>
</table>

Remarks
A domain error occurs if the argument is a negative value.
sqrt() returns the square root of x.
This function may not be implemented on all platforms.

See Also
"Inlined Intrinsics Option" on page 174
"pow" on page 202

Listing 25.17  Example of sqrt() Usage

#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 64.0;
    printf("The square root of \%f is \%f.\n", x, sqrt(x));
    return 0;
}

Output:
The square root of 64.000000 is 8.000000.
math.h
Floating Point Math Facilities

sqrtf
Implements the sqrt() function for float type values. See “sqrt” on page 207.

sqrtl
Implements the sqrt() function for long double type values. See “sqrt” on page 207.

tan
Computes tangent of the argument.
#include <math.h>
double tan(double x);
float tanf(float x);
long double tanl(long double x);

Remarks
A range error may occur if the argument is close to an odd multiple of pi divided by 2.
tan() returns the tangent of x. x is measured in radians.
This function may not be implemented on all platforms.

See Also
“Inlined Intrinsics Option” on page 174
“cos” on page 184
“sin” on page 204

Listing 25.18 Example of tan() Usage
#include <math.h>

Table 25.31 tan

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to compute</th>
</tr>
</thead>
</table>

#include <stdio.h>

int main(void)
{
    double x = 0.5;
    printf("The tangent of %f is %f.\n", x, tan(x));
    return 0;
}

Output:
The tangent of 0.500000 is 0.546302.

## tanf

Implements the tan() function for float type values. See “tan” on page 208.

## tanl

Implements the tan() function for long double type values. See “tan” on page 208.

## tanh

Compute the hyperbolic tangent.

```c
#include <math.h>

double tanh(double x);
float tanhf(float x);
long double tanhl(long double x);
```

### Table 25.32 tanh

<table>
<thead>
<tr>
<th>x</th>
<th>float, double or long double</th>
<th>value to compute</th>
</tr>
</thead>
</table>

MSL C Reference Version 10
Remarks

\texttt{tanh()} returns the hyperbolic tangent of \( x \).

This function may not be implemented on all platforms.

See Also

“cosh” on page 186

“sinh” on page 205

Listing 25.19 Example of \texttt{tanh()} Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 0.5;

    printf("The hyperbolic tangent of %f is %f.\n", x, tanh(x));
    return 0;
}
```

Output:
The hyperbolic tangent of 0.500000 is 0.462117.

\textbf{tanhf}

Implements the \texttt{tanh()} function for float type values. See “tanh” on page 209.

\textbf{tanhl}

Implements the \texttt{tanh()} function for long double type values. See “tanh” on page 209.
HUGE_VAL

The largest floating point value with the same sign possible for a function’s return.

#include <math.h>
Varies by CPU

Remarks

If the result of a function is too large to be represented as a value by the return type, the function should return HUGE_VAL. It is the largest floating point value with the same sign as the expected return type.

This function may not be implemented on all platforms.

C99 Implementations

Although not formally accepted by the ANSI/ISO committee these proposed math functions are already implemented on some platforms.

acosh

Acosh computes the (non-negative) arc or inverse hyperbolic cosine of x in the range [0, +INF].

#include <math.h>
double acosh(double x);

Table 25.33 acosh

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to compute</th>
</tr>
</thead>
</table>

Remarks

A domain error occurs for argument x is less than 1 and a range error occurs if x is too large.

The (non-negative) arc hyperbolic cosine of x.

This function may not be implemented on all platforms.
**math.h**
*C99 Implementations*

### See Also

“acos” on page 178

### Listing 25.20  Example of acosh() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double a = 3.14;
    printf("The arc hyperbolic cosine of \%f is \%f.\n\n", a, acosh(a));
    return 0;
}
```

Output:
The arc hyperbolic cosine of 3.140000 is 1.810991.

---

**asinh**

Asinh computes the arc or inverse hyperbolic sine.

```c
#include <math.h>

double asinh(double x);
```

### Table 25.34  asinh

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to compute</th>
</tr>
</thead>
</table>

### Remarks

- A range error occurs if the magnitude of x is too large.
- The arc hyperbolic sine of the argument x.
- This function may not be implemented on all platforms.

### See Also

“asin” on page 179
Listing 25.21  Example of asinh() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double b = 3.14;
    printf("The arc hyperbolic sine of %f is %f.\n\n", b, asinh(b));
    return 0;
}
```

Output:
The arc hyperbolic sine of 3.140000 is 1.861813

---

atanh

The function atanh computes the arc hyperbolic tangent.
```c
#include <math.h>
double atanh(double x);
```

Table 25.35  atanh

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to compute</th>
</tr>
</thead>
</table>

Remarks

The arc hyperbolic tangent of \( x \).

A domain error occurs for arguments not in the range \([-1,+1]\]

This function may not be implemented on all platforms.

See Also

“atan” on page 180

Listing 25.22  Example of atanh() Usage

```c
#include <math.h>
#include <stdio.h>
```
```c
#include <math.h>

int main(void)
{
    double c = 0.5;
    printf("The arc hyperbolic tan of %f is %f.\n\n", c, atanh(c));
    return 0;
}
```

Output:
The arc hyperbolic tan of 0.500000 is 0.549306.

### cbrt

The cbrt functions compute the real cube root
```c
#include <math.h>
double cbrt(double x);
float cbrtf(float fx);
long double cbrtl(long double lx);
```

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value being cubed</th>
</tr>
</thead>
<tbody>
<tr>
<td>fx</td>
<td>float</td>
<td>The value being cubed</td>
</tr>
<tr>
<td>lx</td>
<td>long double</td>
<td>The value being cubed</td>
</tr>
</tbody>
</table>

**Remarks**

The cbrt functions returns the real cube root of the argument.
This function may not be implemented on all platforms.

**See Also**

“sqrt” on page 207
**copysign**

The function `copysign` produces a value with the magnitude of `x` and the sign of `y`. The `copysign` function regards the sign of zero as positive. It produces a `NaN` with the sign of `y` if `x` is `NaN`.

```c
#include <math.h>
double copysign(double x, double y);
```

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>Magnitude</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>double</td>
<td>The sign argument</td>
</tr>
</tbody>
</table>

**Remarks**

A value with the magnitude of `x` and the sign of `y`.

This function may not be implemented on all platforms.

**Listing 25.23 Example of copysign() Usage**

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double e = +10.0;
    double f = -3.0;
    printf("Copysign(%f, %f) = %f.\n\n", e, f, copysign(e, f));
    return 0;
}
```

Output:

Copysign(10.000000, -3.000000) = -10.000000.
The erf function is used in probability.

```c
#include <math.h>
double erf(double x);
```

**Remarks**

The function erf( ) is defined as:

\[
\text{erf}(x) = \left( \frac{2}{\sqrt{\pi}} \right) \int_0^x e^{-t^2} dt
\]

The error function of \( x \) is returned.

This function may not be implemented on all platforms.

**Listing 25.24 Example of erf() Usage**

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double g = +10.0;
    printf("The error function of (%f) = %f.\n\n", g, erf(g));
    return 0;
}
```

Output:
The error function of (10.000000) = 1.000000
erfc

The erfc() function computes the complement of the error function.

```c
#include <math.h>
double erfc(double x);
```

The erfc() function computes the complement of the error function of `x`:

```
erfc(x) = 1 - ( erf (x) = 2/sqrt(pi) *  
( integral from 0 to x of exp(-t^2) dt )) 
```

The complementary error function of `x` is returned.

This function may not be implemented on all platforms.

**Listing 25.25  Example of erfc() Usage**

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double h = +10.0;
    printf("The inverse error function of (%f) = %f.\n\n", h,erfc(h));
    return 0;
}
```

Output:
The inverse error functions of (10.000000) = 0.000000

exp2

The function exp2 computes the base-2 exponential.

```c
#include <math.h>
double exp2(double x);
```
### exp2

The function `exp2` computes the base-2 exponential. In other words, `exp2(b)` solves for the `x` in `(b = 2^x)`. A range error occurs if the magnitude of `x` is too large. The function returns the base-2 exponential of `x`: `2^x`. This function may not be implemented on all platforms.

**Remarks**

- The function `exp2` computes the base-2 exponential. In other words, `exp2(b)` solves for the `x` in `(b = 2^x)`. A range error occurs if the magnitude of `x` is too large.
- The function returns the base-2 exponential of `x`: `2^x`.
- This function may not be implemented on all platforms.

**See Also**

- "pow" on page 202

### Listing 25.26 Example of exp2() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double i = 12;
    printf("2^%f = %f.\n\n",i,i, exp2(i));
    return 0;
}
```

Output:

```
2^(12.000000) = 4096.000000.
```

---

### expm1

The function `expm1` computes the base-e exponential minus 1.

```c
#include <math.h>

double expm1(double x);
```
The function `expm1` computes the base-e exponential minus 1. Written as:

\[ \text{expm1}(x) = (e^x) - 1.0 \]

A range error occurs if x is too large. For small magnitude x, `expm1(x)` is expected to be more accurate than `exp(x) - 1`.

The base-e exponential of x, minus 1: 
\( (e^x) - 1 \) is returned.

This function may not be implemented on all platforms.

### Listing 25.27  Example of `expm1()` Usage
```
#include <math.h>
#include <stdio.h>

int main(void)
{
    double j = 12;
    printf("(e - 1)^%f = %f.\n\n",j,expm1(j));
    return 0;
}
```

Output:
\( (e - 1)^{12.000000} = 162753.791419. \)

---

The function `fdim` computes the positive difference of its arguments.

```
#include <math.h>

double fdim(double x, double y);
```
Remarks
This function returns the value of x - y if x is greater than y else zero. If x is less than or equal to y a range error may occur. This function may not be implemented on all platforms.

Listing 25.28  Example of fdim() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double k = 12;
    double l = 4;
    printf('|(%.f - %.f)| = %.f.\n\n", k, l, fdim(k, l));
    return 0;
}
```

Output:
| ( 12.000000 - 4.0000000 ) | = 8.0000000.

fma

The fma functions return the sum of the third argument plus the product of the first two arguments rounded as one ternary operation.

```c
#include <math.h>

double fma(double x, double y, double z);
float fmaf(float fx, float fy, float fz);
long double fmal(long double lx, long double ly, long double lz);
```
The fma functions compute \((x \cdot y) + z\), rounded as one ternary operation:

The fma functions compute the value (as if) to infinite precision and round once to the result format, according to the rounding mode characterized by the value of \texttt{FLT\_ROUNDS}.

The fma functions returns the result of \((x\cdot y) + z\).

This function may not be implemented on all platforms.

### See Also

“round” on page 236

### fmax

The function fmax computes the maximum numeric value of its argument

```c
#include <math.h>
double fmax(double x, double y);
```
Remarks
The maximum value of x or y is returned.
This function may not be implemented on all platforms.

See Also
“fmin” on page 222

Listing 25.29 Example of fmax() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double m = 4;
    double n = 6;
    printf("fmax(%f, %f)=%f.\n\n", m, n, fmax(m, n));
    return 0;
}
```

Output:
fmax(4.000000, 6.000000) = 6.000000.

fmin
The function fmin computes the minimum numeric value of its arguments.

```c
#include <math.h>

double fmin(double x, double y);
```
**Remarks**

Fmin returns the minimum numeric value of its arguments.
This function may not be implemented on all platforms.

**See Also**

“fmax” on page 221

**Listing 25.30  Example of fmin() Usage**

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double o = 4;
    double p = 6;
    printf("fmin(%f, %f) = %f.\n\n", o, p, fmin(o, p));
    return 0;
}
```

Output:
```
fmin(4.000000, 6.000000) = 4.000000.
```

**gamma**

The gamma( ) function computes loge G(x).

```c
#include <math.h>
double gamma (double x);
```

**Table 25.45  fmin**

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>First argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>double</td>
<td>Second argument</td>
</tr>
</tbody>
</table>

| Table 25.46  gamma**

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to be computed</th>
</tr>
</thead>
</table>
Remarks

The `gamma()` function computes \( \log e \, G(x) \), where \( G(x) \) is defined as the integral of \( \int_0^\infty e^{-t} \times t^{x-1} \) dt from 0 to infinity. The sign of \( G(x) \) is returned in the external integer `signgam`.

The argument \( x \) need not be a non-positive integer, ( \( G(x) \) is defined over the real numbers, except the non-positive integers).

An application wishing to check for error situations should set `errno` to 0 before calling `lgamma()`. If `errno` is non-zero on return.

- If the return value is NaN, an error has occurred.
- A domain error occurs if \( x \) is equal to zero or if \( x \) is a negative integer.
- A range error may occur.

The gamma function of \( x \) is returned.

This function may not be implemented on all platforms.

See Also

“`lgamma`” on page 226

hypot

The function `hypot` computes the square root of the sum of the squares of the arguments.

```
#include <math.h>
double hypot(double x, double y);
```

Table 25.47  hypot

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The first value to be squared</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>double</td>
<td>The second value to be squared</td>
</tr>
</tbody>
</table>

Remarks

Hypot computes the square root of the sum of the squares of \( x \) and \( y \) without undue overflow or underflow.

A range error may occur.

The square root of the sum of the squares of \( x \) and \( y \) is returned.
This function may not be implemented on all platforms.

“Inlined Intrinsics Option” on page 174

Listing 25.31  Example of hypot() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double r = 4;
    double s = 4;
    printf("(%f^2 + %f^2)^(.5) = %f
\n",r,s,hypot(r,s));
    return 0;
}
```

Output:

\[(4.000000^2 + 4.000000^2)^{.5} = 5.656854\]

ilogb

The ilogb functions determine the exponent of the argument as a signed int value.

```c
#include <math.h>
int ilogb(double x);
int ilogbf(float y);
int ilogbl(long double z);
```

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The whose exponent is determined</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>float</td>
<td>The whose exponent is determined</td>
</tr>
<tr>
<td>z</td>
<td>long double</td>
<td>The whose exponent is determined</td>
</tr>
</tbody>
</table>
math.h
C99 Implementations

Remarks
The ilogb functions extract the exponent of x as a signed int value. If x is zero they compute the value FP_ILOGB0; if x is infinite they compute the value INT_MAX; if x is a NaN they compute the value FP_ILOGBNAN; otherwise, they are equivalent to calling the corresponding logb function and casting the returned value to type int.
A rangeerror may occur if x is 0.
The ilogb functions return the exponent of x as a signed int value.
This function may not be implemented on all platforms.
This function may not be implemented on all platforms.

See Also
“exp” on page 187

Igamma
The lgamma() function computes the same thing as the gamma().
#include <math.h>
double lgamma(double x);

Table 25.49 lgamma

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to be computed</th>
</tr>
</thead>
</table>

Remarks
The lgamma() function computes the same thing as the gamma() with the addition of absolute value signs $\log_e |G(x)|$, where $G(x)$ is defined as the integral of $e^{-t} * t^{(x-1)}$ from 0 to infinity.
The sign of $G(x)$ is returned in the external integer signgam. The argument x need not be a non-positive integer, ($G(x)$ is defined over the real numbers, except the non-positive integers).
An application wishing to check for error situations should set errno to 0 before calling lgamma(). If errno is non-zero on return, or the return value is NaN, an error has occurred.
lgamma() may create a range error occurs if x is too large
The log of the absolute value of gamma of x.
This function may not be implemented on all platforms.

**See Also**

“gamma” on page 223

### log1p

The function log1p computes the base-e logarithm.

```c
#include <math.h>
double log1p(double x);
```

**Remarks**

The function log1p computes the base-e logarithm. Which can be denoted as

\[
\log1p = \log_e(1.0 + x)
\]

The value of \( x \) must be greater than −1.0.

For small magnitude \( x \), \( \log1p(x) \) is expected to be more accurate than \( \log(x+1) \)

- A domain error occurs if \( x \) is less than negative one.
- A range error may occur if \( x \) is equal to one.

The base-e logarithm of 1 plus \( x \) is returned.

This function may not be implemented on all platforms.

**See Also**

“log” on page 198

### Listing 25.32  Example of log1p() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double u = 5;
    printf("log1p computes log1p(%f) = %f\n",u,log1p(u));
    return 0;
}
```
The function \texttt{log2} computes the base-2 logarithm.

\begin{verbatim}
#include <math.h>

double log2(double x);
\end{verbatim}

\textbf{Table 25.51  log2}
\begin{tabular}{|c|c|lc|}
\hline
x & double & The value being computed \\
\hline
\end{tabular}

\textbf{Remarks}

The function \texttt{log2} computes the base-2 logarithm which can be denoted as:

\[ \log_2(x) = \log_2(x) \]

The value of \( x \) must be positive.

- A domain error may occur if \( x \) is less than zero.
- A range error may occur if \( x \) is equal to zero.

The base-2 logarithm of \( x \) is returned.

This function may not be implemented on all platforms.

\textbf{See Also}

“\texttt{log}” on page 198

\textbf{Listing 25.33  Example of log2() Usage}

\begin{verbatim}
#include <math.h>
#include <stdio.h>

int main(void)
{
   double v = 5;
   printf("log2(\%f) = \%f\n\n",v,log2(v));
   return 0;
}
\end{verbatim}
The `logb()` function computes the exponent of `x`.

```c
#include <math.h>
double logb(double x);
```

### Table 25.52 `logb`

<table>
<thead>
<tr>
<th><code>x</code></th>
<th><code>double</code></th>
<th>The value being computed</th>
</tr>
</thead>
</table>

### Remarks

The `logb()` function computes the exponent of `x`, which is the integral part of 
\[ \log_r |x| , \]
as a signed floating point value, for non-zero `x`, where `r` is the 
radx of the machine's floating-point arithmetic. If `x` is subnormal it is treated as though it were normalized.

A range error may occur if `x` is equal to zero.

The exponent of `x` as a signed integral value in the format of the `x` argument.

This function may not be implemented on all platforms.

### See Also

“Inlined Intrinsics Option” on page 174

### Listing 25.34 Example of `logb()` Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double w = 5;
    printf("logb(%f) = %f\n\n",w,logb(w));
    return 0;
}
```
**math.h**

*C99 Implementations*

Output:
\[
\log_b(5.000000) = 2.000000
\]

---

**nan**

The function `nan` tests for NaN.

```c
#include <math.h>

double nan(const char *tagp);
```

<table>
<thead>
<tr>
<th>tagp</th>
<th>const char *</th>
<th>A character string</th>
</tr>
</thead>
</table>

**Remarks**

See "Quiet NaN" on page 174, for more information.

A quiet NaN is returned, if available.

This function may not be implemented on all platforms.

**See Also**

"isnan" on page 177

"NaN Not a Number" on page 173

---

**nearbyint**

The function `nearbyint` rounds off the argument to an integral value.

```c
#include <math.h>

double nearbyint(double x);
```

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to be computed</th>
</tr>
</thead>
</table>

---
Remarks
Nearbyint, computes like rint but doesn't raise an inexact exception.
The argument is returned as an integral value in floating point format.
This function may not be implemented on all platforms.

Listing 25.35 Example of nearbyint() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double x = 5.7;
    printf("nearbyint(%f) = %f\n", x, nearbyint(x));
    return 0;
}
```

Output:
nearbyint(5.700000) = 6.000000

nextafter
The nextafter function determines the next representable value in the type of the function.

```c
#include <math.h>
float nextafter(float x, float y);
double nextafter(double x, double y);
long double nextafter(long double x, long double y);
```

Table 25.55 nextafter

<table>
<thead>
<tr>
<th>x</th>
<th>float double</th>
<th>current representable value</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>float double</td>
<td>direction</td>
</tr>
</tbody>
</table>
Math.h
C99 Implementations

Remarks
The nextafter function determines the next representable value in the type of the function, after x in the direction of y, where x and y are first converted to the type of the function. Thus, if y is less than x, nextafter( ) returns the largest representable floating-point number less than x.

The next representable value after x is returned.

This function may not be implemented on all platforms.

Listing 25.36 Example of nextafter() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double y = 7;
    double z = 10;
    printf("nextafter(%f,%f) = %f\n\n",y,z,nextafter(y,z));
    return 0;
}
```

Output:
Nextafter(7.000000,10.000000) = 7.000000

remainder

Remainder computes the remainder x REM y required by IEC 559.

```c
#include <math.h>
double remainder(double x, double y);
```

Table 25.56 remainder

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The first value</th>
</tr>
</thead>
<tbody>
<tr>
<td>y</td>
<td>double</td>
<td>The second value</td>
</tr>
</tbody>
</table>
Remarks

The remainder() function returns the floating point remainder $r = x - ny$ when $y$ is non-zero. The value $n$ is the integral value nearest the exact value $x/y$. When $|n - x/y| = \_\_$, the value $n$ is chosen to be even.

The behavior of remainder() is independent of the rounding mode.

The remainder $x \text{ REM } y$ is returned.

This function may not be implemented on all platforms.

See Also

"remquo” on page 233

Listing 25.37 Example of remainder() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double var1 = 2;
    double var2 = 4;
    printf("remainder(%f,%f) = %f\\n",var1,var2,remainder(var1,var2));
    return 0;
}
```

Output:
remainder(2.000000,4.000000) = 2.000000

remquo

The function remquo computes the same remainder as the remainder function.

```c
#include <math.h>

double remquo(double x, double y, int *quo);
```

Table 25.57 remquo

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>First value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Remarks

The argument quo points to an object whose sign is the sign as x/y and whose magnitude is congruent mod $2^n$ to the magnitude of the integral quotient of x/y, where $n \geq 3$.

The value of x may be so large in magnitude relative to y that an exact representation of the quotient is not practical.

The remainder of x and y is returned.

This function may not be implemented on all platforms.

See Also

“remainder” on page 232

# rint

The function rint rounds off the argument to an integral value. Rounds its argument to an integral value in floating-point format using the current rounding direction.

```c
#include <math.h>
double rint(double x);
```

## rint

Table 25.58  rint

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to be computed</th>
</tr>
</thead>
</table>

Remarks

The argument in integral value in floating point format is returned.

This function may not be implemented on all platforms.

See Also

“rinttol” on page 235
# include <math.h>
#include <stdio.h>

int main(void)
{
    double varONE = 2.5;
    printf("rint(\%f) = \%f\n\n",varONE,rint(varONE));
    return 0;
}

Output:
rint(2.500000) = 2.000000

### rinttol

Rinttol rounds its argument to the nearest integral value using the current rounding direction.

#include <math.h>
long int rinttol(double x);

### Table 25.59 rinttol

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>Value being rounded</th>
</tr>
</thead>
</table>

### Remarks

If the rounded range is outside the range of long, result is unspecified

The argument in integral value in floating point format is returned.

This function may not be implemented on all platforms.

### See Also

“rint” on page 234
math.h
C99 Implementations

round

Round rounds its argument to an integral value in floating-point format.

```c
#include <math.h>
double round(double x);
```

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The value to be rounded</th>
</tr>
</thead>
</table>

Remarks

Rounding halfway cases away from zero, regardless of the current rounding direction.

The argument rounded to an integral value in floating point format nearest to is returned but is never larger in magnitude than the argument.

This function may not be implemented on all platforms.

See Also

"roundtol" on page 237

Listing 25.39 Example of round() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double varALPHA = 2.4;
    printf("round(%.1f) = %f\n",varALPHA,round(varALPHA));
    return 0;
}
```

Output:

```
round(2.400000) = 2.000000
```

Table 25.60  round

- x: double
- The value to be rounded
roundtol

The function roundtol rounds its argument to the nearest integral value. Rounding halfway cases away from zero, regardless of the current rounding direction.

```c
#include <math.h>
long int roundtol(double round);
```

**Table 25.61 roundtol**

<table>
<thead>
<tr>
<th>round</th>
<th>double</th>
<th>The value being rounded</th>
</tr>
</thead>
</table>

**Remarks**

- If the rounded range is outside the range of long, result is unspecified
- The argument rounded to an integral value in long int format is returned.
- This function may not be implemented on all platforms.

**See Also**

“round” on page 236

scalb

The function scalb computes \( x \times \text{FLT\_RADIX}^n \) efficiently, not normally by computing \( \text{FLT\_RADIX}^n \) explicitly.

```c
#include <math.h>
double scalb(double x, long int n);
```

**Table 25.62 scalb**

<table>
<thead>
<tr>
<th>x</th>
<th>double</th>
<th>The original value</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>long int</td>
<td>Power value</td>
</tr>
</tbody>
</table>

**Remarks**

- A range error may occur
- The function scalb returns \( x \times \text{FLT\_RADIX}^n \).
This function may not be implemented on all platforms.

trunc

Trunc rounds its argument to an integral value in floating-point format nearest to but no larger in magnitude than the argument.

#include <math.h>
double trunc(double x);

### Remarks

For 68k processors returns an integral value.
The trunc function returns an argument to an integral value in floating-point format.
This function may not be implemented on all platforms.

### Listing 25.40 Example of trunc() Usage

```c
#include <math.h>
#include <stdio.h>

int main(void)
{
    double varPHI = 2.4108;
    printf("trunc(%f) = %f\n", varPHI, trunc(varPHI));
    return 0;
}
```

Output:
trunc(2.410800) = 2.000000
Process.h

The header Process.h defines the threadex functions _beginthreadex and _endthreadex.

Overview of Process.h

This header file defines the facilities as follows:
- "_beginthread" on page 239 begins a thread.
- "_beginthreadex" on page 240 begins a with local data.
- "_endthread" on page 241 ends thread for _beginthread.
- "_endthreadex" on page 242 ends thread for _beginthreadex.

__beginthread

This function starts a thread for a multi-threaded application.

```c
#include <process.h>
long _beginthread(void (__cdecl *inCodeAddress)(void *)
    thread,
    unsigned int inStackSize, void *inParameter);
```

**Table 26.1 _beginthread**

<table>
<thead>
<tr>
<th>thread</th>
<th>void *</th>
<th>The address of the thread function</th>
</tr>
</thead>
<tbody>
<tr>
<td>inStackSize</td>
<td>int</td>
<td>Set by the linkers /STACK switch, 1MB is the default</td>
</tr>
<tr>
<td>inParameter</td>
<td>void *</td>
<td>The same as the lpvThreadParameter used in CreateThread() that is used to pass an initialization routine.</td>
</tr>
</tbody>
</table>
Remarks
The thread runs concurrently with the rest of the code.
The thread handle is returned or zero upon failure.
A Windows only function—this function may not be implemented on all versions.

See Also
"_endthread" on page 241
"_beginthreadex" on page 240

_beginthreadex
Begins a thread.
#include <process.h>
HANDLE __cdecl _beginthreadex(
    LPSECURITY_ATTRIBUTES inSecurity,
    DWORD inStacksize,
    LPTHREAD_START_ROUTINE inCodeAddress,
    LPVOID inParameter,
    DWORD inCreationFlags,
    LPDWORD inThreadID);

Table 26.2 _beginthreadex

<table>
<thead>
<tr>
<th>inSecurity</th>
<th>LPSECURITY_ATTRIBUTES</th>
<th>Security Attributes, NULL is the default attributes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>inStacksize</td>
<td>DWORD *</td>
<td>Set by the linkers /STACK switch, 1MB is the default</td>
</tr>
<tr>
<td>inCodeAddress</td>
<td>LPTHREAD_START_ROUTINE</td>
<td>The address of the function containing the code where the new thread should start.</td>
</tr>
<tr>
<td>inParameter</td>
<td>LPVOID</td>
<td>The same as the lpvThreadParameter used in CreateThread() that is used to pass an initialization routine.</td>
</tr>
</tbody>
</table>
The function _beginthreadex is similar to the Windows call CreateThread except this functions properly creates the local data used by MSL.

A HANDLE variable is returned if successful.

A Windows only function—this function may not be implemented on all versions.

See Also

“_endthreadex” on page 242

Table 26.2 _beginthreadex (continued)

<table>
<thead>
<tr>
<th>inCreationFlags</th>
<th>DWORD</th>
<th>If zero begins thread immediately, if CREATE_SUSPENDED it waits before executing.</th>
</tr>
</thead>
<tbody>
<tr>
<td>inThreadID</td>
<td>LPDWORD</td>
<td>An variable to store the ID assigned to a new thread.</td>
</tr>
</tbody>
</table>

The function _beginthreadex is similar to the Windows call CreateThread except this functions properly creates the local data used by MSL.

A HANDLE variable is returned if successful.

A Windows only function—this function may not be implemented on all versions.

See Also

“_endthreadex” on page 242

_endthread

This function ends a thread called by _beginthread.

#include <process.h>

void _endthread(void);

Remarks

This facility has no parameters.

There is no return value for this function.

Windows only compatible function.

See Also

“_beginthread” on page 239

“_endthreadex” on page 242
Process.h
Overview of Process.h

_endthreadex

Exits the thread.
#include <process.h>
VOID __cdecl _endthreadex(DWORD inReturnCode);

Table 26.3 _endthreadex

<table>
<thead>
<tr>
<th>inReturnCode</th>
<th>DWORD</th>
<th>The exit code is passed through this argument.</th>
</tr>
</thead>
</table>

Remarks
The function _endthreadex is similar to the Windows call ExitThread except this functions properly destroys the thread local data used by MSL.
There is no return.
A Windows only function—this function may not be implemented on all versions.

See Also
“_beginthreadex” on page 240
The `setjmp.h` header file provides a means of saving and restoring a processor state. The facilities that do this are "`longjmp`" and "`setjmp`":

**Overview of setjmp.h**

The `setjmp.h` header file provides a means of saving and restoring a processor state. The `setjmp.h` functions are typically used for programming error and low-level interrupt handlers.

- The function "`setjmp` on page 245" saves the current calling environment—the current processor state—in its `jmp_buf` argument. The `jmp_buf` type, an array, holds the processor program counter, stack pointer, and relevant data and address registers.
- The function "`longjmp` on page 244" restores the processor to its state at the time of the last `setjmp()` call. In other words, `longjmp()` returns program execution to the last `setjmp()` call if the `setjmp()` and `longjmp()` pair use the same `jmp_buf` variable as arguments.

**Non-local Jumps and Exception Handling**

Because the `jmp_buf` variable can be global, the `setjmp` and `longjmp` calls do not have to be in the same function body.

A `jmp_buf` variable must be initialized with a call to `setjmp()` before being used with `longjmp()`. Calling `longjmp()` with an un-initialized `jmp_buf` variable may crash the program. Variables assigned to registers through compiler optimization may be corrupted during execution between `setjmp()` and `longjmp()` calls. This situation can be avoided by declaring affected variables as `volatile`. 
longjmp

Restore the processor state saved by `setjmp()`.

```c
#include <setjmp.h>
void longjmp(jmp_buf env, int val);
```

<table>
<thead>
<tr>
<th>env</th>
<th>jmp_buf</th>
<th>The current processor state</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>int</td>
<td>A value returned by <code>setjmp()</code></td>
</tr>
</tbody>
</table>

**Remarks**

The `longjmp()` function restores the calling environment (i.e. returns program execution) to the state saved by the last called `setjmp()` to use the `env` variable. Program execution continues from the `setjmp()` function. The `val` argument is the value returned by `setjmp()` when the processor state is restored.

The `longjmp` function is redefined when AltVec support is enabled. The programmer must ensure that both the “to” compilation unit and “from” compilation unit have AltVec enabled. Failure to do so will create an undesired result.

After `longjmp` is completed, program execution continues as if the corresponding invocation of the `setjmp` macro had just returned the value specified by `val`. The `longjmp` function cannot cause the `setjmp` macro to return the value 0; if `val` is 0, the `setjmp` macro returns the value 1.

The `env` variable must be initialized by a previously executed `setjmp()` before being used by `longjmp()` to avoid undesired results in program execution.

This function may not be implemented on all platforms.

**See Also**

“`setjmp` on page 245”
“`signal` on page 251”
“`abort` on page 405”
# setjmp

Save the processor state for `longjmp()`.

```c
#include <setjmp.h>
int setjmp(jmp_buf env);
```

## Table 27.2 setjmp

<table>
<thead>
<tr>
<th>env</th>
<th>jmp_buf</th>
<th>The current processor state</th>
</tr>
</thead>
</table>

## Remarks

The `setjmp()` function saves the calling environment—data and address registers, the stack pointer, and the program counter—in the `env` argument. The argument must be initialized by `setjmp()` before being passed as an argument to `longjmp()`. For example usage, see Listing 27.1.

The `setjmp` function is redefined when AltiVec support is enabled. The programmer must ensure that both the “from” compilation unit and “to” compilation unit have AltiVec enabled. Failure to do so will create an undesired result.

When it is first called, `setjmp()` saves the processor state and returns 0. When `longjmp()` is called program execution jumps to the `setjmp()` that saved the processor state in `env`. When activated through a call to `longjmp()`, `setjmp()` returns `longjmp()`'s `val` argument.

This function may not be implemented on all platforms.

## See Also

- "longjmp" on page 244
- "signal" on page 251
- "abort" on page 405

## Listing 27.1 Example of setjmp() Usage

```c
#include <setjmp.h>
#include <stdio.h>
#include <stdlib.h>

// Let main() and doerr() both have
// access to global env
```
volatile jmp_buf env;

void doerr(void);
int main(void)
{
  int i, j, k;

  printf("Enter 3 integers that total less than 100.\n");
  printf("A zero sum will quit.\n\n");

  // If the total of entered numbers is not less than 100,
  // program execution is restarted from this point.
  if (setjmp(env) != 0)
    printf("Try again, please.\n");

  do {
    scanf("%d %d %d", &i, &j, &k);
    if ( (i + j + k) == 0)
      exit(0); // quit program
    printf("%d + %d + %d = %d\n", i, j, k, i+j+k);
    if ( (i + j + k) >= 100)
      doerr(); // error!
  } while (1); // loop forever

  return 0;
}

void doerr(void) // this is the error handler
{
  printf("The total is >= 100!\n");
  longjmp(env, 1);
}

Output:

Enter 3 integers that total less than 100.
A zero sum will quit.

10 20 30
10 + 20 + 30 = 60

-4 5 1000
-4 + 5 + 1000 = 1001

The total is >= 100!
Try again, please.

0 0 0
setjmp.h
Overview of setjmp.h
The signal.h header file lists the software interrupt specifications.

Overview of signal.h

Signals are software interrupts. There are signals for aborting a program, floating point exceptions, illegal instruction traps, user-signaled interrupts, segment violation, and program termination.

- **Table 28.1** lists the macros in the signal.h file.
- "signal" on page 251 specifies how a signal is handled: a signal can be ignored, handled in a default manner, or be handled by a programmer-supplied signal handling function.
- "raise" on page 253 calls the signal handling function.
- "Signal Function Handling Arguments" on page 251 describes the pre-defined signal handling macros that expand to functions.

Signal handling

Signals are invoked, or raised, using the `raise()` function. When a signal is raised its associated function is executed.

With the MSL C implementation of signal.h, a signal can only be invoked through the function "raise" on page 253, and, in the case of the SIGABRT signal, through the function "abort" on page 405. When a signal is raised, its signal handling function is executed as a normal function call.

The default signal handler for all signals except SIGTERM is SIG_DFL. The SIG_DFL function aborts a program with the `abort()` function, while the SIGTERM signal terminates a program normally with the `exit()` function.

The ANSI C Standard Library specifies that the SIG prefix used by the signal.h macros is reserved for future use. The programmer should avoid using the prefix to prevent conflicts with future specifications of the Standard Library.

The type typedef `char sig_atomic_t` in signal.h can be accessed as an incorruptible, atomic entity during an asynchronous interrupt.
signal.h
Overview of signal.h

The number of signals is defined by \texttt{__signal_max} given a value in this header.

\textbf{CAUTION} Using unprotected re-entrant functions such as printf(), getchar(), malloc(), etc. functions from within a signal handler is not recommended in any system that can throw signals in hardware. Signals are in effect interrupts, and can happen anywhere, including when you're already within a function. Even functions that protect themselves from re-entry in a multi-threaded case can fail if you re-enter them from a signal handler.

\begin{table}[h]
\centering
\begin{tabular}{ |l|p{0.7\textwidth} |}
\hline
\textbf{Macro} & \textbf{Details} \\
\hline
SIGABRT & Abort signal. This macro is defined as a positive integer value. This signal is called by the \texttt{abort()} function. \\
\hline
SIGBREAK & Terminates calling program. \\
\hline
SIGFPE & Floating point exception signal. This macro is defined as a positive integer value. \\
\hline
SIGILL & Illegal instruction signal. This macro is defined as a positive integer value. \\
\hline
SIGINT & Interactive user interrupt signal. This macro is defined as a positive integer value. \\
\hline
SIGSEGV & Segment violation signal. This macro is defined as a positive integer value. \\
\hline
SIGTERM & Terminal signal. This macro is defined as a positive integer value. When raised this signal terminates the calling program by calling the \texttt{exit()} function. \\
\hline
\end{tabular}
\caption{signal.h Macros}
\end{table}

The \texttt{signal()} function specifies how a signal is handled: a signal can be ignored, handled in a default manner, or be handled by a programmer-supplied signal handling function. Table 28.2 lists the pre-defined signal handling macros.
**signal.h**  
*Overview of signal.h*

---

### Table 28.2 Signal Function Handling Arguments

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIG_IGN</td>
<td>This macro expands to a pointer to a function that returns void. It is used as a function argument in <code>signal()</code> to designate that a signal be ignored.</td>
</tr>
<tr>
<td>SIG_DFL</td>
<td>This macro expands to a pointer to a function that returns void. This signal handler quits the program without flushing and closing open streams.</td>
</tr>
<tr>
<td>SIG_ERR</td>
<td>A macro defined like SIG_IGN and SIG_DFL as a function pointer. This value is returned when <code>signal()</code> cannot honor a request passed to it.</td>
</tr>
</tbody>
</table>

---

**signal**

Set signal handling.

```
#include <signal.h>
void (*signal(int sig, void (*func)(int)))(int);
```

**Table 28.3 signal**

<table>
<thead>
<tr>
<th>sig</th>
<th>int</th>
<th>A number associated with the signal handling function</th>
</tr>
</thead>
<tbody>
<tr>
<td>func</td>
<td>void *</td>
<td>A pointer to a signal handling function</td>
</tr>
</tbody>
</table>

**Remarks**

The `signal()` function returns a pointer to a signal handling routine that takes an `int` value argument. For example usage, see Listing 28.1.

The sig argument is the signal number associated with the signal handling function. The signals defined in `signal.h` are listed in Table 28.1.
The `func` argument is the signal handling function. This function is either programmer-supplied or one of the pre-defined signal handlers described in “Signal Function Handling Arguments” on page 251.

When it is raised, a signal handler's execution is preceded by the invocation of `signal(sig, SIG_DFL)`. This call to `signal()` effectively disables the user's handler. It can be reinstalled by placing a call within the user handler to `signal()` with the user's handler as its function argument.

`signal()` returns a pointer to the signal handling function set by the last call to `signal()` for signal `sig`. If the request cannot be honored, `signal()` returns `SIG_ERR`.

This function may not be implemented on all platforms.

“`abort`” on page 405

“`atexit`” on page 408

“`exit`” on page 420

**Listing 28.1 Example of signal() Usage**

```c
#include <signal.h>
#include <stdio.h>
#include <stdlib.h>

void userhandler(int);

void userhandler(int sig)
{
    char c;

    printf("userhandler!\nPress return.\n");

    /* wait for the return key to be pressed */
    c = getchar();
}

int main(void)
{
    void (*handlerptr)(int);
    int i;

    handlerptr = signal(SIGINT, userhandler);
    if (handlerptr == SIG_ERR)
        printf("Can't assign signal handler.\n");
```

```
for (i = 0; i < 10; i++) {
    printf("%d\n", i);
    if (i == 5) raise(SIGINT);
}
return 0;
}

Output:

0
1
2
3
4
5
userhandler!
Press return.

6
7
8
9

raise

Raise a signal.
#include <signal.h>
int raise(int sig);

Table 28.4 raise

<table>
<thead>
<tr>
<th>sig</th>
<th>int</th>
<th>A signal handling function</th>
</tr>
</thead>
</table>

Remarks

The `raise()` function calls the signal handling function associated with signal `sig`.

`raise()` returns a zero if the signal is successful; it returns a nonzero value if it is unsuccessful.

This function may not be implemented on all platforms.

The SIOUX (Simple Input and Output User eXchange) libraries handle Graphical User Interface issues. Such items as menus, windows, and events are handled so your program doesn’t need to for C and C++ programs.

Overview of SIOUX

The following section describes the Macintosh versions of the console emulation interface known as SIOUX. The facilities and structure members for the Standard Input Output User eXchange console interface are “Using SIOUX” and “SIOUX for Macintosh”.

- “Using SIOUX” on page 255 is a general description of SIOUX properties.
- “SIOUX for Macintosh” on page 256 explains the (Simple Input and Output User eXchange) library for the Macintosh Operating Systems.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also

“MSL Extras Library Headers” on page 4 for information on POSIX naming conventions.

Using SIOUX

Sometimes you need to port a program that was originally written for a command line interface such as DOS or UNIX. Or you need to write a new program quickly and don’t have the time to write a complete Graphical User Interface that handles windows, menus, and events.

To help you, CodeWarrior provides you with the SIOUX libraries, which handles all the Graphical User Interface items such as menus, windows, and titles so your program doesn’t need to. It creates a window that’s much like a dumb terminal or TTY but with scrolling. You can write to it and read from it with the standard C functions and C++ operators, such as printf(), scanf(), getchar(), putchar() and the C++ inserter and extractor operators << and >>. The SIOUX and WinSIOUX
libraries also creates a File menu that lets you save and print the contents of the window. The Macintosh hosted SIOUX includes an Edit menu that lets you cut, copy, and paste the contents in the window. For information on Macintosh redirecting to or from file the stdin, stdout, cout, and cin input output or commandline arguments.

Macintosh only—this function may not be implemented on all Mac OS versions.

See Also

“Overview of console.h” on page 41.

NOTE

If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

SIoux for Macintosh

SIoux for Macintosh contains the following segments.

- “Creating a Project with SIOUX” on page 257 shows a running SIOUX program.
- “Customizing SIOUX” on page 258 shows how to customize your SIOUX window.
  - “The SIOUXSettings Structure” on page 259 list structure members that may be set for altering SIOUX’s appearance
- “Using SIOUX windows in your own application” on page 264 contains information for using Mac OS facilities with in your SIOUX project.
  - “path2fss” on page 265 a function similar to PBMakeFSSpec.
  - “SIOUXHandleOneEvent” on page 265 allows you to use an even in SIOUX
  - “SIOUXSetTitle” on page 267 allows you to specify a custom title for SIOUX’s window

NOTE

A WASTE© by Marco Piovanelli based SIOUX console is available as a pre-release version. This will allow screen output of over 32k characters. All normal SIOUX functions should work but normal pre-release precautions should be taken. Please read all release notes.

The window is a re-sizable, scrolling text window, where your program reads and writes text. It saves up to 32K of your program’s text.

With the commands from the Edit menu, you can cut and copy text from the SIOUX window and paste text from other applications into the SIOUX window. With the commands in the File menu, you can print or save the contents of the SIOUX window.
To stop your program at any time, press Command-Period or Control-C. The SIOUX application keeps running so you can edit or save the window’s contents. If you want to exit when your program is done or avoid the dialog asking whether to save the window, see “Changing what happens on quit” on page 263.

To quit out of the SIOUX application at any time, choose Quit from the File menu. If you haven’t saved the contents of the window, the application displays a dialog asking you whether you want to save the contents of the window now. If you want to remove the status line, see “Showing the status line” on page 264.

Creating a Project with SIOUX

To use the SIOUX library, create a project from a project stationery pads that creates an Console style project.

In this chapter, standard input and standard output refer to stdin, stdout, cin, and cout. Standard error reporting such as stderr, clog, and cerr is not redirected to a file using ccommand().

If you want only to write to or read from standard input and output, you don’t need to call any special functions or include any special header files. When your program refers to standard input or output, the SIOUX library kicks in automatically and creates a SIOUX window for it.

NOTE Remember that functions like printf() and scanf() use standard input and output even though these symbols do not appear in their parameter lists.

If you want to customize the SIOUX environment, you must #include SIOUX.h and modify SIOUXSettings before you use standard input or output. As soon as you use one of them, SIOUX creates a window and you cannot modify it. For more information, see “Customizing SIOUX” on page 258.

If you want to use a SIOUX window in a program that has its own event loop, you must modify SIOUXSettings and call the function SIOUXHandleOneEvent(). For more information, see “Using SIOUX windows in your own application” on page 264.

If you want to add SIOUX to a project you already created, the project must contain certain libraries.

A PPC project must either contain at least these libraries:

- MSL_All_PPC.Lib
- InterfaceLib
- MathLib
Or at least:

- MSL C.PPC.Lib
Customizing SIOUX

This following sections describe how you can customize the SIOUX environment by modifying the structure SIOUXSettings. SIOUX examines the data fields of SIOUXSettings to determine how to create the SIOUX window and environment.

NOTE To customize SIOUX, you must modify SIOUXSettings before you call any function that uses standard input or output. If you modify SIOUXSettings afterwards, SIOUX does not change its window.

The first three sections, “Changing the font and tabs” on page 261, “Changing the size and location” on page 262, and “Showing the status line” on page 264, describe how to customize the SIOUX window. The next section, “Changing what happens on quit” on page 263, describe how to modify how SIOUX acts when you quit it. The last section,
“Using SIOUX windows in your own application” on page 264, describes how you can use a SIOUX window in your own Macintosh program. 

Table 29.1 summarizes what’s in the SIOUXSettings structure.

Table 29.1 The SIOUXSettings Structure

<table>
<thead>
<tr>
<th>This field…</th>
<th>Specifies…</th>
</tr>
</thead>
<tbody>
<tr>
<td>char initializeTB</td>
<td>Whether to initialize the Macintosh toolbox.</td>

<tr>
<td>int sleep</td>
<td>The default value for the sleep setting is zero. Zero gets the most speed out of SIOUX by telling the system to not give time to other processes during a WaitNextEvent call. A more appropriate setting (that is more friendly to other processes) is to set the sleep value to GetCaretTime().</td>
</tr>
</tbody>
</table>
SIouxSettings.asktosaveonclose = false;

/* Don’t show the status line */
SIouxSettings.showstatusline = false;

/* Make the window large enough to fit 1 line of text that contains 12 characters. */
SIouxSettings.columns = 12;
SIouxSettings.rows = 1;

/* Place the window’s top left corner at (5,40). */
SIouxSettings.toppixel = 40;
SIouxSettings.leftpixel = 5;

/* Set the font to be 48-point, bold, italic Times. */
SIouxSettings.fontsize = 48;
SIouxSettings.fontface = bold + italic;
GetFNum("\ptimes", &familyID);
SIouxSettings.fontid = familyID;

printf("Hello World!");
return 0;
}

Changing the font and tabs

This section describes how to change how SIOUX handles tabs with the field tabspaces and how to change the font with the fields fontid, fontsize, and fontface.

NOTE The status line in the SIOUX window writes its messages with the font specified in the fields fontid, fontsize, and fontface. If that font is too large, the status line may be unreadable. You can remove the status line by setting the field showstatusline to false, as described in “Showing the status line” on page 264.

To change the font in the SIOUX window, set fontid to one of these values defined in the header file Fonts.h:

- courier where the ID is kFontIDCourier
- geneva where the ID is kFontIDGeneva
- helvetica where the ID is kFontIDHelvetica
- monaco where the ID is kFontIDMonaco
• newYork where the ID is kFontIDNewYork
• symbol where the ID is kFontIDSymbol
• times where the ID is kFontIDTimes

By default, fontid is monaco.

To change the character style for the font, set fontface to one of these values:
• normal
• bold
• italic
• underline
• outline
• shadow
• condense
• extend

To combine styles, add them together. For example, to write text that’s bold and italic, set
fontface to bold + italic. By default, fontface is normal.

To change the size of the font, set fontsize to the size. By default, fontsize is 9.

The field tabspaces controls how SIOUX handles tabs. If tabspaces is any number
greater than 0, SIOUX prints that number of spaces required to get to the next tab position
instead of a tab. If tabspaces is 0, it prints a tab. In the SIOUX window, a tab looks
like a single space, so if you are printing a table, you should set tabspaces to an
appropriate number, such as 4 or 8. By default, tabspaces is 4.

The sample below sets the font to 12-point, bold, italic New York and substitutes 4 spaces
for every tab:

SIOUXSettings.fontsize = 12;
SIOUXSettings.fontface = bold + italic;
SIOUXSettings.fontid = kFontIDNewYork;
SIOUXSettings.tabsaces = 4;

Changing the size and location

SIOUX lets you change the size and location of the SIOUX window.

To change the size of the window, set rows to the number of lines of text in the window
and set columns to the number of characters in each line. SIOUX checks the font you
specified in fontid, fontsize, and fontface and creates a window that will be
large enough to contain the number of lines and characters you specified. If the window is
too large to fit on your monitor, SIOUX creates a window only as large as the monitor can contain.

For example, the code below creates a window that contains 10 lines with 40 characters per line:

```c
SIOUXSettings.rows = 10;
SIOUXSettings.columns = 40;
```

By default, the SIOUX window contains 24 rows with 80 characters per row.

To change the position of the SIOUX window, set `toppixel` and `leftpixel` to the point where you want the top left corner of the SIOUX window to be. By setting `toppixel` to 38 and `leftpixel` to 0, you can place the window as far left as possible and just under the menu bar. Notice that if `toppixel` is less than 38, the SIOUX window is under the menu bar. If `toppixel` and `leftpixel` are both 0, SIOUX doesn’t place the window at that point but instead centers it on the monitor.

For example, the code below places the window just under the menu bar and near the left edge of the monitor:

```c
SIOUXSettings.toppixel = 40;
SIOUXSettings.leftpixel = 5;
```

### Changing what happens on quit

The fields `autocloseonquit` and `asktosaveonclose` let you control what SIOUX does when your program is over and SIOUX closes its window.

The field `autocloseonquit` determines what SIOUX does when your program has finished running. If `autocloseonquit` is `true`, SIOUX automatically exits. If `autocloseonquit` is `false`, SIOUX continues to run, and you must choose Quit from the File menu to exit. By default, `autocloseonquit` is `false`.

For example, the code below quits the SIOUX application as soon as your program is done and doesn’t ask you to save the output:

```c
SIOUXSettings.autocloseonquit = true;
SIOUXSettings.asktosaveonclose = false;
```
Showing the status line

The field showstatusline lets you control whether the SIOUX window displays a status line, which contains such information as whether the program is running, handling output, or waiting for input. If showstatusline is true, the status line is displayed. If showstatusline is false, the status line is not displayed. By default, showstatusline is false.

Using SIOUX windows in your own application

This section explains how you can limit how much SIOUX controls your program. But first, you need to understand how SIOUX works with your program. You can consider the SIOUX environment to be an application that calls your main() function as just another function. Before SIOUX calls main(), it performs some initialization to set up the Macintosh Toolbox and its menu. After main() completes, SIOUX cleans up what it created. Even while main() is running, SIOUX sneaks in whenever it performs input or output, acting on any menu you’ve chosen or command key you’ve pressed.

However, SIOUX lets you choose how much work it does for you. You can choose to handle your own events, set up your own menus, and initialize the Macintosh Toolbox yourself.

When you want to write an application that handles its own events and uses SIOUX windows for easy input and output, set the field standalone to false before you use standard input or output. SIOUX doesn’t use its event loop and sets the field autocloseonquite to true for you, so the application exits as soon as your program is done. In your event loop, you need to call the function SIOUXHandleOneEvent(), described on “Using SIOUX windows in your own application” on page 264.

When you don’t want to use SIOUX’s menus, set the field setupmenus to false. If standalone is also false, you won’t be able to create menus, and your program will have none. If standalone is true, you can create and handle your own menus.

When you want to initialize the Macintosh Toolbox yourself, set the field initializeTB to false. The field standalone does not affect initializeTB.

For example, these lines set up SIOUX for an application that handles its own events, creates its own menus, and initializes the Toolbox:

```c
SIOUXSettings.standalone = false;
SIOUXSettings.setupmenus = false;
SIOUXSettings.initializeTB = false;
```
**path2fss**

This function is similar to PBMakeFSSpec.

```c
#include <path2fss.h>
OSErr __path2fss
    (const char * pathName, FSSpecPtr spec)
```

**Remarks**

This function is similar to PBMakeFSSpec with four major differences:

- Takes only a path name as input (as a C string) no parameter block.
- Only makes FSSpecs for files, not directories.
- Works on *any* HFS Mac (Mac 512KE, Mac Plus or later) under any system version that supports HFS.
- Deals correctly with MFS disks (correctly traps file names longer than 63 chars and returns bdNamErr).

Like PBMakeFSSpec, this function returns fnfErr if the specified file does not exist but the FSSpec is still valid for the purposes of creating a new file.

Errors are returned for invalid path names or path names that specify directories rather than files.

Macintosh only—this function may not be implemented on all Mac OS versions.

---

**SIOUXHandleOneEvent**

Handles an event for a SIOUX window.

```c
#include <SIOUX.h>
Boolean SIOUXHandleOneEvent(EventRecord *event);
```
Before you handle an event, call `SIOUXHandleOneEvent()` so SIOUX can update its windows when necessary. The argument `event` should be an event that `WaitNextEvent()` or `GetNextEvent()` returned. The function returns `true` if it handled the event and `false` if it didn’t. If `event` is a NULL pointer, the function polls the event queue until it receives an event.

If it handles the event, `SIOUXHandleOneEvent()` returns `true`. Otherwise, `SIOUXHandleOneEvent()` returns `false`.

Macintosh only—this function may not be implemented on all Mac OS versions.

Listing 29.2 Example of `SIOUXHandleOneEvent()` Usage

```c
void MyEventLoop(void)
{
    EventRecord event;
    RgnHandle cursorRgn;
    Boolean gotEvent, SIOUXDidEvent;

    cursorRgn = NewRgn();

    do {
        gotEvent = WaitNextEvent(everyEvent, &event,
                                  MyGetSleep(), cursorRgn);

        /* Before handling the event on your own,
         * call SIOUXHandleOneEvent() to see whether
         * the event is for SIOUX.
         */
        if (gotEvent)
            SIOUXDidEvent = SIOUXHandleOneEvent(&event);

        if (!SIOUXDidEvent)
            DoEvent(&event);
    } while (!gDone)
}
```

Table 29.3 `SIOUXHandleOneEvent`

<table>
<thead>
<tr>
<th>event</th>
<th>EventRecord*</th>
<th>A pointer to a toolbox event</th>
</tr>
</thead>
</table>

Remarks
SIOUXsetTitle

To set the title of the SIOUX output window.

```c
#include <SIOUX.h>
extern void SIOUXSetTitle(unsigned char title[256])
```

**Table 29.4 SIOUXSetTitle**

<table>
<thead>
<tr>
<th>title</th>
<th>unsigned char []</th>
<th>A pascal string</th>
</tr>
</thead>
</table>

**Remarks**

You must call the SIOUXSetTitle() function after an output to the SIOUX window. The function SIOUXSetTitle() does not return an error if the title is not set. A write to console is not performed until a new line is written, the stream is flushed or the end of the program occurs.

**NOTE** The argument for SIOUXSetTitle() is a pascal string, not a C style string.

There is no return value from SIOUXSetTitle()

Macintosh only—this function may not be implemented on all Mac OS versions.

**Listing 29.3 Example of SIOUXSetTitle() Usage**

```c
#include <stdio.h>
#include <SIOUX.h>

int main(void)
{
    printf("Hello World\n");
    SIOUXSetTitle("\pMy Title");
    return 0;
}
```
The `stat.h` header file contains several functions that are useful for porting a program from UNIX.

### Overview of `stat.h`

This header file defines the facilities as follows:

- "Stat Structure and Definitions" on page 269 explains the stat struct and types.
- "chmod" on page 272 gets or sets a file's attributes.
- "fstat" on page 273 gets information about an open file.
- "mkdir" on page 275 makes a directory for a folder.
- "stat" on page 276 gets statistics of a file.

### `stat.h` and UNIX Compatibility

Generally, you don't want to use these functions in new programs. Instead, use their counterparts in the native API.

**NOTE** If you're porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

### See Also

"MSL Extras Library Headers" on page 4 for information on POSIX naming conventions.

### Stat Structure and Definitions

The header `stat.h` includes the `stat` (and `_stat`, for Windows) structure, listed in Table 30.2. It also has several type definitions and file mode definitions. The necessary types are listed in Table 30.1. The file modes are listed in Table 30.3. File mode macros are listed in Table 30.4 and Table 30.5.

### chmod

Gets or sets file attributes.

```c
#include <stat.h>

int chmod(const char *, mode_t);
int _chmod(const char *, mode_t);
```
Overview of stat.h

Remarks

The file attributes as a mask is returned or a negative one on failure.
This function may not be implemented on all platforms.

See Also

“fstat” on page 273

Table 30.6 chmod

<table>
<thead>
<tr>
<th>path</th>
<th>const char *</th>
<th>The file to change modes on</th>
</tr>
</thead>
<tbody>
<tr>
<td>mod</td>
<td>mode_t</td>
<td>A mask of the new file attributes</td>
</tr>
</tbody>
</table>

Remarks

Gets information about an open file.
#include <stat.h>

int fstat(int fildes, struct stat *buf);
int _fstat(int fildes, struct stat *buf);

Table 30.7 fstat

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
<th>A file descriptor</th>
</tr>
</thead>
<tbody>
<tr>
<td>buf</td>
<td>struct stat *</td>
<td>The stat structure address</td>
</tr>
</tbody>
</table>

Remarks

This function gets information on the file associated with fildes and puts the information in the structure that buf points to. The structure contains the fields listed in “Stat Structure and Definitions” on page 269.
If it is successful, fstat() returns zero. If it encounters an error, fstat() returns -1 and sets errno.
This function may not be implemented on all platforms.
stat.h
Overview of stat.h

See Also
“stat” on page 276

Listing 30.1 Example of fstat() Usage

```c
#include <stdio.h>
#include <time.h>
#include <unix.h>

int main(void)
{
    struct stat info;
    int fd;

    fd = open("mytest", O_WRONLY | O_CREAT | O_TRUNC);
    write(fd, "Hello world!
", 13);

    fstat(fd, &info);
    /* Get information on the open file. */

    printf("File mode:         0x%lx\n", info.st_mode);
    printf("File ID:           0x%lx\n", info.st_ino);
    printf("Volume ref. no.:  0x%lx\n", info.st_dev);
    printf("Number of links:   %hd\n", info.st_nlink);
    printf("User ID:           %lu\n", info.st_uid);
    printf("Group ID:          %lu\n", info.st_gid);
    printf("File size:         %ld\n", info.st_size);
    printf("Access time:       %s", ctime(&info.st_atime));
    printf("Modification time: %s", ctime(&info.st_mtime));
    printf("Creation time: %s", ctime(&info.st_ctime));

    close(fd);
    return 0;
}
```

This program may print the following:

File mode: 0x800
File ID: 0x5ACA
Volume ref. no.: 0xFFFFFFFF
Number of links: 1
User ID: 200
Device type: 0
File size: 13
**mkdir**

Makes a folder.

```c
#include <stat.h>
int mkdir(const char *path, int mode);
int _mkdir(const char *path);
```

<table>
<thead>
<tr>
<th>path</th>
<th>const char *</th>
<th>The path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>int</td>
<td>The open mode (Not applicable for Windows)</td>
</tr>
</tbody>
</table>

**Remarks**

This function creates the new folder specified in `path`. It ignores the argument `mode`.

If it is successful, `mkdir()` returns zero. If it encounters an error, `mkdir()` returns `-1` and sets `errno`.

This function may not be implemented on all platforms.

**See Also**

- “unlink” on page 535
- “rmdir” on page 529

**Listing 30.2 Example of mkdir() on Macintosh OS**

```c
#include <stdio.h>
#include <stat.h>

int main(void)
{
    if( mkdir(":Asok", 0) == 0)
        printf("Folder Asok is created");

    return 0;
}
```

**Listing 30.2 Example of mkdir() on Windows**

```c
#include <stdio.h>

int main(void)
{
    if( mkdir(":Asok", 0) == 0)
        printf("Folder Asok is created");

    return 0;
}
```
stat.h
Overview of stat.h

#include <stat.h>

int main(void)
{
    if( mkdir("\.\Asok") == 0)
        printf("Folder Asok is created");
    return 0;
}

Output
Creates a folder named Asok as a sub-folder of the current folder

stat

Gets information about a file.

#include <stat.h>

int stat(const char *path, struct stat *buf);
int _stat(const char *path, struct stat *buf);

Table 30.9  stat

<table>
<thead>
<tr>
<th>path</th>
<th>const char *</th>
<th>The path name</th>
</tr>
</thead>
<tbody>
<tr>
<td>buf</td>
<td>struct stat *</td>
<td>A pointer to the stat struct</td>
</tr>
</tbody>
</table>

Remarks
This function gets information on the file specified in path and puts the information in the structure that buf points to. The structure contains the fields listed in "Stat Structure and Definitions" on page 269. If it is successful, stat() returns zero. This function may not be implemented on all platforms.

Listing 30.3 Example of stat() Usage

```c
#include <stdio.h>
#include <time.h>
#include <unix.h>

int main(void)
{
    struct stat info;
    stat("Akbar:System Folder:System", &info);
    /* Get information on the System file. */
    printf("File mode: 0x%lX\n", info.st_mode);
    printf("File ID: 0x%lX\n", info.st_ino);
    printf("Volume ref. no.: 0x%lX\n", info.st_dev);
    printf("Number of links: %hd\n", info.st_nlink);
    printf("User ID: %lu\n", info.st_uid);
    printf("Group ID: %lu\n", info.st_gid);
    printf("File size: %ld\n", info.st_size);
    printf("Access time: %s", ctime(&info.st_atime));
    printf("Modification time: %s", ctime(&info.st_mtime));
    printf("Creation time: %s", ctime(&info.st_ctime));
    return 0;
}
```

This program may print the following:

File mode: 0x800
File ID: 0x4574
Volume ref. no.: 0x0
Number of links: 1
User ID: 200
Group ID: 100
File size: 30480
Access time: Mon Apr 17 19:46:37 1995
Modification time: Mon Apr 17 19:46:37 1995
Creation time: Fri Oct 7 12:00:00 1994
stat.h
Overview of stat.h

umask

Sets a UNIX style file creation mask.

#include <stat.h> /* Macintosh */

mode_t umask(mode_t cmask)
mode_t _umask(mode_t cmask)

<table>
<thead>
<tr>
<th>cmask</th>
<th>mode_t</th>
<th>permission bitmask</th>
</tr>
</thead>
</table>

Remarks

The function umask is used for calls to open(), creat() and mkdir() to turn off permission bits in the mode argument.

If _MSL_POSIX true and you are compiling for Macintosh or Windows umask returns mode_t and takes a mode_t otherwise it takes an int type.

NOTE The permission bits are not used on either the Mac nor Windows. The function is provided merely to allow compilation and compatibility.

The previous mask. Zero is returned for Mac and Windows operating systems. if _MSL_POSIX is on and you are on mac and win umask returns mode_t.

This function may not be implemented on all platforms.

"creat, _wcreate" on page 118
"open, _wopen" on page 121
"mkdir" on page 275
The stdarg.h header file allows the creation of functions that accept a variable number of arguments.

Overview of stdarg.h

This header file defines the facilities as follows:

- “va_arg” on page 280 returns an argument value.
- “va_copy” on page 280 copies and initializes a variable argument list.
- “va_end” on page 281 cleans the stack to allow a proper function return.
- “va_start” on page 282 initializes the variable-length argument list.

Variable Arguments for Functions

The stdarg.h header file allows the creation of functions that accept a variable number of arguments.

A variable-length argument function is defined with an ellipsis (...) as its last argument. For example:

```c
int funnyfunc(int a, char c, ...);
```

The function is written using the va_list type, the va_start(), va_arg() and the va_end() macros.

The function has a va_list variable declared within it to hold the list of function arguments. The macro “va_start” on page 282 initializes the va_list variable and is called before gaining access to the arguments. The macro “va_arg” on page 280 returns each of the arguments in va_list. When all the arguments have been processed through va_arg(), the macro “va_end” on page 281 is called to allow a normal return from the function.
stdarg.h
Overview of stdarg.h

va_arg
Macro to return an argument value.
#include <stdarg.h>
type va_arg(va_list ap, type type);

Table 31.1 va_arg

<table>
<thead>
<tr>
<th>ap</th>
<th>va_list</th>
<th>A variable list</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>type</td>
<td>The type of the argument value to be obtained</td>
</tr>
</tbody>
</table>

Remarks
The va_arg() macro returns the next argument on the function's argument list. The argument returned has the type defined by type. The ap argument must first be initialized by the va_start() macro. The va_arg() macro returns the next argument on the function's argument list of type. This function may not be implemented on all platforms.

See Also
“va_end” on page 281
“va_start” on page 282
For example of va() usage, see “Example of va_start() Usage” on page 282.

va_copy
Copies and initializes a variable argument list.
#include <stdarg.h>
void va_copy(va_list dest, va_list src)
va_copy

Table 31.2 va_copy

<table>
<thead>
<tr>
<th>dest</th>
<th>va_list</th>
<th>The va_list being initialized</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>va_list</td>
<td>The source va_list being copied</td>
</tr>
</tbody>
</table>

Remarks

The va_copy() macro makes a copy of the variable list src in a state as if the va_start macro had been applied to it followed by the same sequence of va_arg macros as had been applied to src to bring it into its present state. There is no return for this facility. This function may not be implemented on all platforms.

See Also

“Variable Arguments for Functions” on page 279

va_end

Prepare a normal function return.

#include <stdarg.h>

void va_end(va_list ap);

Table 31.3 va_end

<table>
<thead>
<tr>
<th>ap</th>
<th>va_list</th>
<th>A variable list</th>
</tr>
</thead>
</table>

Remarks

The va_end() function cleans the stack to allow a proper function return. The function is called after the function's arguments are accessed with the va_arg() macro. This function may not be implemented on all platforms.

See Also

“va_arg” on page 280
“va_start” on page 282
va_start

Initialize the variable-length argument list.

```c
#include <stdarg.h>
void va_start(va_list ap, ParmN Parm);
```

### Remarks

The `va_start()` macro initializes and assigns the argument list to `ap`. The `ParmN` parameter is the last named parameter before the ellipsis (`...`) in the function prototype. For example usage, see Listing 31.1.

This function may not be implemented on all platforms.

### See Also

- “va_arg” on page 280
- “va_end” on page 281

### Listing 31.1 Example of va_start() Usage

```c
#include <stdarg.h>
#include <string.h>
#include <stdio.h>

void multisum(int *dest, ...);

int main(void)
{
    int all;
    all = 0;
    multisum(&all, 13, 1, 18, 3, 0);
    printf("%d\n", all);
    return 0;
}
```
void multisum(int *dest, ...)
{
    va_list ap;
    int n, sum = 0;

    va_start(ap, dest);

    while ((n = va_arg(ap, int)) != 0)
        sum += n;  /* add next argument to dest */
    *dest = sum;  /* add to destination */
    va_end(ap);  /* clean things up before leaving */
}

Output: 3
The `stdbool.h` header file defines types used for boolean integral values.

### Overview of stdbool.h

The `stdbool.h` header file consists of definitions in Table 32.1 only if the compiler support for c99 has been turned on using the C99 pragma.

```
#pragma c99 on | off | reset
```

#### Table 32.1 Defines in stdbool.h

<table>
<thead>
<tr>
<th>bool</th>
<th>_Bool</th>
</tr>
</thead>
<tbody>
<tr>
<td>true</td>
<td>1</td>
</tr>
<tr>
<td>false</td>
<td>0</td>
</tr>
<tr>
<td>__bool_true_false_are_defined</td>
<td>1</td>
</tr>
</tbody>
</table>

### Remarks

There are no other defines in this header.

This function may not be implemented on all platforms.
stddef.h

The stddef.h header file defines commonly used macros and types that are used throughout the ANSI C Standard Library.

Overview of stddef.h

The commonly used definitions macros and types are defined in stddef.h

- “NULL” on page 287 defines NULL.
- “offsetof” on page 287 is the offset of a structure’s member.
- “ptrdiff_t” on page 288 is used for pointer differences.
- “size_t” on page 288 is the return from a size of operation.
- “wchar_t” on page 288 is a wide character type.

NULL

The NULL macro is the null pointer constant used in the Standard Library.

Remarks

This definition may not be implemented on all platforms.

offsetof

The offsetof(structure, member) macro expands to an integral expression of type size_t. The value returned is the offset in bytes of a member, from the base of its structure.

NOTE

If the member is a bit field the result is undefined.

Remarks

This macro may not be implemented on all platforms.
stddef.h

Overview of stddef.h

ptrdiff_t

The `ptrdiff_t` type is the signed integral type used for holding the result of subtracting one pointer's value from another.

Remarks

This type may not be implemented on all platforms.

size_t

The `size_t` type is an unsigned integral type returned by the `sizeof()` operator.

Remarks

This type may not be implemented on all platforms.

wchar_t

The `wchar_t` type is an integral type capable of holding all character representations of the wide character set.

Remarks

This type may not be implemented on all platforms.
The header `stdint.h` defines types used for standard integral values.

**Overview of stdint.h**

The `stdint.h` header file consists of integer types listed as follows:

- “Integer Types” on page 289
- “Limits of Specified-width Integer Types” on page 291
- “Macros for Integer Constants” on page 295
- “Macros for Greatest-width Integer Constants” on page 295

**NOTE** The types in this header may not be implemented on all platforms.

**Integer Types**

The header `stdint.h` contains several integer types.

- Table 34.1, “Exact Width Integer Type”
- Table 34.2, “Minimum Width Integer Type”
- Table 34.3, “Fastest Minimum-Width Integer Types”
- Table 34.4, “Integer Types Capable of Holding Object Pointers”
- Table 34.5, “Greatest Width Integer Types”

Macros for Integer Constants

The macros expand to integer constants suitable for initializing objects that have integer types.

- `INT8_C(value) value`
- `INT16_C(value) value`
- `INT32_C(value) value ## L`
- `INT64_C(value) value ## LL`
- `UINT8_C(value) value ## U`
- `UINT16_C(value) value ## U`
- `UINT32_C(value) value ## UL`
- `UINT64_C(value) value ## ULL`

Macros for Greatest-width Integer Constants

The `INTMAX_C` macro expands to an integer constant with the value of its argument and the type `intmax_t`.

- `INTMAX_C(value) value ## LL`

The `UINTMAX_C` macro expands to an integer constant with the value of its argument and the type `uintmax_t`.

- `UINTMAX_C(value) value ## ULL`
The `stdio.h` header file provides functions for input/output control.

**Overview of stdio.h**

The `stdio.h` header file provides functions for input/output control. There are functions for creating, deleting, and renaming files, functions to allow random access, as well as to write and read text and binary data.

This header file defines the facilities as follows:

- “`clearerr`” on page 302 clears an error from a stream.
- “`fclose`” on page 304 closes a file.
- “`fdopen`” on page 306 converts a file descriptor to a stream.
- “`feof`” on page 307 detects the end of a file.
- “`ferror`” on page 309 checks a file error status.
- “`fflush`” on page 310 flushes a stream.
- “`fgetc`” on page 312 gets a character from a file.
- “`fgetpos`” on page 314 gets a file position from large files.
- “`fgets`” on page 316 gets a string from a file.
- “`_fileno`” on page 317 gets the file number (Windows version only).
- “`fopen`” on page 317 opens a file for manipulation.
- “`fprintf`” on page 320 prints formatted output to a file.
- “`fputc`” on page 328 writes a character to a file.
- “`fputs`” on page 330 writes a string to a file.
- “`fread`” on page 331 reads a file.
- “`freopen`” on page 333 reopens a file.
- “`fscanf`” on page 335 scans a file.
- “`fseek`” on page 341 moves to a file position.
- “`fsetpos`” on page 343 sets a file position for large files.
- “`ftell`” on page 344 tells a file offset.
Overview of stdio.h

- “fwide” on page 345 determines a character orientation.
- “fwrite” on page 347 writes to a file.
- “getc” on page 348 gets a character from a stream.
- “getchar” on page 349 gets a character from stdin.
- “gets” on page 351 gets a string from stdin.
- “perror” on page 352 writes an error to stderr.
- “printf” on page 353 writes a formatted output to stdout.
- “putc” on page 362 writes a character to a stream.
- “putchar” on page 363 writes a character to stdout.
- “puts” on page 365 writes a string to stdout.
- “remove” on page 366 removes a file.
- “rename” on page 367 renames a file.
- “rewind” on page 368 resets the file indicator to the beginning.
- “scanf” on page 370 scans stdin for input.
- “setbuf” on page 375 sets the buffer size for a stream.
- “setvbuf” on page 377 sets the stream buffer size and scheme.
- “snprintf” on page 379 writes a number of characters to a buffer.
- “sprintf” on page 380 writes to a character buffer.
- “sscanf” on page 381 scans a string.
- “tmpfile” on page 382 creates a temporary file.
- “tmpnam” on page 384 creates a temporary name.
- “ungetc” on page 385 places a character back in a stream.
- “vfprintf” on page 387 writes variable arguments to file.
- “vfscanf” on page 389 a variable argument scanf.
- “vprintf” on page 391 writes variable arguments to stdout.
- “vsscanf” on page 393 reads formatted text from a character strin (variable scanf).
- “_wfopen” on page 399 opens a wide character file.
- “_wfreopen” on page 399 reopening a wide character file.
- “_wremove” on page 400 removes a wide character file.
- “_wrename” on page 401 renames wide character file.
Standard input/output

Streams

A stream is a logical abstraction that isolates input and output operations from the physical characteristics of terminals and structured storage devices. They provide a mapping between a program’s data and the data as actually stored on the external devices. Two forms of mapping are supported, for text streams and for binary streams. See “Text Streams and Binary Streams” on page 300, for more information.

Streams also provide buffering, which is an abstraction of a file designed to reduce hardware I/O requests. Without buffering, data on an I/O device must be accessed one item at a time. This inefficient I/O processing slows program execution considerably. The stdio.h functions use buffers in primary storage to intercept and collect data as it is written to or read from a file. When a buffer is full its contents are actually written to or read from the file, thereby reducing the number of I/O accesses. A buffer's contents can be sent to the file prematurely by using the fflush() function.

The stdio.h header offers three buffering schemes: unbuffered, block buffered, and line buffered. The setvbuf() function is used to change the buffering scheme of any output stream.

When an output stream is unbuffered, data sent to it are immediately read from or written to the file.

When an output stream is block buffered, data are accumulated in a buffer in primary storage. When full, the buffer's contents are sent to the destination file, the buffer is cleared, and the process is repeated until the stream is closed. Output streams are block buffered by default if the output refers to a file.

A line buffered output stream operates similarly to a block buffered output stream. Data are collected in the buffer, but are sent to the file when the line is completed with a newline character (‘\n’).

A stream is declared using a pointer to a FILE. There are three FILE pointers that are automatically opened for a program: FILE *stdin, FILE *stdout, and FILE *stderr. The FILE pointers stdin and stdout are the standard input and output files, respectively, for interactive console I/O. The stderr file pointer is the standard error output file, where error messages are written to. The stderr stream is written to the console. The stdin and stdout streams are line buffered while the stderr stream is unbuffered.
**Text Streams and Binary Streams**

In a binary stream, there is no transformation of the characters during input or output and what is recorded on the physical device is identical to the program’s internal data representation.

A text stream consists of sequence of characters organized into lines, each line terminated by a new-line character. To conform to the host system’s convention for representing text on physical devices, characters may have to be added altered or deleted during input and output. Thus, there may not be a one-to-one correspondence between the characters in a stream and those in the external representation. These changes occur automatically as part of the mapping associated with text streams. Of course, the input mapping is the inverse of the output mapping and data that are output and then input through text streams will compare equal with the original data.

In MSL, the text stream mapping affects only the linefeed (LF) character, ‘\n’ and the carriage return (CR) character, ‘\r’. The semantics of these two control characters are:

- `\n` Moves the current print location to the start of the next line.
- `\r` Moves the current print location to the start of the current line.

where “current print location” is defined as “that location on a display device where the next character output by the fputc function would appear”.

The ASCII character set defines the value of LF as 0x0a and CR as 0x0d and these are the values that these characters have when they are part of a program's data. On physical devices in the Macintosh operating system, newline characters are represented by 0x0d and CR as 0x0a; in other words, the values are interchanged. To meet this requirement, the MSL C library for the Mac, interchanges these values while writing a file and again while reading so that a text stream will be unchanged by writing to a file and then reading back.

MPW chose 0x0a for the newline character in its text file, so, when the MPW switch is on, this interchange of values does not take place. However, if you use this option, you must use the MSL C and C++ libraries that were compiled with this option on.

These versions of the libraries are marked with an N (on 68k) or NL (on PPC), for example ANSI (N/2) C.68k.Lib or ANSI (NL) C.PPC.Lib. See the notes on the mpwc_newline pragma in the CodeWarrior C Compilers Reference.

On Windows, the situation is different. There, lines are terminated with the character pair CR/LF. As a consequence, in the Windows implementation of MSL, when a text stream is written to a file, a single newline character is converted to the character pair CR/LF and the reverse transformation is made during reading.

The library routines that read a file have no means of determining the mode in which text files were written and thus some assumptions have to be made. On the Mac, it is assumed that the Mac convention is used. Under MPW, it is assumed that the MPW convention is to be used and on Windows, the DOS convention.
**stdio.h**

*Standard input/output*

---

**File position indicator**

The file position indicator is another concept introduced by the `stdio.h` header. Each opened stream has a file position indicator acting as a cursor within a file. The file position indicator marks the character position of the next read or write operation. A read or write operation advances the file position indicator. Other functions are available to adjust the indicator without reading or writing, thus providing random access to a file.

Note that console streams, `stdin`, `stdout`, and `stderr` in particular, do not have file position indicators.

**End-of-file and errors**

Many functions that read from a stream return the `EOF` value, defined in `stdio.h`. The `EOF` value is a nonzero value indicating that the end-of-file has been reached during the last read or write.

Some `stdio.h` functions also use the `errno` global variable. Refer to the `errno.h` header section. The use of `errno` is described in the relevant function descriptions below.

**Wide Character and Byte Character Stream Orientation**

There are two types of stream orientation for input and output, a wide character (`wchar_t`) oriented and a byte (`char`) oriented. A stream is without orientation after that stream has been associated with a file, until an operation occurs.

Once any operation is performed on that stream, that stream becomes oriented by that operation to be either byte oriented or wide character oriented and remains that way until the file has been closed and reopened.

After a stream orientation is established, any call to a function of the other orientation is not applied. That is, a byte-oriented input/output function does not have an effect on a wide-oriented stream.

**Unicode**

Unicode encoded characters are represented and manipulated in MSL as wide characters of type `wchar_t` and can be manipulated with the wide character functions defined in the C Standard.

<table>
<thead>
<tr>
<th>Table 35.1 Byte Oriented Functions</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fgetc</code></td>
</tr>
<tr>
<td><code>fread</code></td>
</tr>
</tbody>
</table>
Stream Orientation and Standard Input/Output

The three predefined associated streams, stdin, stdout, and stderr are without orientation at program startup. If any of the standard input/output streams is closed it is not possible to reopen and reconnect that stream to the console. However, it is possible to reopen and connect the stream to a named file.

The C and C++ input/output facilities share the same stdin, stdout and stderr streams.

clearerr

Clear a stream's end-of-file and error status.

#include <stdio.h>

void clearerr(FILE *stream);
The `clearerr()` function resets the end-of-file status and error status for stream. The end-of-file status and error status are also reset when a stream is opened.

This function may not be implemented on all platforms.

**See Also**

- “`ferror`” on page 309
- “`fopen`” on page 317
- “`fseek`” on page 341
- “`rewind`” on page 368

**Listing 35.1 Example of clearerr() Usage**

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;

    static char name[] = "myfoo";
    char buf[80];

    // create a file for output
    if ( (f = fopen(name, "w")) == NULL) {
        printf("Can't open %s.\n", name);
        exit(1);
    }

    // output text to the file
    fprintf(f, "chair table chest\n");
    fprintf(f, "desk raccoon\n");

    // close the file
    fclose(f);

    // open the same file again for input
```
```c
if ( (f = fopen(name, "r")) == NULL) {
    printf("Can't open %s.\n", name);
    exit(1);
}

// read all the text until end-of-file
for (; feof(f) == 0; fgets(buf, 80, f))
    fputs(buf, stdout);

printf("feof() for file %s is %d.\n", name, feof(f));
printf("Clearing end-of-file status. . .\n");
clearerr(f);
printf("feof() for file %s is %d.\n", name, feof(f));

// close the file
fclose(f);

return 0;
}
```

### fclose

Close an open file.

```c
#include <stdio.h>

int fclose(FILE *stream);
```

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
</table>

### Remarks

The `fclose()` function closes a file created by `fopen()`, `freopen()`, or `tmpfile()`. The function flushes any buffered data to its file and closes the...
stream. After calling fclose(), stream is no longer valid and cannot be used with file functions unless it is reassigned using fopen(), freopen(), or tmpfile().

All of a program's open streams are flushed and closed when a program terminates normally. fclose() closes then deletes a file created by tmpfile().

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

close() returns a zero if it is successful and returns an EOF if it fails to close a file.

This function may not be implemented on all platforms.

“freopen” on page 333
“tmpfile” on page 382
“abort” on page 405
“exit” on page 420

Listing 35.2 Example of fclose() Usage

```c
#include <stdio.h>
#include <stdlib.h>
int main(void)
{
    FILE *f;
    static char name[] = "myfoo";

    // create a new file for output
    if ( (f = fopen(name, "w")) == NULL) {
        printf("Can't open %s.
", name);
        exit(1);
    }

    // output text to the file
    fprintf(f, "pizza sushi falafel\n");
    fprintf(f, "escargot sprocket\n");

    // close the file
    if (fclose(f) == -1) {
        printf("Can't close %s.
", name);
        exit(1);
    }
}
```
Output to file myfoo:
pizza sushi falafel
escargot sprocket

fdopen

Converts a file descriptor to a stream.

```
#include <stdio.h>

FILE *fdopen(int fildes, char *mode);
FILE *_fdopen(int fildes, char *mode);
```

Table 35.5  fdopen

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A file descriptor, which is integer file number that can be obtained from the function fileno().</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>mode</th>
<th>char *</th>
</tr>
</thead>
<tbody>
<tr>
<td>The file opening mode</td>
<td></td>
</tr>
</tbody>
</table>

Remarks

This function creates a stream for the file descriptor fildes. You can use the stream with such standard I/O functions as fprintf() and getchar(). In MSL C/C++, it ignores the value of the mode argument.

If it is successful, fdopen() returns a stream. If it encounters an error, fdopen() returns NULL.

This function may not be implemented on all platforms.

See Also

“fileno” on page 83
“open, _wopen” on page 121
Listing 35.3  Example of fdopen() Usage

```c
#include <stdio.h>
#include <unix.h>

int main(void)
{
    int fd;
    FILE *str;

    fd = open("mytest", O_WRONLY | O_CREAT);

    /* Write to the file descriptor */
    write(fd, "Hello world!\n", 13);
    /* Convert the file descriptor to a stream */
    str = fdopen(fd,"w");

    /* Write to the stream */
    fprintf(str, "My name is %s.\n", getlogin());

    /* Close the stream. */
    fclose(str);
    /* Close the file descriptor */
    close(fd);
    return 0;
}
```

feof

Check the end-of-file status of a stream.

```c
#include <stdio.h>
int feof(FILE *stream);
```

Table 35.6  feof

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
</tr>
</thead>
<tbody>
<tr>
<td>A pointer to a FILE stream</td>
<td></td>
</tr>
</tbody>
</table>

Remarks

The feof() function checks the end-of-file status of the last read operation on stream. The function does not reset the end-of-file status.
On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

feof() returns a nonzero value if the stream is at the end-of-file and returns zero if the stream is not at the end-of-file.

This function may not be implemented on all platforms.

See Also

“clearerr” on page 302
“ferror” on page 309

Listing 35.4 Example of feof() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    static char filename[80], buf[80] = "";

    // get a filename from the user
    printf("Enter a filename to read.\n");
    gets(filename);

    // open the file for input
    if (( f = fopen(filename, "r")) == NULL) {
        printf("Can't open %s.\n", filename);
        exit(1);
    }

    // read text lines from the file until
    // feof() indicates the end-of-file
    for (; feof(f) == 0 ; fgets(buf, 80, f) )
    { printf(buf);

    // close the file
    fclose(f);

    return 0;
}
```

Output:
Enter a filename to read.
itwerks
stdio.h

Standard input/output

The quick brown fox
jumped over the moon.

ferror

Check the error status of a stream.
#include <stdio.h>
int ferror(FILE *stream);

Table 35.7  ferror

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
</table>

Remarks

The ferror() function returns the error status of the last read or write operation on stream. The function does not reset its error status.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

ferror() returns a nonzero value if stream’s error status is on, and returns zero if stream’s error status is off.

This function may not be implemented on all platforms.

#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    char filename[80], buf[80];
    int ln = 0;

    // get a filename from the user
stdio.h
Standard input/output

printf("Enter a filename to read.\n");
gets(filename);

// open the file for input
if (( f = fopen(filename, "r")) == NULL) {
    printf("Can't open %s.\n", filename);
    exit(1);
}

// read the file one line at a time until end-of-file
do {
    fgets(buf, 80, f);
    printf("Status for line %d: %d.\n", ln++, ferror(f));
} while (feof(f) == 0);

// close the file
fclose(f);

return 0;

---

Output:
Enter a filename to read.
itwerks
Status for line 0: 0.
Status for line 1: 0.
Status for line 2: 0.

---

flush

Empty a stream's buffer to its host environment.

#include <stdio.h>

int fflush(FILE *stream);

Table 35.8 flush

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
</table>

Remarks

The fflush() function empties stream's buffer to the file associated with stream. If the stream points to an output stream or an update stream in which the
most recent operation was not input, the fflush function causes any unwritten data for that stream to be delivered to the host environment to be written to the file; otherwise the behavior is undefined.

The fflush() function should not be used after an input operation.

Using fflush() for input streams especially the standard input stream (stdin) is undefined and is not supported and will not flush the input buffer.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

The function fflush() returns EOF if a write error occurs, otherwise it returns zero.

This function may not be implemented on all platforms.

fgetc

Read the next character from a stream.

```c
#include <stdio.h>
int fgetc(FILE *stream);
```

Table 35.9 fgetc

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
</table>

Remarks

The `fgetc()` function reads the next character from `stream` and advances its file position indicator.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

`fgetc()` returns the character as an unsigned char converted to an `int`. If the end-of-file has been reached or a read error is detected, `fgetc()` returns `EOF`. The difference between a read error and end-of-file can be determined by the use of `feof()`.

If the file is opened in update mode (+) a file cannot be read from and then written to without repositioning the file using one of the file positioning functions (`fseek()`, `fsetpos()`, or `rewind()`) unless the last read or write reached the end-of-file.

This function may not be implemented on all platforms.

#### Listing 35.7 Example of fgetc() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    char filename[80], c;

    // get a filename from the user
    printf("Enter a filename to read.\n");
    gets(filename);

    // open the file for input
    if ((f = fopen(filename, "r")) == NULL) {
        printf("Can't open %s.\n", filename);
        exit(1);
    }

    // read the file one character at a time until
    // end-of-file is reached
    while ( (c = fgetc(f)) != EOF)
    {
        putchar(c); // print the character

        // close the file
        fclose(f);
    }

    return 0;
}
```

---

Output:

Enter a filename to read.

foofoo

fgetpos

Get a stream's current file position indicator value.

#include <stdio.h>

int fgetpos(FILE *stream, fpos_t *pos);

Table 35.10  fgetpos

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>pos</td>
<td>fpos_t*</td>
<td>A pointer to a file position type</td>
</tr>
</tbody>
</table>

Remarks

The fgetpos() function is used in conjunction with the fsetpos() function to allow random access to a file. The fgetpos() function gives unreliable results when used with streams associated with a console (stdin, stderr, stdout).

While the fseek() and ftell() functions use long integers to read and set the file position indicator, fgetpos() and fsetpos() use fpos_t values to operate on larger files. The fpos_t type, defined in stdio.h, can hold file position indicator values that do not fit in a long int.

The fgetpos() function stores the current value of the file position indicator for stream in the fpos_t variable pos points to.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

fgetpos() returns zero when successful and returns a nonzero value when it fails.

This function may not be implemented on all platforms.

    fgetpos(f, &pos);
  }

  // close the file
  fclose(f);

  return 0;
}
stdio.h
Standard input/output

Output:
Enter a filename to read.
myfoo
Reading each line twice.
Once: chair table chest
Twice: chair table chest
Once: desk raccoon
Twice: desk raccoon

fgets
Read a character array from a stream.
#include <stdio.h>
char *fgets(char *s, int n, FILE *stream);

Table 35.11 fgets

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>int</td>
<td>The maximum number of chars read</td>
</tr>
<tr>
<td>stream</td>
<td>FILE *</td>
<td>A pointer to a FILE stream</td>
</tr>
</tbody>
</table>

Remarks

The fgets() function reads characters sequentially from stream beginning at the current file position, and assembles them into s as a character array. The function stops reading characters when n-1 characters have been read. The fgets() function finishes reading prematurely if it reaches a newline (‘\n’) character or the end-of-file. For example usage, see Listing 35.16.

If the file is opened in update mode (+) a file cannot be read from and then written to without repositioning the file using one of the file positioning functions (fseek(), fsetpos(), or rewind()) unless the last read or write reached the end-of-file.

Unlike the gets() function, fgets() appends the newline character (‘\n’) to s. It also null terminates the characters written into the character array.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.
fgets() returns a pointer to s if it is successful. If it reaches the end-of-file before reading any characters, s is untouched and fgets() returns a null pointer (NULL). If an error occurs fgets() returns a null pointer and the contents of s may be corrupted.

This function may not be implemented on all platforms.

“Wide Character and Byte Character Stream Orientation” on page 301
“gets” on page 351

_fileno

This function is described in extras.h as “fileno” on page 83 in this header it is Windows only.

fopen

Open a file as a stream.

#include <stdio.h>

FILE *fopen(const char *filename, const char *mode);

Table 35.12 fopen

<table>
<thead>
<tr>
<th>filename</th>
<th>const char *</th>
<th>The filename of the file to open</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>const char *</td>
<td>The file opening mode</td>
</tr>
</tbody>
</table>

Remarks

The fopen() function opens a file specified by filename, and associates a stream with it. The fopen() function returns a pointer to a FILE. This pointer is used to refer to the file when performing I/O operations.

The mode argument specifies how the file is to be used. Table 35.13 shows the values for mode.
UPDATE MODE

A file opened with an update mode ("+") is buffered. The file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream's buffer. This can be done with the fflush() function or one of the file positioning operations (fseek(), fsetpos(), or rewind()). Similarly, a file cannot be read from and then written to without repositioning the file using one of the file positioning functions unless the last read or write reached the end-of-file.

All file modes, except the append modes ("a", "a+", "ab", "ab+") set the file position indicator to the beginning of the file. The append modes set the file position indicator to the end-of-file.

NOTE  Write modes, even if in Write and Read (w+, wb+) delete any current data in a file when the file is opened.

Table 35.13  Open Modes for fopen()

fprintf

Send formatted text to a stream.
#include <stdio.h>
int fprintf(FILE *stream,
        const char *format, ...);
Remarks

The `fprintf()` function writes formatted text to `stream` and advances the file position indicator. Its operation is the same as `printf()` with the addition of the `stream` argument. Refer to the description of `printf()`.

If the file is opened in update mode (+) the file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream's buffer. This can be done with the `fflush()` function or one of the file positioning operations (`fseek()`, `fsetpos()`, or `rewind()`).

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

**Output Control String and Conversion Specifiers**

The `format` character array contains normal text and conversion specifications. Conversion specifications must have matching arguments in the same order in which they occur in `format`.

The various elements of the format string is specified in the ANSI standards to be in this order from left to right:

- A percent sign
- Optional flags `-`, `+`, `0`, `#` or space
- Optional minimum field width specification
- Optional precision specification
- Optional size specification
- Conversion specifier `c,d,e,E,f,F,g,G,i,n,o,p,s,u,x,X` or `%`

A conversion specification describes the format its associated argument is to be converted to. A specification starts with a percent sign (%), optional flag characters, an optional minimum width, an optional precision width, and the necessary, terminating conversion type. Doubling the percent sign (%%) results in the output of a single %.

An optional flag character modifies the formatting of the output; it can be left or right justified, and numerical values can be padded with zeroes or output in alternate forms. More than one optional flag character can be used in a conversion specification. Table 35.16 describes the flag characters.
The optional minimum width is a decimal digit string. If the converted value has more characters that the minimum width, it is expanded as required. If the converted value has fewer characters than the minimum width, it is, by default, right justified (padded on the left). If the - flag character is used, the converted value is left justified (padded on the right).

The maximum minimum field width allowed in MSL Standard Libraries is 509 characters.

The optional precision width is a period character (.) followed by decimal digit string. For floating point values, the precision width specifies the number of digits to print after the decimal point. For integer values, the precision width functions identically to, and cancels, the minimum width specification. When used with a character array, the precision width indicates the maximum width of the output.

A minimum width and a precision width can also be specified with an asterisk (*) instead of a decimal digit string. An asterisk indicates that there is a matching argument, preceding the conversion argument, specifying the minimum width or precision width.

The terminating character, the conversion type, specifies the conversion applied to the conversion specification's matching argument. Table 35.17 describes the conversion type characters.

Table 35.15 and Table 35.18 also include other modifiers for formatted output functions.

**MSL AltiVec Extensions for Fprintf**

The AltiVec extensions to the standard printf family of functions is supported in Main Standard Libraries.

Separator arguments after % and before any specifier may be any character or may be the @ symbol. The @ symbol is a non-Motorola extension that will use a specified string as a specifier.

In the specific case of a 'c' specifier any char may be used as a separator. For all other specifiers '*' , '+' , '#', ',' may not be used.

Listing 35.23 demonstrates their use.

Table 35.16  Flag Specifiers For formatted Output Functions

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>The conversion will be left justified.</td>
</tr>
<tr>
<td>+</td>
<td>The conversion, if numeric, will be prefixed with a sign (+ or -). By default, only negative numeric values are prefixed with a minus sign (-).</td>
</tr>
<tr>
<td>space</td>
<td>If the first character of the conversion is not a sign character, it is prefixed with a space. Because the plus sign flag character (+) always prefixes a numeric value with a sign, the space flag has no effect when combined with the plus flag.</td>
</tr>
<tr>
<td>#</td>
<td>For c, d, i, and u conversion types, the # flag has no effect. For s conversion types, a pointer to a Pascal string, is output as a character string. For o conversion types, the # flag prefixes the conversion with a 0. For x conversion types with this flag, the conversion is prefixed with a 0x. For e, E, f, g, and G conversions, the # flag forces a decimal point in the output. For g and G conversions with this flag, trailing zeroes after the decimal point are not removed.</td>
</tr>
<tr>
<td>0</td>
<td>This flag pads zeroes on the left of the conversion. It applies to d, i, o, u, x, X, e, E, f, g, and G conversion types. The leading zeroes follow sign and base indication characters, replacing what would normally be space characters. The minus sign flag character overrides the 0 flag character. The 0 flag is ignored when used with a precision width for d, i, o, u, x, and X conversion types.</td>
</tr>
<tr>
<td>@</td>
<td><strong>AltIVec</strong>: This flag indicates a pointer to a string specified by an argument. This string will be used as a separator for vector elements.</td>
</tr>
</tbody>
</table>

</tr>
</thead>
<tbody>
<tr>
<td>d</td>
<td>The corresponding argument is converted to a signed decimal.</td>
</tr>
<tr>
<td>i</td>
<td>The corresponding argument is converted to a signed decimal.</td>
</tr>
<tr>
<td>o</td>
<td>The argument is converted to an unsigned octal.</td>
</tr>
<tr>
<td>u</td>
<td>The argument is converted to an unsigned decimal.</td>
</tr>
<tr>
<td>x, X</td>
<td>The argument is converted to an unsigned hexadecimal. The x conversion type uses lowercase letters (abcdef) while X uses uppercase letters (ABCDEF).</td>
</tr>
<tr>
<td>n</td>
<td>This conversion type stores the number of items output by printf() so far. Its corresponding argument must be a pointer to an int.</td>
</tr>
<tr>
<td>f, F</td>
<td>The corresponding floating point argument (float, or double) is printed in decimal notation. The default precision is 6 (6 digits after the decimal point). If the precision width is explicitly 0, the decimal point is not printed. For the f conversion specifier, a double argument representing infinity produces [-]inf; a double argument representing a NaN (Not a number) produces [-]nan. For the F conversion specifier, [-]INF or [-]NAN are produced instead.</td>
</tr>
</tbody>
</table>
### Table 35.17 Conversion Specifiers for Formatted Output Functions (continued)

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>e, E</td>
<td>The floating point argument (float or double) is output in scientific notation: ([-\ ]b.aaaetEee). There is one digit (b) before the decimal point. Unless indicated by an optional precision width, the default is 6 digits after the decimal point (aaa). If the precision width is 0, no decimal point is output. The exponent (ee) is at least 2 digits long. The e conversion type uses lowercase e as the exponent prefix. The E conversion type uses uppercase E as the exponent prefix.</td>
</tr>
<tr>
<td>g, G</td>
<td>The g conversion type uses the f or e conversion types and the G conversion type uses the f or E conversion types. Conversion type e (or E) is used only if the converted exponent is less than -4 or greater than the precision width. The precision width indicates the number of significant digits. No decimal point is output if there are no digits following it.</td>
</tr>
<tr>
<td>c</td>
<td>The corresponding argument is output as a character.</td>
</tr>
<tr>
<td>s</td>
<td>The corresponding argument, a pointer to a character array, is output as a character string. Character string output is completed when a null character is reached. The null character is not output.</td>
</tr>
<tr>
<td>p</td>
<td>The corresponding argument is taken to be a pointer. The argument is output using the X conversion type format.</td>
</tr>
</tbody>
</table>
fwrite() returns the number of arguments written or a negative number if an error occurs. This function may not be implemented on all platforms.

### Listing 35.10 Example of fprintf() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    static char filename[] = "myfoo";
    int a = 56;
    char c = 'M';
    double x = 483.582;

    // create a new file for output
    if ((f = fopen(filename, "w")) == NULL) {
        printf("Can't open %s.\n", filename);
        exit(1);
    }

    // ... (more code)

    fclose(f);
    return 0;
}
```
stdio.h
Standard input/output

)

// output formatted text to the file
fprintf(f, "%10s %4.4f %-10d\n%10c", filename, x, a, c);

// close the file
fclose(f);

return 0;
}

Output to file foo:
myfoo 483.5820 56  M

fputc
Write a character to a stream.
#include <stdio.h>
int fputc(int c, FILE *stream);

Table 35.19  fputc

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>The character to write to a file</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>FILE *</td>
<td>A pointer to a FILE stream</td>
</tr>
</tbody>
</table>

Remarks

The fputc() function writes the character c to stream and advances stream's file position indicator. Although the c argument is an unsigned int, it is converted to a char before being written to stream. fputc() is written as a function, not as a macro.

If the file is opened in update mode (+) the file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream's buffer. This can be done with the fflush() function or one of the file positioning operations (fseek(), fsetpos(), or rewind()).

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.
fputc() returns the character written if it is successful, and returns EOF if it fails.

This function may not be implemented on all platforms.

See Also

“Wide Character and Byte Character Stream Orientation” on page 301
“putc” on page 362
“putchar” on page 363

Listing 35.11  Example of fputc() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    int letter;

    // create a new file for output
    if (( f = fopen("foofoo", "w")) == NULL) {
        printf("Can't create file.\n");
        exit(1);
    }

    // output the alphabet to the file one letter
    // at a time
    for (letter = 'A'; letter <= 'Z'; letter++)
        fputc(letter, f);
    fclose(f);

    return 0;
}
```

Output to file foofoo:

ABCDEFGHIJKLMNOPQRSTUVWXYZ
stdio.h
Standard input/output

fputs

Write a character array to a stream.

#include <stdio.h>
int fputs(const char *s, FILE *stream);

Table 35.20  fputs

<table>
<thead>
<tr>
<th>s</th>
<th>const char *</th>
<th>The string to write to a file</th>
</tr>
</thead>
<tbody>
<tr>
<td>stream</td>
<td>FILE *</td>
<td>A pointer to a FILE stream</td>
</tr>
</tbody>
</table>

Remarks

The fputs() function writes the array pointed to by s to stream and advances the file position indicator. The function writes all characters in s up to, but not including, the terminating null character. Unlike puts(), fputs() does not terminate the output of s with a newline (‘\n’).

If the file is opened in update mode (+) the file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream’s buffer. This can be done with the fflush() function or one of the file positioning operations (fseek(), fsetpos(), or rewind()).

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

fputs() returns a zero if successful, and returns a nonzero value when it fails.

This function may not be implemented on all platforms.

See Also

“Wide Character and Byte Character Stream Orientation” on page 301
“puts” on page 365

Listing 35.12  Example of fputs() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
```
// create a new file for output
if ((f = fopen("foofoo", "w")) == NULL) {
    printf("Can't create file.\n");
    exit(1);
}

// output character strings to the file
fputs("undo\n", f);
fputs("copy\n", f);
fputs("cut\n", f);
fputs("rickshaw\n", f);

// close the file
fclose(f);

return 0;

Output to file foofoo:
undo
copy
cut
rickshaw

fread
Read binary data from a stream.
#include <stdio.h>
size_t fread(void *ptr, size_t size,
    size_t nmemb, FILE *stream);

Table 35.21 fread

<table>
<thead>
<tr>
<th>ptr</th>
<th>void *</th>
<th>A pointer to the read destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>size_t</td>
<td>The size of the array elements pointed to</td>
</tr>
</tbody>
</table>
The `fread()` function reads a block of binary or text data and updates the file position indicator. The data read from stream are stored in the array pointed to by ptr. The size and nmemb arguments describe the size of each item and the number of items to read, respectively.

The `fread()` function reads nmemb items unless it reaches the end-of-file or a read error occurs.

If the file is opened in update mode (+) a file cannot be read from and then written to without repositioning the file using one of the file positioning functions (fseek(), fsetpos(), or rewind()) unless the last read or write reached the end-of-file.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

`fread()` returns the number of items read successfully.

This function may not be implemented on all platforms.

{
    FILE *f;
    static char s[BUFSIZE] = "The quick brown fox";
    char target[BUFSIZE];
```
// create a new file for output and input
if ((f = fopen("foo", "w+")) == NULL) {
    printf("Can't create file.\n");
    exit(1);
}

// output to the stream using fwrite()
fwrite(s, sizeof(char), BUFSIZE, f);

// move to the beginning of the file
rewind(f);

// now read from the stream using fread()
fread(target, sizeof(char), BUFSIZE, f);

// output the results to the console
puts(s);
puts(target);

// close the file
fclose(f);
return 0;

Output:
The quick brown fox
The quick brown fox

freopen

Re-direct a stream to another file.

#include <stdio.h>
FILE *freopen(const char *filename,
              const char *mode, FILE *stream);
stdio.h
Standard input/output

Table 35.22  freopen

<table>
<thead>
<tr>
<th>filename</th>
<th>const char *</th>
<th>The name of the file to re-open</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>const char *</td>
<td>The file opening mode</td>
</tr>
<tr>
<td>stream</td>
<td>FILE *</td>
<td>A pointer to a FILE stream</td>
</tr>
</tbody>
</table>

Remarks
The freopen() function changes the file that stream is associated with to another file. The function first closes the file the stream is associated with, and opens the new file, filename, with the specified mode, using the same stream.

fopen() returns the value of stream, if it is successful. If fopen() fails it returns a null pointer (NULL).

This function may not be implemented on all platforms.

“fopen” on page 317

Listing 35.14  Example of freopen() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;

    // re-direct output from the console to a new file
    if (( f = freopen("newstdout", "w+", stdout)) == NULL) {
        printf("Can't create new stdout file.\n");
        exit(1);
    }

    printf("If all goes well, this text should be in\n");
    printf("a text file, not on the screen via stdout.\n");
    fclose(f);

    return 0;
}
```
fscanf

Read formatted text from a stream.

#include <stdio.h>
int fscanf(FILE *stream, const char *format, ...);

Table 35.23 fscanf

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>const char *</td>
<td>A format string</td>
</tr>
</tbody>
</table>

Remarks

The fscanf() function reads programmer-defined, formatted text from stream. The function operates identically to the scanf() function with the addition of the stream argument indicating the stream to read from. Refer to the scanf() function description.

If the file is opened in update mode (+) a file cannot be read from and then written to without repositioning the file using one of the file positioning functions (fseek(), fsetpos(), or rewind()) unless the last read or write reached the end-of-file.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

Input Control String and Conversion Specifiers

The format argument is a character array containing normal text, white space (space, tab, newline), and conversion specifications. The normal text specifies literal characters that must be matched in the input stream. A white space character indicates that white space characters are skipped until a non-white space character is reached. The conversion specifications indicate what characters in the input stream are to be converted and stored.

The conversion specifications must have matching arguments in the order they appear in format. Because scanf() stores data in memory, the arguments matching the conversion specification arguments must be pointers to objects of the relevant types.

A conversion specification consists of the percent sign (%) prefix, followed by an optional maximum width or assignment suppression, and ending with a conversion type. A percent sign can be skipped by doubling it in format; %% signifies a single % in the input stream.
stdio.h
Standard input/output

An optional width is a decimal number specifying the maximum width of an input field. scanf() will not read more characters for a conversion than is specified by the width.

An optional assignment suppression character (*) can be used to skip an item by reading it but not assigning it. A conversion specification with assignment suppression must not have a corresponding argument.

The last character, the conversion type, specifies the kind of conversion requested. Table 35.24 and Table 35.24 describe the length specifier and conversion type characters.

**MSL AltivVec Extensions for Scanf**

The AltivVec extensions to the standard scanf family of functions is supported in Main Standard Libraries.

Separator arguments after % and before any specifier may be any character or may be the @ symbol. The @ symbol is a non-Motorola extension that will use a specified string as a specifier.

In the specific case of a 'c' specifier any char may be used as a separator. For all other specifiers '-', '+', '#', ' ' may not be used.

Listing 35.31 demonstrates their use.

**Table 35.24 Length Specifiers for Formatted Input**

The conversion specifier %[ allows you to specify a scanset, which is a sequence of characters that will be read and stored in the string pointed to by the scanset’s corresponding argument. The characters between the [ and the terminating ] define the scanset. A null character is appended to the end of the character sequence.

Input stream characters are read until a character is found that is not in the scanset. If the first character of scanset is a circumflex (^) then input stream characters are read until a character from the scanset is read. A null character is appended to the end of the character array.

Thus, the conversion specifier %[abcdef] specifies that the scanset is abcdef and any of the characters ‘a’ through ‘f’ are to be accepted and stored. As soon as

</tr>
<tr>
<td>[scanset]</td>
<td>Input stream characters are read and filtered determined by the scanset. See &quot;Scanset&quot; for a full description.</td>
</tr>
</tbody>
</table>

**Scanset**

The conversion specifier %[ allows you to specify a scanset, which is a sequence of characters that will be read and stored in the string pointed to by the scanset’s corresponding argument. The characters between the [ and the terminating ] define the scanset. A null character is appended to the end of the character sequence.

Input stream characters are read until a character is found that is not in the scanset. If the first character of scanset is a circumflex (^) then input stream characters are read until a character from the scanset is read. A null character is appended to the end of the character array.

Thus, the conversion specifier %[abcdef] specifies that the scanset is abcdef and any of the characters ‘a’ through ‘f’ are to be accepted and stored. As soon as
any character outside this set is encountered, reading and storing will cease. Thus, for example, assuming we have the declaration:

```c
char str[20];
```

the execution of

```c
sscanf("acdfxbe", "^[abcdef]*", str);
```

will store `acdf` in `str`; the ‘`x’` and following characters will not be stored because the ‘`x’` is not in the scanset.

If the first character of the scanset is the circumflex, `^`, then the following characters will define a set of characters such that encountering any one of them will cause reading and storing to stop; any character outside a scanset defined in this way will be accepted, we will call this an exclusionary scanset. Thus execution of

```c
sscanf("stuvawxyz", "^[^abcdef]", str);
```

will store `stuv` in `str`. If you want `^` to be part of the scanset, you cannot list it as the first character otherwise it will be interpreted as introducing the members of an exclusionary scanset. Thus `%[^abc]` defines the exclusionary scanset `abc` whereas `%[a^bc]` defines the scanset `abc^`. `%[^abc]` defines the exclusionary scanset `abc^`, as does `%[^abc]`.

If you want `)` to be in the scanset, it must be the first character of the scanset, immediately following the `%` or, to be in an exclusionary scanset, immediately after the `^`, for example, `%[]abc` or `%[^abc]`. In any other position, the `)` will be interpreted as terminating the scanset.

To include the `-` character in the scanset, it must be either listed first (possibly after an initial `^` or last, thus for example, `%[-abc]`, `%[abc-]`, `%[^-abc]`, or `%[^abc-]`). The C Standard explicitly states:

- If a `-` character is in the scanlist and is not the first, nor the second where the first character is a `^`, nor the last character, the behavior is implementation defined.

MSL interprets such a use of `-` in a scanlist as defining a range of characters; thus, the specification `%[a-z]` as being the equivalent of `%[abcdefgijklmnopqrstuvwxyz]`. You should bear in mind that this is MSL’s interpretation and such usage may be interpreted differently in other C library implementations. Note also that it is assumed that the numeric value of the character before the `-` is less than that of the one after. If this relationship does not hold undefined and probably unwanted effects may be experienced.

`fscanf()` returns the number of items read or, if an input error occurs before any conversions, the value `EOF`. If there is an error in reading data that is inconsistent with the format string, `fscanf()` sets `errno` to a nonzero value. `fscanf()` returns `EOF` if it reaches the end-of-file.

This function may not be implemented on all platforms.

“scanf” on page 370

Listing 35.15 Example of fscanf() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    int i;
    double x;
    char c;

    // create a new file for output and input
    if (( f = fopen("foobar", "w+")) == NULL) {
        printf("Can't create new file.
        exit(1);
    }

    // output formatted text to the file
    fprintf(f, "%d\n%f\n%c\n", 45, 983.3923, 'M');

    // go to the beginning of the file
    rewind(f);

    // read from the stream using fscanf()
    fscanf(f, "%d %lf %c", &i, &x, &c);

    // close the file
    fclose(f);

    printf("The integer read is %d.\n", i);
    printf("The floating point value is %f.\n", x);
    printf("The character is %c.\n", c);

    return 0;
}
```

Output:
The integer read is 45.
The floating point value is 983.392300. The character is M.

**fseek**

Move the file position indicator.

```
#include <stdio.h>
int fseek(FILE *stream, long offset, int whence);
```

**Table 35.26 fseek**

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>offset</td>
<td>long</td>
<td>The offset to move in bytes</td>
</tr>
<tr>
<td>whence</td>
<td>int</td>
<td>The starting position of the offset</td>
</tr>
</tbody>
</table>

**Remarks**

The `fseek()` function moves the file position indicator to allow random access to a file. For example usage, see Listing 35.16.

The function moves the file position indicator either absolutely or relatively. The `whence` argument can be one of three values defined in `stdio.h`: SEEK_SET, SEEK_CUR, SEEK_END.

The SEEK_SET value causes the file position indicator to be set `offset` bytes from the beginning of the file. In this case `offset` must be equal or greater than zero.

The SEEK_CUR value causes the file position indicator to be set `offset` bytes from its current position. The `offset` argument can be a negative or positive value.

The SEEK_END value causes the file position indicator to be set `offset` bytes from the end of the file. The `offset` argument must be equal or less than zero.

The `fseek()` function undoes the last `ungetc()` call and clears the end-of-file status of `stream`.

**NOTE** The function `fseek` has limited use when used with MS DOS text files opened in text mode because of the carriage return/line feed translations. For more information review "Text Streams and Binary Streams" on page 300. The `fseek` operations may be incorrect near the end of the file due to eol translations.
The only `fseek` operations guaranteed to work in MS DOS text files opened in text mode are:

- Using the offset returned from `ftell()` and seeking from the beginning of the file.
- Seeking with an offset of zero from `SEEK_SET`, `SEEK_CUR` and `SEEK_END`.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

`fseek()` returns zero if it is successful and returns a nonzero value if it fails.

This function may not be implemented on all platforms.

- “ftell” on page 344

**Listing 35.16 Example of fseek() Usage**

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    long int pos1, pos2, newpos;
    char filename[80], buf[80];

    // get a filename from the user
    printf("Enter a filename to read.
");
    gets(filename);

    // open a file for input
    if ((f = fopen(filename, "r")) == NULL) {
        printf("Can't open %s.
", filename);
        exit(1);
    }

    printf("Reading last half of first line.
");

    // get the file position indicator before and after
    // reading the first line
    pos1 = ftell(f);
    fgets(buf, 80, f);
    pos2 = ftell(f);
    printf("Whole line: %s\n", buf);
}
```
// calculate the middle of the line
newpos = (pos2 - pos1) / 2;

fseek(f, newpos, SEEK_SET);
fgets(buf, 80, f);
printf("Last half: %s\n", buf);

// close the file
fclose(f);

return 0;
}

Output:
Enter a filename to read.
itwerks
Reading last half of first line.
Whole line: The quick brown fox

Last half: brown fox

fsetpos

Set the file position indicator.

#include <stdio.h>

int fsetpos(FILE *stream, const fpos_t *pos);

Table 35.27  fsetpos

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
</tr>
</thead>
<tbody>
<tr>
<td>pos</td>
<td>fpos_t</td>
</tr>
</tbody>
</table>

A pointer to a FILE stream

A pointer to a file positioning type

Remarks

The fsetpos() function sets the file position indicator for stream using the value pointed to by pos. The function is used in conjunction with fgetpos() when dealing with files having sizes greater than what can be represented by the long int argument used by fseek().
fsetpos() undoes the previous call to ungetc() and clears the end-of-file status.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

fsetpos() returns zero if it is successful and returns a nonzero value if it fails. This function may not be implemented on all platforms.

See Also
“fgetpos” on page 314
“fseek” on page 341
“ftell” on page 344

For example usage of “fgetpos”, see Listing 35.8.

ftell

Return the current file position indicator value.

#include <stdio.h>

long int ftell(FILE *stream);

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
</table>

Remarks

The ftell() function returns the current value of stream's file position indicator. It is used in conjunction with fseek() to provide random access to a file.

The function will not work correctly when it is given a stream associated to a console file, such as stdin, stdout, or stderr, where a file indicator position is not applicable. Also, ftell() cannot handle files with sizes larger than what can be represented with a long int. In such a case, use the fgetpos() and fsetpos() functions.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

ftell(), when successful, returns the current file position indicator value. If it fails, ftell() returns -1L and sets the global variable errno to a nonzero value.
This function may not be implemented on all platforms.

See Also

“errno” on page 75, “fgetpos” on page 314

### fwide

Determine the orientation of a stream.

```c
#include <stdio.h>
int fwide(FILE *stream, int orientation);
```

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to the stream being tested</th>
</tr>
</thead>
<tbody>
<tr>
<td>orientation</td>
<td>int</td>
<td>The desired orientation</td>
</tr>
</tbody>
</table>

Remarks

The `fwide` function determines the orientation of the stream pointed to by `stream`. If the value of orientation is greater than zero and `stream` is without orientation, `stream` is made to be wide oriented. If the value of orientation is less than zero and `stream` is without orientation, `stream` is made to be byte oriented. Otherwise, the value of orientation is zero and the function does not alter the orientation of the stream. In all cases, if `stream` already has an orientation, it will not be changed.

The `fwide` function returns a value greater than zero if, after the call, the `stream` has wide orientation, a value less than zero if the `stream` has byte orientation, or zero if the `stream` has no orientation.

This function may not be implemented on all platforms.

Listing 35.17  Example of `fwide()` Usage

```c
#include <stdio.h>

int main()
{
    FILE * fp;
    char filename[FILENAME_MAX];
    int orientation;
    char * cptr;
```
cptr = tmpnam(filename);
fp = fopen(filename, "w");
orientation = fwide(fp, 0);

// A newly opened file has no orientation
printf("Initial orientation = %i\n", orientation);
fprintf(fp, "abcdefghijklmnopqrstuvwxyz\n");

// A byte oriented output operation will set the orientation
// to byte oriented
orientation = fwide(fp, 0);

printf("Orientation after fprintf = %i\n", orientation);
fclose(fp);
fp = fopen(filename, "r");
orientation = fwide(fp, 0);
printf("Orientation after reopening = %i\n", orientation);
orientation = fwide(fp, -1);

// fwide with a non-zero orientation argument will set an
// unoriented file's orientation
printf("Orientation after fwide = %i\n", orientation);
orientation = fwide(fp, 1);

// but will not change the file's orientation if it
// already has an orientation
printf("Orientation after second fwide = %i\n",orientation);
fclose(fp);
remove(filename);

return 0;
}

Output:
Initial orientation = 0
Orientation after fprintf = -1
Orientation after reopening = 0
Orientation after fwide = -1
Orientation after second fwide = -1
fwrite

Write binary data to a stream.

#include <stdio.h>

size_t fwrite(const void *ptr, size_t size,
              size_t nmemb, FILE *stream);

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ptr</td>
<td>void *</td>
</tr>
<tr>
<td>size</td>
<td>size_t</td>
</tr>
<tr>
<td>nmemb</td>
<td>size_t</td>
</tr>
<tr>
<td>stream</td>
<td>FILE *</td>
</tr>
</tbody>
</table>

Remarks

The fwrite() function writes nmemb items of size bytes each to stream. The items are contained in the array pointed to by ptr. After writing the array to stream, fwrite() advances the file position indicator accordingly.

If the file is opened in update mode (+) the file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream's buffer. This can be done with the fflush() function or one of the file positioning operations (fseek(), fsetpos(), or rewind()).

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

fwrite() returns the number of items successfully written to stream.

This function may not be implemented on all platforms.

See Also

“Wide Character and Byte Character Stream Orientation” on page 301
"fread" on page 331

For example of fread() usage, see Listing 35.13.
getc

Read the next character from a stream.

```c
#include <stdio.h>
int getc(FILE *stream);
```

### Table 35.31 getc

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
</table>

### Remarks

The `getc()` function reads the next character from `stream`, advances the file position indicator, and returns the character as an `int` value. Unlike the `fgetc()` function, `getc()` is implemented as a macro.

If the file is opened in update mode (+) it cannot be read from and then written to without being repositioned using one of the file positioning functions (`fseek()`, `fsetpos()`, or `rewind()`) unless the last read or write reached the end-of-file.

`getc()` returns the next character from the stream or returns `EOF` if the end-of-file has been reached or a read error has occurred.

This function may not be implemented on all platforms.

- “Wide Character and Byte Character Stream Orientation” on page 301
- “fgetc” on page 312
- “fputc” on page 328
- “getchar” on page 349
- “putchar” on page 363

### Listing 35.18 Example of getc() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    char filename[80], c;
```
// get a filename from the user
printf("Enter a filename to read.\n");
scanf("%s", filename);

// open a file for input
if (( f = fopen(filename, "r")) == NULL) {
    printf("Can't open %s.\n", filename);
    exit(1);
}

// read one character at a time until end-of-file
while ( (c = getc(f)) != EOF)
    putchar(c);

// close the file
fclose(f);
return 0;
}

Output
Enter a filename to read.
foofoo
0 1 2 3 4 5 6 7 8 9
10 11 12 13 14 15 16 17 18 19

80 81 82 83 84 85 86 87 88 89
90 91 92 93 94 95 96 97 98 99

getchar

Get the next character from stdin.
#include <stdio.h>
int getchar(void);
Remarks

The `getchar()` function reads a character from the stdin stream.

The function `getchar()` is implemented as `getc(stdin)` and as such `getchar`'s return may be delayed or optimized out of program order if stdin is buffered. For most implementations, stdin is line buffered.

`getchar()` returns the value of the next character from stdin as an int if it is successful. `getchar()` returns EOF if it reaches an end-of-file or an error occurs.

This function may not be implemented on all platforms.

See also:

- “Wide Character and Byte Character Stream Orientation” on page 301
- “fgets” on page 312
- “getc” on page 348
- “putchar” on page 363

Listing 35.19 Example of getchar() Usage

```c
#include <stdio.h>

int main(void)
{
    int c;

    printf("Enter characters to echo, * to quit.\n");

    // characters entered from the console are echoed
    // to it until a * character is read
    while ( (c = getchar()) != '*' )
        putchar(c);

    printf("\nDone!\n");

    return 0;
}
```

Output:

Enter characters to echo, * to quit.
I’m experiencing deja-vu *
I’m experiencing deja-vu
Done!
gets

Read a character array from stdin.

```c
#include <stdio.h>
char *gets(char *s);
```

### Remarks

The `gets()` function reads characters from stdin and stores them sequentially in the character array pointed to by `s`. Characters are read until either a newline or an end-of-file is reached.

Unlike `fgets()`, the programmer cannot specify a limit on the number of characters to read. Also, `gets()` reads and ignores the newline character (`\n`) so that it can advance the file position indicator to the next line. The newline character is not stored in `s`. Like `fgets()`, `gets()` terminates the character string with a null character.

If an end-of-file is reached before any characters are read, `gets()` returns a null pointer (NULL) without affecting the character array at `s`. If a read error occurs, the contents of `s` may be corrupted.

`gets()` returns `s` if it is successful and returns a null pointer if it fails.

This function may not be implemented on all platforms.

- “fgets” on page 316

### Listing 35.20  Example of `gets()` Usage

```c
#include <stdio.h>
#include <string.h>

int main(void)
{
    char buf[100];
    
    return 0;
}
```
stdio.h

Standard input/output

```c
#include "stdio.h"

void perror(const char *s);

Remarks
  If s is not NULL or a pointer to a null string the perror() function outputs to
  stderr the character array pointed to by s followed by a colon and a space
  ’: ’. Then, the error message that would be returned by strerror() for
  the current value of the global variable errno.
  This function may not be implemented on all platforms.
```

“abort” on page 405

“errno” on page 75

Listing 35.21  Example of perror() Usage

```c
#include <errno.h>
#include <stdio.h>

int main()
{
    perror("No error reported as");
    errno = EDOM;
    perror("Domain error reported as");
    errno = ERANGE;
    perror("Range error reported as");

    return 0;
}
```

Output

No error reported as: No Error
Domain error reported as: Domain Error
Range error reported as: Range Error

printf

Output formatted text.

```c
#include <stdio.h>

int printf(const char *format, ...);
```

Table 35.34 printf

<table>
<thead>
<tr>
<th>format</th>
<th>const char *</th>
<th>A format string</th>
</tr>
</thead>
</table>

Remarks

The printf() function outputs formatted text. The function takes one or more arguments, the first being format, a character array pointer. The optional arguments following format are items (integers, characters, floating point values,
etc.) that are to be converted to character strings and inserted into the output of `format` at specified points.

The `printf()` function sends its output to `stdout`.

Printf Control String and Conversion Specifiers

The `format` character array contains normal text and conversion specifications. Conversion specifications must have matching arguments in the same order in which they occur in `format`.

The various elements of the format string is specified in the ANSI standards to be in this order from left to right.

- A percent sign
- Optional flags -,+,0,# or space
- Optional minimum field width specification
- Optional precision specification
- Optional size specification
- Conversion specifier `c,d,e,E,f,F,g,G,i,n,o,p,u,x,X` or `%`

A conversion specification describes the format its associated argument is to be converted to. A specification starts with a percent sign (`%`), optional flag characters, an optional minimum width, an optional precision width, and the necessary, terminating conversion type. Doubling the percent sign (`%%`) results in the output of a single `%`.

An optional flag character modifies the formatting of the output; it can be left or right justified, and numerical values can be padded with zeroes or output in alternate forms. More than one optional flag character can be used in a conversion specification. Table 35.36 describes the flag characters.

The optional minimum width is a decimal digit string. If the converted value has more characters that the minimum width, it is expanded as required. If the converted value has fewer characters than the minimum width, it is, by default, right justified (padded on the left). If the `-` flag character is used, the converted value is left justified (padded on the right).

The maximum minimum field width allowed in MSL Standard Libraries is 509 characters.

The optional precision width is a period character (`.`) followed by decimal digit string. For floating point values, the precision width specifies the number of digits to print after the decimal point. For integer values, the precision width functions identically to, and cancels, the minimum width specification. When used with a character array, the precision width indicates the maximum width of the output.
A minimum width and a precision width can also be specified with an asterisk (*) instead of a decimal digit string. An asterisk indicates that there is a matching argument, preceding the conversion argument, specifying the minimum width or precision width.

The terminating character, the conversion type, specifies the conversion applied to the conversion specification's matching argument. Table 35.37 describes the conversion type characters.

Table 35.35 and Table 35.38 also include other modifiers for formatted output functions.

### MSL AltiVec Extensions for Printf

The AltiVec extensions to the standard printf family of functions is supported in Main Standard Libraries.

Separator arguments after % and before any specifier may be any character or may be the @ symbol. The @ symbol is a non-Motorola extension that will use a specified string as a specifier.

In the specific case of a 'c' specifier any char may be used as a separator. For all other specifiers '-', '+', '#', ' ' may not be used.

Listing 35.23 demonstrates their use.

Table 35.36  Flag Specifiers For formatted Output Functions

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>The conversion will be left justified.</td>
</tr>
<tr>
<td>+</td>
<td>The conversion, if numeric, will be prefixed with a sign (+ or -). By default, only negative numeric values are prefixed with a minus sign (-).</td>
</tr>
<tr>
<td>space</td>
<td>If the first character of the conversion is not a sign character, it is prefixed with a space. Because the plus sign flag character (+) always prefixes a numeric value with a sign, the space flag has no effect when combined with the plus flag.</td>
</tr>
</tbody>
</table>
# For c, d, i, and u conversion types, the # flag has no effect. For s conversion types, a pointer to a Pascal string, is output as a character string. For o conversion types, the # flag prefixes the conversion with a 0. For x conversion types with this flag, the conversion is prefixed with a 0x. For e, E, f, g, and G conversions, the # flag forces a decimal point in the output. For g and G conversions with this flag, trailing zeroes after the decimal point are not removed.

0 This flag pads zeroes on the left of the conversion. It applies to d, i, o, u, x, X, e, E, f, g, and G conversion types. The leading zeroes follow sign and base indication characters, replacing what would normally be space characters. The minus sign flag character overrides the 0 flag character. The 0 flag is ignored when used with a precision width for d, i, o, u, x, and X conversion types.

@ AltiVec: This flag indicates a pointer to a string specified by an argument. This string will be used as a separator for vector elements.

### Table 35.37 Conversion Specifiers for Formatted Output Functions

<tr>
<td>o</td>
<td>The argument is converted to an unsigned octal.</td>
</tr>
<tr>
<td>u</td>
<td>The argument is converted to an unsigned decimal.</td>
</tr>
</tbody>
</table>
Table 35.37 Conversion Specifiers for Formatted Output Functions (continued)

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x, X</td>
<td>The argument is converted to an unsigned hexadecimal. The x conversion type uses lowercase letters (abcdef) while X uses uppercase letters (ABCDEF).</td>
</tr>
<tr>
<td>n</td>
<td>This conversion type stores the number of items output by printf() so far. Its corresponding argument must be a pointer to an int.</td>
</tr>
<tr>
<td>f, F</td>
<td>The corresponding floating point argument (float, or double) is printed in decimal notation. The default precision is 6 (6 digits after the decimal point). If the precision width is explicitly 0, the decimal point is not printed. For the f conversion specifier, a double argument representing infinity produces [-inf]; a double argument representing a NaN (Not a number) produces [-nan]. For the F conversion specifier, [-INF or [-NAN are produced instead.</td>
</tr>
<tr>
<td>e, E</td>
<td>The floating point argument (float or double) is output in scientific notation: [-b].aaaatEee. There is one digit (b) before the decimal point. Unless indicated by an optional precision width, the default is 6 digits after the decimal point (aaa). If the precision width is 0, no decimal point is output. The exponent (ee) is at least 2 digits long. The e conversion type uses lowercase e as the exponent prefix. The E conversion type uses uppercase E as the exponent prefix.</td>
</tr>
<tr>
<td>g, G</td>
<td>The g conversion type uses the f or e conversion types and the G conversion type uses the f or E conversion types. Conversion type e (or E) is used only if the converted exponent is less than -4 or greater than the precision width. The precision width indicates the number of significant digits. No decimal point is output if there are no digits following it.</td>
</tr>
</tbody>
</table>
stdio.h
Standard input/output

printf(), like fprintf(), sprintf(), vfprintf(), and vprintf(), returns the number of arguments that were successfully output. printf() returns a negative value if it fails.
This function may not be implemented on all platforms.

vector=10
vector=11
vector=12
# putc

Write a character to a stream.

```c
#include <stdio.h>

int putc(int c, FILE *stream);
```

## Remarks

The `putc()` function outputs `c` to `stream` and advances `stream`'s file position indicator.

The `putc()` works identically to the `fputc()` function, except that it is written as a macro.

If the file is opened in update mode (+) the file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream's buffer. This can be done with the `fflush()` function or one of the file positioning operations (`fseek()`, `fsetpos()`, or `rewind()`).

`putc()` returns the character written when successful and return `EOF` when it fails.

This function may not be implemented on all platforms.

## See Also

“Wide Character and Byte Character Stream Orientation” on page 301
“fputc” on page 328
Listing 35.24  Example of putc() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    static char filename[] = "checkputc";
    static char test[] = "flying fish and quail eggs";
    int i;

    // create a new file for output
    if ((f = fopen(filename, "w")) == NULL) {
        printf("Can't open %s.
", filename);
        exit(1);
    }

    // output the test character array
    // one character at a time using putc()
    for (i = 0; test[i] > 0; i++)
        putc(test[i], f);

    // close the file
    fclose(f);

    return 0;
}
```

Output to file checkputc
flying fish and quail eggs

**putchar**

Write a character to stdout.

```c
#include <stdio.h>

int putchar(int c);
```
The `putchar()` function writes character `c` to `stdout`.

`putchar()` returns `c` if it is successful and returns `EOF` if it fails.

This function may not be implemented on all platforms.

### See Also

- “Wide Character and Byte Character Stream Orientation” on page 301
- “fputc” on page 328
- “putc” on page 362

### Listing 35.25 Example of putchar() Usage

```c
#include <stdio.h>

int main(void)
{
    static char test[] = "running jumping walking tree
";
    int i;

    // output the test character one character
    // at a time until the null character is found.
    for (i = 0; test[i] != '\0'; i++)
        putchar(test[i]);

    return 0;
}
```

Output:
```
running jumping walking tree
```
puts

Write a character string to stdout.

```
#include <stdio.h>
int puts(const char *s);
```

**Table 35.41 puts**

<table>
<thead>
<tr>
<th>s</th>
<th>const char *</th>
<th>The string written to stdout</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Remarks**

The `puts()` function writes a character string array to stdout, stopping at, but not including the terminating null character. The function also appends a newline (`\n`) to the output.

`puts()` returns zero if successful and returns a nonzero value if it fails.

This function may not be implemented on all platforms.

**See Also**

“Wide Character and Byte Character Stream Orientation” on page 301
“fputs” on page 330

**Listing 35.26 Example of puts() Usage**

```
#include <stdio.h>

int main(void)
{
    static char s[] = "car bus metro werks";
    int i;

    // output the string 10 times
    for (i = 0; i < 10; i++)
    {
        puts(s);
    }

    return 0;
}
```

Output:

car bus metro werks
```c
#include <stdio.h>
int remove(const char *filename);
```

### Table 35.42 remove

<table>
<thead>
<tr>
<th>filename</th>
<th>const char *</th>
<th>The name of the file to be deleted</th>
</tr>
</thead>
</table>

### Remarks

The `remove()` function deletes the named file specified by `filename`. `remove()` returns 0 if the file deletion is successful, and returns a nonzero value if it fails.

This function may not be implemented on all platforms.

### See Also

### Listing 35.27 Example of remove() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
```

---

366 MSL C Reference Version 10
```c
char filename[40];

// get a filename from the user
printf("Enter the name of the file to delete.\n");
gets(filename);

// delete the file
if (remove(filename) != 0) {
    printf("Can't remove %s.\n", filename);
    exit(1);
}
return 0;
}
```

## rename

Change the name of a file.

```c
#include <stdio.h>
int rename(const char *old, const char *new);
```

### Table 35.43 rename

<table>
<thead>
<tr>
<th>old</th>
<th>const char *</th>
<th>The old file name</th>
</tr>
</thead>
<tbody>
<tr>
<td>new</td>
<td>const char *</td>
<td>The new file name</td>
</tr>
</tbody>
</table>

### Remarks

The `rename()` function changes the name of a file, specified by `old` to the name specified by `new`.

`rename()` returns a nonzero if it fails and returns zero if successful.

This function may not be implemented on all platforms.

### See Also

- “`rename`” on page 401
- “`freopen`” on page 333
- “`remove`” on page 366
<stdio.h>
Standard input/output

Listing 35.28 Example of rename() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    char oldname[50]; // current filename
    char newname[50]; // new filename

    // get the current filename from the user
    printf("Please enter the current filename.\n");
    gets(oldname);

    // get the new filename from the user
    printf("Please enter the new filename.\n");
    gets(newname);

    // rename oldname to newname
    if (rename(oldname, newname) != 0) {
        printf("Can't rename %s to %s.\n", oldname, newname);
        exit(1);
    }
    return 0;
}
```

Output:
Please enter the current filename.
boots.txt
Please enter the new filename.
sandals.txt

rewind
Reset the file position indicator to the beginning of the file.
```c
#include <stdio.h>

void rewind(FILE *stream);
```
The `rewind()` function sets the file indicator position of stream such that the next write or read operation will be from the beginning of the file. It also undoes any previous call to `ungetc()` and clears stream's end-of-file and error status. On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

This function may not be implemented on all platforms.

{
    FILE *f;
    char filename[80], buf[80];

    // get a filename from the user
    printf("Enter a filename to read.\n");
    gets(filename);

    // open a file for input
    if ((f = fopen(filename, "r")) == NULL) {
        printf("Can't open %s.\n", filename);
        exit(1);
    }

    printf("Reading first line twice.\n");

    // move the file position indicator to the beginning
    // of the file
    rewind(f);

    // read the first line
    fgets(buf, 80, f);
}"
```
stdio.h
Standard input/output

```c
printf("Once: %s\n", buf);

// move the file position indicator to the
// beginning of the file
rewind(f);

// read the first line again
fgets(buf, 80, f);
printf("Twice: %s\n", buf);

// close the file
fclose(f);

return 0;
```

Output:
Enter a filename to read.
itwerks
Reading first line twice.
Once: flying fish and quail eggs
Twice: flying fish and quail eggs

scanf

Read formatted text.
#include <stdio.h>
int scanf(const char *format, ...);

Table 35.45  scanf

<table>
<thead>
<tr>
<th>format</th>
<th>const char *</th>
<th>The format string</th>
</tr>
</thead>
</table>

Remarks

The scanf() function reads text and converts the text read to programmer specified types.
Scanf Control String and Conversion Specifiers

The `format` argument is a character array containing normal text, white space (space, tab, newline), and conversion specifications. The normal text specifies literal characters that must be matched in the input stream. A white space character indicates that white space characters are skipped until a non-white space character is reached. The conversion specifications indicate what characters in the input stream are to be converted and stored.

The conversion specifications must have matching arguments in the order they appear in `format`. Because `scanf()` stores data in memory, the matching conversion specification arguments must be pointers to objects of the relevant types.

A conversion specification consists of the percent sign (%) prefix, followed by an optional maximum width or assignment suppression, and ending with a conversion type. A percent sign can be skipped by doubling it in `format`; `%%` signifies a single % in the input stream.

An optional width is a decimal number specifying the maximum width of an input field. `scanf()` will not read more characters for a conversion than is specified by the width.

An optional assignment suppression character (*) can be used to skip an item by reading it but not assigning it. A conversion specification with assignment suppression must not have a corresponding argument.

The last character, the conversion type, specifies the kind of conversion requested. Table 35.46 and Table 35.47 describe the length specifier and conversion type characters.

MSL Altivec Extensions for Scanf

The Altivec extensions to the standard scanf family of functions is supported in Main Standard Libraries.

Separator arguments after % and before any specifier may be any character or may be the @ symbol. The @ symbol is a non-Motorola extension that will use a specified string as a specifier.

In the specific case of a'c' specifier any char may be used as a separator. For all other specifiers '-', '+', '#', ' ' may not be used.

<tr>
<td>c</td>
<td>A character is read. White space characters are not skipped, but read using this conversion specifier.</td>
</tr>
<tr>
<td>p</td>
<td>A pointer address is read. The input format should be the same as that output by the p conversion type in printf().</td>
</tr>
<tr>
<td>n</td>
<td>This conversion type does not read from the input stream but stores the number of characters read so far in its corresponding argument.</td>
</tr>
<tr>
<td>[scanset]</td>
<td>Input stream characters are read and filtered determined by the scanset. See &quot;Scanset&quot; for a full description.</td>
</tr>
</tbody>
</table>

`scanf()` returns the number of items successfully read and returns EOF if a conversion type does not match its argument or and end-of-file is reached.
This function may not be implemented on all platforms.

Listing 35.30  Example of scanf() Usage

```c
#include <stdio.h>

int main(void)
{
    int i;
    unsigned int j;
    char c;
    char s[40];
    double x;

    printf("Enter an integer surrounded by ! marks\n");
    scanf("%!d!", &i);
    printf("Enter three integers\n");
    printf("in hexadecimal, octal, or decimal.\n");
    // note that 3 integers are read, but only the last two
    // are assigned to i and j
    scanf("%*i %i %ui", &i, &j);

    printf("Enter a character and a character string.\n");
    scanf("%c %10s", &c, s);

    printf("Enter a floating point value.\n");
    scanf("%lf", &x);

    return 0;
}
```

Output:
Enter an integer surrounded by ! marks
!94!
Enter three integers
in hexadecimal, octal, or decimal.
1A 6 24
Enter a character and a character string.
Enter a floating point value.
A
Listing 35.31 Example of AltiVec Scanf Extensions

```c
#include <stdio.h>

int main(void)
{
    vector signed char v8, vs8;
    vector unsigned short v16;
    vector signed long v32;
    vector float vf32;

    scanf("1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16", "%vd", &v8);
    scanf("1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16", "%,vd", &vs8);
    scanf("abcdefgh", "%vhc", &v16);
    scanf("1, 4, 300, 400", "%,3lvd", &v32);
    scanf("1.10, 2.22, 3.333, 4.4444", "%,5vf", &vf32);

    return 0;
}
```

The Result is:

<table>
<thead>
<tr>
<th>v8</th>
<th>v8</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16</td>

</tr>
</tbody>
</table>

setbuf

Change the buffer size of a stream.

```c
#include <stdio.h>

void setbuf(FILE *stream, char *buf);
```

Table 35.48 setbuf

<table>
<thead>
<tr>
<th>Stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buf</td>
<td>char *</td>
<td>A buffer for input or output</td>
</tr>
</tbody>
</table>
Remarks

The `setbuf()` function allows the programmer to set the buffer size for stream. It should be called after stream is opened, but before it is read from or written to.

The function makes the array pointed to by buf the buffer used by stream. The buf argument can either be a null pointer or point to an array of size BUFSIZ defined in stdio.h.

If buf is a null pointer, the stream becomes unbuffered.

This function may not be implemented on all platforms.

“malloc” on page 427

Listing 35.32 Example of setbuf() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    char name[80];

    // get a filename from the user
    printf("Enter the name of the file to write to.
");
    gets(name);

    // create a new file for output
    if ( (f = fopen(name, "w")) == NULL) {
        printf("Can't open file %s.
", name);
        exit(1);
    }

    setbuf(f, NULL); // turn off buffering

    // this text is sent directly to the file without buffering
    fprintf(f, "Buffering is now off\n");
    fprintf(f, "for this file.\n");

    // close the file
    fclose(f);
```

stdio.h

`stdio.h`

Standard input/output

```c
return 0;
}
```

Output:
Enter the name of the file to write to.
bufftest

---

**setvbuf**

Change the buffering scheme for a stream.

```c
#include <stdio.h>

int setvbuf(FILE *stream, char *buf, int mode, size_t size);
```

---

**Table 35.49 setvbuf**

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>buf</td>
<td>char *</td>
<td>A buffer for input and output</td>
</tr>
<tr>
<td>mode</td>
<td>int</td>
<td>A buffering mode</td>
</tr>
<tr>
<td>size</td>
<td>size_t</td>
<td>The size of the buffer</td>
</tr>
</tbody>
</table>

**Remarks**

The `setvbuf()` allows the manipulation of the buffering scheme as well as the size of the buffer used by stream. The function should be called after the stream is opened but before it is written to or read from.

The `buf` argument is a pointer to a character array. The `size` argument indicates the size of the character array pointed to by `buf`. The most efficient buffer size is a multiple of `BUFSIZ`, defined in `stdio.h`.

If `buf` is a null pointer, then the operating system creates its own buffer of `size` bytes.

The `mode` argument specifies the buffering scheme to be used with `stream`. `mode` can have one of three values defined in `stdio.h`: `_IOFBF`, `_IOLBF`, and `_IONBF`.

- `_IOFBF` specifies that `stream` be buffered.
- `_IOLBF` specifies that `stream` be line buffered.
stdio.h
Standard input/output

- `_IONBF` specifies that stream be unbuffered
  - `setvbuf()` returns zero if it is successful and returns a nonzero value if it fails.
  - This function may not be implemented on all platforms.

**See Also**
- "setbuf" on page 375
- "malloc" on page 427

**Listing 35.33 Example of setvbuf() Usage**

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    char name[80];

    // get a filename from the user
    printf("Enter the name of the file to write to.\n");
    gets(name);

    // create a new file for output
    if ( (f = fopen(name, "w")) == NULL) {
        printf("Can't open file %s.\n", name);
        exit(1);
    }

    setvbuf(f, NULL, _IOLBF, 0); // line buffering
    fprintf(f, "This file is now\n");
    fprintf(f, "line buffered.\n");

    // close the file
    fclose(f);

    return 0;
}
```

Output:
Enter the name of the file to write to.
buffy
snprintf

Format a character string array.

#include <stdio.h>

int snprintf(char * s, size_t n, const char * format, ...);

Table 35.50 snprintf

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>A string to write to</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>char *</td>
<td></td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td></td>
</tr>
<tr>
<td>format</td>
<td>const char *</td>
<td>The format string</td>
</tr>
</tbody>
</table>

Remarks

The snprintf() function works identically to fprintf() except that the output is written into the array s instead of to a stream. If n is zero nothing is written; otherwise, any characters beyond the n-1st are discarded rather than being written to the array and a null character is appended at the end.

For specifications concerning the output control string and conversion specifiers, see “Output Control String and Conversion Specifiers” on page 321.

Snprintf() returns the number of characters that would have been assigned to s, had n been sufficiently large, not including the null character or a negative value if an encoding error occurred. Thus, the null-terminated output will have been completely written if and only if the returned value is nonnegative and less than n.

This function may not be implemented on all platforms.

Listing 35.34 Example of snprintf() Usage

#include <stdio.h>

int main()
{
    int i = 1;
    static char s[] = "Programmer";
    char dest[50];
    int retval;

    retval = snprintf(dest, 5, "%s is number %d!", s, i);

    // further processing...
}
stdio.h
Standard input/output

```c
printf("n too small, dest = |%s|, retval = %i\n", dest, retval);
retval = snprintf(dest, retval, "%s is number %d!", s, i);
printf("n right size, dest = |%s|, retval = %i\n", dest, retval);
return 0;
```

Output:
```
n too small, dest = |Prog|, retval = 23
n right size, dest = |Programmer is number 1|, retval = 23
```

**sprintf**

Format a character string array.

```c
#include <stdio.h>
int sprintf(char *s, const char *format, ...);
```

Table 35.51  sprintf

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>A string to write to</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>const char *</td>
<td>The format string</td>
</tr>
</tbody>
</table>

**Remarks**

The `sprintf()` function works identically to `printf()` with the addition of the `s` parameter. Output is stored in the character array pointed to by `s` instead of being sent to `stdout`. The function terminates the output character string with a null character.

For specifications concerning the output control string and conversion specifiers, see "Output Control String and Conversion Specifiers" on page 321.

`sprintf()` returns the number of characters assigned to `s`, not including the null character.

This function may not be implemented on all platforms.

**See Also**

"Wide Character and Byte Character Stream Orientation" on page 301
"fprintf" on page 320
Listing 35.35  Example of sprintf() Usage

```c
#include <stdio.h>

int main(void)
{
    int i = 1;
    static char s[] = "CodeWarrior";
    char dest[50];

    sprintf(dest, "%s is number %d!", s, i);
    puts(dest);
    return 0;
}
```

Output:
CodeWarrior is number 1!

---

**sscanf**

Read formatted text into a character string.

```
#include <stdio.h>

int sscanf(char *s, const char *format, ...);
```

**Table 35.52  sscanf**

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>The string to be scanned</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>const char *</td>
<td>The format string</td>
</tr>
</tbody>
</table>

**Remarks**

The `sscanf()` operates identically to `scanf()` but reads its input from the character array pointed to by `s` instead of `stdin`. The character array pointed to `s` must be null terminated.

For specifications concerning the input control string and conversion specifications, see "Input Control String and Conversion Specifiers" on page 335. Also see "Scanset" on page 338, for a full description of the use of `scansets`. 
stdio.h
Standard input/output

scanf() returns the number of items successfully read and converted and returns
EOF if it reaches the end of the string or a conversion specification does not match
its argument.

This function may not be implemented on all platforms.

See Also
“Wide Character and Byte Character Stream Orientation” on page 301
“fscanf” on page 335
“scanf” on page 370

Listing 35.36 Example of sscanf() Usage

```
#include <stdio.h>

int main(void)
{
    static char in[] = "figs cat pear 394 road 16!";
    char s1[20], s2[20], s3[20];
    int i;

    // get the words figs, cat, road,
    // and the integer 16
    // from in and store them in s1, s2, s3, and i,
    // respectively
    sscanf(in, "%s %s pear 394 %s %d!", s1, s2, s3, &i);
    printf("%s %s %s %d\n", s1, s2, s3, i);

    return 0;
}
```

Output:
figs cat road 16

tmpfile

Open a temporary file.
```
#include <stdio.h>

FILE *tmpfile(void);
```
Remarks

The `tmpfile()` function creates and opens a binary file that is automatically removed when it is closed or when the program terminates.

tmpfile() returns a pointer to the `FILE` variable of the temporary file if it is successful. If it fails, `tmpfile()` returns a null pointer (NULL).

This function may not be implemented on all platforms.

See Also

“fopen” on page 317
“tmpnam” on page 384

Listing 35.37  Example of tmpfile() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;

    // create a new temporary file for output
    if ( (f = tmpfile()) == NULL) {
        printf("Can't open temporary file.\n");
        exit(1);
    }

    // output text to the temporary file
    fprintf(f, "watch clock timer glue\n");

    // close AND DELETE the temporary file
    // using fclose()
    fclose(f);

    return 0;
}
```
tmpnam

Creates a unique temporary filename.

```c
#include <stdio.h>
char *tmpnam(char *s);
```

### Remarks

The `tmpnam()` functions creates a valid filename character string that will not conflict with any existing filename. A program can call the function up to `TMP_MAX` times before exhausting the unique filenames `tmpnam()` generates.

The `TMP_MAX` macro is defined in `stdio.h`.

The `s` argument can either be a null pointer or pointer to a character array. The character array must be at least `L_tmpnam` characters long. The new temporary filename is placed in this array. The `L_tmpnam` macro is defined in `stdio.h`.

If `s` is `NULL`, `tmpnam()` returns with a pointer to an internal static object that can be modified by the calling program.

Unlike `tmpfile()`, a file created using a filename generated by the `tmpnam()` function is not automatically removed when it is closed.

`tmpnam()` returns a pointer to a character array containing a unique, non-conflicting filename. If `s` is a null pointer (`NULL`), the pointer refers to an internal static object. If `s` points to a character array, `tmpnam()` returns the same pointer.

This function may not be implemented on all platforms.

### See Also

- “fopen” on page 317
- “tmpfile” on page 382

### Listing 35.38 Example of tmpnam() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
```

```c
Table 35.53  tmpnam

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>A temporary file name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

```c
384  MSL C Reference Version 10
```
FILE *f;
char *tempname;
int c;

// get a unique filename
tempname = tmpnam("tempwerks");

// create a new file for output
if ( (f = fopen(tempname, "w")) == NULL) {
    printf("Can't open temporary file %s\n", tempname);
    exit(1);
}

// output text to the file
fprintf(f, "shoe shirt tie trousers\n");
fprintf(f, "province\n");

// close the file
fclose(f);

// delete the file
remove(tempname);

return 0;

---

**ungetc**

Place a character back into a stream.

```
#include <stdio.h>

int ungetc(int c, FILE *stream);
```

**Table 35.54 ungetc**

<table>
<thead>
<tr>
<th>c</th>
<th>int</th>
<th>The character to return to a file</th>
</tr>
</thead>
<tbody>
<tr>
<td>stream</td>
<td>FILE *</td>
<td>A pointer to a FILE stream</td>
</tr>
</tbody>
</table>
Remarks

The `ungetc()` function places character `c` back into stream's buffer. The next read operation will read the character placed by `ungetc()`. Only one character can be pushed back into a buffer until a read operation is performed.

The function's effect is ignored when an `fseek()`, `fsetpos()`, or `rewind()` operation is performed.

`ungetc()` returns `c` if it is successful and returns `EOF` if it fails.

This function may not be implemented on all platforms.

See Also

“Wide Character and Byte Character Stream Orientation” on page 301
“fseek” on page 341
“fsetpos” on page 343
“rewind” on page 368

Listing 35.39 Example of ungetc() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    int c;

    // create a new file for output and input
    if ( (f = fopen("myfoo", "w+")) == NULL) {
        printf("Can't open myfoo.\n");
        exit(1);
    }

    // output text to the file
    fprintf(f, "The quick brown fox\n");
    fprintf(f, "jumped over the moon.\n");

    // move the file position indicator
    // to the beginning of the file
    rewind(f);

    printf("Reading each character twice.\n");

    // read a character
    while ( (c = fgetc(f)) != EOF) {
```
putchar(c);
  // put the character back into the stream
  ungetc(c, f);
  c = fgetc(f);  // read the same character again
  putchar(c);
}

close(f);

return 0;

Output
Reading each character twice.
THhe qquuiicckk bbrroownn ffooxx
jjuummppeedd oovveerr tthhee mmoooonn..

---

#vfprintf

Write formatted output to a stream.

#include <stdarg.h>
#include <stdio.h>
int vfprintf(FILE *stream, const char *format, va_list arg);

Table 35.55 vfprintf

| stream | FILE * | A pointer to a FILE stream |
| format | const char * | The format string |
| arg | va_list | The variable argument list |

Remarks

The vfprintf() function works identically to the fprintf() function. Instead of the variable list of arguments that can be passed to fprintf(), vfprintf() accepts its arguments in the array arg of type va_list which must have been initialized by the va_start() macro from the stdarg.h header file. The vfprintf() does not invoke the va_end macro.
NOTE  On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

For specifications concerning the output control string and conversion specifiers, see "Output Control String and Conversion Specifiers" on page 321.

`vfprintf()` returns the number of characters written or EOF if it failed.

This function may not be implemented on all platforms.

See Also

"Wide Character and Byte Character Stream Orientation" on page 301
"fprintf" on page 320
"printf" on page 353
"Overview of stdarg.h" on page 279

Listing 35.40  Example of vfprintf() Usage

```c
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>

int fpr(FILE *, char *, ...);

int main(void)
{
    FILE *f;
    static char name[] = "foo";
    int a = 56, result;
    double x = 483.582;

    // create a new file for output
    if (( f = fopen(name, "w")) == NULL) {
        printf("Can't open %s.
", name);
        exit(1);
    }

    // format and output a variable number of arguments
    // to the file
    result = fpr(f, "%10s %4.4f %-10d
", name, x, a);

    // close the file
    fclose(f);

    return 0;
}
```
stdio.h
Standard input/output

// fpr() formats and outputs a variable
// number of arguments to a stream using
// the vfprintf() function
int fpr(FILE *stream, char *format, ...) {
    va_list args;
    int retval;

    va_start(args, format);  // prepare the arguments
    retval = vfprintf(stream, format, args);  // output them
    va_end(args);  // clean the stack
    return retval;
}

Output to file foo:
foo 483.5820 56

vfscanf
Read formatted text from a stream.
#include <stdarg.h>
#include <stdio.h>
int vfscanf(FILE *stream, const char *format, va_list arg);

Table 35.56 vfscanf

<table>
<thead>
<tr>
<th>stream</th>
<th>FILE *</th>
<th>A pointer to a FILE stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>const char *</td>
<td>The format string</td>
</tr>
<tr>
<td>arg</td>
<td>va_list</td>
<td>The variable argument list</td>
</tr>
</tbody>
</table>

Remarks
The vfscanf() function works identically to the fscanf() function. Instead of the variable list of arguments that can be passed to fscanf(), vfscanf() accepts its arguments in the array arg of type va_list, which must have been initialized by the
va_start() macro from the stdarg.h header file. The vfscanf() does not invoke the va_end macro.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

For specifications concerning the output control string and conversion specifiers, see Table 35.35, Table 35.36, Table 35.37, and Table 35.38.

vfscanf() returns the number of items assigned, which can be fewer than provided for in the case of an early matching failure. If an input failure occurs before any conversion, vfscanf() returns EOF.

This function may not be implemented on all platforms.

“scanf” on page 370
“fscanf” on page 335

Listing 35.41 Example of vfscanf() Usage

```c
#include <stdio.h>
#include <stdlib.h>
#include <stdarg.h>

int fsc(FILE *, char *, ...);

int main(void)
{
    FILE *f;
    int i;
    double x;
    char c;
    int numassigned;
    // create a new file for output and input
    if (( f = fopen("foobar", "w+")) == NULL) {
        printf("Can't create new file.\n");
        exit(1);
    }
    // output formatted text to the file
    fprintf(f, "%d\n%f\n%c\n", 45, 983.3923, 'M');
    // go to the beginning of the file
    rewind(f);
    // read from the stream using fscanf()
    numassigned = fsc(f, "%d %lf %c", &i, &x, &c);
    // close the file
    fclose(f);
    printf("The number of assignments is %d.\n", numassigned);
    return 0;
}
```
stdio.h
Standard input/output

```c
printf("The integer read is %d.\n", i);
printf("The floating point value is %f.\n", x);
printf("The character is %c.\n", c);
return 0;
}

// fsc() scans an input stream and inputs
// a variable number of arguments using
// the vfscanf() function
int fsc(FILE *stream, char *format, ...)
{
    va_list args;
    int retval;

    va_start(args, format); // prepare the arguments
    retval = vfscanf(stream, format, args);
    va_end(args); // clean the stack
    return retval;
}
```

Output:
The number of assignments is 3.
The integer read is 45.
The floating point value is 983.392300.
The character is M.

---

**vprintf**

Write formatted output to stdout.

```c
#include <stdio.h>

int vprintf(const char *format, va_list arg);
```

**Table 35.57 vprintf**

<table>
<thead>
<tr>
<th>format</th>
<th>const char *</th>
<th>The format string</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg</td>
<td>va_list</td>
<td>A variable argument list</td>
</tr>
</tbody>
</table>

**Remarks**

The `vprintf()` function works identically to the `printf()` function. Instead of the variable list of arguments that can be passed to `printf()`, `vprintf()`
accepts its arguments in the array of type va_list processed by the va_start() macro from the stdarg.h header file.

For specifications concerning the output control string and conversion specifiers, see “Output Control String and Conversion Specifiers” on page 321.

vprintf() returns the number of characters written or a negative value if it failed.

This function may not be implemented on all platforms.

“Wide Character and Byte Character Stream Orientation” on page 301
“fprintf” on page 320
“printf” on page 353
“Overview of stdarg.h” on page 279

Listing 35.42  Example of vprintf() Usage

```c
#include <stdio.h>
#include <stdarg.h>

int pr(char *, ...);

int main(void)
{
    int a = 56;
    double f = 483.582;
    static char s[] = "Valerie";

    // output a variable number of arguments to stdout
    pr("%15s %4.4f %-10d\n", s, f, a);

    return 0;
}

// pr() formats and outputs a variable number of arguments
// to stdout using the vprintf() function
int pr(char *format, ...)
{
    va_list args;
    int retval;
    va_start(args, format); // prepare the arguments
    retval = vprintf(format, args);
    va_end(args); // clean the stack
    return retval;
}
```
stdio.h
Standard input/output

)

Output:
Valerie 483.5820 56 *

vsnprintf
Format a character string array.
#include <stdarg.h>
#include <stdio.h>
int vsnprintf(char * s, size_t n,
  const char * format, va_list arg);

Table 35.58 vsnprintf

<table>
<thead>
<tr>
<th>s</th>
<th>char*</th>
<th>A string to write to</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>size_t</td>
<td>Max number of chars to be written to s</td>
</tr>
<tr>
<td>format</td>
<td>const char*</td>
<td>The format string</td>
</tr>
<tr>
<td>arg</td>
<td>va_list</td>
<td>A variable argument list</td>
</tr>
</tbody>
</table>

Remarks
The vsnprintf() function works identically to snprintf(), except that the variable list of arguments that can be passed to snprintf() is replaced by an array arg of type va_list, which must have been initialized by the va_start() macro from the stdarg.h header file. The vsnprintf() does not invoke the va_end macro. If n is zero nothing is written; otherwise, any characters beyond the n-list are discarded rather than being written to the array and a null character is appended at the end.

For specifications concerning the output control string and conversion specifiers, see “Output Control String and Conversion Specifiers” on page 321.

Vsnprintf() returns the number of characters that would have been assigned to s, had n been sufficiently large, not including the null character or a negative value if an encoding error occurred. Thus, the null-terminated output will have
stdio.h
Standard input/output

been completely written if and only if the returned value is nonnegative and less
than n.
This function may not be implemented on all platforms.

See Also
“Wide Character and Byte Character Stream Orientation” on page 301
“printf” on page 353
“fprintf” on page 380
“Overview of stdarg.h” on page 279

Listing 35.43 Example of vsnprintf() Usage

```c
#include <stdarg.h>
#include <stdio.h>

int sp(char *, size_t, char *, ...);

int main()
{
    int i = 1;
    static char s[] = "Isabelle";
    char dest[50];
    int retval;
    retval = sp(dest, 5, "%s is number %d!", s, i);
    printf("n too small, dest = |%s|, retval = %i
", dest, retval);
    retval = sp(dest, retval, "%s is number %d!", s, i);
    printf("n right size, dest = |%s|, retval = %i
", dest, retval);
    return 0;
}

// sp() formats and outputs a variable number of arguments
// to a character string using the vsnprintf() function
int sp(char * s, size_t n, char *format,...)
{
    va_list args;
    int retval;
    va_start(args, format);  // prepare the arguments
    retval = vsnprintf(s, n, format, args);
    va_end(args);  // clean the stack
    return retval;
}
```

394
vsprintf

Write formatted output to a string.
#include <stdio.h>
int vsprintf(char *s,
    const char *format, va_list arg);

Table 35.59  vsprintf

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>A string to write to</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>const char *</td>
<td>The format string</td>
</tr>
<tr>
<td>arg</td>
<td>va_list</td>
<td>A variable argument list</td>
</tr>
</tbody>
</table>

Remarks

The vsprintf() function works identically to the sprintf() function. Instead of the variable list of arguments that can be passed to sprintf(), vsprintf() accepts its arguments in the array of type va_list processed by the va_start() macro from the stdarg.h header file.

For specifications concerning the output control string and conversion specifiers, see “Output Control String and Conversion Specifiers” on page 321.

vsprintf() returns the number of characters written to s not counting the terminating null character. Otherwise, EOF on failure.

This function may not be implemented on all platforms.

See Also

“Wide Character and Byte Character Stream Orientation” on page 301
“printf” on page 353
“sprint” on page 380
“Overview of stdarg.h” on page 279
Listing 35.44 Example of vsprintf() Usage

```c
#include <stdio.h>
#include <stdarg.h>

int spr(char *, char *, ...);

int main(void)
{
    int a = 56;
    double x = 1.003;
    static char name[] = "Charlie";
    char s[50];

    // format and send a variable number of arguments
    // to character array s
    spr(s, "%10s\n %f\n %-10d\n", name, x, a);
    puts(s);

    return 0;
}

// spr() formats and sends a variable number of
// arguments to a character array using the sprintf()
// function
int spr(char *s, char *format, ...)
{
    va_list args;
    int retval;

    va_start(args, format); // prepare the arguments
    retval = vsprintf(s, format, args);
    va_end(args); // clean the stack
    return retval;
}
```

Output:
Charlie
1.003000
56
vsscanf

Read formatted text from a character string.

#include <stdarg.h>
#include <stdio.h>
int vsscanf(const char * s,
            const char * format, va_list arg);

Table 35.60 vsscanf

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>The character string to be scanned</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>char *</td>
<td>The format string</td>
</tr>
<tr>
<td>arg</td>
<td>va_list</td>
<td>The variable argument list</td>
</tr>
</tbody>
</table>

Remarks

The vsscanf() function works identically to the scanf() function. Instead of the variable list of arguments that can be passed to scanf(), vsscanf() accepts its arguments in the array arg of type va_list, which must have been initialized by the va_start() macro from the stdarg.h header file. The vfscanf() does not invoke the va_end macro.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

For specifications concerning the output control string and conversion specifiers, see Table 35.35, Table 35.36, Table 35.37, Table 35.38.

vfscanf() returns the number of items assigned, which can be fewer than provided for in the case of an early matching failure. If an input failure occurs before any conversion, vfscanf() returns EOF.

This function may not be implemented on all platforms.

“scanf” on page 370
“fscanf” on page 335
Listing 35.45 Example of Vsscanf() Usage

```c
#include <stdio.h>
#include <stdarg.h>

int ssc(char *, char *, ...);

int main(void)
{
    static char in[] = "figs cat pear 394 road 16!";
    char s1[20], s2[20], s3[20];
    int i;

    // get the words figs, cat, road,
    // and the integer 16
    // from in and store them in s1, s2, s3, and i,
    // respectively
    ssc(in, "%s %s pear 394 %s %d!", s1, s2, s3, &i);
    printf("%s %s %s %d\n", s1, s2, s3, i);

    return 0;
}

// ssc() scans a character string and inputs
// a variable number of arguments using
// the vsscanf() function
int ssc(char * s, char *format, ...)
{
    va_list args;
    int retval;

    va_start(args, format);  // prepare the arguments
    retval = vsscanf(s, format, args);
    va_end(args);  // clean the stack
    return retval;
}
```

Output:
figs cat road 16
_wfopen

Open a file as a stream with a wide character file name.

```c
#include <stdio.h>
FILE * _wfopen(const wchar_t *wfilename, const wchar_t *wmode);
```

Table 35.61  _wfopen

<table>
<thead>
<tr>
<th>wfilename</th>
<th>const wchar_t *</th>
<th>The wide character filename of the file to open</th>
</tr>
</thead>
<tbody>
<tr>
<td>wmode</td>
<td>const wchar_t *</td>
<td>The wide character file opening mode</td>
</tr>
</tbody>
</table>

Remarks

The _wfopen() function is a wide character implementation of “fopen” on page 317.
This function may not be implemented on all platforms.

See Also

“freopen” on page 333
“fopen” on page 317

_wfreopen

Re-direct a stream to another file as a wide character version.

```c
#include <stdio.h>
FILE * _wfreopen(const wchar_t *wfilename, const wchar_t *wmode, FILE *stream);
```

The `_wfreopen()` function is a wide character implementation of “freopen” on page 333. This function may not be implemented on all platforms.

See Also

“freopen” on page 333
“_wfopen” on page 399

----------

`_wremove`

Delete a file.

```c
#include <stdio.h>
int _wremove(const wchar_t *wfilename);
```

Table 35.63  _wremove

<table>
<thead>
<tr>
<th>wfilename</th>
<th>const wchar_t *</th>
<th>The name of the wide character file to be deleted</th>
</tr>
</thead>
</table>

Remarks

The `_fremove()` function is a wide character variation of “remove” on page 366. This function may not be implemented on all platforms.

See Also

“remove” on page 366

----------

MSL C Reference Version 10
_wrename

Change the name of a file.

```c
#include <stdio.h>
int _wrename(const char *wold, const wchar_t *wnew);
```

**Table 35.64  _wrename**

<table>
<thead>
<tr>
<th>wold</th>
<th>const wchar_t *</th>
<th>The old wide character file name</th>
</tr>
</thead>
<tbody>
<tr>
<td>wnew</td>
<td>const wchar_t *</td>
<td>The new wide character file name</td>
</tr>
</tbody>
</table>

**Remarks**

The _wrename() function implements a wide character variation of "rename" on page 367.

This function may not be implemented on all platforms.

**See Also**

- "rename" on page 367
- "_wtmpnam"

_wtmpnam

Create a unique temporary filename wide character variant.

```c
#include <stdio.h>
wchar_t * _wtmpnam(wchar_t *ws);
```

**Table 35.65  _wtmpnam**

<table>
<thead>
<tr>
<th>ws</th>
<th>wchar_t *</th>
<th>A temporary wide character file name</th>
</tr>
</thead>
</table>
The \texttt{\_wtmpnam()} functions creates a valid filename wide character string that will not conflict with any existing filename. It is implemented for a wide character array in the same manner as \texttt{tmpnam} on page 384.

This function may not be implemented on all platforms.

\textbf{See Also}

\texttt{fopen} on page 317

\texttt{tmpfile} on page 382
stdlib.h

The stdlib.h header file provides groups of closely related functions for string conversion, pseudo-random number generation, memory management, environment communication, searching and sorting, multibyte character conversion, and integer arithmetic.

Overview of stdlib.h

The stdlib.h header file provides groups of closely related functions as follows:

- “String Conversion Functions” on page 403
- “Pseudo-random Number Generation Functions” on page 404
- “Memory Management Functions” on page 404
- “Environment Communication Functions” on page 404
- “Searching And Sorting Functions” on page 404
- “Multibyte Conversion Functions” on page 405
- “Integer Arithmetic Functions” on page 405

String Conversion Functions

The string conversion functions are as follows:

- “atof” on page 410
- “atoi” on page 411
- “atol” on page 412
- “atoll” on page 412
- “strtof” on page 437
- “strtol” on page 438
- “strtold” on page 441
- “strtoul” on page 443
- “strtoull” on page 444
Pseudo-random Number Generation Functions
The pseudo-random number generation functions are

- “rand” on page 432
- “rand_r” on page 433
- “srand” on page 435

Memory Management Functions
The memory management functions are

- “calloc” on page 417
- “free” on page 422
- “malloc” on page 427
- “realloc” on page 434
- “vec_calloc” on page 446
- “vec_free” on page 447
- “vec_malloc” on page 448
- “vec_realloc” on page 448

Environment Communication Functions
The environment communication functions are

- “abort” on page 405
- “atexit” on page 408
- “exit” on page 420
- “_Exit” on page 422
- “getenv” on page 423
- “_putenv” on page 430
- “system” on page 446

Searching And Sorting Functions
The searching and sorting functions are

- “bsearch” on page 413
- “qsort” on page 431
Multibyte Conversion Functions

The multibyte conversion functions convert UTF-8 multibyte characters to wchar_t type characters (defined in stddef.h). The functions are

- “mblen” on page 428
- “mbstowcs” on page 428
- “mbtowc” on page 429
- “wcstombs” on page 449
- “wctomb” on page 450

Integer Arithmetic Functions

The integer arithmetic functions are

- “abs” on page 406
- “div” on page 419
- “labs” on page 424
- “llabs” on page 425
- “ldiv” on page 425

Many of the stdlib.h functions use the size_t type as well as the NULL and MB_CUR_MAX macros, which are defined in stdlib.h. The macro MB_CUR_MAX defines the maximum number of bytes in a single multibyte character.

abort

Abnormal program termination.

```c
#include <stdlib.h>
void abort(void)
```

Remarks

The abort() function raises the SIGABRT signal and quits the program to return to the operating system.

The abort() function will not terminate the program if a programmer-installed signal handler uses longjmp() instead of returning normally.

This function may not be implemented on all platforms.
stdlib.h
Overview of stdlib.h

See Also
“assert” on page 27
“longjmp” on page 244
“raise” on page 253
“signal” on page 251
“atexit” on page 408
“exit” on page 420

Listing 36.1 Example of abort() Usage

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    char c;

    printf("Aborting the program.\n");
    printf("Press return.\n");

    // wait for the return key to be pressed
    c = getchar();

    // abort the program
    abort();

    return 0;
}
```

Output:
Aborting the program.
Press return.

abs

Compute the absolute value of an integer.

```c
#include <stdlib.h>
int abs(int i);
```
abs() returns the absolute value of its argument. Note that the two's complement representation of the smallest negative number has no matching absolute integer representation.
This function may not be implemented on all platforms.

See Also

“fabs” on page 188
“labs” on page 424

Listing 36.2 Example of abs() Usage

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    int i = -20;
    long int j = -48323;
    long long k = -922372036854773307;

    printf("Absolute value of %d is %d.\n", i, abs(i));
    printf("Absolute value of %ld is %ld.\n", j, labs(j));
    printf("Absolute value of %lld is %lld.\n", k, llabs(k));

    return 0;
}
```

Output:
Absolute value of -20 is 20.
Absolute value of -48323 is 48323.
Absolute value of -922372036854773307 is 922372036854773307.

---

Table 36.1 abs

<table>
<thead>
<tr>
<th>i</th>
<th>The value being computed</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td></td>
</tr>
<tr>
<td>int</td>
<td></td>
</tr>
</tbody>
</table>

abs() returns the absolute value of its argument. Note that the two's complement representation of the smallest negative number has no matching absolute integer representation.
This function may not be implemented on all platforms.
atexit

Install a function to be executed at a program's exit.

```c
#include <stdlib.h>
int atexit(void (*func)(void));
```

<table>
<thead>
<tr>
<th>Table 36.2  atexit</th>
</tr>
</thead>
<tbody>
<tr>
<td>func</td>
</tr>
</tbody>
</table>

**Remarks**

The `atexit()` function adds the function pointed to by `func` to a list. When `exit()` is called, each function on the list is called in the reverse order in which they were installed with `atexit()`. After all the functions on the list have been called, `exit()` terminates the program.

The `stdio.h` library, for example, installs its own exit function using `atexit()`. This function flushes all buffers and closes all open streams.

`atexit()` returns a zero when it succeeds in installing a new exit function and returns a nonzero value when it fails.

This function may not be implemented on all platforms.

**See Also**

“exit” on page 420

**Listing 36.3  Example of atexit() Usage**

```c
#include <stdlib.h>
#include <stdio.h>

// Prototypes
void first(void);
void second(void);
void third(void);

int main(void)
{
    atexit(first);
    atexit(second);
    atexit(third);
}
```
```c
printf("exiting program\n\n");
return 0;
}

void first(void)
{
    int c;

    printf("First exit function.\n");
    printf("Press return.\n");
    // wait for the return key to be pressed
    c = getchar();
}

void second(void)
{
    int c;

    printf("Second exit function.\n");
    printf("Press return.\n");
    c = getchar();
}

void third(void)
{
    int c;

    printf("Third exit function.\n");
    printf("Press return.\n");
    c = getchar();
}
```

Output:
Third exit function.
Press return.

Second exit function.
Press return.

First exit function.
Press return.
**stdlib.h**

*Overview of stdlib.h*

---

**atof**

Convert a character string to a numeric value of type double.

```c
#include <stdlib.h>
double atof(const char *nptr);
```

**Table 36.3 atof**

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>The character being converted</th>
</tr>
</thead>
</table>

**Remarks**

The `atof()` function converts the character array pointed to by `nptr` to a floating point value of type `double`. Except for its behavior on error, this function is the equivalent of the call `strtod(nptr, NULL);`

This function sets the global variable `errno` to `ERANGE` if the converted value cannot be expressed as a floating point value of type `double`. `atof()` returns a floating point value of type `double`. This function may not be implemented on all platforms.

**See Also**

“atoi” [page 411](#)
“atol” [page 412](#)
“errno” [page 75](#)
“strtol” [page 435](#)
“scanf” [page 370](#)

**Listing 36.4 Example of atof(), atoi(), atol() Usage**

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    int i;
    long int j;
    float f;
    static char si[] = "-493", si[] = "63870";
```
**stdlib.h**

Overview of stdlib.h

```c
static char sf[] = "1823.4034";

f = atof(sf);
i = atoi(si);
j = atol(sli);

printf("%f %d %ld\n", f, i, j);
return 0;
```

Output:
1823.403400 -493 63870

---

**atoi**

Convert a character string to a value of type int.

```
#include <stdlib.h>
int atoi(const char *nptr);
```

Table 36.4  atoi

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>The string to be converted</th>
</tr>
</thead>
</table>

Remarks

The `atoi()` function converts the character array pointed to by `nptr` to an integer value. Except for its behavior on error, this function is the equivalent of the call `(int)strtol(nptr, (char **)NULL, 10);

This function sets the global variable `errno` to `ERANGE` if the converted value cannot be expressed as a value of type `int`.

`atoi()` returns an integer value of type `int`.

This function may not be implemented on all platforms.

See Also

"atof" on page 410
"atol" on page 412
"errno" on page 75
stdlib.h

Overview of stdlib.h

“strtol” on page 438
“scanf” on page 370

atol

Convert a character string to a value of type long.

#include <stdlib.h>

long int atol(const char *nptr);

Table 36.5 atol

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>The string to be converted</th>
</tr>
</thead>
</table>

Remarks

The atol() function converts the character array pointed to by nptr to an integer of type long int. Except for its behavior on error, this function is the equivalent of the call strtol(nptr, (char **)NULL, 10);

This function sets the global variable errno to ERANGE if the converted value cannot be expressed as a value of type long int.

atol() returns an integer value of type long int.

This function may not be implemented on all platforms.

See Also

“atof” on page 410
“atoi” on page 411
“errno” on page 75
“strtol” on page 438
“scanf” on page 370

atoll

Convert a character string to a value of type long long.

#include <stdlib.h>

long long atoll(const char *nptr);
The `atoll()` function converts the character array pointed to by `nptr` to an integer of type `long long`. Except for its behavior on error, this function is the equivalent of the call `strtoll(nptr, (char **)NULL, 10);`

This function sets the global variable `errno` to `ERANGE` if the converted value cannot be expressed as a value of type `long int`.

`atoll()` returns an integer value of type `long long`.

This function may not be implemented on all platforms.

See Also

“`atof`” on page 410
“`atoi`” on page 411

### bsearch

This function uses the binary search algorithm to make an efficient search of a sorted array for an item.

```c
#include <stdlib.h>

void *bsearch(const void *key, const void *base, 
size_t num, size_t size, 
int (*compare) (const void *, const void *))
```

#### Table 36.7 bsearch

<table>
<thead>
<tr>
<th>key</th>
<th>const void *</th>
<th>Search criteria see remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>base</td>
<td>const void *</td>
<td>The array to be searched see remarks</td>
</tr>
<tr>
<td>num</td>
<td>size_t</td>
<td>Number of elements see remarks</td>
</tr>
</tbody>
</table>
stdlib.h
Overview of stdlib.h

Table 36.7 bsearch (continued)

<table>
<thead>
<tr>
<th>size</th>
<th>size_t</th>
<th>Size of an array element see remarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>compare</td>
<td>const void *</td>
<td>A pointer to a function used for comparison see remarks</td>
</tr>
</tbody>
</table>

Remarks

The key argument points to the item you want to search for.

The base argument points to the first byte of the array to be searched. This array must already be sorted in ascending order. This order is based on the comparison requirements of the function pointed to by the compare argument.

The num argument specifies the number of array elements to search.

The size argument specifies the size of an array element.

The compare argument is a pointer to a programmer-supplied function that is used to compare two elements of the array. That compare function takes two array element pointers as arguments. The first argument is the key that was passed to bsearch() as the first argument to bsearch(). The second argument is a pointer to an element of the array passed as the second argument to bsearch().

For explanation, we will call the arguments search_key and array_element. The compare function compares the search_key to the array element. If the search_key and the array_element are equal, the function will return zero. If the search_key is less than the array_element, the function will return a negative value. If the search_key is greater than the array_element, the function will return a positive value.

bsearch() returns a pointer to the element in the array matching the item pointed to by key. If no match was found, bsearch() returns a null pointer (NULL).

This function may not be implemented on all platforms.

See Also

“qsort” on page 431

Listing 36.5 Example of bsearch Usage

```c
// A simple telephone directory manager
// This program accepts a list of names and
// telephone numbers, sorts the list, then
// searches for specified names.
```
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

// Maximum number of records in the directory.
#define MAXDIR 40

typedef struct
{
    char lname[15]; // keyfield--see comp() function
    char fname[15];
    char phone[15];
} DIRENTRY; // telephone directory record

int comp(const DIRENTRY *, const DIRENTRY *);
DIRENTRY *look(char *);
DIRENTRY directory[MAXDIR]; // the directory itself
int reccount; // the number of records entered

int main(void)
{
    DIRENTRY *ptr;
    int lastlen;
    char lookstr[15];

    printf("Telephone directory program.\n");
    printf("Enter blank last name when done.\n");

    reccount = 0;
    ptr = directory;
    do {
        printf("\nLast name: ");
        gets(ptr->lname);
        printf("First name: ");
        gets(ptr->fname);
        printf("Phone number: ");
        gets(ptr->phone);
        if ( (lastlen = strlen(ptr->lname)) > 0) {
            reccount++;
            ptr++;
        }
    } while ( (lastlen > 0) && (reccount < MAXDIR) );

    printf("Thank you. Now sorting. . .\n");

    // sort the array using qsort()
    qsort(directory, reccount,
stdio.h
Overview of stdio.h

```c
sizeof(directory[0]), (void *)comp);

printf("Enter last name to search for, \n");
printf("blank to quit, \n");
printf("\nLast name: ");
gets(lookstr);

while ( (lastlen = strlen(lookstr)) > 0) {
    ptr = look(lookstr);
    if (ptr != NULL)
        printf("%s, %s: %s\n",
            ptr->lname,
            ptr->fname,
            ptr->phone);
    else printf("Can't find %s.\n", lookstr);
    printf("\nLast name: ");
    gets(lookstr);
}

printf("Done.\n");

return 0;
}

int comp(const DIRENTRY *rec1, const DIRENTRY *rec2)
{
    return (strcmp((char *)rec1->lname, 
                   (char *)rec2->lname));
}

// search through the array using bsearch()
DIRENTRY *look(char k[])
{
    return (DIRENTRY *) bsearch(k, directory, reccount,
                                 sizeof(directory[0]), (void *)comp);
}
```

Output
Telephone directory program.
Enter blank last name when done.

Last name: Mation
First name: Infor
Phone number: 555-1212

Last name: Bell
First name: Alexander
calloc

Allocate space for a group of objects.

```c
#include <stdlib.h>

void *calloc(size_t nmemb, size_t elemsize);
```

<table>
<thead>
<tr>
<th>Table 36.8 calloc</th>
</tr>
</thead>
<tbody>
<tr>
<td>nmemb</td>
</tr>
<tr>
<td>elemsize</td>
</tr>
</tbody>
</table>

Remarks

The `calloc()` function allocates contiguous space for `nmemb` elements of size `elemsize`. The space is initialized with all bits zero. `calloc()` returns a pointer to the first byte of the memory area allocated. `calloc()` returns a null pointer (NULL) if no space could be allocated. This function may not be implemented on all platforms.
Listing 36.6  Example of calloc() Usage

```c
#include <stdlib.h>
#include <stdio.h>
#include <string.h>

int main(void)
{
    static char s[] = "CodeWarrior compilers";
    char *sptr1, *sptr2, *sptr3;

    // allocate the memory three different ways
    // one: allocate a thirty byte block of
    // uninitialized memory
    sptr1 = (char *) malloc(30);
    strcpy(sptr1, s);
    printf("Address of sptr1: %p\n", sptr1);

    // two: allocate twenty bytes of uninitialized memory
    sptr2 = (char *) malloc(20);
    printf("sptr2 before reallocation: %p\n", sptr2);
    strcpy(sptr2, s);
    // now re-allocate ten extra bytes (for a total of
    // thirty bytes)
    //
    // note that the memory block pointed to by sptr2 is
    // still contiguous after the call to realloc()
    sptr2 = (char *) realloc(sptr2, 30);
    printf("sptr2 after reallocation: %p\n", sptr2);

    // three: allocate thirty bytes of initialized memory
    sptr3 = (char *) calloc(strlen(s), sizeof(char));
    strcpy(sptr3, s);
    printf("Address of sptr3: %p\n", sptr3);
    puts(sptr1);
    puts(sptr2);
    puts(sptr3);

    // release the allocated memory to the heap
    free(sptr1);
}
```
free(sptr2);
free(sptr3);

return 0;
}

Output:
Address of sptr1: 5e5432
sptr2 before reallocation: 5e5452
sptr2 after reallocation: 5e5468
Address of sptr3: 5e5488
CodeWarrior compilers

CodeWarrior compilers

---

div

Compute the integer quotient and remainder.

```c
#include <stdlib.h>
div_t div(int numer, int denom);
```

<table>
<thead>
<tr>
<th>numer</th>
<th>int</th>
<th>The numerator</th>
</tr>
</thead>
<tbody>
<tr>
<td>denom</td>
<td>int</td>
<td>The denominator</td>
</tr>
</tbody>
</table>

**Remarks**

The `div_t` type is defined in `stdlib.h` as

```c
typedef struct { int quot, rem; } div_t;
```

div() divides denom into numer and returns the quotient and remainder as a `div_t` type.

This function may not be implemented on all platforms.

**See Also**

“fmod” on page 191
“ldiv” on page 425
“div_t” on page 73
Listing 36.7 Example of div() Usage

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
    div_t result;
    ldiv_t lresult;

    int d = 10, n = 103;
    long int ld = 1000L, ln = 1000005L;

    result = div(n, d);
    lresult = ldiv(ln, ld);

    printf("%d / %d has a quotient of %d\n",
           n, d, result.quot);
    printf("and a remainder of %d\n", result.rem);
    printf("%ld / %ld has a quotient of %ld\n",
           ln, ld, lresult.quot);
    printf("and a remainder of %ld\n", lresult.rem);

    return 0;
}
```

Output:
103 / 10 has a quotient of 10
and a remainder of 3
1000005 / 1000 has a quotient of 1000
and a remainder of 5

exit

Terminate a program normally.

```c
#include <stdlib.h>
void exit(int status);
```

<table>
<thead>
<tr>
<th>status</th>
<th>int</th>
<th>The exit error value</th>
</tr>
</thead>
</table>

MSL C Reference Version 10
Remarks

The `exit()` function calls every function installed with `atexit()` in the reverse order of their installation, flushes the buffers and closes all open streams, then calls the Toolbox system call `ExitToShell()`.

`exit()` does not return any value to the operating system. The `status` argument is kept to conform to the ANSI C Standard Library specification.

This function may not be implemented on all platforms.

See Also

“`abort`” on page 405

“`atexit`” on page 408

Listing 36.8 Example of exit() Usage

```c
#include <stdio.h>
#include <stdlib.h>

int main(void)
{
    FILE *f;
    int count;

    // create a new file for output exit on failure
    if (( f = fopen("foofoo", "w")) == NULL) {
        printf("Can't create file.\n");
        exit(1);
    }

    // output numbers 0 to 9
    for (count = 0; count < 10; count++)
        fprintf(f, "%5d", count);

    // close the file
    fclose(f);

    return 0;
}
```

stdlib.h
Overview of stdlib.h

_Exit

The _Exit function causes normal program termination

```c
#include <stdlib.h>
void _Exit(int status);
```

<table>
<thead>
<tr>
<th>Table 36.11</th>
<th>_Exit</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
<td>int</td>
</tr>
</tbody>
</table>

Remarks

This function can not return but a status value is passed back to the calling host in the same manner as in the function “exit” on page 420.

The effects on open buffers is implementation defined.

This function may not be implemented on all platforms.

See Also

“abort” on page 405

“atexit” on page 408

For example usage of exit(). see Listing 36.8.

free

Release previously allocated memory to heap.

```c
#include <stdlib.h>
void free(void *ptr);
```

<table>
<thead>
<tr>
<th>Table 36.12</th>
<th>free</th>
</tr>
</thead>
<tbody>
<tr>
<td>ptr</td>
<td>void *</td>
</tr>
</tbody>
</table>

Remarks

The free() function releases a previously allocated memory block, pointed to by ptr, to the heap. The ptr argument should hold an address returned by the
memory allocation functions `calloc()`, `malloc()`, or `realloc()`. Once the memory block pointed to by `ptr` has been released, it is no longer valid. The `ptr` variable should not be used to reference memory again until it is assigned a value from the memory allocation functions. For example usage, see Listing 36.6.

This function may not be implemented on all platforms.

See Also

- “calloc” on page 417
- “malloc” on page 427
- “realloc” on page 434

### getenv

Environment list access.

```
#include <stdlib.h>
char *getenv(char *name);
```

### Table 36.13  getenv

<table>
<thead>
<tr>
<th>name</th>
<th>char *</th>
<th>A buffer for the environment list</th>
</tr>
</thead>
</table>

### Remarks

For Macintosh systems, the `getenv()` is an empty function that always returns a null pointer (`NULL`). It is included in the CodeWarrior `stdlib.h` header file to conform to the ANSI C Standard Library specification.

`getenv()` returns `NULL` for the Mac. For Windows, `getenv()` returns zero on failure or the environmental variable.

This function may not be implemented on all platforms.

See Also

- “system” on page 446

### Listing 36.9  Example of getenv() Usage

```c
#include <stdio.h>
```
#include <stdlib.h>

int main(void)
{
    char *value;
    char *var = "path";

    if( (value = getenv(var)) == NULL)
    { printf("%s is not a environmental variable", var);}
    else
    { printf("%s = %s \n", var, value);}

    return 0;
}

Result:
path = c:\program files\Freescale\codewarrior;c:\WINNT\system32

---

**labs**

Compute long integer absolute value.

```c
#include <stdlib.h>
long int labs(long int j);
```

### Table 36.14 labs

<table>
<thead>
<tr>
<th>j</th>
<th>long int</th>
<th>The variable to be computed</th>
</tr>
</thead>
</table>

**Remarks**

labs() returns the absolute value of its argument as a value of type long int.

For example usage, see Listing 36.2.

This function may not be implemented on all platforms.

**See Also**

“fabs” on page 188

“abs” on page 406
ldiv

Compute the long integer quotient and remainder.

#include <stdlib.h>

ldiv_t ldiv(long int numer, long int denom);

Table 36.15 ldiv

<table>
<thead>
<tr>
<th>numer</th>
<th>long int</th>
<th>The numerator</th>
</tr>
</thead>
<tbody>
<tr>
<td>denom</td>
<td>long int</td>
<td>The denominator</td>
</tr>
</tbody>
</table>

Remarks

The ldiv_t type is defined in stdlib.h as

typedef struct {
    long int quot, rem;
} ldiv_t;

ldiv() divides denom into numer and returns the quotient and remainder as an ldiv_t type. For example usage, see Listing 36.7.

This function may not be implemented on all platforms.

See Also

“fmod” on page 191
“div” on page 419
“ldiv_t” on page 74
“lldiv_t” on page 74

llabs

Compute long long integer absolute value.

#include <stdlib.h>

long long llabs(long long j);
Overview of stdlib.h

Table 36.16 llabs

<table>
<thead>
<tr>
<th>l</th>
<th>long long</th>
<th>The variable to be computed</th>
</tr>
</thead>
</table>

Remarks
llabs() returns the absolute value of its argument as a value of type long long. For example usage, see Listing 36.2.
This function may not be implemented on all platforms.

See Also
“fabs” on page 188
“abs” on page 406

lldiv

Compute the long long integer quotient and remainder.

#include <stdlib.h>
lldiv_t lldiv(long long numer, long long denom);

Table 36.17 lldiv

<table>
<thead>
<tr>
<th>numer</th>
<th>long long</th>
<th>The numerator</th>
</tr>
</thead>
<tbody>
<tr>
<td>denom</td>
<td>long long</td>
<td>The denominator</td>
</tr>
</tbody>
</table>

Remarks
The lldiv_t type is defined in <div_t.h> as
typedef struct {
    long long quot, rem;
} lldiv_t;

lldiv() divides denom into numer and returns the quotient and remainder as an lldiv_t type.
This function may not be implemented on all platforms.
malloc

Allocate a block of heap memory.

```c
#include <stdlib.h>
void *malloc(size_t size);
```

### Remarks

The `malloc()` function allocates a block of contiguous heap memory `size` bytes large. If the argument for `malloc()` is zero, the behavior is unspecified. Dependent upon the system, either a null pointer is returned, or the behavior is as if the `size` was not zero, except that the returned pointer can not be used to access an object. For example usage, see Listing 36.6.

`malloc()` returns a pointer to the first byte of the allocated block if it is successful and return a null pointer if it fails.

This function may not be implemented on all platforms.

- “free” on page 422
- “realloc” on page 434
Compute the length of an encoded multibyte character, encoded as defined by the
LC_CTYPE category of the current locale.

```c
#include <stdlib.h>
int mblen(const char *s, size_t n);
```

**Table 36.19 mblen**

<table>
<thead>
<tr>
<th>s</th>
<th>const char *</th>
<th>The multibyte array to measure</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum size</td>
</tr>
</tbody>
</table>

**Remarks**

The `mblen()` function returns the length of the multibyte character pointed to by
`s`. It examines a maximum of `n` characters.

If `s` is a null pointer, the `mblen` function returns a nonzero or zero value
signifying whether multibyte encoding do or do not have state-dependent
encoding. If `s` is not a null pointer, the `mblen` function either returns 0 (if `s`
points to the null character), or returns the number of bytes that are contained in
the multibyte.

This function may not be implemented on all platforms.

**See Also**

“Locale Specification” on page 165
“mbtowc” on page 429

Convert a multibyte character array encoded as defined by the LC_CTYPE category of
the current locale to a wchar_t array.

```c
#include <stdlib.h>
size_t mbstowcs(wchar_t *pwcs,
    const char *s, size_t n);
```
Overview of stdlib.h

429

Remarks

The MSL C implementation of mbstowcs() converts a sequence of multibyte characters encoded as defined by the LC_CTYPE category of the current locale from the character array pointed to by s and stores not more than n of the corresponding Unicode characters into the wide character array pointed to by pwcs. No multibyte characters that follow a null character (which is converted into a null wide character) will be examined or converted.

If an invalidly encoded character is encountered, mbstowcs() returns the value (size_t)(-1). Otherwise mbstowcs() returns the number of elements of the array pointed to by pwcs modified, not including any terminating null wide character.

This function may not be implemented on all platforms.

See Also

“Locale Specification” on page 165
“wcstombs” on page 449

mbtowc

Translate a multibyte character, encoded as defined by the LC_CTYPE category of the current locale, to a wchar_t type.

#include <stdlib.h>

int mbtowc(wchar_t *pwc, const char *s, size_t n);
Overview of stdlib.h

Table 36.21 mbtowc

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwc</td>
<td>wchar_t *</td>
<td>The wide character destination</td>
</tr>
<tr>
<td>s</td>
<td>const char *</td>
<td>The string to convert</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum wide characters to convert</td>
</tr>
</tbody>
</table>

Remarks

If s is not a null pointer, the `mbtowc()` function examines at most n bytes starting with the byte pointed to by s to determine whether the next multibYTE character is a complete and valid encoding of a Unicode character encoded as defined by the LC_CTYPE category of the current locale. If so, and pwc is not a null pointer, it converts the multibYTE character, pointed to by s, to a character of type wchar_t, pointed to by pwc. `mbtowc()` returns -1 if n is zero and s is not a null pointer or if s points to an incomplete or invalid multibYTE encoding.

`mbtowc()` returns 0 if s is a null pointer or s points to a null character (\'\0\'). `mbtowc()` returns the number of bytes of s required to form a complete and valid multibYTE encoding of the Unicode character.

In no case will the value returned be greater than n or the value of the macro MB_CUR_MAX.

This function may not be implemented on all platforms.

See Also

“Locale Specification" on page 165
“mblen” on page 428
“wctomb” on page 450

__putenv

This function lets you enter an argument into the environment list.

```c
#include <stdlib.h>
char *__putenv(const char *name);
```
The function `_putenv()` returns NULL on success or minus one on failure to enter the environmental variable.
This function may not be implemented on all platforms.

**See Also**
- “getenv” on page 423
- “system” on page 446

### qsort

Sort an array.

```c
#include <stdlib.h>

void qsort(void *base, size_t nmemb, size_t size,
           int (*compare) (const void *, const void *))
```

**Remarks**

The `qsort()` function sorts an array using the quicksort algorithm. It sorts the array without displacing it; the array occupies the same memory it had before the call to `qsort()`. For example usage, see Listing 36.5.

The `base` argument is a pointer to the base of the array to be sorted.

The `nmemb` argument specifies the number of array elements to sort.

---

**Table 36.22 _putenv**

<table>
<thead>
<tr>
<th>name</th>
<th>const char *</th>
<th>The item to add to the environment list</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

**Table 36.23 qsort**

<table>
<thead>
<tr>
<th>base</th>
<th>void *</th>
<th>A pointer to the array to be sorted</th>
</tr>
</thead>
<tbody>
<tr>
<td>nmemb</td>
<td>size_t</td>
<td>The number of elements</td>
</tr>
<tr>
<td>size</td>
<td>size_t</td>
<td>The size of the elements</td>
</tr>
<tr>
<td>compare</td>
<td>void *</td>
<td>A pointer to a comparison function</td>
</tr>
</tbody>
</table>
Overview of stdlib.h

The `size` argument specifies the size of an array element. The `compare` argument is a pointer to a programmer-supplied compare function. The function takes two pointers to different array elements and compares them based on the key. If the two elements are equal, `compare` must return a zero. The `compare` function must return a negative number if the first element is less than the second. Likewise, the function must return a positive number if the first argument is greater than the second.

This function may not be implemented on all platforms.

**See Also**

“`bsearch` on page 413”

### rand

Generate a pseudo-random integer value.

```c
#include <stdlib.h>
int rand(void);
```

**Remarks**

A sequence of calls to the `rand()` function generates and returns a sequence of pseudo-random integer values from 0 to `RAND_MAX`. The `RAND_MAX` macro is defined in `stdlib.h`.

By seeding the random number generator using `srand()`, different random number sequences can be generated with `rand()`.

`rand()` returns a pseudo-random integer value between 0 and `RAND_MAX`. This function may not be implemented on all platforms.

**See Also**

“`srand` on page 435”

Listing 36.10 Example of `rand()` Usage

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
{
  int i;
  unsigned int seed;
```
# Overview of stdlib.h

### rand_r

Reentrant function to generate a pseudo-random integer value.

```c
#include <stdlib.h>
int rand_r(unsigned int *context);
```

### Table 36.24 rand_r

<table>
<thead>
<tr>
<th>context</th>
<th>unsigned int *</th>
<th>The context seed value</th>
</tr>
</thead>
</table>

### Remarks

The `rand_r()` function provides the same service as "rand" on page 432, yet it also combines the functionality of `srand()` as well. The result of `rand_r()`...
is equivalent to calling `srand()` with a context seed value, then calling `rand()`. The difference is that for `rand_r()`, the caller provides the storage for the context seed value.

This function may require extra library support.

This function may not be implemented on all platforms.

See Also

“rand” on page 432
“srand” on page 435

realloc

Change the size of an allocated block of heap memory.

```c
#include <stdlib.h>

void *realloc(void *ptr, size_t size);
```

<table>
<thead>
<tr>
<th>ptr</th>
<th>void *</th>
<th>A pointer to an allocated block of memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>size_t</td>
<td>The size of memory to reallocate</td>
</tr>
</tbody>
</table>

Remarks

The `realloc()` function changes the size of the memory block pointed to by `ptr` to `size` bytes. The `size` argument can have a value smaller or larger than the current size of the block `ptr` points to. The `ptr` argument should be a value assigned by the memory allocation functions `calloc()` and `malloc()`. For example usage, see Listing 36.6.

If `size` is 0, the memory block pointed to by `ptr` is released. If `ptr` is a null pointer, `realloc()` allocates `size` bytes.

The old contents of the memory block are preserved in the new block if the new block is larger than the old. If the new block is smaller, the extra bytes are cut from the end of the old block.

`realloc()` returns a pointer to the new block if it is successful and `size` is greater than 0. `realloc()` returns a null pointer if it fails or `size` is 0.

This function may not be implemented on all platforms.
stdlib.h
Overview of stdlib.h

"vec_realloc" on page 448
"calloc" on page 417
"free" on page 422
"malloc" on page 427

srand

Sets the seed for the pseudo-random number generator.
#include <stdlib.h>
void srand(unsigned int start);

Remarks
The srand() function sets the seed for the pseudo-random number generator to start. Further calls of srand() with the same seed value produces the same sequence of random numbers. For example usage, see Listing 36.10.
This function may not be implemented on all platforms.

See Also
"rand" on page 432

strtod

Character array conversion to floating point value of type double.
#include <stdlib.h>
double strtod(const char *nptr, char **endptr);

Table 36.26 srand

<table>
<thead>
<tr>
<th>seed</th>
<th>unsigned int</th>
<th>A seeding value</th>
</tr>
</thead>
</table>

See Also
"rand" on page 432
The `strtod` function converts a character array, pointed to by `nptr`, to a floating point value of type `double`. The character array can be in either decimal or hexadecimal floating point constant notation (e.g. `103.578`, `1.03578e+02`, or `0x1.9efef9p+6`).

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to a value of type `double`.

In other than the “C” locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

`strtod()` returns a floating point value of type `double`. If `nptr` cannot be converted to an expressible double value, `strtod()` returns `HUGE_VAL`, defined in `math.h`, and sets `errno` to `ERANGE`.

This function may not be implemented on all platforms.

### Remarks

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>A Null terminated array to convert</th>

### Listing 36.11 Example of `strtod()` and `strtold()` Usage

```c
#include <stdlib.h>
#include <stdio.h>

int main(void)
```

---

436  MSL C Reference Version 10
Overview of stdlib.h

stdlib.h

Stdlib.h functions:

- strtol
- strtoul
- strtoll
- strtold

Character array conversion to floating point values of type `double`, `long double`, and `long long double`.

```c
#include <stdlib.h>

float strtof(const char *nptr, char **endptr);
```

Output:

Value = 103.578000 remainder of string = | 777|
Value = 103.578000 remainder of string = | 777|
Value = 103.748997 remainder of string = | 777|
Value = 103.578000 remainder of string = | 777|
Value = 103.578000 remainder of string = | 777|
Value = 103.748997 remainder of string = | 777|

---

```c
{  
double f;
long double lf;
static char sf1[] = "103.578 777";
static char sf2[] = "1.03578e+02 777";
static char sf3[] = "0x1.9efef9p+6 777";
char *endptr;

f = strtod(sf1, &endptr);
printf("Value = %f remainder of string = |%s|\n", f, endptr);

f = strtod(sf2, &endptr);
printf("Value = %f remainder of string = |%s|\n", f, endptr);

f = strtod(sf3, &endptr);
printf("Value = %f remainder of string = |%s|\n", f, endptr);

lf = strtold(sf1, &endptr);
printf("Value = %lf remainder of string = |%s|\n", lf, endptr);

lf = strtold(sf2, &endptr);
printf("Value = %lf remainder of string = |%s|\n", lf, endptr);

lf = strtold(sf3, &endptr);
printf("Value = %lf remainder of string = |%s|\n", lf, endptr);

return 0;
}  
```
The `strtof()` function converts a character array, pointed to by `nptr`, to a floating point value of type `float`. The character array can be in either decimal or hexadecimal floating point constant notation (e.g. 103.578, 1.03578e+02, or 0x1.9efef9p+6).

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to a value of type `float`.

In other than the “C” locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

`strtof()` returns a floating point value of type `float`. If `nptr` cannot be converted to an expressible float value, `strtof()` returns `HUGE_VAL`, defined in `math.h`, and sets `errno` to `ERANGE`.

This function may not be implemented on all platforms.

### See Also

- “`strtol`” on page 438
- “`strtod`” on page 435

### `strtol`

Character array conversion to an integral value of type `long int`.

```c
#include <stdlib.h>

long int strtol(const char *nptr, char **endptr, int base);
```
Overview of stdlib.h

Remarks

The `strtol()` function converts a character array, pointed to by `nptr`, expected to represent an integer expressed in radix base, to an integer value of type `long int`. If the sequence pointed to by `nptr` is a minus sign, the value resulting from the conversion is negated in the return value.

The `base` argument in `strtol()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If `base` is 0, then `strtol()` converts the character array based on its format. Character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to a long int value.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

`strtol()` returns an integer value of type `long int`. If the converted value is less than `LONG_MIN`, `strtol()` returns `LONG_MIN` and sets `errno` to `ERANGE`. If the converted value is greater than `LONG_MAX`, `strtol()` returns `LONG_MAX` and sets `errno` to `ERANGE`. The `LONG_MIN` and `LONG_MAX` macros are defined in `limits.h`.

This function may not be implemented on all platforms.

Listing 36.12  Example of strtol(), strtoul(), strtoll(), and strtoull() Usage

```c
#include <stdlib.h>
#include <stdio.h>
int main(void)
{
    long int i;
    unsigned long int j;
    long long int lli;
    unsigned long long ull;
    static char si[] = "4733 777";
    static char sb[] = "0x10*****";
    static char sc[] = "66E00M???";
    static char sd[] = "Q0N5OM abcd";

    char *endptr;
    i = strtol(si, &endptr, 10);
    printf("%ld remainder of string = |%s|\n", i, endptr);
    i = strtol(si, &endptr, 8);
    printf("%ld remainder of string = |%s|\n", i, endptr);
    j = strtoul(sb, &endptr, 0);
    printf("%lu remainder of string = |%s|\n", j, endptr);
    j = strtoul(sb, &endptr, 16);
    printf("%lu remainder of string = |%s|\n", j, endptr);
    lli = strtoll(sc, &endptr, 36);
    printf("%lld remainder of string = |%s|\n", lli, endptr);
    ull = strtoull(sd, &endptr, 27);
    printf("%llu remainder of string = |%s|\n", ull, endptr);
    return 0;
}
```

Output:
4733 remainder of string = | 777|
2523 remainder of string = | 777|
16 remainder of string = |*****|
16 remainder of string = |*****|
373527958 remainder of string = |???|
373527958 remainder of string = | abcd|
**Overview of stdlib.h**

---

**strtol**

Character array conversion to floating point value of type long double.

```c
#include <stdlib.h>
long double strtol(const char *nptr, char **endptr);
```

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>A Null terminated array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>char **</td>
<td>A pointer to a position in nptr that follows the converted part</td>
</tr>
</tbody>
</table>

**Remarks**

The **strtol**() function converts a character array, pointed to by `nptr`, to a floating point value of type long double. The character array can be in either decimal or hexadecimal floating point constant notation (e.g. `103.578`, `1.03578e+02`, or `0x1.9efef9p+6`). For example usage, see **Listing 36.11**.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to a value of type double.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

**strtol**() returns a floating point value of type `long double`. If `nptr` cannot be converted to an expressible double value, **strtol**() returns `HUGE_VAL`, defined in `math.h`, and sets `errno` to `ERANGE`.

This function may not be implemented on all platforms.

Overview of stdlib.h

strtol
Character array conversion to integer value of type long long int.

#include <stdlib.h>

(unsigned long int) strtol(const char *nptr,
  char **endptr, int base);

Table 36.31 strtol

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>A Null terminated array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>char **</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

Remarks
The strtol() function converts a character array, pointed to by nptr, expected to represent an integer expressed in radix base to an integer value of type long long int. If the sequence pointed to by nptr is a minus sign, the value resulting from the conversion is negated in the return value. For example usage, see Listing 36.12.

The base argument in strtol() specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then strtol() converts the character array based on its format. Character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the endptr argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by nptr. This position marks the first character that is not convertible to a long int value.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.
Overview of stdlib.h

strtol() returns an unsigned integer value of type `long long int`. If the converted value is less than `LLONG_MIN`, `strtol()` returns `LLONG_MIN` and sets `errno` to `ERANGE`. If the converted value is greater than `LLONG_MAX`, `strtol()` returns `LLONG_MAX` and sets `errno` to `ERANGE`. The `LLONG_MIN` and `LLONG_MAX` macros are defined in `limits.h`

This function may not be implemented on all platforms.

**strtof**

Character array conversion to integer value of type unsigned long int.

```
#include <stdlib.h>

unsigned long int strtol(const char *nptr,
               char **endptr, int base);
```

Table 36.32  `strtol`

<table>
<thead>
<tr>
<th>nptr</th>
<th>const char *</th>
<th>A Null terminated array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>char **</td>
<td>A pointer to a position in nptry that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

Remarks

The `strtol()` function converts a character array, pointed to by `nptr`, to an integer value of type `unsigned long int`, in base. If the sequence pointed to by `nptr` is a minus sign, the value resulting from the conversion is negated in the return value. For example usage, see Listing 36.12.
The base argument in `strtoul()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then `strtol()` and `strtoul()` convert the character array based on its format. Character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to the functions' respective types.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

The function `strtoul()` returns an unsigned integer value of type `unsigned long int` (which may have a negative sign if the original string was negative.) If the converted value is greater than `ULONG_MAX`, `strtoul()` returns `ULONG_MAX` and sets `errno` to `ERANGE`. The `ULONG_MAX` macro is defined in `limits.h`.

This function may not be implemented on all platforms.

**strtoull**

Character array conversion to integer value of type `unsigned long long int`.

```
#include <stdlib.h>

unsigned long long int strtoull(const char *nptr, char **endptr, int base);
```
stdlib.h

Overview of stdlib.h

Table 36.33  strtoul

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nptr</td>
<td>const char *</td>
<td>A Null terminated array to convert</td>
</tr>
<tr>
<td>endptr</td>
<td>char **</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

Remarks

The `strtoull()` function converts a character array, pointed to by `nptr`, expected to represent an integer expressed in radix base to an integer value of type `unsigned long long int`. If the sequence pointed to by `nptr` is a minus sign, the value resulting from the conversion is negated in the return value. For example usage, see Listing 36.12.

The base argument in `strtoull()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then `strtoull()` converts the character array based on its format. Character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the character array pointed to by `nptr`. This position marks the first character that is not convertible to a long int value.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

The function `strtoull()` returns an unsigned integer value of type `unsigned long long int` (which may have a negative sign if the original string was negative.) If the converted value is greater than `ULLONG_MAX`, `strtoull()` returns `ULLONG_MAX` and sets `errno` to `ERANGE`. The `ULLONG_MAX` macro is defined in `limits.h`.

This function may not be implemented on all platforms.

“`strtol`” on page 443
**stdlib.h**

*Overview of stdlib.h*

**“strtol” on page 442**

---

**system**

Environment list assignment.

#include <stdlib.h>

int system(const char *string);

**NOTE**

The `system()` function is an empty function on MacOS.

`system()` returns zero if successful or minus one on failure.

This function may not be implemented on all platforms.

**See Also**

“`getenv` on page 423”

---

**vec_calloc**

Clears and allocates memory on a 16 byte alignment.

#include <stdlib.h>

void * vec_calloc(size_t nmemb, size_t size);

**Table 36.34  vec_calloc**

<table>
<thead>
<tr>
<th>nmemb</th>
<th>size_t</th>
<th>Number of elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>size_t</td>
<td>The size of the elements</td>
</tr>
</tbody>
</table>

**Remarks**

The `vec_calloc()` function allocates contiguous space for `nmemb` elements of `size`. The space is initialized with zeroes.
vec_calloc() returns a pointer to the first byte of the memory area allocated. vec_calloc() returns a null pointer (NULL) if no space could be allocated. This function may not be implemented on all platforms.

See Also
“calloc” on page 417
“free” on page 447
“vec_malloc” on page 448
“vec_realloc” on page 448

vec_free

Frees memory allocated by vec_malloc, vec_calloc and vec_realloc

#include <stdlib.h>

void vec_free(void *ptr);

Table 36.36 vec_free

<table>
<thead>
<tr>
<th>ptr</th>
<th>void *</th>
<th>A pointer to the allocated memory</th>
</tr>
</thead>
</table>

Remarks
The vec_free() function releases a previously allocated memory block, pointed to by ptr, to the heap. The ptr argument should hold an address returned by the memory allocation functions vec_calloc(), vec_malloc(), or vec_realloc(). Once the memory block ptr points to has been released, it is no longer valid. The ptr variable should not be used to reference memory again until it is assigned a value from the memory allocation functions.

There is no return.
This function may not be implemented on all platforms.

See Also
“free” on page 422
“vec_calloc” on page 446
“vec_malloc” on page 448
“vec_realloc” on page 448
 vec_malloc

Allocates memory on a 16 byte alignment.

#include <stdlib.h>

void * vec_malloc(size_t size);

Table 36.37  vec_malloc

<table>
<thead>
<tr>
<th>size</th>
<th>size_t</th>
<th>The size in bytes of the allocation</th>
</tr>
</thead>
</table>

Remarks

The vec_malloc() function allocates a block of contiguous heap memory size bytes large.

vec_malloc() returns a pointer to the first byte of the allocated block if it is successful and return a null pointer if it fails.

This function may not be implemented on all platforms.

See Also

“malloc” on page 427
“vec_free” on page 447
“vec_calloc” on page 446
“vec_realloc” on page 448

 vec_realloc

Reallocates memory on a 16 byte alignment.

#include <stdlib.h>

void * vec_realloc(void * ptr, size_t size);
vec_realloc() returns a pointer to the new block if it is successful and size is greater than 0. realloc() returns a null pointer if it fails or size is 0. This function may not be implemented on all platforms.

See Also
“realloc” on page 434
“vec_free” on page 447
“vec_calloc” on page 446
“vec_malloc” on page 448

wcstombs
Translate a wchar_t type character array to a multibyte character array encoded as defined by the LC_CTYPE category of the current locale.

#include <stdlib.h>
size_t wcstombs(char *s, const wchar_t *pwcs, size_t n);

Table 36.39 wcstombs

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>A multibyte string buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwcs</td>
<td>const wchar_t *</td>
<td>A pointer to a wide character string to be converted</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to convert</td>
</tr>
</tbody>
</table>
Remarks

The MSL C implementation of the `wcstombs()` function converts a character array containing `wchar_t` type Unicode characters to a character array containing multibyte characters encoded as defined by the LC_CTYPE category of the current locale. The `wchar_t` type is defined in `stddef.h`. Each wide character is converted as if by a call to the `wctomb()` function. No more than `n` bytes will be modified in the array pointed to by `s`.

The function terminates prematurely if a null character is reached.

`wcstombs()` returns the number of bytes modified in the character array pointed to by `s`, not including a terminating null character, if any.

This function may not be implemented on all platforms.

See Also

“Locale Specification” on page 165, “mbstowcs” on page 428

wctomb

Translate a `wchar_t` type to a multibyte character encoded as defined by the LC_CTYPE category of the current locale.

```c
#include <stdlib.h>
int wctomb(char *s, wchar_t wchar);
```

Table 36.40 wctomb

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>A multibyte string buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>wchar</td>
<td>wchar_t</td>
<td>A wide character to convert</td>
</tr>
</tbody>
</table>

Remarks

The MSL C implementation of the `wctomb()` function converts a `wchar_t` type Unicode character to a multibyte character encoded as defined by the LC_CTYPE category of the current locale. If `s` is not a null pointer, the encoded multibyte character is stored in the array whose first element is pointed to by `s`. At most `MB_CUR_MAX` characters are stored. If `wchar` is a null wide character, a null byte is stored.

`wctomb()` returns 1 if `s` is not null and returns 0, otherwise it returns the number of bytes that are contained in the multibyte character stored in the array whose first element is pointed to by `s`. 
This function may not be implemented on all platforms.

Non Standard <stdlib.h> Functions

Various non standard functions are included in the header <stdlib.h> for legacy source code and compatibility with operating system frameworks and application programming interfaces.

- For the function `gcvt`, see “gcvt” on page 85 for a full description.
- For the function `itoa`, see “itoa” on page 87 for a full description.
- For the function `itow`, see “itow” on page 88 for a full description.
- For the function `ltoa`, see “ltoa” on page 88 for a full description.
- For the function `makepath`, see “makepath” on page 90 for a full description.
- For the function `splitpath`, see “splitpath” on page 92 for a full description.
- For the function `ultoa`, see “ultoa” on page 105 for a full description.
- For the function `wtoi`, see “wtoi” on page 115 for a full description.
stdlib.h
Non Standard <stdlib.h> Functions
The `string.h` header file provides functions for comparing, copying, concatenating, and searching character arrays and arrays of larger items.

### Overview of string.h

The `string.h` header file provides multiple functions with and without length limits, with and without case sensitivity for comparing, copying, concatenating, and searching character arrays and generic arrays of larger items in memory.

The function naming convention used in `string.h` determines the type of data structure(s) a function manipulates.

A function with an `str` prefix operates on character arrays terminated with a null character (`\0`). The `str` functions are as follows:

- "`strcat` on page 459" concatenates strings.
- "`strchr` on page 460" searches by character.
- "`strcmp` on page 461" compares strings.
- "`strcpy` on page 464" copies strings.
- "`strcoll` on page 462" compares string lexicographically.
- "`strcspn` on page 465" finds a substring in a string.
- "`strerror` on page 466" retrieves an error message from an `errno` variable.
- "`strerror_r` on page 467" translates an error number into an error message (re-entrant version of `strerror`).
- "`strlen` on page 468" returns string’s length.
- "`strpbrk` on page 473" looks for an occurrence of a character from one string in another.
- "`strrchr` on page 474" searches a string for a character.
- "`strspn` on page 475" searches for a character not in one string in another.
- "`strstr` on page 476" searches a string for a string.
- "`strtok` on page 477" retrieves the next token or substring.
- "`strxfrm` on page 479" transforms a string to a locale.
A function with an `strn` prefix operates on character arrays of a length specified as a function argument. The `strn` functions are:

- “strncat” on page 469 concatenates strings with length specified.
- “strncmp” on page 470 compares strings with length specified.
- “strncpy” on page 472 copies a specified number of characters.

A function with a `mem` prefix operates on arrays of items or contiguous blocks of memory. The size of the array or block of memory is specified as a function argument. The `mem` functions are:

- “memchr” on page 454 searches a memory block for a character.
- “memcmp” on page 456 compares a memory block.
- “memcpy” on page 457 copies a memory block.
- “memmove” on page 458 moves a memory block.
- “memset” on page 458 sets a value for a memory block.

The nonstandard functions with a ‘stri’ prefix operate on strings ignoring case.

---

### memchr

Search for an occurrence of a character.

```c
#include <string.h>

void *memchr(const void *s, int c, size_t n);
```

<table>
<thead>
<tr>
<th>Table 37.1 memchr</th>
<th>s</th>
<th>const void *</th>
<th>The memory to search</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>int</td>
<td>The char to search for</td>
<td></td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to search</td>
<td></td>
</tr>
</tbody>
</table>

**Remarks**

The `memchr` () function looks for the first occurrence of `c` in the first `n` characters of the memory area pointed to by `s`.

`memchr` () returns a pointer to the found character, or a null pointer (NULL) if `c` cannot be found.

This function may not be implemented on all platforms.
#include <string.h>
#include <stdio.h>

define ARRAYSIZE 100

int main(void)
{
    // s1 must by same length as s2 for this example!
    static char s1[ARRAYSIZE] = "laugh* giggle 231!";
    static char s2[ARRAYSIZE] = "grunt sigh# snort!";
    char dest[ARRAYSIZE];
    char *strptr;
    int len1, len2, lendest;

    // Clear destination string using memset()
    memset( (char *)dest, '\0', ARRAYSIZE);

    // String lengths are needed by the mem functions
    // Add 1 to include the terminating '\0' character
    len1 = strlen(s1) + 1;
    len2 = strlen(s2) + 1;
    lendest = strlen(dest) + 1;

    printf(" s1=%s
 s2=%s
 dest=%s
", s1, s2, dest);

    if (memcmp( (char *)s1, (char *)s2, len1) > 0)
        memcpy( (char *)dest, (char *)s1, len1);
    else
        memcpy( (char *)dest, (char *)s2, len2);

    printf(" s1=%s
 s2=%s
 dest=%s
", s1, s2, dest);

    // copy s1 onto itself using memchr() and memmove()
    strptr = (char *)memchr( (char *)s1, '*', len1);
    memmove( (char *)strptr, (char *)s1, len1);

    printf(" s1=%s
 s2=%s
 dest=%s
", s1, s2, dest);
}

Listing 37.1  Example of memchr() Usage
string.h
Overview of string.h

Output:
s1=laugh* giggle 231!
s2=grunt sigh# snort!
dest=

s1=laugh* giggle 231!
s2=grunt sigh# snort!
dest=laugh* giggle 231!

s1=laugh laugh* giggle 231!
s2=grunt sigh# snort!
dest=laugh* giggle 231!

memcmp

Compare two blocks of memory.
#include <string.h>
int memcmp(const void *s1,
    const void *s2, size_t n);

Table 37.2 memcmp

<table>
<thead>
<tr>
<th>s1</th>
<th>const void *</th>
<th>The memory to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const void *</td>
<td>The comparison memory</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to compare</td>
</tr>
</tbody>
</table>

Remarks
The memcmp() function compares the first n characters of s1 to s2 one character at a time. For example usage, see Listing 37.1.

memcmp() returns a zero if all n characters pointed to by s1 and s2 are equal.
memcmp() returns a negative value if the first non-matching character pointed to by s1 is less than the character pointed to by s2.
memcmp() returns a positive value if the first non-matching character pointed to by s1 is greater than the character pointed to by s2.
This function may not be implemented on all platforms.
See Also

“strcmp” on page 461
“strncmp” on page 470

memcpy

Copy a contiguous memory block.

#include <string.h>
void *memcpy(void *dest,
            const void *source, size_t n);

Table 37.3  memcpy

<table>
<thead>
<tr>
<th>dest</th>
<th>void *</th>
<th>The destination memory</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>const void *</td>
<td>The source to copy</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to copy</td>
</tr>
</tbody>
</table>

Remarks

The memcpy() function copies the first n characters from the item pointed to by source to the item pointed to by dest. The behavior of memcpy() is undefined if the areas pointed to by dest and source overlap. The memmove() function reliably copies overlapping memory blocks. For example usage, see Listing 37.1.

memcpy() returns the value of dest.

This function may not be implemented on all platforms.

See Also

“memmove” on page 458
“strcpy” on page 464
“strncpy” on page 472
string.h
Overview of string.h

memmove

Copy an overlapping contiguous memory block.

#include <string.h>
void *memmove(void *dest, const void *source, size_t n);

Table 37.4 memmove

<table>
<thead>
<tr>
<th>dest</th>
<th>void *</th>
<th>The Memory destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>const void *</td>
<td>The source to be moved</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to move</td>
</tr>
</tbody>
</table>

Remarks

The memmove() function copies the first n characters of the item pointed to by source to the item pointed to by dest. For example usage, see Listing 37.1. Unlike memcpy(), the memmove() function safely copies overlapping memory blocks.

memmove() returns the value of dest.

This function may not be implemented on all platforms.

See Also

“memcpy” on page 457
“memset” on page 458
“strcpy” on page 464
“strncpy” on page 472

memset

Set the contents of a block of memory to the value of a single character.

#include <string.h>
void *memset(void *dest, int c, size_t n);
The `memset()` function assigns `c` to the first `n` characters of the item pointed to by `dest`. For example usage, see Listing 37.1.

`memset()` returns the value of `dest`.

This function may not be implemented on all platforms.

### strcat

Concatenate two character arrays.

```c
#include <string.h>

char *strcat(char *dest, const char *source);
```

#### Table 37.6  strcat

<table>
<thead>
<tr>
<th>dest</th>
<th>char *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>const char *</td>
<td></td>
</tr>
</tbody>
</table>

**Remarks**

The `strcat()` function appends a copy of the character array pointed to by `source` to the end of the character array pointed to by `dest`. The `dest` and `source` arguments must both point to null terminated character arrays. `strcat()` null terminates the resulting character array.

`strcat()` returns the value of `dest`.

This function may not be implemented on all platforms.

**See Also**

“strcpy” on page 464
Listing 37.2 Example of strcat() Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    char s1[100] = "The quick brown fox ";
    static char s2[] = "jumped over the lazy dog."

    strcat(s1, s2);
    puts(s1);

    return 0;
}
```

Output:
The quick brown fox jumped over the lazy dog.

strchr

Search for an occurrence of a character.

```c
#include <string.h>
char *strchr(const char *s, int c);
```

Table 37.7 strchr

<table>
<thead>
<tr>
<th>s</th>
<th>const char *</th>
<th>The string to search</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>int</td>
<td>The char to search for</td>
</tr>
</tbody>
</table>

Remarks

The strchr() function searches for the first occurrence of the character c in the character array pointed to by s. The s argument must point to a null terminated character array.

strchr() returns a pointer to the successfully located character. If it fails, strchr() returns a null pointer (NULL).

This function may not be implemented on all platforms.
Overview of string.h

See Also

“memchr” on page 454
“strchr” on page 474

Listing 37.3  Example of strchr() Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s[] = "tree * tomato eggplant garlic";
    char *strptr;

    strptr = strchr(s, '*');
    puts(strptr);
    return 0;
}
```

Output:
* tomato eggplant garlic

strcmp

Compare two character arrays.
```
#include <string.h>
int strcmp(const char *s1, const char *s2);
```

Remarks

The `strcmp()` function compares the character array pointed to by `s1` to the character array pointed to by `s2`. Both `s1` and `s2` must point to null terminated character arrays.
**Overview of string.h**

`strcmp()` returns a zero if `s1` and `s2` are equal, a negative value if `s1` is less than `s2`, and a positive value if `s1` is greater than `s2.

This function may not be implemented on all platforms.

**See Also**

- “memcmp” on page 456
- “strcoll” on page 462
- “strncmp” on page 470

**Listing 37.4 Example of strcmp() Usage**

```c
#include <string.h>
#include <stdio.h>

int main (void)
{
    static char s1[] = "butter", s2[] = "olive oil";
    char dest[20];

    if (strcmp(s1, s2) < 0)
        strcpy(dest, s2);
    else
        strcpy(dest, s1);

    printf(" s1=%s\n s2=%s\n dest=%s\n", s1, s2, dest);

    return 0;
}
```

Output:

- s1=butter
- s2=olive oil
- dest=olive oil

**strcoll**

Compare two character arrays according to locale.

```c
#include <string.h>

int strcoll(const char *s1, const char *s2);
```
Remarks

The `strcoll()` function compares two character arrays based on the `LC_COLLATE` component of the current locale.

The MSL C implementation of `strcoll()` compares two character arrays using `strcmp()`. It is included in the string library to conform to the ANSI C Standard Library specification.

`strcoll()` returns zero if `s1` is equal to `s2`, a negative value if `s1` is less than `s2`, and a positive value if `s1` is greater than `s2`.

This function may not be implemented on all platforms.

See Also

- “Locale Specification” on page 165
- “memcmp” on page 456
- “strcmp” on page 461
- “strncmp” on page 470,

Listing 37.5 Example of `strcoll()` Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s1[] = "aardvark", s2[] = "xylophone";
    int result;
    result = strcoll(s1, s2);
    if (result < 1)
        printf("%s is less than %s\n", s1, s2);
    else
        printf("%s is equal or greater than %s\n", s1, s2);
    return 0;
}
```
string.h
Overview of string.h

Output:
aardvark is less than xylophone

strcpy

Copy one character array to another.
#include <string.h>
char *strcpy(char *dest, const char *source);

Remarks

The strcpy() function copies the character array pointed to by source to the
character array pointed to dest. The source argument must point to a null
terminated character array. The resulting character array at dest is null terminated
as well.
If the arrays pointed to by dest and source overlap, the operation of
strcpy() is undefined.
strcpy() returns the value of dest.
This function may not be implemented on all platforms.

See Also

“memcpy” on page 457
“memmove” on page 458
“strncpy” on page 472

Listing 37.6  Example of strcpy() Usage

#include <string.h>
#include <stdio.h>

int main(void)
{

char d[30] = "";
static char s[] = "CodeWarrior";

printf(" s=%s\n d=%s\n", s, d);
strcpy(d, s);
printf(" s=%s\n d=%s\n", s, d);

return 0;
}

Output:
s=CodeWarrior
d=
s=CodeWarrior
d=CodeWarrior

strcspn

Find the first character in one string that is in another.

#include <string.h>
size_t strcspn(const char *s1, const char *s2);

Table 37.11 strcspn

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The string to count</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const char *</td>
<td>The list string of character to search for</td>
</tr>
</tbody>
</table>

Remarks

The strcspn() function finds the first character in the null terminated character string s1 that is also in the null terminated string s2. For this purpose, the null terminators are considered part of the strings. The function starts examining characters at the beginning of s1 and continues searching until a character in s1 matches a character in s2.

strcspn() returns the index of the first character in s1 that matches a character in s2.

This function may not be implemented on all platforms.
string.h
Overview of string.h

“strpbrk” on page 473
“strspn” on page 475

Listing 37.7 Example of strcspn() Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s1[] = "chocolate *cinnamon* 2 ginger";
    static char s2[] = "1234*";
    int i;

    printf(" s1 = %s
             s2 = %s
", s1, s2);
    i = strcspn(s1, s2);
    printf("Index returned by strcspn %d
           Indexed character  = %c
", i);
    return 0;
}
```

Output:
s1 = chocolate *cinnamon* 2 ginger
s2 = 1234*
Index returned by strcspn 10
Indexed character  = *

---

strerror

Translate an error number into an error message.

```c
#include <string.h>
char *strerror(int errnum);
```

Table 37.12 strerror

<table>
<thead>
<tr>
<th>errnum</th>
<th>int</th>
<th>The error number to be translated.</th>
</tr>
</thead>
</table>

---
Remarks

The `strerror()` function returns a pointer to a null terminated character array that contains an error message. The array pointed to may not be modified by the program, but may be overwritten by a subsequent call to the `strerror` function.

`strerror()` returns a pointer to a null terminated character array containing an error message that corresponds to `errnum`. Although normally the integer value in `errnum` will come from the global variable `errno`, `strerror()` will provide a message translation for any value of type int.

This function may not be implemented on all platforms.

Listing 37.8 Example of `strerror()` Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    puts(strerror(8));
    puts(strerror(ESIGPARM));

    return 0;
}
```

Output:
unknown error (8)
Signal Error

`strerror_r`

Translate an error number into an error message.

```c
#include <string.h>

int strerror_r(int errnum, char *str, size_t bufflen);
```

Table 37.13 `strerror_r`

<table>
<thead>
<tr>
<th>errnum</th>
<th>int</th>
<th>The error number to be translated.</th>
</tr>
</thead>
</table>

`strerror_r`
**Remarks**

The `strerror_r()` function provides the same service as "`strerror` on page 466" but is reentrant. The difference is that `strerror()` would return a pointer to the error string, and that pointer was internal to the library implementation. For `strerror_r()`, the caller provides the storage `str` and the size of the storage `bufflen`.

On a successful call to `strerror_r()`, the function result is zero. If any error occurs, the function result is an error code.

This function may require extra library support.

This function may not be implemented on all platforms.

**See Also**

"`strerror` on page 466"

---

**strlen**

Compute the length of a character array.

```c
#include <string.h>

size_t strlen(const char *s);
```

**Remarks**

The `strlen()` function computes the number of characters in a null terminated character array pointed to by `s`. The null character (`'\0'`) is not added to the character count.

`strlen()` returns the number of characters in a character array not including the terminating null character.
# Overview of string.h

This function may not be implemented on all platforms.

## Listing 37.9 Example of strlen() Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s[] = "antidisestablishmentarianism";
    printf("The length of %s is %ld.\n", s, strlen(s));
    return 0;
}
```

Output:
The length of antidisestablishmentarianism is 28.

## strncat

Append a specified number of characters to a character array.

```c
#include <string.h>
char *strncat(char *dest, const char *source, size_t n);
```

<table>
<thead>
<tr>
<th>dest</th>
<th>char *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>const char *</td>
<td>The source to append</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to append</td>
</tr>
</tbody>
</table>

**Remarks**

The `strncat()` function appends a maximum of `n` characters from the character array pointed to by `source` to the character array pointed to by `dest`. The `dest` argument must point to a null terminated character array. The `source` argument does not necessarily have to point to a null terminated character array.
string.h
Overview of string.h

If a null character is reached in source before n characters have been appended, strncat() stops.
When done, strncat() terminates dest with a null character ('\0').
strncat() returns the value of dest.
This function may not be implemented on all platforms.

See Also
“strcat” on page 459

Listing 37.10 Example of strncat() Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s1[100] = "abcdefghijklmnopqrstuv";
    static char s2[] = "wxyz0123456789";

    strncat(s1, s2, 4);
    puts(s1);

    return 0;
}
```

Output:
abcdefghijklmnopqrstuvwxyz

strncmp

Compare a specified number of characters.

```
#include <string.h>

int strncmp(const char *s1, const char *s2, size_t n);
```

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The string to compare</th>
</tr>
</thead>
</table>

strncmp
Overview of string.h

The `strncpy()` function compares \( n \) characters of the character array pointed to by \( s_1 \) to \( n \) characters of the character array pointed to by \( s_2 \). Neither \( s_1 \) nor \( s_2 \) needs to be null terminated character arrays.

The function stops prematurely if it reaches a null character before \( n \) characters have been compared.

`strncpy()` returns a zero if the first \( n \) characters of \( s_1 \) and \( s_2 \) are equal, a negative value if \( s_1 \) is less than \( s_2 \), and a positive value if \( s_1 \) is greater than \( s_2 \).

This function may not be implemented on all platforms.

**Remarks**

**See Also**

- “memcmp” on page 456
- “strcmp” on page 461

**Listing 37.11  Example of `strncpy()` Usage**

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s1[] = "12345anchor", s2[] = "12345zebra";

    if (strncpy(s1, s2, 5) == 0)
        printf("%s is equal to %s\n", s1, s2);
    else
        printf("%s is not equal to %s\n", s1, s2);

    return 0;
}
```

Output:

12345anchor is equal to 12345zebra
string.h
Overview of string.h

strncpy

Copy a specified number of characters.

#include <string.h>
char *strncpy(char *dest, const char *source, size_t n);

Table 37.17  strncpy

<table>
<thead>
<tr>
<th>dest</th>
<th>char *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>const char *</td>
<td>The source to copy</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to copy</td>
</tr>
</tbody>
</table>

Remarks

The strncpy() function copies a maximum of n characters from the character array pointed to by source to the character array pointed to by dest. Neither dest nor source need necessarily point to null terminated character arrays. Also, dest and source must not overlap.

If a null character (\'\0\') is reached in source before n characters have been copied, strncpy() continues padding dest with null characters until n characters have been added to dest.

The function does not terminate dest with a null character if n characters are copied from source before reaching a null character.

strncpy() returns the value of dest.

This function may not be implemented on all platforms.

See Also

“memmove” on page 458
“strcpy” on page 464

Listing 37.12  Example of strncpy Usage

#include <string.h>
#include <stdio.h>

int main(void)
```
{ 
    char d[50];
    static char s[] = "123456789ABCDEFG";
    strncpy(d, s, 9);
    puts(d);
    return 0;
}
```

Output:
123456789

**strpbrk**

Look for the first occurrence of any one of an array of characters in another.

```c
#include <string.h>
char *strpbrk(const char *s1, const char *s2);
```

**Table 37.18 strpbrk**

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The string being searched</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const char *</td>
<td>A list of characters to search for</td>
</tr>
</tbody>
</table>

**Remarks**

The `strpbrk()` function searches the character array pointed to by `s1` for the first occurrence of a character in the character array pointed to by `s2`.

Both `s1` and `s2` must point to null terminated character arrays.

`strpbrk()` returns a pointer to the first character in `s1` that matches any character in `s2`, and returns a null pointer (NULL) if no match was found.

This function may not be implemented on all platforms.

**See Also**

“`strcspn`” on page 465
string.h
Overview of string.h

Listing 37.13  Example of strpbrk Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s1[] = "orange banana pineapple *plum";
    static char s2[] = "**#$";
    puts(strpbrk(s1, s2));
    return 0;
}
```

Output:
*plum

strrchr

Searches a string for the last occurrence of a character.

```c
#include <string.h>
char *strrchr(const char *s, int c);
```

Table 37.19  strrchr

<table>
<thead>
<tr>
<th>s</th>
<th>const char *</th>
<th>The string to search</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>int</td>
<td>A character to search for</td>
</tr>
</tbody>
</table>

Remarks

The `strrchr()` function searches for the last occurrence of `c` in the character array pointed to by `s`. The `s` argument must point to a null terminated character array.

`strrchr()` returns a pointer to the character found or returns a null pointer (NULL) if it fails.

This function may not be implemented on all platforms.
### strspn

Find the first character in one string that is not in another.

```c
#include <string.h>
size_t strspn(const char *s1, const char *s2);
```

#### Table 37.20  strspn

<table>
<thead>
<tr>
<th>s1</th>
<th>const char *</th>
<th>The string to search</th>
</tr>
</thead>
<tbody>
<tr>
<td>s2</td>
<td>const char *</td>
<td>A list of characters to look for</td>
</tr>
</tbody>
</table>

#### Remarks

The `strspn()` function finds the first character in the null terminated character string `s1` that is not in the null terminated string `s2`. The function starts examining characters at the beginning of `s1` and continues searching until a character in `s1` does not match any character in `s2`.

Both `s1` and `s2` must point to null terminated character arrays.
**strspn()** returns the index of the first character in `s1` that does not match a character in `s2`.

This function may not be implemented on all platforms.

**See Also**

“strpbrk” on page 473

“strcsn” on page 465

**Listing 37.15  Example of strspn() Usage**

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    static char s1[] = "create *build* construct";
    static char s2[] = "create *");
    printf(" s1 = %s
 s2 = %s
", s1, s2);
    printf(" %d
", strspn(s1, s2));
    return 0;
}
```

Output:
```
s1 = create *build* construct
s2 = create *
8
```
**Remarks**

The `strstr()` function searches the character array pointed to by `s1` for the first occurrence of the character array pointed to by `s2`. Both `s1` and `s2` must point to null terminated (`'\0'`) character arrays.

`strstr()` returns a pointer to the first occurrence of `s2` in `s1` and returns a null pointer (NULL) if `s2` cannot be found.

This function may not be implemented on all platforms.

**See Also**

“`memchr`” on page 454

int main(void)
{
    static char s1[] = "tomato carrot onion";
    static char s2[] = "on";
    puts(strstr(s1, s2));
    return 0;
}
```

Output:

```
onion
```

---

**strtok**

Extract tokens within a character array.

```c
#include <string.h>

char *strtok(char *str, const char *sep);
```
Overview of string.h

### Remarks

The `strtok()` function divides a null terminated character array pointed to by `str` into separate “tokens”. The `sep` argument points to a null terminated character array containing one or more separator characters. The tokens in `str` are extracted by successive calls to `strtok()`. `strtok()` works by a sequence of calls to the `strtok()` function. The first call is made with the string to be divided into tokens, as the first argument. Subsequent calls use `NULL` as the first argument and returns pointers to successive tokens of the separated string.

The first call to `strtok()` causes it to search for the first character in `str` that does not occur in `sep`. If no character other than those in the `sep` string can be found, `strtok()` returns a null pointer (NULL). If no characters from the `sep` string are found it returns a pointer to the original string. Otherwise the function returns a pointer to the beginning of this first token.

Subsequent calls to `strtok()` are made with a `NULL` `str` argument causing it to return pointers to successive tokens in the original `str` character array. If no further tokens exist, `strtok()` returns a null pointer.

Both `str` and `sep` must be null terminated character arrays.

The `sep` argument can be different for each call to `strtok()`. `strtok()` modifies the character array pointed to by `str`.

When first called `strtok()` returns a pointer to the first token in `str`. If nothing but separator characters are found `strtok` returns a null pointer.

Subsequent calls to `strtok()` with a NULL `str` argument causes `strtok()` to return a pointer to the next token or return a null pointer (NULL) when no more tokens exist.

This function may not be implemented on all platforms.

### Listing 37.17 Example of `strtok()` Usage

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
```

Table 37.22 `strtok`

<table>
<thead>
<tr>
<th>str</th>
<th>char *</th>
<th>The string to be separate</th>
</tr>
</thead>
<tbody>
<tr>
<td>sep</td>
<td>const char *</td>
<td>The separator string</td>
</tr>
</tbody>
</table>
static char s[50] = "(ape+bear)*(cat+dog)";
char *token;
char *separator = "()+*";

/* first call to strtok() */
token = strtok(s, separator);

while(token != NULL)
{
    puts(token);
    token = strtok(NULL, separator);
}

return 0;

Output:
ape
bear
cat
dog

**strxfrm**

Transform a locale-specific character array.

#include <string.h>

size_t strxfrm(char *dest, const char *source, size_t n);

<table>
<thead>
<tr>
<th>dest</th>
<th>char *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
<td>const char *</td>
<td>The source to be transformed</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to transform</td>
</tr>
</tbody>
</table>

**Remarks**

The strxfrm() function copies characters from the character array pointed to by source to the character array pointed to by dest, transforming each character as
specified by the LC_COLLATE component of the current locale. The `strxfrm` function transforms the string pointed to by source and places the resulting string into the array pointed to by dest. The transformation is such that if the `strcmp` function is applied to two transformed strings, it returns a value greater than, equal to, or less than zero, corresponding to the result of the `strcoll` function applied to the same two original strings.

The MSL C implementation of `strxfrm()` copies a maximum of n characters from the character array pointed to by source to the character array pointed to by dest using the `strncpy()` function. It is included in the string library to conform to the ANSI C Standard Library specification. `strxfrm()` returns the length of dest after it has received source.

This function may not be implemented on all platforms.

**See Also**
- "Locale Specification" on page 165
- "strcpy" on page 464

**Listing 37.18 Example of strxfrm() Usage**

```c
#include <string.h>
#include <stdio.h>

int main(void)
{
    char d[50];
    static char s[] = "123456789ABCDEFG";
    size_t result;

    result = strxfrm(d, s, 30);

    printf("%d characters copied: %s\n", result, d);

    return 0;
}
```

**Output:**
16 characters copied: 123456789ABCDEFG
Non Standard `<string.h>` Functions

Various non standard functions are included in the header `<string.h>` for legacy source code and compatibility with operating system frameworks and application programming interfaces.

tgmath.h

The header `tgmath.h` includes the header `math.h` and defines type-generic macros for those math functions.

Overview of tgmath.h

The `tgmath.h` header file consists of type-generic macros for most math functions listed in Table 38.1.

NOTE Main Standard Library for C does not include complex types and complex type-generic equivalents

The macros in this header may not be implemented on all platforms.

The `time.h` header file provides access to the computer system clock, date and time conversion functions, and time-formatting functions.

**Overview of time.h**

This header file defines the facilities as follows:

- “struct tm” on page 487 is a structure for storing time data.
- “tzname” on page 488 contains an array that stores the time zone abbreviations.
- “asctime” on page 488 converts a tm structure type to a char array.
- “asctime_r” on page 489 is a reentrant version of asctime.
- “clock” on page 490 determines the relative time since the system was started.
- “ctime” on page 492 converts a time_t type to a char array.
- “ctime_r” on page 493 is a reentrant version of ctime.
- “difftime” on page 494 determines the difference between two times.
- “gmtime” on page 495 determines Greenwich Mean Time.
- “gmtime_r” on page 496 is a reentrant version of gmtime.
- “localtime” on page 497 determines the local time.
- “localtime_r” on page 497 is a reentrant version of localtime.
- “mktime” on page 498 converts a tm structure to time_t type.
- “strftime” on page 499 formats time as a C string.
- “time” on page 505 determines a number of seconds from a set time.
- “tzset” on page 506 internalizes the time zone to that of the application.

**Date and time**

The `time.h` header file provides access to the computer system clock, date and time conversion functions, and formatting functions.

Three data types are defined in `time.h`: `clock_t`, `time_t`, and `tm`. 
**Type clock_t**

The `clock_t` type is a numeric, system dependent type returned by the `clock()` function.

**Type time_t**

The `time_t` type is a system dependent type used to represent a calendar date and time.

**Remarks**

The type `time_t`'s range and precision are defined in the C standard as implementation defined. The MSL C implementation uses an unsigned long for `time_t` and it represents the number of UTC seconds since 1900 January 1. If his value exceeds the size of the maximum value for unsigned long (`ULONG_MAX = 4,294,967,295`) the result is undefined. A value of greater than 136 for `tm_year` will exceed this limit. Similarly, since `time_t` is unsigned, negative values for `tm_year` are also out of range.

The ANSI/ISO C Standard does not specify a start date, therefore an arbitrarily chosen Jan. 1, 1970 is used for the MSL C Library. These routines are not meant to be intermixed with any specific API time functions. However some conversion constants are available in the OS specific headers (e.g. `time.mac.h`).
The struct `tm` type contains a field for each part of a calendar date and time.

```c
#include <time.h>
struct tm {
    int tm_sec;
    int tm_min;
    int tm_hour;
    int tm_mday;
    int tm_mon;
    int tm_year;
    int tm_wday;
    int tm_yday;
    int tm_isdst;
};
```

**Remarks**

See Table 39.1 for the `tm` structure members.

The `tm_isdst` flag is positive if Daylight Savings Time is in effect, zero if it is not, and negative if such information is not available.

This structure may not be implemented on all platforms.

**Table 39.1 tm Structure Members**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

</tbody>
</table>

tzname

The _tzname_ array contains the names (abbreviations) of the time zones for local standard time and DST.

This function may not be implemented on all platforms.

#include <time.h>
extern char *tzname[2];

This function may not be implemented on all platforms.

See Also

“tzset” on page 506

asctime

Convert a _tm_ structure to a character array.

#include <time.h>
char *asctime(const struct tm *timeptr);

Table 39.2 asctime

<table>
<thead>
<tr>
<th>timeptr</th>
<th>const struct tm *</th>
<th>A pointer to a <em>tm</em> structure that holds the time information</th>
</tr>
</thead>
</table>

Remarks

The _asctime()_ function converts a _tm_ structure, pointed to by _timeptr_, to a character array. The _asctime()_ and _ctime()_ functions use the same calendar
time.h
Date and time

time format. This format, expressed as a `strftime()` format string is "%a %b %e %H:%M: %S %Y". For example: Tue Apr 4 15:17:23 2000.

`asctime()` returns a null terminated character array pointer containing the converted `tm` structure.

This function may not be implemented on all platforms.

**See Also**

“`ctime`” on page 492

“`strftime`” on page 499

**Listing 39.1  Example of asctime() Usage**

```c
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t systime;
    struct tm *currtime;

    systime = time(NULL);
    currtime = localtime(&systime);

    puts(asctime(currtime));
    return 0;
}
```

Output:
Tue Nov 30 12:56:05 1993

---

**asctime_r**

Reentrant function to convert a `tm` structure to a character array.

```c
#include <time.h>

char * asctime_r(const struct tm * tm, char * s);
```
time.h
Date and time

Table 39.3 asctime_r

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>tm</td>
<td>const struct tm *</td>
<td>A pointer to a tm structure that holds the time information</td>
</tr>
<tr>
<td>s</td>
<td>char *</td>
<td>Storage for the time string</td>
</tr>
</tbody>
</table>

Remarks

The `asctime_r()` function provides a reentrant version of “asctime” on page 488. The difference is that `asctime()` will return a pointer to the time string, and that pointer is internal to the library implementation. For `asctime_r()`, the caller provides the storage for string `s` and the size of the storage must be at least 26 characters long.

The `asctime_r()` function always returns the value of `s`.

This function may require extra library support.

This function may not be implemented on all platforms.

See Also

“asctime” on page 488
“ctime” on page 492
“strftime” on page 499

clock

A program relative invocation of the system time.

```
#include <time.h>
clock_t clock(void);
```

Remarks

This function is used to obtain values of type `clock_t` which may be used to calculate elapsed times during the execution of a program. To compute the elapsed time in seconds, divide the `clock_t` value by `CLOCKS_PER_SEC`, a macro defined in `time.h`.

The programmer should be aware that `clock_t`, defined in `time.h`, has a finite size that varies depending upon the target system.
The `clock()` function returns a `clock_t` type value representing the approximation of time since the system was started. There is no error value returned if an error occurs.

This function may not be implemented on all platforms.

**Listing 39.2 Example of clock() Usage**

```c
#include <time.h>
#include <stdio.h>

int main()
{
    clock_t start, end;
    double secs = 0;
    int stop = 0;

    fprintf(stderr, "Press enter to start");
    getchar();
    start = clock();

    while (stop != 'x')
    {
        fprintf(stderr, "Press enter to terminate");
        getchar();
        end = clock();
        secs = (double)(end - start) /CLOCKS_PER_SEC;
        fprintf(stderr, "Elapsed seconds = %f \n", secs);
        fprintf(stderr, "Press enter to start again ");
        stop = getchar();
        start = clock();
    }

    printf("\n** Program has terminated ** \n");
    return 0;
}
```

**Output:**
Press enter to start <enter>
Press enter to terminate <enter>
Elapsed seconds = 1.200000
Press enter to start again or enter x to terminate: <enter>
Press enter to terminate <enter>
Elapsed seconds = 1.033333
Press enter to start again or enter x to terminate: <x enter>
ctime

Convert a time_t type to a character array.

#include <time.h>

char *ctime(const time_t *timer);

Table 39.4  ctime

<table>
<thead>
<tr>
<th>timer</th>
<th>const time_t*</th>
<th>The address of the time_t variable</th>
</tr>
</thead>
</table>

Remarks

The ctime() function converts a time_t type to a character array with the same format as generated by asctime().

ctime() returns a null terminated character array pointer containing the converted time_t value.

This function may not be implemented on all platforms.

See Also

“asctime” on page 488
“strftime” on page 499

Listing 39.3  Example of ctime() Usage

#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t systime;
    systime = time(NULL);
    puts(ctime(&systime));
    return 0;
}
ctime_r

Convert a time_t type to a character array but reentrant safe.
#include <time.h>
char * ctime_r(const time_t * timer, char * s);

Table 39.5 ctime_r

<table>
<thead>
<tr>
<th>timer</th>
<th>const time_t *</th>
<th>The address of the time_t variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>char *</td>
<td>The storage string</td>
</tr>
</tbody>
</table>

Remarks

The ctime_r() function provides the same service as “ctime” on page 492. The difference is that ctime() would return a pointer to the time string, and that pointer was internal to the library implementation. For ctime_r(), the caller provides the storage for string s and the size of the storage must be at least 26 characters long.

The ctime_r() function always returns the value of s.

This function may require extra library support.

This function may not be implemented on all platforms.

See Also

“asctime” on page 488
“ctime” on page 492
“strftime” on page 499
time.h
Date and time

difftime

Compute the difference between two time_t types.
#include <time.h>
double difftime(time_t t1, time_t t2);

Table 39.6  difftime

<table>
<thead>
<tr>
<th>t1</th>
<th>time_t</th>
<th>A time_t variable to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>t2</td>
<td>time_t</td>
<td>A time_t variable to compare</td>
</tr>
</tbody>
</table>

difftime() returns the difference of t1 minus t2 expressed in seconds.
This function may not be implemented on all platforms.

Listing 39.4  Example of difftime Usage

#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t t1, t2;
    struct tm *currtime;
    double midnight;

    time(&t1);
    currtime = localtime(&t1);
    currtime->tm_sec = 0;
    currtime->tm_min = 0;
    currtime->tm_hour = 0;
    currtime->tm_mday++;
    t2 = mktime(currtime);
    midnight = difftime(t1, t2);
    printf("There are %f seconds until midnight.\n", midnight);

    return 0;
}
There are 27892.000000 seconds until midnight.

**gmtime**

Convert a `time_t` value to Coordinated Universal Time (UTC), which is the new name for Greenwich Mean Time.

```c
#include <time.h>
struct tm *gmtime(const time_t *timer);
```

**Remarks**

The `gmtime` function converts the calendar time pointed to by `timer` into a broken-down time, expressed as UTC.

The `gmtime()` function returns a pointer to that object.

This function may not be implemented on all platforms.

**See Also**

“`gmtime_r` on page 496

“`localtime` on page 497

**Listing 39.5 Example of gmtime Usage**

```c
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t systime;
    struct tm *utc;

    systime = time(NULL);
```
```c
utc = gmtime(&systime);
printf("Universal Coordinated Time:\n");
puts(asctime(utc));
return 0;
```

Output:
Universal Coordinated Time:
Thu Feb 24 18:06:10 1994

---

**gmtime_r**

Convert a `time_t` value to Coordinated Universal Time (UTC), which is the new name for Greenwich Mean Time but is reentrant safe.

```c
#include <time.h>
struct tm * gmtime_r(const time_t * timer, struct tm * tm);
```

**Table 39.8 gmtime_r**

<table>
<thead>
<tr>
<th>timer</th>
<th>const time_t*</th>
<th>The address of the time_t variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>tm</td>
<td>struct tm *</td>
<td>A storage location for the converted time</td>
</tr>
</tbody>
</table>

**Remarks**

The `gmtime_r()` function provides the same service as "gmtime" on page 495. The difference is that `gmtime()` would return a pointer to the converted time, and that pointer was internal to the library implementation. For `gmtime_r()`, the caller provides the storage for the `tm struct`.

The `gmtime_r()` function always returns the value of `tm`.

This function may require extra library support.

This function may not be implemented on all platforms.

**See Also**

"gmtime" on page 495
**localtime**

Convert a `time_t` type to a `struct tm` type.

```c
#include <time.h>
struct tm *localtime(const time_t *timer);
```

**Table 39.9 localtime**

<table>
<thead>
<tr>
<th>timer</th>
<th>const time_t *</th>
<th>The address of the time_t variable</th>
</tr>
</thead>
</table>

**Remarks**

The `localtime()` function converts a `time_t` type, pointed to by `timer`, and returns it as a pointer to an internal `struct tm` type. The `struct tm` pointer is static; it is overwritten each time `localtime()` is called. For example usage, see Listing 39.4.

`localtime()` converts `timer` and returns a pointer to a `struct tm`.

This function may not be implemented on all platforms.

**See Also**

“mktime” on page 498

---

**localtime_r**

Convert a `time_t` type to a `struct tm` type but is reentrant.

```c
#include <time.h>
struct tm *localtime_r(const time_t *timer, struct tm *tm);
```

**Table 39.10 localtime_r**

<table>
<thead>
<tr>
<th>timer</th>
<th>const time_t *</th>
<th>The address of the time_t variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>tn</td>
<td>struct tm *</td>
<td>The storage location</td>
</tr>
</tbody>
</table>

---

MSL C Reference Version 10 497
Remarks

The `localtime_r()` function provides the same service as “localtime” on page 497 but is reentrant. The difference is that `localtime()` would return a pointer to the converted time, and that pointer was internal to the library implementation. For `localtime_r()`, the caller provides the storage for the `tm` struct.

The `localtime_r()` function always returns the value of `tm`.

This function may require extra library support.

This function may not be implemented on all platforms.

See Also

“localtime” on page 497
“mktime” on page 498

**mktime**

Convert a struct `tm` item to a `time_t` type.

```c
#include <time.h>

time_t mktime(struct tm *timeptr);
```

**Table 39.11 mktime**

<table>
<thead>
<tr>
<th>timeptr</th>
<th>struct tm *</th>
<th>The address of the tm structure</th>
</tr>
</thead>
</table>

Remarks

The `mktime()` function converts a struct `tm` type and returns it as a `time_t` type. For example usage, see Listing 39.4.

The function also adjusts the fields in `timeptr` if necessary. The `tm_sec`, `tm_min`, `tm_hour`, and `tm_day` are processed such that if they are greater than their maximum, the appropriate carry-overs are computed. For example, if `timeptr->tm_min` is 65, `timeptr->tm_hour` will be incremented by 1 and `timeptr->min` will be set to 5.

The function also computes the correct values for `timeptr->tm_wday` and `timeptr->tm_yday`.

`mktime()` returns the converted `tm` structure as a `time_t` type.

This function may not be implemented on all platforms.
See Also

“localtime” on page 497

strftime

Format a tm structure.

```c
#include <time.h>
size_t strftime(char *s, size_t maxsize,
               const char *format,
               const struct tm *timeptr);
```

| s         | char * | A string to hold the formatted time |
| maxsize   | size_t | Max length of formatted string     |
| format    | const char * | The format string                  |
| timeptr   | const struct tm * | The address of the time structure |

Remarks

The `strftime()` function converts a `tm` structure to a character array using a programmer supplied format.

The `s` argument is a pointer to the array to hold the formatted time.

The `maxsize` argument specifies the maximum length of the formatted character array.

The `timeptr` argument points to a `tm` structure containing the calendar time to convert and format.

The `format` argument points to a character array containing normal text and format specifications similar to a `printf()` function format string. Format specifiers are prefixed with a percent sign (%). Doubling the percent sign (%%) will output a single %.

If any of the specified values are outside the normal range, the characters stored are unspecified.
In the “C” locale, the E and O modifiers are ignored. Also, some of the formats are dependent on the LC_TIME component of the current locale.

See Table 39.13 for a list of format specifiers.

<td>U</td>
<td>The week number of the year as a decimal number from 00 to 53. Sunday is considered the first day of the week.</td>
</tr>
<tr>
<td>w</td>
<td>The weekday as a decimal number from 0 to 6. Sunday is (0) zero.</td>
</tr>
<tr>
<td>W</td>
<td>The week of the year as a decimal number from 00 to 51. Monday is the first day of the week.</td>
</tr>
<tr>
<td>x</td>
<td>The date representation of the current locale, equivalent to ‘%A %B %d %Y’</td>
</tr>
<tr>
<td>X</td>
<td>The time representation of the current locale, equivalent to ‘%T’</td>
</tr>
</tbody>
</table>
The `strftime()` function returns the total number of characters in the argument ‘s’ if the total number of characters including the null character in the string argument ‘s’ is less than the value of ‘maxlen’ argument. If it is greater, `strftime()` returns 0.

This function may not be implemented on all platforms.

### Listing 39.6 Example of strftime() Usage

```c
#include <time.h>
#include <stdio.h>
#include <string.h>

int main(void)
{
    time_t lclTime;
    struct tm *now;
    char ts[256]; /* time string */

    lclTime = time(NULL);
    now = localtime(&lclTime);

    strftime(ts, 256,
        "Today's abr.name is %a", now);
    puts(ts);

    strftime(ts, 256,
        "Today's full name is %A", now);
```
puts(ts);

strftime(ts, 256,
   "Today's abbreviated month name is %b", now);
puts(ts);

strftime(ts, 256,
   "Today's full month name is %B", now);
puts(ts);

strftime(ts, 256,
   "Today's date and time is %c", now);
puts(ts);

strftime(ts, 256,
   "The day of the month is %d", now);
puts(ts);

strftime(ts, 256,
   "The 24-hour clock hour is %H", now);
puts(ts);

strftime(ts, 256,
   "The 12-hour clock hour is %h", now);
puts(ts);

strftime(ts, 256,
   "Today's day number is %j", now);
puts(ts);

strftime(ts, 256,
   "Today's month number is %m", now);
puts(ts);

strftime(ts, 256,
   "The minute is %M", now);
puts(ts);

strftime(ts, 256,
   "The AM/PM is %p", now);
puts(ts);

strftime(ts, 256,
   "The second is %S", now);
puts(ts);

strftime(ts, 256,
   "The week number of the year, \
starting on a Sunday is %U", now);
puts(ts);

strftime(ts, 256, "The number of the week is %w", now);
puts(ts);

strftime(ts, 256, "The week number of the year, starting on a Monday is %W", now);
puts(ts);

strftime(ts, 256, "The date is %x", now);
puts(ts);

strftime(ts, 256, "The time is %X", now);
puts(ts);

strftime(ts, 256, "The last two digits of the year are %y", now);
puts(ts);

strftime(ts, 256, "The year is %Y", now);
puts(ts);

strftime(ts, 256, "%Z", now);
if (strlen(ts) == 0)
    printf("The time zone cannot be determined\n");
else
    printf("The time zone is %s\n", ts);

    return 0;
}

Results
Today's abr.name is Wed
Today's full name is Wednesday
Today's aabr.month name is Apr
Today's month name is April
Today's date and time is Wednesday April 05 10:50:44 2000
The day of the month is 05
The 24-hour clock hour is 10
The 12-hour clock hour is 10
Today's day number is 096
Today's month number is 04
The minute is 50
The AM/PM is am
The second is 44
The week number of the year, starting on a Sunday is 14
The number of the week is 3
The week number of the year, starting on a Monday is 14
The date is Wednesday April 05 2000
The time is 10:50:44
The last two digits of the year are 00
The year is 2000
The time zone cannot be determined

**time**

Return the current system calendar time.

```c
#include <time.h>

time_t time(time_t *timer);
```

<table>
<thead>
<tr>
<th>timer</th>
<th>time_t*</th>
<th>The address of the time_t variable</th>
</tr>
</thead>
</table>

**Remarks**

The `time()` function returns the computer system's calendar time. If `timer` is not a null pointer, the calendar time is also assigned to the item it points to.

`time()` returns the system current calendar time.

This function may not be implemented on all platforms.

**Listing 39.7 Example of time() Usage**

```c
#include <time.h>
#include <stdio.h>

int main(void)
{
    time_t systime;
    systime = time(NULL);
    puts(ctime(&systime));
    return 0;
}
```
time.h

Non Standard <time.h> Functions

Output:
Tue Nov 30 13:06:47 1993

tzset

The function tzset() reads the value of the “TZ” environment variable and internalizes it into the time zone functionality of the program.

#include <time.h>
void tzset(void);

Remarks
The function tzset() reads the value of the “TZ” environment variable and internalizes it into the time zone functionality of the program.

This function may not be implemented on all platforms.

See Also
“tzname” on page 488

Non Standard <time.h> Functions

Various non standard functions are included in the header time.h for legacy source code and compatibility with operating system frameworks and application programming interfaces.

- For the function strdate see “strdate” on page 94, for a full description
- “asctime r” on page 489 is a reentrant version of asctime
- “ctime r” on page 493 is a reentrant version of ctime
- “gmtime r” on page 496 is a reentrant version of gmtime
- “localtime r” on page 497 is a reentrant version of localtime
timeb.h

The timeb.h header file provides access to the computer system clock, date and time conversion functions, and time formatting functions. Currently, this header is implemented for Windows only.

Overview of timeb.h

This header file defines the facilities as follows:

- "struct timeb" on page 507 lists the elements of the timeb structure.
- "ftime" on page 508 stores the current time in a buffer that the programmer can allocate.

This struct is Windows x86 only at this time.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also

"MSL Extras Library Headers” on page 4 for information on POSIX naming conventions.

struct timeb

The timeb struct is used to store the time of a milliseconds timer, timezone, and timezone flag.

Table 40.1 timeb Structure Members

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>time_t time</td>
<td>A type used to represent calendar date and time See &quot;Type time_t&quot; on page 486</td>
</tr>
<tr>
<td>unsigned short millitm</td>
<td>Current time in milliseconds</td>
</tr>
</tbody>
</table>
Overview of timeb.h

Remarks

The dstflag flag is true if the daylight savings time is in effect

This structure may not be implemented on all platforms.

ftime

The function ftime and _ftime gets the current time and stores it in a struct that is allocated by the programmer.

```c
#include <timeb.h>
void ftime(struct timeb * timebptr);
void _ftime(struct timeb * timebptr);
```

Remarks

The elements of the struct timeb are listed in Table 40.1.

This function may not be implemented on all platforms.

See Also

“ctime” on page 492.

Listing 40.1 Example of ftime Usage

```c
#include <sys\timeb.h>
#include <stdio.h>
```
int main()
{
    struct timeb tbuf;
    ftime( &tbuf);

    printf("Time is \%s", ctime(&tbuf.time));

    return 0;
}
timeb.h

Overview of timeb.h
The header file `unistd.h` contains several functions that are useful for porting a program from UNIX.

**Overview of unistd.h**

The header file `unistd.h` contains several functions that are useful for porting a program from UNIX. These functions are similar to the functions in many UNIX libraries. However, since the UNIX and other operating systems have some fundamental differences, they cannot be identical. The descriptions of the functions explain the differences.

This header file defines the facilities as follows:

- "access" on page 512 determines the files accessibility.
- "chdir" on page 513 changes the directory.
- "close" on page 515 closes a file opened with open.
- "cuserid" on page 518 retrieves the current user’s ID.
- "cwait" on page 519 instructs to wait for a process to end.
- "dup" on page 520 duplicates a file handle.
- "dup2" on page 520 duplicates a file handle unto an existing handle.
- "exec functions" on page 521 executes programs from within a program.
- "getcwd" on page 523 gets the current working directory.
- "getlogin" on page 524 returns a login name.
- "getpid" on page 525 returns the process ID.
- "isatty" on page 526 determines if a file ID is attached to a terminal.
- "lseek" on page 527 seeks a position on a file stream.
- "read" on page 528 reads when opened with open.
- "rmdir" on page 529 removes a directory or folder.
- "sleep" on page 532 pauses a program.
- "spawn functions" on page 533 spawns a child process.
- "ttyname" on page 534 determines a terminal ID.
unistd.h
Overview of unistd.h

- "unlink" on page 535 deletes a file.
- "write" on page 536 writes to a binary file stream.

unistd.h and UNIX Compatibility
Generally, you don’t want to use these functions in new programs. Instead, use their counterparts in the native API.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also
Table 1.1 for information on POSIX naming conventions.

access
Determines the files accessibility.
#include <unistd.h>
int access(const char *fname, int mode);

Table 41.1 access

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>fname</td>
<td>const char *</td>
<td>The file to check</td>
</tr>
<tr>
<td>mode</td>
<td>int</td>
<td>The file mode to test for</td>
</tr>
</tbody>
</table>

Remarks
If the access is allowed then zero is returned. A negative number is returned if the access is not allowed.
This function may not be implemented on all platforms.
Table 41.2 lists the file modes that may be tested.
Table 41.2 Access Test Modes

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>F_OK</td>
<td>Test for existence of file</td>
</tr>
<tr>
<td>R_OK</td>
<td>Test for read permission</td>
</tr>
<tr>
<td>W_OK</td>
<td>Test for write permission</td>
</tr>
<tr>
<td>X_OK</td>
<td>Test for execute permission</td>
</tr>
</tbody>
</table>

See Also
- “creat, _wcreate” on page 118
- “open, _wopen” on page 121
- “close” on page 515

chdir

Change the current directory.
#include <unistd.h>
int chdir(const char *path);
int _chdir(const char *path);

Table 41.3 chdir

<table>
<thead>
<tr>
<th>path</th>
<th>char *</th>
<th>The new pathname</th>
</tr>
</thead>
</table>

Remarks
The function chdir() is used to change from one directory to a different directory or folder. For example usage, see Listing 41.1.
chdir() returns zero, if successful. If unsuccessful chdir() returns negative one and sets errno.
This function may not be implemented on all platforms.

See Also
- “errno” on page 75
Listing 41.1 Example of chdir() Usage

```c
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <stat.h>

#define SIZE FILENAME_MAX
#define READ_OR_WRITE 0x0 /* fake a UNIX mode */

int main(void)
{
    char folder[SIZE];
    char curFolder[SIZE];
    char newFolder[SIZE];
    int folderExisted = 0;

    /* Get the name of the current folder or directory */
    getcwd(folder, SIZE);
    printf("The current Folder is: %s", folder);

    /* create a new sub folder */
    /* note mode parameter ignored on Mac */
    sprintf(newFolder, "%s%" Sub", folder, "Sub");
    if( mkdir(newFolder, READ_OR_WRITE ) == -1 )
    {
        printf("\nFailed to Create folder");
        folderExisted = 1;
    }

    /* change to new folder */
    if( chdir( newFolder ) )
    {
        puts("\nCannot change to new folder");
        exit(EXIT_FAILURE);
    }

    /* show the new folder or folder */
    getcwd(curFolder, SIZE);
    printf("The current folder is: %s", curFolder);

    /* go back to previous folder */
    if( chdir(folder) )
    {
        puts("\nCannot change to old folder");
        exit(EXIT_FAILURE);
    }
```

/* show the new folder or folder */
getcwd( curFolder, SIZE );
printf("The current folder is again: %s", curFolder);

if (!folderExisted)
{
/* remove newly created directory */
if (rmdir(newFolder))
    { 
        puts("Cannot remove new folder");
        exit(EXIT_FAILURE);
    }
else
    puts("New folder removed");

/* attempt to move to non-existant directory */
if (chdir(newFolder))
    puts("Cannot move to non-existant folder");
else
    puts("Pre-existing folder not removed");

return 0;
}

Output
The current Folder is: Macintosh HD:C Reference:
The current folder is: Macintosh HD:C Reference:
The current folder is again: Macintosh HD:C Reference:
New folder removed
Cannot move to non-existant folder
For Windows, refer to "Example of rmdir() Usage" on page 530.

---

**close**

Close an open file.

```c
#include <unistd.h>
int close(int fildes);
```

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
<th>The file descriptor</th>
</tr>
</thead>
</table>

---

*MSL C Reference Version 10*
Remarks

The close() function closes the file specified by the argument. This argument is the value returned by open(). For example usage, see Listing 41.2.

If successful, close() returns zero. If unsuccessful, close() returns negative one and sets errno.

This function may not be implemented on all platforms.

See Also

"open, _wopen" on page 121
"fclose" on page 304
"errno" on page 75

Listing 41.2  Example of close() Usage

```
#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <string.h>
#include <unistd.h>

#define SIZE FILENAME_MAX
#define MAX 1024

char fname[SIZE] = "DonQ.txt";

int main(void)
{
    int fdes;
    char temp[MAX];
    char *Don = "In a certain corner of la Mancha, the name of
    which I do not choose to remember, ...";
    char *Quixote = "there lived
    none of those country\n    gentlemen, who adorn their\nhalls with rusty lance\n    and worm-eaten targets.";

    /* NULL terminate temp array for printf */
    memset(temp, '\0', MAX);

    /* open a file */
    if((fdes = open(fname, O_RDWR | O_CREAT ))== -1)
    {
        perror("Error");
    }
}"
```
printf(“Can not open %s”, fname);
exit( EXIT_FAILURE);
}

/* write to a file */
if( write(fdes, Don, strlen(Don)) == -1)
{
    printf(“%s Write Error\n”, fname);
    exit( EXIT_FAILURE )
}

/* move back to over write ... characters */
if( lseek( fdes, -3L, SEEK_CUR ) == -1L)
{
    printf(“Seek Error”);
    exit( EXIT_FAILURE )
}

/* write to a file */
if( write(fdes, Quixote, strlen(Quixote)) == -1)
{
    printf(“Write Error”);
    exit( EXIT_FAILURE )
}

/* move to beginning of file for read */
if( lseek( fdes, 0L, SEEK_SET ) == -1L)
{
    printf(“Seek Error”);
    exit( EXIT_FAILURE )
}

/* read the file */
if( read( fdes, temp, MAX ) == 0)
{
    printf(“Read Error”);
    exit( EXIT_FAILURE);
}

/* close the file */
if(close(fdes))
{
    printf(“File Closing Error”);
    exit( EXIT_FAILURE )
}

puts(temp);
unistd.h

Overview of unistd.h

    return 0;
}

Result
In a certain corner of la Mancha, the name of which I do not choose to remember, there lived one of those country gentlemen, who adorn their halls with rusty lance and worm-eaten targets.

cuserid

Retrieve the current user’s ID.

#include <unistd.h>
char *cuserid(char *string);

Table 41.5 cuserid

<table>
<thead>
<tr>
<th>string</th>
<th>char *</th>
<th>The user ID as a string</th>
</tr>
</thead>
</table>

Remarks
The function cuserid() returns the user name associated with the current process. If the string argument is NULL, the file name is stored in an internal buffer. If it is not NULL, it must be at least FILENAME_MAX large. For example usage, see Listing 41.3.

For the MacOS, the login name is returned.
cuserid() returns a character pointer to the current user’s ID.

For the MacOS, the users name is set using the sharing control panel
This function may not be implemented on all platforms.

Listing 41.3  Example of cuserid() Usage

#include <stdio.h>
#include <unistd.h>

int main(void)
{
    char *c_id = NULL;
    printf("The current user ID is %s\n", cuserid(c_id));
return 0;
}

Result
The current user ID is CodeWarror

cwait

Wait for a process to terminate.

```c
#include <unistd.h>
int cwait(int *termstat, int pid, int action);
int _cwait(int *termstat, int pid, int action);
```

<table>
<thead>
<tr>
<th>termstat</th>
<th>int</th>
<th>The termination status</th>
</tr>
</thead>
<tbody>
<tr>
<td>pid</td>
<td>int</td>
<td>Process ID</td>
</tr>
<tr>
<td>action</td>
<td>int</td>
<td>The action is ignored</td>
</tr>
</tbody>
</table>

Remarks
The process exit code is returned.
Windows compatible function.

See Also
“exec functions” on page 521
“spawn functions” on page 533
**unistd.h**
*Overview of unistd.h*

---

**dup**

Duplicates a file handle.

```c
#include <io.h>
int dup(int _a);
int _dup(int _a);
```

**Table 41.7  dup**

<table>
<thead>
<tr>
<th>_a</th>
<th>int</th>
<th>A file handle to duplicate</th>
</tr>
</thead>
</table>

**Remarks**

Creates a new file handle for an open file with the same attributes as the original file handle.

A new file handle is returned upon success or a negative one otherwise.

This function may not be implemented on all platforms.

**See Also**

“dup2” on page 520

---

**dup2**

Duplicates a file handle unto an existing handle.

```c
#include <io.h>
int dup2(int _a, int _b);
int _dup2(int _a, int _b);
```

**Table 41.8  dup2**

<table>
<thead>
<tr>
<th>_a</th>
<th>int</th>
<th>A file handle to duplicate</th>
</tr>
</thead>
<tbody>
<tr>
<td>_b</td>
<td>int</td>
<td>An existing file handle</td>
</tr>
</tbody>
</table>
Remarks

Associates a file handle for an open file with the same attributes as the original file handle. If the file associated with the second argument is open when _dup2 is called, the old file is closed.

Zero is returned upon success and a negative one upon failure.

This function may not be implemented on all platforms.

See Also

“dup” on page 520

exec functions

Load and execute a child process within the current program memory.

The suffix on the exec name determines the method that the child process operates.

- P will search the path variable
- L is used for known argument lists number
- V is for an unknown argument list number
- E allows you to alter an environment for the child process

exec

#include <unistd.h>

int exec(const char *path, ...);
int _exec(const char *path, ...);

execl

int execl(const char *path, ...);
int _execl(const char *path, ...);

execlp

int execlp(const char *path, ...);
int _execlp(const char *path, ...);

execlpe

int execlpe(const char *path, ...);
int _execlpe(const char *path, ...);
**unistd.h**  
*Overview of unistd.h*

---

**execp**

```c
int execp(const char *path, ...);
int _execp(const char *path, ...);
```

**execv**

```c
int execv(const char *path, ...);
int _execv(const char *path, ...);
```

**execve**

```c
int execve(const char *path, ...);
int _execve(const char *path, ...);
```

**excevp**

```c
int excevp(const char *path, ...);
int _excevp(const char *path, ...);
```

---

### Table 41.9 excevp

<table>
<thead>
<tr>
<th>path</th>
<th>const char *</th>
<th>The commandline pathname to execute</th>
</tr>
</thead>
<tbody>
<tr>
<td>...</td>
<td>...</td>
<td>A variable list of arguments</td>
</tr>
</tbody>
</table>

---

**Remarks**

Launches the application named and then quits upon successful launch. For example usage, see [Listing 41.4](#).

If successful `exec()` returns zero. If unsuccessful `exec()` returns negative one and sets `errno` according to the error.

These functions may not be implemented on all platforms.

---

**See Also**

“Overview of errno.h” on page 75

---

**Listing 41.4 Example of exec() Usage**

```c
#include <stdio.h>
```
#include <unistd.h>

#define SIZE FILENAME_MAX
char appName[SIZE] = "SimpleText";

int main(void)
{
    printf("Original Program\n");
    exec(appName);
    printf("program terminated"); /* not displayed */
    return 0;
}

result
Display "Original Program"
after the close of the program the SimpleText application is launched

getcwd
Get the current directory.

#include <unistd.h>
char *getcwd(char *buf, int size);
char *__getcwd(char *buf, int size);

Table 41.10  getcwd

<table>
<thead>
<tr>
<th>buf</th>
<th>char</th>
<th>A buffer to hold the pathname of the current working directory</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>int</td>
<td>The size of the buffer</td>
</tr>
</tbody>
</table>

Remarks
The function getcwd() takes two arguments. One is a buffer large enough to store the full directory pathname, the other argument is the size of that buffer. For example usage, see Listing 41.1.

If successful, getcwd() returns a pointer to the buffer. If unsuccessful, getcwd() returns NULL and sets errno.
getlogin

Retrieve the username that started the process.

```c
#include <unistd.h>
char *getlogin(void);
```

Remarks

The function `getlogin()` retrieves the name of the user who started the program. For example usage, see Listing 41.5.

The Mac doesn't have a login, so this function returns the Owner Name from the File Sharing Setup Control Panel.

`getlogin()` returns a character pointer.

This function may not be implemented on all platforms.

Listing 41.5  Example of `getlogin()` Usage

```c
#include <stdio.h>
#include <unistd.h>

int main(void)
{
    printf("The login name is %s\n", getlogin());
    return 0;
}
```

result

The login name is CodeWarrior
getpid

Retrieve the process identification number.

#include <unistd.h>

Table 41.11 getpid() Macros

<table>
<thead>
<tr>
<th>Macro</th>
<th>Represents</th>
</tr>
</thead>
<tbody>
<tr>
<td>#define getpid()</td>
<td>Process ID</td>
</tr>
<tr>
<td>#define getppid()</td>
<td>Parent process ID</td>
</tr>
<tr>
<td>#define getuid()</td>
<td>Real user ID</td>
</tr>
<tr>
<td>#define geteuid()</td>
<td>Effective user ID</td>
</tr>
<tr>
<td>#define getgid()</td>
<td>Real group ID</td>
</tr>
<tr>
<td>#define getegid()</td>
<td>Effective group ID</td>
</tr>
<tr>
<td>#define getpgrp()</td>
<td>Process group ID</td>
</tr>
</tbody>
</table>

Remarks

The getpid() function returns the unique number (Process ID) for the calling process. For example usage, see Listing 41.6.

getpid() returns an integer value.

These various related getpid() type functions don't really have any meaning on the Mac. The values returned are those that would make sense for a typical user process under UNIX.

getpid() always returns a value. There is no error returned.

This function may not be implemented on all platforms.

Listing 41.6 Example of getpid() Usage

#include <stdio.h>
#include <unistd.h>

int main(void)
{
    printf("The process ID is %d\n", getpid());
unistd.h
Overview of unistd.h

    return 0;
}

Result
The process ID is 9000

isatty

Determine a specified file_id
#include <unistd.h>
int isatty(int fildes);
int _isatty(int fildes);

Table 41.12 isatty

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
<th>The file descriptor</th>
</tr>
</thead>
</table>

Remarks
The function isatty() determines if a specified file_id is attached to the console, or if re-direction is in effect. For example usage, see Listing 41.7.
isatty() returns a non-zero value if the file is attached to the console. It returns zero if Input/Output redirection is in effect.
This function may not be implemented on all platforms.

See Also
“ccommand” on page 41

Listing 41.7 Example of isatty() ttname() Usage

#include <console.h>
#include <stdio.h>
#include <unistd.h>
#include <unix.h>

int main(int argc, char **argv)
{
    int i;
    int file_id;
argc = ccommand(&argv);

file_id = isatty(fileno(stdout));
if(!file_id )
{
for (i=0; i < argc; i++)
    printf("command line argument [%d] = %s\n", i, argv[i]);
}
else printf("Output to window");

printf("The associated terminal is %s", ttymname(file_id) );

return 0;
}

Result if file redirection is chosen using the command line arguments
Freescale CodeWarrior.
Written to file selected:

command line argument [0] = CRef
command line argument [1] = Freescale
command line argument [2] = CodeWarrior
The associated terminal is SIOUX

Iseek

Seek a position on a file stream.
#include <unistd.h>
long lseek(int fildes, long offset, int origin);

Table 41.13  Iseek

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
<th>The file descriptor</th>
</tr>
</thead>
<tbody>
<tr>
<td>offset</td>
<td>long</td>
<td>The offset to move in bytes</td>
</tr>
<tr>
<td>origin</td>
<td>int</td>
<td>The starting point of the seek</td>
</tr>
</tbody>
</table>
unistd.h
Overview of unistd.h

Remarks

The function `lseek()` sets the file position location a specified byte offset from a specified initial location. For example usage, see Listing 41.2.

The origin of the offset must be one of the positions listed in Table 41.14.

Table 41.14 The lseek Offset Positions

<table>
<thead>
<tr>
<th>Macro</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEEK_SET</td>
<td>Beginning of file</td>
</tr>
<tr>
<td>SEEK_CUR</td>
<td>Current Position</td>
</tr>
<tr>
<td>SEEK_END</td>
<td>End of File</td>
</tr>
</tbody>
</table>

If successful, `lseek()` returns the absolute offset as the number of bytes from the beginning of the file after the seek has occurred. If unsuccessful, it returns a value of negative one long integer.

This function may not be implemented on all platforms.

read

Read from a file stream that has been opened in binary mode for unformatted Input/Output.

```c
#include <unistd.h>
int read(int fildes, char *buf, int count);
```

Table 41.15 read

<table>
<thead>
<tr>
<th>fildes</th>
<th>int</th>
<th>The file descriptor</th>
</tr>
</thead>
</table>
read()

The function `read()` copies the number of bytes specified by the `count` argument, from the file to the character buffer. File reading begins at the current position. The position moves to the end of the read position when the operation is completed.

### Remarks

The function `read()` copies the number of bytes specified by the `count` argument, from the file to the character buffer. File reading begins at the current position. The position moves to the end of the read position when the operation is completed.

### NOTE

This function should be used in conjunction with `unistd.h:write()`, and `fcntl.h:open()` only.

`read()` returns the number of bytes actually read from the file. In case of an error a value of negative one is returned and `errno` is set.

This function may not be implemented on all platforms.

### See Also

- “fread” on page 331
- “open, _wopen” on page 121

For example of `read()` usage, see Listing 41.2.

---

### rmdir

Delete a directory or folder.

```c
#include <unistd.h>
int rmdir(const char *path);
```

### Remarks

The `rmdir()` function removes the directory (folder) specified by the argument.
If successful, \texttt{rmdir()} returns zero. If unsuccessful, \texttt{rmdir()} returns negative one and sets \texttt{errno}.

This function may not be implemented on all platforms.

\textbf{See Also}

“\texttt{mkdir}” on page 275

“\texttt{errno}” on page 75

\textbf{Listing 41.8  Example of rmdir() Usage}

```c
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>
#include <stat.h>

#define SIZE FILENAME_MAX
#define READ_OR_WRITE 0x0 /* fake a UNIX mode */

int main(void)
{
  char folder[SIZE];
  char curFolder[SIZE];
  char newFolder[SIZE];
  int folderExisted = 0;

  /* Get the name of the current folder or directory */
  getcwd( folder, SIZE);
  printf(“The current Folder is: %s”, folder);

  /* create a new sub folder */
  /* note mode parameter ignored on Mac */
  sprintf(newFolder,”%s%s”, folder, ”.\Sub”);
  if( mkdir(newFolder, READ_OR_WRITE ) == -1 )
  {
    printf(“\nFailed to Create folder”);
    folderExisted = 1;
  }

  /* change to new folder */
  if( chdir( newFolder) )
  {
    puts(“\nCannot change to new folder”);
    exit(EXIT_FAILURE);
  }

  /* show the new folder or folder */
```
getcwd( curFolder, SIZE );
printf("\nThe current folder is: %s", curFolder);

/* go back to previous folder */
if( chdir(folder) )
{
    puts("\nCannot change to old folder");
    exit(EXIT_FAILURE);
}

/* show the new folder or folder */
getcwd( curFolder, SIZE );
printf("\nThe current folder is again: %s", curFolder);

if (!folderExisted)
{
    /* remove newly created directory */
    if (rmdir(newFolder))
    {
        puts("\nCannot remove new folder");
        exit(EXIT_FAILURE);
    }
    else
        puts("\nNew folder removed");

    /* attempt to move to non-existant directory */
    if (chdir(newFolder))
        puts("Cannot move to non-existant folder");
    }
    else
        puts("\nPre-existing folder not removed");

    return 0;
}

Output
The current Folder is: C:\Programming\CW\Console
The current folder is: C:\Programming\CW\Console\Sub
The current folder is again: C:\Programming\CW\Console
New folder removed
Cannot move to non-existant folder
For Macintosh, refer to "Example of chdir() Usage" on page 514.
unistd.h
Overview of unistd.h

sleep
Delay program execution for a specified number of seconds.
#include <unistd.h>
unsigned int sleep(unsigned int sleep);

Table 41.17 sleep

<table>
<thead>
<tr>
<th>sleep</th>
<th>unsigned int</th>
<th>The length of time in seconds</th>
</tr>
</thead>
</table>

Remarks
The function `sleep()` delays execution of a program for the time indicated by the unsigned integer argument. For the Macintosh system there is no error value returned. For example usage, see Listing 41.9.
The function `sleep()` returns zero.
This function may not be implemented on all platforms.

Listing 41.9 Example of sleep() Usage

```c
#include <stdio.h>
#include <unistd.h>

int main(void)
{
    printf("Output to window\n");
    fflush(stdout); /* needed to force output */
    sleep(3);
    printf("Second output to window");
    return 0;
}
```

Result
Output to window
< there is a delay now >
spawn functions

The `spawn` family of functions create and run other processes (child processes). The suffix on the `spawn` name determines the method that the child process operates.

- `P` will search the path variable
- `L` is used for known argument lists number
- `V` is for an unknown argument list number
- `E` allows you to alter an environment for the child process

**spawnl**

```c
int spawnl(int,const char *, ...);
int _spawnl(int,const char *, ...);
```

**spawnv**

```c
int spawnv(int,const char *,const char *const*);
int _spawnv(int,const char *,const char *const*);
```

**spawnle**

```c
int spawnle(int,const char *,...);
int _spawnle(int,const char *,...);
```

**spawnve**

```c
int spawnve(int,const char *,const char *const*, const char *const*);
int _spawnve(int,const char *,const char *const*, const char *const*);
```

**spawnlp**

```c
int spawnlp(int,const char *,...);
int _spawnlp(int,const char *,...);
```
spawnvp

int spawnvp(int,const char *,const char *const *);
int _spawnvp(int,const char *,const char *const *);

spawnlpe

int spawnlpe(int,const char *,...);
int _spawnlpe(int,const char *,...);

spawnvpe

int spawnvpe(int,const char *,const char *const *, const char *const *);
int _spawnvpe(int,const char *,const char *const *, const char *const *);

Remarks

All spawn functions take a variable argument list as a parameter.
The child process’s exit status is returned.
These functions may not be implemented on all platforms.

See Also

“exec functions” on page 521

ttyname

Retrieve the name of the terminal associated with a file ID.
#include <unistd.h>
char *ttyname(int fildes);

<table>
<thead>
<tr>
<th>Table 41.18</th>
<th>ttyname</th>
</tr>
</thead>
<tbody>
<tr>
<td>fildes</td>
<td>int</td>
</tr>
</tbody>
</table>
Remarks

The function `ttyname()` retrieves the name of the terminal associated with the file ID. For example usage, see Listing 41.7.

`ttyname()` returns a character pointer to the name of the terminal associated with the file ID, or NULL if the file ID doesn't specify a terminal.

This function may not be implemented on all platforms.

**unlink**

Delete (unlink) a file.

```c
#include <unistd.h>
int unlink(const char *path);
```

<table>
<thead>
<tr>
<th>path</th>
<th>const char *</th>
<th>A pathname of the file to remove</th>
</tr>
</thead>
</table>

**Remarks**

The function `unlink()` removes the specified file from the directory. For example usage, see Listing 41.10.

If successful, `unlink()` returns zero. If unsuccessful, it returns a negative one.

This function may not be implemented on all platforms.

**See Also**

“rmdir” on page 529

“mkdir” on page 275

**Listing 41.10  Example of unlink() Usage**

```c
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

#define SIZE FILENAME_MAX

int main(void)
{
```
FILE *fp;
char fname[SIZE] = "Test.txt";

/* create a file */
if( (fp =fopen( fname,"w") ) == NULL )
{
    printf("Can not open %s for writing", fname);
    exit( EXIT_FAILURE);
}
else printf("%s was opened for writing\n",fname);

/* display it is available */
if( !fclose(fp) ) printf("%s was closed\n",fname);

/* delete file */
if( unlink(fname) )
{
    printf("%s was not deleted",fname);
    exit( EXIT_FAILURE );
}

/* show it can't be re-opened */
if( (fp =fopen( fname,"r")) == NULL )
{
    printf("Can not open %s for reading it was deleted",fname);
    exit( EXIT_FAILURE);
}
else printf("%s was opened for reading\n",fname);

return 0;
}

Result
Test.txt was opened for writing
Test.txt was closed
Can not open Test.txt for reading it was deleted

write

Write to a file stream that has been opened in binary mode for unformatted output.

#include <unistd.h>

int write(int fildes, const char* buf, size_t count)
The function `write()` copies the number of bytes in the `count` argument from the character array buffer to the file `fildes`. The file position is then incremented by the number of bytes written. For example usage, see Listing 41.2.

This function should be used in conjunction with “read” on page 528, and “open, _wopen” on page 121 only.

`write()` returns the number of bytes actually written.

This function may not be implemented on all platforms.

- “open, _wopen” on page 121
unistd.h
Overview of unistd.h
The `unix.h` header file contains two global variables.

**Overview of unix.h**

The header file `unix.h` contains two global variables that are useful for console interface programs for setting a Mac OS file creator and file type.

The globals variables in `unix.h` are as follows:

- `_fcreator` on page 539 sets a Macintosh file creator.
- `_ftype` on page 540 sets a Macintosh file type.

**UNIX Compatibility**

Generally, you don’t want to use these functions in new programs. Instead, use their counterparts in the native API.

**NOTE** If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

---

**_fcreator**

To specify a Macintosh file creator.

```c
#include <unix.h>
extern long _fcreator
```

**Remarks**

Use the global `_fcreator` to set the creator type for files created using the Standard C Libraries. For example usage, see [Listing 42.1](#).

This global identifier is Macintosh Only.
unix.h
Overview of unix.h

_ftype

To specify a Macintosh file type.
#include <unix.h>
extern long _ftype;

Remarks
Use the global _ftype to set the creator type for files created using the Standard C Libraries. For example usage, see Listing 42.1.
The value assigned to _fcreate and _ftype is a ResType (i.e. four character constant).
This global identifier is Macintosh only

Listing 42.1 Usage of Global Variables to Set file Creator and Type
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <unix.h>

#define oFile "test file"
const char *str = "CodeWarrior Software at Work";

int main(void)
{
    FILE *fp;
    _fcreate = 'ttxt';
    _ftype = 'TEXT';

    // create a new file for output and input
    if (( fp = fopen(oFile, "w+")) == NULL)
    {
        printf("Can't create file.\n");
        exit(1);
    }

    fwrite(str, sizeof(char), strlen(str), fp);
    fclose(fp);

    return 0;
}
// output to the file using fwrite()
CodeWarrior Software at Work
unix.h
Overview of unix.h
The **utime.h** header file contains several functions that are useful for porting a program from UNIX.

## Overview of utime.h

The header file **utime.h** contains several functions that are useful for porting a program from UNIX. These functions are similar to the functions in many UNIX libraries. However, since the UNIX and Macintosh operating systems have some fundamental differences, they cannot be identical. The descriptions of the functions tell you what the differences are.

This header file defines the facilities as follows:

- **utime** on page 543 sets a file modification time.
- **utimes** on page 546 sets a series of file modification times.

## utime.h and UNIX Compatibility

Generally, you don’t want to use these functions in new programs. Instead, use their counterparts in the native API.

**NOTE** If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

### See Also

Table 1.1 for information on POSIX naming conventions.

---

### utime

Sets a file’s modification time.

```c
#include <utime.h>

int utime(const char *path, /* Mac */ const struct utimbuf
```
utime.h
Overview of utime.h

```c
int utime(const char *path, /* Windows */ struct utimbuf *buf);
```

**Remarks**

This function sets the modification time for the file specified in `path`. Since the Macintosh does not have anything that corresponds to a file’s access time, it ignores the `actime` field in the `utimbuf` structure.

If `buf` is NULL, `utime()` sets the modification time to the current time. If `buf` points to a `utimbuf` structure, `utime()` sets the modification time to the time specified in the `modtime` field of the structure.

The `utimbuf` structures contain the fields in Table 43.2.

If it is successful, `utime()` returns zero. If it encounters an error, `utime()` returns -1 and sets `errno`.

This function may not be implemented on all platforms.

**See Also**

“ctime” on page 492
“mktime” on page 498
Listing 43.1 Example for utime() Usage

```c
#include <stdio.h>
#include <stdlib.h>
#include <unix.h>

int main(void)
{
    struct utimbuf timebuf;
    struct tm date;
    struct stat info;
    FILE * fp;

    fp = fopen("mytest", "w");
    if(!fp)
    {
        fprintf(stderr,"Could not open file");
        exit(EXIT_FAILURE);
    }
    fprintf(fp,"test");
    fclose(fp);
    /* Create a calendar time for Midnight, Apr. 4, 1994. */
    date.tm_sec=0;    /* Zero seconds */
    date.tm_min=0; /* Zero minutes */
    date.tm_hour=0; /* Zero hours */
    date.tm_mday=4;   /* 4th day */
    date.tm_mon=3; /* .. of April */
    date.tm_year=94; /* ...in 1994 */
    date.tm_isdst=-1; /* Not daylight savings */
    timebuf.modtime=mktime(&date);
    /* Convert to calendar time. */
    /* Change modification date to Midnight, Apr. 4, 1994. */
    utime("mytest", &timebuf);
    stat("mytest", &info);
    printf("Mod date is %s", ctime(&info.st_mtime));
    /* Change modification date to current time */
    utime("mytest", NULL);
    stat("mytest", &info);
```
**utime.h**

*Overview of utime.h*

```c
printf("Mod date is %s", ctime(&info.st_mtime));
return 0;
}
```

This program might display the following to standard output:

```
Mod date is Mon Apr  4 00:00:00 1994
Mod date is Mon Jul 10 17:45:17 2000
```

---

**utimes**

Sets a file’s modification time

```c
#include <utime.h>
int utimes(const char *path, struct timeval buf[2]);
```

<table>
<thead>
<tr>
<th>Table 43.3 utimes</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>path</strong></td>
</tr>
<tr>
<td><strong>buf</strong></td>
</tr>
</tbody>
</table>

**Remarks**

This function sets the modification time for the file specified in path to the second element of the array buf. Each element of the array buf is a `timeval` structure, which has the fields in Table 43.4.

<table>
<thead>
<tr>
<th>Table 43.4 The timeval Structure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field</strong></td>
</tr>
<tr>
<td>int tv_sec</td>
</tr>
<tr>
<td>int tv_usec</td>
</tr>
</tbody>
</table>

The first element of buf is the access time.
Since the Macintosh does not have anything that corresponds to a file’s access time, it ignores that element of the array.

If it is successful, `utimes()` returns 0. If it encounters an error, `utimes()` returns -1 and sets `errno`.

This function may not be implemented on all platforms.

```c
#include <stdio.h>
#include <unix.h>
#include <time.h>

int main(void)
{
    struct tm date;
    struct timeval buf[2];
    struct stat info;

    /* Create a calendar time for Midnight, Sept. 9, 1965. */
    date.tm_sec=0;      /* Zero seconds */
    date.tm_min=0;      /* Zero minutes */
    date.tm_hour=0;     /* Zero hours */
    date.tm_mday=9;     /* 9th day */
    date.tm_mon=8;      /* .. of September */
    date.tm_year=65;    /* ...in 1965 */
    date.tm_isdst=-1;   /* Not daylight savings */
    buf[1].tv_sec=mktime(&date); /* Convert to calendar time. */
    utimes("mytest", buf);
    stat("mytest", &info);
    printf("Mod date is %s", ctime(&info.st_mtime));
}
```
This program prints the following to standard output:
Mod date is Thu Sep  9 00:00:00 1965
utsname.h

The utsmame.h header file contains several functions that are useful for porting a program from UNIX.

Overview of utsmame.h

These utsmame.h functions are similar to the functions in many UNIX libraries. However, since the UNIX and Macintosh operating systems have some fundamental differences, they cannot be identical. The descriptions of the functions tell you the differences.

The header utsmame.h has one function: “uname” on page 549, which retrieves information on the system you are using.

utsname.h and UNIX Compatibility

Generally, you don’t want to use these functions in new programs. Instead, use their counterparts in the Macintosh Toolbox.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

- “wcssrchr” on page 587 behaves like strrchr for wide character arrays.
- “wcsnnspn” on page 589 behaves like strspn for wide character arrays.
- “wcsnstr” on page 589 behaves like strstr for wide character arrays.
- “wcstof” on page 590 behaves like strtod for wide character arrays.
- “wcsftol” on page 591 behaves like strtok for wide character arrays.
- “wcstok” on page 592 behaves like strtok for wide character arrays.
- “wcstol” on page 593 behaves like strtol for wide character arrays.
- “wcstold” on page 594 behaves like strtold for wide character arrays.
- “wcstoll” on page 595 behaves like strtoll for wide character arrays.
- “wcstout” on page 596 behaves like strtoull for wide character arrays.
- “wcstoull” on page 598 behaves like strxfrm for wide character arrays.
- “wmemchr” on page 601 behaves like memchr for wide character arrays.
- “wmemcpy” on page 603 behaves like memcpy for wide character arrays.
- “wmemcmp” on page 602 behaves like memcmp for wide character arrays.
• “wmemmove” on page 603 behaves like `memmove` for wide character arrays.
• “wmemset” on page 604 behaves like `memset` for wide character arrays.

**Multibyte Character Functions**

- “`mbrlen`” on page 564 behaves like `strlen` for multibyte character arrays
- “`mbrtowc`” on page 564 converts multibyte characters to wide character arrays
- “`mbsinit`” on page 566 determines the multibyte conversion status
- “`mbsrtowcs`” on page 567 converts multibyte strings to wide character strings
- “`wctomb`” on page 577 converts wide characters to multibyte character arrays
- “`wcsrtombs`” on page 587 converts wide character strings to multibyte strings.

**Conversion Functions**

- “`btowc`” on page 557 converts byte characters to wide character arrays
- “`wctob`” on page 600 converts wide characters to byte character arrays

**Wide Character and Byte Character Stream Orientation**

There are two types of stream orientation for input and output, a wide character (wchar_t) oriented and a byte (char) oriented. A stream is un-oriented after that stream is associated with a file, until a byte or wide character input/output operation occurs.

Once any input/output operation is performed on that stream, that stream becomes oriented by that operation to be either byte oriented or wide character oriented and remains that way until the file has been closed and reopened.

**Table 45.1 Byte Oriented Functions in Stdio.h**

<td>vfprintf</td>
</tr>
</tbody>
</table>
Unicode

Unicode, also known as UCS-2 (Universal Character Set containing 2 bytes) is a fixed-width encoding scheme that uses 16 bits per character. Characters are represented and manipulated in MSL as wide characters of type `wchar_t` and can be manipulated with the wide character functions defined in the C Standard.

Multibyte Characters

A Unicode character may be encoded as a sequence of one or more 8-bit characters, this is a multibyte character. There are two types of multibyte encoding, modal and non-modal. With modal encoding, a conversion state is associated with a multibyte string; this state is akin to the shift state of a keyboard. With non-modal encoding, no such state is involved and the first character of a multibyte sequence contains information about the number of characters in the sequence. The actual encoding scheme is defined in the LC_CTYPE component of the current locale.

In MSL, two encoding schemes are available, a direct encoding where only a single byte is used and the non-modal UTF-8 (UCS Transformation Format -8) encoding scheme is used where each Unicode character is represented by one to three 8-bit characters. For Unicode characters in the range 0x0000 to 0x007F the encoding is direct and only a single byte is used.
Stream Orientation and Standard Input/Output

The three predefined associated streams, stdin, stdout, and stderr are un-oriented at program startup. If any of the standard input/output streams are closed it is not possible to reopen and reconnect that stream to the console. However, it is possible to reopen and connect the stream to a named file.

The C and C++ input/output facilities share the same stdin, stdout and stderr streams.

Definitions

The header wchar.h includes specific definitions for use with wide character sets.

Table 45.3 Wide Character Definitions

<table>
<thead>
<tr>
<th>Defines</th>
<th>Definitions</th>
</tr>
</thead>
<tbody>
<tr>
<td>mbstate_t</td>
<td>A value that can hold the conversion state for mode-dependent multibyte encoding</td>
</tr>
<tr>
<td>WCHAR_MIN</td>
<td>Minimum value of a wide char</td>
</tr>
<tr>
<td>WCHAR_MAX</td>
<td>Maximum value of a wide char</td>
</tr>
<tr>
<td>WEOF</td>
<td>A value that differs from any member of the wide character set and is used to denote end of file</td>
</tr>
<tr>
<td>win_t</td>
<td>An int type that can hold any wide character representation and WEOF</td>
</tr>
</tbody>
</table>

btowc

The function `btowc()` converts a single byte character to a wide character.

```c
#include <wchar.h>

wint_t btowc(int c);
```

Table 45.4 btowc

<table>
<thead>
<tr>
<th>int</th>
<th>c</th>
<th>The character to be converted</th>
</tr>
</thead>
</table>
**wchar.h**
*Overview of wchar.h*

**Returns**

The function btowc() returns the wide character representation of the argument or WEOF is returned if c has the value EOF or if the current locale specifies that UTF-8 encoding is to be used and unsigned char c does not constitute a valid single-byte UTF-8 encoded character.

This function may not be implemented on all platforms.

**See Also**

“wctob” on page 600

---

**fgetwc**

Gets a wide character from a file stream.

```c
#include <wchar.h>

wchar_t fgetwc(FILE * file);
```

**Table 45.5 fgetwc**

<table>
<thead>
<tr>
<th>file</th>
<th>FILE *</th>
<th>The input stream to retrieve from</th>
</tr>
</thead>
</table>

**Remarks**

Performs the same task as fgetc for wide character

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

Returns the wide character or WEOF for an error

This function may not be implemented on all platforms.

**See Also**

“Wide Character and Byte Character Stream Orientation” on page 555

“fgets” on page 312
### wchar.h

**Overview of wchar.h**

#### fgetws

The function `fgetws()` reads a wide character string from a file stream.

```c
#include <wchar.h>
wchar_t *fgetws(wchar_t * s, int n, FILE * file);
```

**Remarks**

- Behaves like `fgets()` for wide characters.
- On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.
- Returns a pointer to `s` if successful or `NULL` for a failure.
- This function may not be implemented on all platforms.

**See Also**

- “Wide Character and Byte Character Stream Orientation” on page 555
- “fgets” on page 316

#### Table 45.6 fgetws

<table>
<thead>
<tr>
<th>s</th>
<th>wchar_t*</th>
<th>A wide char string to receive input</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>int</td>
<td>Maximum number of wide characters to be read</td>
</tr>
<tr>
<td>file</td>
<td>FILE *</td>
<td>A pointer to the input file stream</td>
</tr>
</tbody>
</table>

#### fputwc

Inserts a single wide character into a file stream.

```c
#include <wchar.h>
wchar_t fputwc(wchar_t c, FILE * file);
```
**fputwc**

Inserts a wide character into a file stream

```c
#include <wchar.h>

int fputwc(wchar_t c, FILE * file);
```

<table>
<thead>
<tr>
<th>c</th>
<th>wchar_t</th>
<th>The wide character to insert</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>FILE *</td>
<td>A pointer to the output file stream</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `fputc()` for a wide character type.

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

Returns the wide character written if it is successful, and returns `WEOF` if it fails.

This function may not be implemented on all platforms.

**See Also**

“Wide Character and Byte Character Stream Orientation” on page 555

“fputc” on page 328

**fputws**

Inserts a wide character array into a file stream

```c
#include <wchar.h>

int fputws(const wchar_t * s, FILE * file);
```

<table>
<thead>
<tr>
<th>s</th>
<th>wchar_t *</th>
<th>The string to insert</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>FILE *</td>
<td>A pointer to the output file stream</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `fputs` for a wide character type.

If the file is opened in update mode (+) the file cannot be written to and then read from unless the write operation and read operation are separated by an operation that flushes the stream's buffer. This can be done with the `fflush()` function.
or one of the file positioning operations (fseek(), fsetpos(), or rewind()).
On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.
Returns a zero if successful, and returns a nonzero value when it fails.
This function may not be implemented on all platforms.

See Also

“Wide Character and Byte Character Stream Orientation” on page 555
“fputs” on page 330

fwprintf

Formatted file insertion
#include <wchar.h>
int fwprintf(FILE * file, const wchar_t * format, ...);

Table 45.9  fwprintf

<table>
<thead>
<tr>
<th>file</th>
<th>FILE *</th>
<th>A pointer to the output file stream</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>wchar_t*</td>
<td>The format string</td>
</tr>
<tr>
<td>....</td>
<td></td>
<td>Variable arguments</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as fprintf() for a wide character type.
The fwprintf() function writes formatted text to a wide character stream and advances the file position indicator. Its operation is the same as wprintf() with the addition of the stream argument.
Refer to the "wprintf" on page 605 function for details of the format string.
On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.
Returns the number of arguments written or a negative number if an error occurs
This function may not be implemented on all platforms.
fwscanf

Reads formatted text from a stream.

```
#include <wchar.h>

int fwscanf(FILE * file, const wchar_t * format, ...);
```

### Remarks

Performs the same task as `fscanf` function for the wide character type.

The `fwscanf`() function reads programmer-defined, formatted text from a wide character stream. The function operates identically to the `wscanf`() function with the addition of the `stream` argument indicating the stream to read from.

Refer to the "wscanf" on page 610 function for details of the format string.

**NOTE**

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

Returns the number of items read, which can be fewer than provided for in the event of an early matching failure. If the end of file is reached before any conversions are made, `EOF` is returned.

This function may not be implemented on all platforms.

### See Also

"Wide Character and Byte Character Stream Orientation" on page 555

"wscanf" on page 610
getwc

Reads the next wide character from a wide character stream.

```c
#include <wchar.h>
wchar_t getwc(FILE * file);
```

**Remarks**

Performs the same task as `getc` for a wide character type.

Returns the next wide character from the stream or returns `WEOF` if the end-of-file has been reached or a read error has occurred.

This function may not be implemented on all platforms.

**See Also**

“Wide Character and Byte Character Stream Orientation” on page 555
“getc” on page 348

getwchar

Returns a wide character type from the standard input.

```c
#include <wchar.h>
wchar_t getwchar(void);
```

Has no parameters.

**Remarks**

Performs the same task as `getchar` for a wide character type.

Returns the value of the next wide character from stdin as an int if it is successful. `getwchar()` returns `WEOF` if it reaches an end-of-file or an error occurs.

This function may not be implemented on all platforms.
**wchar.h**

*Overview of wchar.h*

---

**See Also**

“Wide Character and Byte Character Stream Orientation” on page 555

“getwchar” on page 563

---

**mbrlen**

Computes the length of a multibyte character encoded as specified in the `LC_CTYPE` component of the current locale. This function is essentially the same as `mblen()` except that it has an additional parameter of type `mbstate_t*`, which is ignored if the encoding scheme is non-modal.

```c
#include <stdlib.h>

int mbrlen(const char *s, size_t n, mbstate_t *ps);
```

**Table 45.12 mbrlen**

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>const char **</td>
<td>The multibyte array to measure</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The Maximum size</td>
</tr>
<tr>
<td>ps</td>
<td>mbstate_t **</td>
<td>The current state of translation between multibyte and wide character, ignored if the encoding scheme is non-modal.</td>
</tr>
</tbody>
</table>

**Remarks**

The `mbrlen()` function returns the length of the multibyte character pointed to by `s`. It examines a maximum of `n` characters.

The MSL C implementation supports the “C” locale with UTF-8 encoding only and returns the value of `mbtowc(NULL, s, n, pc)`.

`mbrlen()` returns the value of `mbtowc(NULL, s, n, pc)`.

This function may not be implemented on all platforms.

**See Also**

“wcslen” on page 583

“strlen” on page 468
mbrtowc

Translate a multibyte character to a wchar_t type according to the encoding specified in the LC_CTYPE component of the current locale. This function is essentially the same as mbtowcs() except that it has an additional parameter of type mbstate_t*, which is ignored if the encoding scheme is non-modal.

```
#include <stdlib.h>
int mbtowc(wchar_t *pwc, const char *s, size_t n, mbstate_t *ps);
```

**Table 45.13 mbtowc**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwc</td>
<td>wchar_t*</td>
</tr>
<tr>
<td>s</td>
<td>const char*</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
</tr>
<tr>
<td>ps</td>
<td>mbstate_t*</td>
</tr>
</tbody>
</table>

Remarks

If s a null pointer, this call is equivalent to mbtowcs(NULL, "", 1, ps);

If s is not a null pointer, the mbtowc() function examines at most n bytes starting with the byte pointed to by s to determine how many bytes are needed to complete a valid encoding of a Unicode character. If this is less than or equal to n and pwc is not a null pointer, it converts the multibyte character, pointed to by s, to a character of type wchar_t, pointed to by pwc using the encoding scheme specified in the LC_CTYPE component of the current locale.

mbtowc() returns the first of the following values that applies:

Zero, if s points to a null character, which is the value stored.

Greater than zero, if s points to a complete and valid multibyte character of n or fewer bytes, the corresponding Unicode wide character is stored (if pwc is not
wchar.h
Overview of wchar.h

wchar.h

NULL) and the value returned is the number of bytes in the complete multibyte character.

(size_t)(-2) if the next n bytes pointed to by s constitute an incomplete but potentially valid multibyte character. No value is stored.

(size_t)(-1) if the next n or fewer bytes pointed to by s do not constitute a complete and valid multibyte character. The value of EILSEQ is stored in errno but no wide character value is stored.

This function may not be implemented on all platforms.

See Also
“mbsrtowcs” on page 567
“wcrtomb” on page 577
“wcsrtombs” on page 587

mbsinit

Determines if the multi-byte state is the initial conversion state or not.

#include <wchar.h>

int mbsinit(const mbstate_t *ps);

Table 45.14  mbsinit

<table>
<thead>
<tr>
<th>ps</th>
<th>const mbstate_t *</th>
<th>A pointer to a mbstate_t object</th>
</tr>
</thead>
</table>

Remarks

If the status of the object pointed to is a null pointer or is in the initial conversion state a true values is returned otherwise zero is returned.

This function may not be implemented on all platforms.

See Also
“mbsrtowcs” on page 567
“wcrtomb” on page 577
“wcsrtombs” on page 587
**mbsrtowcs**

Convert a multibyte character array to a wchar_t array. This function is essentially the same as mbstowcs() except that it has an additional parameter of type mbstate_t*, which is ignored if the encoding scheme is non-modal.

```c
#include <stdlib.h>
size_t mbsrtowcs(wchar_t *pwcs,
               const char **s, size_t n, mbstate_t * ps);
```

### Table 45.15 mbsrtowcs

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pwcs</td>
<td>wchar_t *</td>
</tr>
<tr>
<td>s</td>
<td>const char **</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
</tr>
<tr>
<td>ps</td>
<td>mbstate_t *</td>
</tr>
</tbody>
</table>

### Remarks

The MSL C implementation of mbsrtowcs() converts a sequence of multibyte characters encoded according to the scheme specified in the LC_CTYPE component of the current locale from the wide character array indirectly pointed to by s and, if pwcs is not a null pointer, stores not more than n of the corresponding Unicode characters into the wide character array pointed to by pwcs. The function terminates prematurely if a null character is reached, in which case the null wide character is stored. or if an invalid multibyte encoding is detected. If conversion stops because a terminating null character is reached, a null pointer is assigned to the object pointed to by s, otherwise a pointer to the address just beyond the last multibyte character converted, if any.

If an invalidly encoded wide character is encountered, mbsrtowcs() stores the value of EILSEQ in errno and returns the value (size_t)(-1). Otherwise
wchar.h
Overview of wchar.h

`mbsrtowcs()` returns the number of multibyte characters successfully converted, not including any terminating null wide character. This function may not be implemented on all platforms.

See Also
“wcsrtombs” on page 587
“mbtowc” on page 565

putwc

Write a wide character type to a stream.

```c
#include <wchar.h>

wchar_t putwc(wchar_t c, FILE * file);
```

<table>
<thead>
<tr>
<th>c</th>
<th>wchar_t</th>
<th>The wide character to output</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>FILE</td>
<td>The output stream</td>
</tr>
</tbody>
</table>

Remarks
Performs the same task as `putc` for a wide character type.
Returns the wide character written when successful and returns `WEOF` when it fails.
This function may not be implemented on all platforms.

See Also
“Wide Character and Byte Character Stream Orientation” on page 555
“putc” on page 362

putwchar

Writes a wide character to standard output.

```c
#include <wchar.h>

wchar_t putwchar(wchar_t c);
```
### wchar.h Overview of wchar.h

**Remarks**

Performs the same task as `putchar` for a wide character type.

Returns `c` if it is successful and returns `WEOF` if it fails.

This function may not be implemented on all platforms.

**See Also**

“Wide Character and Byte Character Stream Orientation” on page 555

“putchar” on page 363

---

### swprintf

Formats text in a wide character type string.

```c
#include <wchar.h>

int swprintf(wchar_t *S, size_t N, const wchar_t * format, ...);
```

**Table 45.18 swprintf**

<table>
<thead>
<tr>
<th>s</th>
<th>wchar_t*</th>
<th>The string buffer to hold the formatted text</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>size_t</td>
<td>Number of characters allowed to be written</td>
</tr>
<tr>
<td>format</td>
<td>wchar_t*</td>
<td>The format string</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td>Variable arguments</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `sprintf` for a wide character type with an additional parameter for the maximum number of wide characters to be written. No more than `n` wide characters will be written including the terminating `NULL` wide character, which is always added unless the `n` is zero.
Refer to the "wprintf" on page 605 function for details of the format string.

Returns the number of characters assigned to $S$, not including the null character, or a negative number if $n$ or more characters were requested to be written.

See Also
"Wide Character and Byte Character Stream Orientation" on page 555
"fwprintf" on page 561
"sprintf" on page 380

**swscanf**

Reads a formatted wide character string.

```c
#include <wchar.h>

int swscanf(const wchar_t * s, const wchar_t * format, ...);
```

<table>
<thead>
<tr>
<th>s</th>
<th>wchar_t*</th>
<th>The string being read</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
<td>wchar_t*</td>
<td>The format string</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td>Variable arguments</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as `scanf` for a wide character type.

Returns the number of items successfully read and converted, which can be fewer than provided for in the event of an early matching failure. If the end of the input string is reached before any conversions are made, EOF is returned.

Refer to the "wscanf" on page 610 function for details of the format string.

This function may not be implemented on all platforms.

See Also
"Wide Character and Byte Character Stream Orientation" on page 555
"scanf" on page 370
vfwscanf

Read formatted text from a wide character stream.

```c
#include <wchar.h>
int vfwscanf(FILE * file,
            const wchar_t * format_str, va_list arg);
```

### Remarks

Performs the same task as `fscanf` for a wide character type.

Refer to the "wscanf" on page 610 function for details of the format string.

#### NOTE

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

vfscanf() returns the number of items assigned, which can be fewer than provided for in the case of an early matching failure. If an input failure occurs before any conversion, vfscanf() returns EOF.

This function may not be implemented on all platforms.

### See Also

"Wide Character and Byte Character Stream Orientation" on page 555
"fscanf" on page 335
vswscanf

Reads formatted text from a wide character string.

```c
#include <wchar.h>

int __vswscanf(const wchar_t * s,
                const wchar_t * format, va_list arg);
```

### Table 45.21 __vswscanf

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>s</td>
<td>wchar_t*</td>
<td>The string being read</td>
</tr>
<tr>
<td>format</td>
<td>wchar_t*</td>
<td>The format string</td>
</tr>
<tr>
<td>.arg</td>
<td>va_list</td>
<td>A variable argument list</td>
</tr>
</tbody>
</table>

### Remarks

The `vswscanf()` function works identically to the `swscanf()` function. Instead of the variable list of arguments that can be passed to `swscanf()`, `vswscanf()` accepts its arguments in the array `arg` of type `va_list`, which must have been initialized by the `va_start()` macro (and possibly subsequent `va_arg` calls) from the `stdarg.h` header file. The `vswscanf()` function does not invoke the `va_end` macro.

Refer to the “wscanf” on page 610 function for details of the format string.

**NOTE**  On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

`vswscanf()` returns the number of items assigned, which can be fewer than provided for in the case of an early matching failure. If an input failure occurs before any conversion, `vswscanf()` returns `EOF`.

This function may not be implemented on all platforms.

### See Also

“Wide Character and Byte Character Stream Orientation” on page 555

**vfwprintf**

Write a formatted text to a file stream.

```c
#include <wchar.h>
int vfwprintf(FILE * file, const wchar_t * format_str, va_list arg);
```

### Remarks

The `vfwprintf()` function works identically to the `fwprintf()` function. Instead of the variable list of arguments that can be passed to `fwprintf()`, `vfwprintf()` accepts its arguments in the array `arg` of type `va_list`, which must have been initialized by the `va_start()` macro (and possibly subsequent `va_arg` calls) from the stdarg.h header file. The `vfwprintf()` function does not invoke the `va_end` macro.

Refer to the “wprintf” on page 605 function for details of the format string.

### NOTE

On embedded/RTOS systems this function only is implemented for stdin, stdout and stderr files.

Returns the number of wide characters written or a negative number if it failed.
This function may not be implemented on all platforms.

### See Also

“Wide Character and Byte Character Stream Orientation” on page 555
“vfprintf” on page 387
vswprintf

Write a formatted output to a wide character string.

```c
#include <stdio.h>
#include <wchar.h>
#include <stdarg.h>

int vswprintf(wchar_t * restrict s, size_t n,
              const wchar_t * restrict format, va_list arg);
```

### Remarks

The vswprintf() function works identically to the swprintf() function. Instead of the variable list of arguments that can be passed to swprintf(), vswprintf() accepts its arguments in the array arg of type va_list, which must have been initialized by the va_start() macro (and possibly subsequent va_arg calls) from the stdarg.h header file. The vfwprintf() function does not invoke the va_end macro.

Refer to the "wprintf" on page 605 function for details of the format string.

The vswprintf function does not invoke the va_end macro.

Returns the number of characters written not counting the terminating null wide character. Otherwise a negative value if a failure occurs.

This function may not be implemented on all platforms.

</table>

**Remarks**

The `vwprintf()` function works identically to the `vprintf()` function. Instead of the variable list of arguments that can be passed to `vprintf()`, `vwprintf()` accepts its arguments in the array `arg` of type `va_list`, which must have been initialized by the `va_start()` macro (and possibly subsequent `va_arg` calls) from the `stdarg.h` header file. The `vwprintf()` function does not invoke the `va_end` macro.

Refer to the "[vprintf on page 605](#)") function for details of the format string.

Returns the number of characters written or a negative value if it failed.

This function may not be implemented on all platforms.

**See Also**

- "[Wide Character and Byte Character Stream Orientation](#)" on page 555
- "[vprintf on page 391](#)"

---

**watof**

Convert a wide character string to a double type

```c
#include <wchar.h>

double watof(wchar_t * str);
```
Table 45.26 wtof

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t</th>
<th>The wide character string to be converted</th>
</tr>
</thead>
</table>

Remarks
Performs the same task as `atof` for a wide character type.
Returns the converted value or, if no conversion could be performed, zero.
This function may not be implemented on all platforms.

See Also
“atof” on page 410

wctomb

Translate a wchar_t type to a multibyte character according to the encoding scheme specified in the `LC_CTYPE` component of the current locale. This function is essentially the same as `wctomb()` except that it has an additional parameter of type `mbstate_t*`, which is ignored if the encoding scheme is non-modal.

```c
#include <stdlib.h>
int wctomb(char *s, wchar_t wchar, mbstate_t *ps);
```

Table 45.27 wctomb

<table>
<thead>
<tr>
<th>s</th>
<th>char *</th>
<th>A multibyte string buffer</th>
</tr>
</thead>
<tbody>
<tr>
<td>wchar</td>
<td>wchar_t</td>
<td>A wide character to convert</td>
</tr>
<tr>
<td>ps</td>
<td>mbstate_t*</td>
<td>The current state of translation between multibyte and wide character, ignored if the encoding scheme is non-modal.</td>
</tr>
</tbody>
</table>

Remarks
If `s` is a null pointer, this call is equivalent to `wctomb(buf, L'\0', ps)` where `buf` is an internal buffer.
If s is not a null pointer, `wcrtomb()` determines the length of the UTF-8 multibyte string that corresponds to the wide character `wchar` and stores that string in the multibyte string pointed to by s. At most `MB_CUR_MAX` bytes are stored.

`wcrtomb()` returns the number of bytes stored in the string s.

This function may not be implemented on all platforms.

**See Also**

“`mbrtowc`” on page 565

“`wcsrtombs`” on page 587

---

**wcscat**

Wide character string concatenation

```c
#include <wchar.h>

wchar_t * wcscat(wchar_t * dst, const wchar_t * src);
```

**Table 45.28  wcscat**

<table>
<thead>
<tr>
<th>dst</th>
<th>wchar_t *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>wchar_t *</td>
<td>The source string</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `strcat` for a wide character type.

Returns a pointer to the destination string

This function may not be implemented on all platforms.

**See Also**

“`strcat`” on page 459
wcschr

Search for an occurrence of a wide character.

```c
#include <wchar.h>
wchar_t * wcschr(const wchar_t * str, const wchar_t chr);
```

Remarks

Performs the same task as `strchr` for a wide character type.

Returns a pointer to the successfully located wide character. If it fails, `wcschr()` returns a null pointer (NULL).

This function may not be implemented on all platforms.

See Also

“strchr” on page 460

wcscmp

Compare two wide character arrays.

```c
#include <wchar.h>
int wcscmp(const wchar_t * str1, const wchar_t * str2);
```

Remarks

Performs the same task as `strcmp` for a wide character type.
**wchar.h**

*Overview of wchar.h*

Returns a zero if `str1` and `str2` are equal, a negative value if `str1` is less than `str2`, and a positive value if `str1` is greater than `str2`.

This function may not be implemented on all platforms.

**See Also**

“`strcmp`” on page 461

“`wmemcmp`” on page 602

---

**wcscoll**

Compare two wide character arrays according to the collating sequence defined in the `LC_COLLATE` component of the current locale.

```c
#include <wchar.h>

int wcscoll(const wchar_t *str1, const wchar_t * str2);
```

**Table 45.31  wcscoll**

<table>
<thead>
<tr>
<th>str1</th>
<th>wchar_t *</th>
<th>First comparison string</th>
</tr>
</thead>
<tbody>
<tr>
<td>str2</td>
<td>wchar_t *</td>
<td>Second comparison string</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `strcoll` for a wide character type.

Returns zero if `str1` is equal to `str2`, a negative value if `str1` is less than `str2`, and a positive value if `str1` is greater than `str2`.

This function may not be implemented on all platforms.

**See Also**

“`strcoll`” on page 462

“`wcscmp`” on page 579

“`wmemcmp`” on page 602
**wcscspn**

Find the first wide character in one wide character string that is also in another.

```c
#include <wchar.h>
size_t wcscspn(const wchar_t * str, const wchar_t * set);
```

**Remarks**

The `wcscspn()` function finds the first wide character in the null terminated wide character string `s1` that is also in the null terminated wide character string `s2`. For this purpose, the null terminators are considered part of the strings. The function starts examining characters at the beginning of `s1` and continues searching until a wide character in `s1` matches a wide character in `s2`.

`wcscspn()` returns the index of the first wide character in `s1` that matches a wide character in `s2`.

This function may not be implemented on all platforms.

**See Also**

“`strcspn” on page 465

---

**wcscpy**

Copy one wide character array to another.

```c
#include <wchar.h>
wchar_t * wcscpy(wchar_t * dst, const wchar_t * src);
```
**wchar.h**

*Overview of wchar.h*

---

### Remarks

The `wcscpy()` function copies the wide character array pointed to by `src` to the wide character array pointed to `dst`. The `src` argument must point to a null terminated wide character array. The resulting wide character array at `dest` is null terminated as well.

If the arrays pointed to by `dest` and `source` overlap, the operation of `strcpy()` is undefined.

Returns a pointer to the destination string.

This function may not be implemented on all platforms.

**See Also**

"*strcpy* on page 464"

---

**wcsftime**

Formats a wide character string for time.

```c
#include <wchar.h>

size_t wcsftime(wchar_t * str, size_t max_size,
const wchar_t * format_str, const struct tm * timeptr);
```

---

### Table 45.34 wcsftime

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_size</td>
<td>size_t</td>
<td>Maximum string size</td>
</tr>
<tr>
<td>format_str</td>
<td>const wchar_t *</td>
<td>The format string</td>
</tr>
<tr>
<td>timeptr</td>
<td>const struct tm *</td>
<td>The time structure containing the calendar time</td>
</tr>
</tbody>
</table>

---

**wchar.h**

*Overview of wchar.h*
**Remarks**

Performs the same task as `strftime` for a wide character type.

The `wcsftime` function returns the total number of characters in the argument `str` if the total number of characters including the null character in the string argument `str` is less than the value of `max_size` argument. If it is greater, `wcsftime` returns 0.

This function may not be implemented on all platforms.

**See Also**

"strftime" on page 499

---

### wcslen

Compute the length of a wide character array.

```c
#include <wchar.h>

size_t (wcslen)(const wchar_t * str);
```

**Table 45.35 wcslen**

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t*</th>
<th>The string to compute</th>
</tr>
</thead>
</table>

**Remarks**

The `wcslen()` function computes the number of characters in a null terminated wide character array pointed to by `str`. The null character (L'\0') is not added to the wide character count.

Returns the number of characters in a wide character array not including the terminating null character.

This function may not be implemented on all platforms.

**See Also**

"strlen" on page 468
wcsncat

Append a specified number of characters to a wide character array.

```c
#include <wchar.h>

wchar_t * wcsncat(wchar_t * dst, const wchar_t * src, size_t n);
```

### Table 45.36 wcsncat

<table>
<thead>
<tr>
<th>dst</th>
<th>wchar_t *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>wchar_t *</td>
<td>The string to be appended</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The number of characters to copy</td>
</tr>
</tbody>
</table>

### Remarks

The `wcsncat()` function appends a maximum of `n` characters from the wide character array pointed to by `src` to the wide character array pointed to by `dst`. The `dst` argument must point to a null terminated wide character array. The `src` argument does not necessarily have to point to a null terminated wide character array.

If a null wide character is reached in `src` before `n` characters have been appended, `wcsncat()` stops.

When done, `wcsncat()` terminates `dst` with a null wide character (L'\0').

Returns a pointer to the destination string.

This function may not be implemented on all platforms.

### See Also

“strncat” on page 469
wcsncmp

Compare not more than a specified number of wide characters.

#include <wchar.h>
int csncmp(const wchar_t * str1,
const wchar_t * str2, size_t n);

Table 45.37 csncmp

<table>
<thead>
<tr>
<th>str1</th>
<th>wchar_t*</th>
<th>First comparison string</th>
</tr>
</thead>
<tbody>
<tr>
<td>str2</td>
<td>wchar_t*</td>
<td>Second comparison string</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>Maximum number of characters to compare</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as strncmp for a wide character type.

Returns a zero if the first n characters of str1 and str2 are equal, a negative value if str1 is less than str2, and a positive value if str1 is greater than str2.

This function may not be implemented on all platforms.

See Also

“strncmp” on page 470

wcsncpy

Copy a specified number of wide characters.

#include <wchar.h>
wchar_t * wcsncpy(wchar_t * dst,
const wchar_t * src, size_t n);
**wchar.h**

*Overview of wchar.h*

---

**Table 45.38 wcsncpy**

<table>
<thead>
<tr>
<th>det</th>
<th>wchar_t *</th>
<th>Destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>wchar_t *</td>
<td>Source to be copied</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>Number of characters to copy</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `strncpy` for a wide character type.

Returns a pointer to the destination string.

This function may not be implemented on all platforms.

**See Also**

“strncpy” on page 472

“wcsncpy” on page 581

---

**wcspbrk**

Look for the first occurrence of an element of an array of wide characters in another.

```
#include <wchar.h>

wchar_t * wcspbrk(const wchar_t * str, const wchar_t * set);
```

**Table 45.39 wcspbrk**

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t *</th>
<th>The string being searched</th>
</tr>
</thead>
<tbody>
<tr>
<td>set</td>
<td>wchar_t *</td>
<td>The search set</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `strpbrk` for a wide character type.

Returns a pointer to the first wide character in `str` that matches any wide character in `set`, and returns a null pointer (NULL) if no match was found.

This function may not be implemented on all platforms.
See Also

“strchr” on page 460

**wcsrchr**

Search a wide character string for the last occurrence of a specified wide character.

```c
#include <wchar.h>

wchar_t * wcsrchr(const wchar_t * str, wchar_t chr);
```

**Remarks**

Performs the same task as *strrchr* for a wide character type.

Returns a pointer to the wide character found or returns a null pointer (NULL) if it fails.

This function may not be implemented on all platforms.

See Also

“strchr” on page 460

**wcsrtombs**

Translate a wchar_t type character array to a multibyte character array. This function is essentially the same as *wcstombs()* except that it has an additional parameter of type mbstate_t*, which is ignored if the encoding scheme is non-modal.

```c
#include <wchar.h>

size_t wcsrtombs(char *dst, const wchar_t **src, size_t n, mbstate_t * ps);
```
Remarks

The MSL implementation of the `wcsrtombs()` function converts a character array containing `wchar_t` type Unicode characters indirectly pointed to by `src` to a character array containing UTF-8 multibyte characters. If `dst` is not a null pointer, these multibyte characters are stored in the array pointed to by `dst`. Conversion continues until either a terminating null wide character is encountered or (if `dst` is not a null pointer) if the translation of the next wide character would cause the total number of bytes to be stored to exceed `n`.

If `dst` is not a null pointer, the `wchar_t *` object pointed to by `src` is assigned either a null pointer if conversion ended because a null wide character was reached or the address just past the last wide character converted.

`wcsrtombs()` returns the number of bytes modified in the character array pointed to by `s`, not including a terminating null character, if any.

This function may not be implemented on all platforms.

wchar.h
Overview of wchar.h

wcsspn

Count the number of wide characters in one wide character array that are in another.
#include <wchar.h>
size_t wcsspn(const wchar_t * str, const wchar_t * set);

Table 45.42 wcsspn

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t*</th>
<th>The searched string</th>
</tr>
</thead>
<tbody>
<tr>
<td>set</td>
<td>const wchar_t*</td>
<td>The search set</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as strspn for a wide character type.
Returns the number of characters in the initial segment of str that contains only characters that are elements of set.
This function may not be implemented on all platforms.

See Also

"strspn" on page 475

wcsstr

Search for a wide character array within another.
#include <wchar.h>
wchar_t* wcsstr(const wchar_t* str, const wchar_t* pat);

Table 45.43 wcsstr

<table>
<thead>
<tr>
<th>str</th>
<th>const wchar_t*</th>
<th>The string to search</th>
</tr>
</thead>
<tbody>
<tr>
<td>pat</td>
<td>const wchar_t*</td>
<td>The string being searched for</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as strstr for a wide character type.
Returns a pointer to the first occurrence of \texttt{s2} in \texttt{s1} and returns a null pointer (NULL) if \texttt{s2} cannot be found.

This function may not be implemented on all platforms.

\textbf{See Also}

"\texttt{strstr}" on page 476

"\texttt{wcschr}" on page 579

\textbf{wcstod}

Converts a wide character array to double values.

\begin{verbatim}
#include <wchar.h>

double wcstod(wchar_t * str, char ** end);
\end{verbatim}

\textbf{Table 45.44 \texttt{wcstod}}

\begin{tabular}{|c|c|}
\hline
str & wchar_t * & The string being converted
\hline
end & char ** & If not null, a pointer to the first position not convertible.
\hline
\end{tabular}

\textbf{Remarks}

The \texttt{wcstod()} function converts a wide character array, pointed to by \texttt{nptr}, to a floating point value of type \texttt{double}. The wide character array can be in either decimal or hexadecimal floating point constant notation (e.g. 103.578, 1.03578e+02, or 0x1.9efef9p+6).

If the \texttt{endptr} argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by \texttt{nptr}. This position marks the first wide character that is not convertible to a value of type double.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

Returns a floating point value of type \texttt{double}. If \texttt{str} cannot be converted to an expressible double value, \texttt{wcstod()} returns \texttt{HUGE_VAL}, defined in \texttt{math.h}, and sets \texttt{errno} to \texttt{ERANGE}.

This function may not be implemented on all platforms.
See Also

“wcstof” on page 591
“strtod” on page 435
“wcstold” on page 594
“errno” on page 75

w cstof

Wide character array conversion to floating point value of type float.

#include <wchar.h>

float wcstof(const wchar_t * restrict nptr, wchar_t ** restrict endptr);

Table 45.45 wcstof

<table>
<thead>
<tr>
<th>nptr</th>
<th>const wchar_t*</th>
<th>A Null terminated wide character array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>wchar_t**</td>
<td>A pointer to a position in nptr that follows the converted part.</td>
</tr>
</tbody>
</table>

Remarks

The wcstof() function converts a wide character array, pointed to by nptr, to a floating point value of type float. The wide character array can be in either decimal or hexadecimal floating point constant notation (e.g. 103.578, 1.03578e+02, or 0x1.9efef9p+6).

If the endptr argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by nptr. This position marks the first wide character that is not convertible to a value of type float.

In other than the “C” locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

wcstof() returns a floating point value of type float. If nptr cannot be converted to an expressible float value, wcstof() returns HUGE_VAL, defined in math.h, and sets errno to ERANGE.

This function may not be implemented on all platforms.
**wchar.h**

*Overview of wchar.h*

---

**See Also**

---

**wcstok**

Extract tokens within a wide character array.

```c
#include <wchar.h>

wchar_t * wcstok(wchar_t * str, const wchar_t * set, wchar_t ** ptr);
```

---

**Table 45.46  wcstok**

<table>
<thead>
<tr>
<th>str</th>
<th>wchar_t *</th>
<th>The string to be modified</th>
</tr>
</thead>
<tbody>
<tr>
<td>set</td>
<td>wchar_t *</td>
<td>The list of wide character to find</td>
</tr>
<tr>
<td>ptr</td>
<td>wchar_t *</td>
<td>Continuation information</td>
</tr>
</tbody>
</table>

---

**Remarks**

Performs the same task as `strtok` for a wide character type however, it makes use of a third argument to contain sufficient information to continue the tokenization process.

When first called, the first argument is non-null. `wcstok()` returns a pointer to the first token in `str` or returns a null pointer if no token can be found.

Subsequent calls to `wcstok()` with a NULL `str` argument causes `wcstok()` to return a pointer to the next token or return a null pointer (NULL) when no more tokens exist. When called with a NULL `str` argument, the value of the `ptr` argument must have been set by a previous call to `wcstok()`.

The `wcstok` function returns a pointer to the first wide character of a token, or a null pointer if there is no token.

This function may not be implemented on all platforms.
wcstol

Wide character array conversion to floating point value of type long int.

```c
#include <wchar.h>
long int wcstol(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base);
```

### Remarks

The `wcstol()` function converts a wide character array, pointed to by `nptr`, to an integer value of type long. The base argument in `wcstold()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then `wcstold()` converts the wide character array based on its format. Wide character arrays beginning with ‘0’ are assumed to be octal, number strings beginning with ‘0x’ or ‘0X’ are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by `nptr`. This position marks the first wide character that is not convertible to a value of type long int.

In other than the “C” locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.
wchar.h
Overview of wchar.h

wchar.h returns an signed integer value of type long int. If the converted value is less than LONG_MIN, wcstol() returns LONG_MIN and sets errno to ERANGE. If the converted value is greater than LONG_MAX, wcstol() returns LONG_MAX and sets errno to ERANGE. The LONG_MIN and LONG_MAX macros are defined in limits.h

This function may not be implemented on all platforms.

See Also
“strtol” on page 438
“errno” on page 75
“wcstoll” on page 595
“wcstoul” on page 596

wcstold
A wide character array conversion to an floating point value of type long double.
#include <wchar.h>
long double wcstold(const wchar_t * restrict nptr,
wchar_t ** restrict endptr);

Table 45.48 wcstold

<table>
<thead>
<tr>
<th>nptr</th>
<th>const wchar_t *</th>
<th>A Null terminated wide character array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>wchar_t **</td>
<td>A pointer to a position in nptry that is not convertible.</td>
</tr>
</tbody>
</table>

Remarks
The wcstold() function converts a wide character array, pointed to by nptr, expected to represent an integer expressed in radix base, to an integer value of type long int. A plus or minus sign (+ or -) prefixing the number string is optional. The wide character array can be in either decimal or hexadecimal floating point constant notation (e.g. 103.578, 1.03578e+02, or 0x1.9efef9p+6).

If the endptr argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by nptr. This position marks the first wide character that is not convertible to a double value.
In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

Returns a floating point value of type long double. If nptr cannot be converted to an expressible double value, wcstold() returns HUGE_VAL, defined in math.h, and sets errno to ERANGE

This function may not be implemented on all platforms.

See Also

“wcstod” on page 590
“wcstof” on page 591
“strtold” on page 441

**wcstoll**

Wide character array conversion to integer value of type long long int.

#include <wchar.h>

long long int wcstoll(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base);

Table 45.49 wcstoll

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nptr</td>
<td>A Null terminated wide wide character array to convert</td>
</tr>
<tr>
<td>endptr</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

Remarks

The wcstoll() function converts a wide character array, pointed to by nptr, expected to represent an integer expressed in radix base to an integer value of type long long int. A plus or minus sign (+ or -) prefixing the number string is optional.
The base argument in \texttt{wcstoll()} specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then \texttt{wcstoll()} converts the wide character array based on its format. Wide character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the \texttt{endptr} argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by \texttt{nptr}. This position marks the first wide character that is not convertible to a long long int value.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

\texttt{wcstoll()} returns an integer value of type \texttt{long long int}. If the converted value is less than \texttt{LLONG_MIN}, \texttt{wcstoll()} returns \texttt{LLONG_MIN} and sets \texttt{errno} to \texttt{ERANGE}. If the converted value is greater than \texttt{LLONG_MAX}, \texttt{wcstoll()} returns \texttt{LLONG_MAX} and sets \texttt{errno} to \texttt{ERANGE}. The \texttt{LLONG_MIN} and \texttt{LLONG_MAX} macros are defined in \texttt{limits.h}

This function may not be implemented on all platforms.

\textbf{See Also}

- "\texttt{wcstol}" on page 593
- "\texttt{wcstoul}" on page 596
- "\texttt{errno}" on page 75

\section*{wcstoul}

Wide character array conversion to integer value of type unsigned long int.

\begin{verbatim}
#include <wchar.h>

unsigned long int wcstoul(const wchar_t * restrict nptr, wchar_t ** restrict endptr, int base);
\end{verbatim}
The `wcstoul()` function converts a wide character array, pointed to by `nptr`, to an integer value of type `unsigned long int`, in base. A plus or minus sign prefix is ignored.

The `base` argument in `wcstoul()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If `base` is 0, then `strtol()` and `wcstoul()` convert the wide character array based on its format. Wide character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by `nptr`. This position marks the first wide character that is not convertible to the functions' respective types.

In other than the "C" locale, additional locale-specific subject sequence forms may be accepted.

This function skips leading white space.

`wcstoul()` returns an unsigned integer value of type `unsigned long int`. If the converted value is greater than `ULONG_MAX`, `wcstoul()` returns `ULONG_MAX` and sets `errno` to `ERANGE`. The `ULONG_MAX` macro is defined in `limits.h`.

This function may not be implemented on all platforms.

**See Also**

**wchar.h**

Overview of wchar.h

“errno” on page 75

---

**wcstoull**

Wide character array conversion to integer value of type unsigned long long int.

```
#include <wchar.h>

unsigned long long int wcstoull(
    const wchar_t * restrict nptr,
    wchar_t ** restrict endptr, int base);
```

**Table 45.51 wcstoull**

<table>
<thead>
<tr>
<th>nptr</th>
<th>const wchar_t*</th>
<th>A Null terminated wide character array to convert</th>
</tr>
</thead>
<tbody>
<tr>
<td>endptr</td>
<td>wchar_t**</td>
<td>A pointer to a position in nptr that is not convertible.</td>
</tr>
<tr>
<td>base</td>
<td>int</td>
<td>A numeric base between 2 and 36</td>
</tr>
</tbody>
</table>

**Remarks**

The `wcstoull()` function converts a wide character array, pointed to by `nptr`, expected to represent an integer expressed in radix `base` to an integer value of type `unsigned long long int`. A plus or minus sign prefix is ignored.

The base argument in `wcstoull()` specifies the base used for conversion. It must have a value between 2 and 36, or 0. The letters a (or A) through z (or Z) are used for the values 10 through 35; only letters and digits representing values less than base are permitted. If base is 0, then `wcstoull()` converts the wide character array based on its format. Wide character arrays beginning with '0' are assumed to be octal, number strings beginning with '0x' or '0X' are assumed to be hexadecimal. All other number strings are assumed to be decimal.

If the `endptr` argument is not a null pointer, it is assigned a pointer to a position within the wide character array pointed to by `nptr`. This position marks the first wide character that is not convertible to a `long long` value.

In other than the “C” locale, additional locale-specific subject sequence forms may be accepted.
This function skips leading white space.

wcstoull() returns an unsigned integer value of type unsigned long long int. If the converted value is greater than ULLONG_MAX, wcstoull() returns ULLONG_MAX and sets errno to ERANGE. The ULLONG_MAX macro is defined in limits.h

This function may not be implemented on all platforms.

“wcstoul” on page 596
“strtoul” on page 443
“errno” on page 75

wcsxfrm

Transform a wide character array as specified in the LC_COLL component of the current locale.

#include <wchar.h>

size_t wcsxfrm(wchar_t * str1, const wchar_t * str2, size_t n);

Table 45.52 wcsxfrm

<table>
<thead>
<tr>
<th>str1</th>
<th>wchar_t*</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>str2</td>
<td>wchar_t*</td>
<td>The source string</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>Maximum number of characters</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as strxfrm for a wide character type.

Returns the length of the transformed wide string in str1, not including the terminating null wide character. If the value returned is n or greater, the contents of str1 are indeterminate.

This function may not be implemented on all platforms.
**wchar.h**  
*Overview of wchar.h*

---

**See Also**  
“strxfrm” on page 479

---

**wctime**

Convert a `time_t` type to a wide character array

```
#include <wchar.h>
wchar_t * wctime(const time_t * timer);
```

**Table 45.53 wctime**

<table>
<thead>
<tr>
<th>timer</th>
<th>const time_t *</th>
<th>The Calendar Time</th>
</tr>
</thead>
</table>

**Remarks**

Performs the same task as `ctime` for a wide character type.

Returns a pointer to wide character array containing the converted `time_t` type

This function may not be implemented on all platforms.

**See Also**

“ctime” on page 492

---

**wctob**

The function `wctob()` converts a wide character to a byte character.

```
#include <wchar.h>
int wctob(wint_t wc);
```

**Table 45.54 wctob**

<table>
<thead>
<tr>
<th>int</th>
<th>wchar_t *</th>
<th>The wide character to be converted</th>
</tr>
</thead>
</table>

---
Returns

The function `wctob()` returns the single byte representation of the argument `wc` as an unsigned char converted to an int or EOF is returned if `wc` does not correspond to a valid multibyte character.

This function may not be implemented on all platforms.

See Also

“`wcrtomb` on page 577”

wmemchr

Search for an occurrence of a specific wide character.

```c
#include <wchar.h>
void * wmemchr(const void * src, int val, size_t n);
```

Table 45.55 `wmemchr`

<table>
<thead>
<tr>
<th>src</th>
<th>const void *</th>
<th>The string to be searched</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>int</td>
<td>The value to search for</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length of a search</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as `memchr()` for a wide character type.

Returns a pointer to the found wide character, or a null pointer (NULL) if `val` cannot be found.

This function may not be implemented on all platforms.

See Also

“`memchr` on page 454”

“`wcschr` on page 579”
**wmemcmp**

Compare two blocks of memory, treated as wide characters.

```c
#include <wchar.h>

int wmemcmp(const void * src1, const void * src2, size_t n);
```

### Table 45.56  wmemcmp

<table>
<thead>
<tr>
<th>src1</th>
<th>const void *</th>
<th>First memory block to compare</th>
</tr>
</thead>
<tbody>
<tr>
<td>src2</td>
<td>const void *</td>
<td>Second memory block to compare</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>Maximum number of wide characters to compare</td>
</tr>
</tbody>
</table>

### Remarks

Performs the same task as `memcmp()` for a wide character type.

The function `wmemcmp` returns a zero if all n characters pointed to by `src1` and `src2` are equal.

The function `wmemcmp` returns a negative value if the first non-matching wide character pointed to by `src1` is less than the wide character pointed to by `src2`.

The function `wmemcmp` returns a positive value if the first non-matching wide character pointed to by `src1` is greater than the wide character pointed to by `src2`.

This function may not be implemented on all platforms.

### See Also

- “memcmp” on page 456
- “wcscmp” on page 579
**wmemcpy**

Copy a contiguous memory block.

```c
#include <wchar.h>
void * (wmemcpy)(void * dst, const void * src, size_t n);
```

**Remarks**

Performs the same task as `memcpy()` for a wide character type.

Returns a pointer to the destination string.

This function may not be implemented on all platforms.

**See Also**

“`memcpy`” on page 457

---

**wmemmove**

Copy an overlapping contiguous memory block.

```c
#include <wchar.h>
void * (wmemmove)(void * dst, const void * src, size_t n);
```

**Table 45.58  wmemmove**

<table>
<thead>
<tr>
<th>dst</th>
<th>void *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>const void *</td>
<td>The source string</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length to copy</td>
</tr>
</tbody>
</table>

---
wmemset

Clear the contents of a block of memory.

```
#include <wchar.h>

void * wmemset(void * dst, int val, size_t n);
```

<table>
<thead>
<tr>
<th>dst</th>
<th>void *</th>
<th>The destination string</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>int</td>
<td>The value to be set</td>
</tr>
<tr>
<td>n</td>
<td>size_t</td>
<td>The maximum length</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as `memset()` for a wide character type.

Returns a pointer to the destination string.

This function may not be implemented on all platforms.

See Also

“memset” on page 458
wprintf

Send formatted wide character text to a standard output.

```c
#include <wchar.h>
int wprintf(const wchar_t * format, ...);
```

<table>
<thead>
<tr>
<th>Table 45.60 wprintf</th>
</tr>
</thead>
<tbody>
<tr>
<td>format</td>
</tr>
<tr>
<td>....</td>
</tr>
</tbody>
</table>

Remarks

Performs the same task as `printf()` for a wide character type.

Returns the number of arguments written or a negative number if an error occurs.

<table>
<thead>
<tr>

</table>
AltiVec: A vector bool char, vector signed char or vector unsigned char when followed by c, d, i, o, u, x or X. A vector float, when followed by f.

AltiVec: A vector short, vector unsigned short, vector bool short or vector pixel when followed by c, d, i, o, u, x or X.

AltiVec: A vector int, vector unsigned int or vector bool int when followed by c, d, i, o, u, x or X.

- The conversion will be left justified.

+ The conversion, if numeric, will be prefixed with a sign (+ or -). By default, only negative numeric values are prefixed with a minus sign (-).

space If the first character of the conversion is not a sign character, it is prefixed with a space. Because the plus sign flag character (+) always prefixes a numeric value with a sign, the space flag has no effect when combined with the plus flag.
# For c, d, i, and u conversion types, the # flag has no effect. For s conversion types, a pointer to a Pascal string, is output as a character string. For o conversion types, the # flag prefixes the conversion with a 0. For x conversion types with this flag, the conversion is prefixed with a 0x. For e, E, f, g, and G conversions, the # flag forces a decimal point in the output. For g and G conversions with this flag, trailing zeroes after the decimal point are not removed.

<table>
<thead>
<tr>
<th>Modifier</th>

<td>The argument is converted to an unsigned octal.</td>
</tr>
<tr>
<td>u</td>
<td>The argument is converted to an unsigned decimal.</td>
</tr>
</tbody>
</table>
### Table 45.63 Conversion Specifiers for Formatted Output Functions (continued)

<table>
<thead>
<tr>
<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>x, X</td>
<td>The argument is converted to an unsigned hexadecimal. The x conversion type uses lowercase letters (abcdef) while X uses uppercase letters (ABCDEF).</td>
</tr>
<tr>
<td>n</td>
<td>This conversion type stores the number of items output by printf() so far. Its corresponding argument must be a pointer to an int.</td>
</tr>
<tr>
<td>f, F</td>
<td>The corresponding floating point argument (float, or double) is printed in decimal notation. The default precision is 6 (6 digits after the decimal point). If the precision width is explicitly 0, the decimal point is not printed. For the f conversion specifier, a double argument representing infinity produces [-]inf; a double argument representing a NaN (Not a number) produces [-]nan. For the F conversion specifier, [-]INF or [-]NAN are produced instead.</td>
</tr>
<tr>
<td>e, E</td>
<td>The floating point argument (float or double) is output in scientific notation: [-]b.aaaattEee. There is one digit (b) before the decimal point. Unless indicated by an optional precision width, the default is 6 digits after the decimal point (aaa). If the precision width is 0, no decimal point is output. The exponent (ee) is at least 2 digits long. The e conversion type uses lowercase e as the exponent prefix. The E conversion type uses uppercase E as the exponent prefix.</td>
</tr>
<tr>
<td>g, G</td>
<td>The g conversion type uses the f or e conversion types and the G conversion type uses the f or E conversion types. Conversion type e (or E) is used only if the converted exponent is less than -4 or greater than the precision width. The precision width indicates the number of significant digits. No decimal point is output if there are no digits following it.</td>
</tr>
</tbody>
</table>
**wchar.h**

<th>Modifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#s</td>
<td>The corresponding argument, a pointer to a Pascal string, is output as a character string. A Pascal character string is a length byte followed by the number characters specified in the length byte. <strong>Note:</strong> This conversion type is an extension to the ANSI C library but applied in the same manner as for other format variations.</td>
</tr>
</tbody>
</table>
wscanf

Reads a wide character formatted text from standard input

```c
#include <wchar.h>

int wscanf(const wchar_t * format, ...);
```

**Table 45.65  wscanf**

<table>
<thead>
<tr>
<th>format</th>
<th>wchar_t*</th>
<th>The format string</th>
</tr>
</thead>
<tbody>
<tr>
<td>....</td>
<td></td>
<td>Variable arguments</td>
</tr>
</tbody>
</table>

**Remarks**

Performs the same task as `scanf()` for a wide character type.

Returns the number of items successfully read and returns `WEOF` if a conversion type does not match its argument or and end-of-file is reached.

</tbody>
</table>
Non Standard <wchar.h> Functions

Various non standard functions are included in the header wchar.h for legacy source code and compatibility with operating system frameworks and application programming interfaces.

- For the function wcsdup, see “wcsdup” on page 107 for a full description.
- For the function wcsicmp, see “wcsicmp” on page 108 for a full description.
- For the function wcslwr, see “wcslwr” on page 109 for a full description.
- For the function wcscmp, see “wcscmp” on page 111 for a full description.
- For the function wcslwr, see “wcslwr” on page 112 for a full description.
- For the function wcsrev, see “wcsrev” on page 113 for a full description.
- For the function wcsset, see “wcsset” on page 114 for a full description.
- For the function wcspnp, see “wcspnp” on page 114 for a full description.
- For the function wcsupr, see “wcsupr” on page 115 for a full description.
- For the function wtoi, see “wtoi” on page 115 for a full description.
wchar.h
Non Standard <wchar.h> Functions
wctype.h

The ctype.h header file supplies macros and functions for testing and manipulation of wide character type.

Overview of wctype.h

This header file defines the facilities as follows:

- "wctype.h Types" on page 616 defines two types used for wide character values.
- "iswalnum" on page 616 tests for alpha-numeric wide characters.
- "iswalpha" on page 616 tests for alphabetical wide characters.
- "iswblank" on page 617 tests for a blank space or space holder.
- "iswctrl" on page 618 tests for control wide characters.
- "iswdigit" on page 618 tests for digital wide characters.
- "iswgraph" on page 619 tests for graphical wide characters.
- "iswlower" on page 619 tests for lower wide characters.
- "iswprint" on page 620 tests for printable wide characters.
- "iswpunct" on page 620 tests for punctuation wide characters.
- "iswspace" on page 621 tests for whitespace wide characters.
- "iswupper" on page 621 tests for uppercase wide characters.
- "iswxdigit" on page 622 tests for a hexadecimal wide character type.
- "towlower" on page 623 converts wide characters to lower case.
- "towupper" on page 624 converts wide characters to upper case.

Mapping Facilities

- "towctrans" on page 623 maps a wide character type to another wide character type.
- "wctrans" on page 624 constructs a value that represents a mapping between wide characters.
wctype.h
Overview of wctype.h

Types
The wctype.h header file contains two types described in Table 46.1 used for wide character manipulations.

Table 46.1  wctype.h Types

| wctrans_t | A scalar type which can represent locale specific character mappings |
| wcypetype_t | A scalar type that can represent locale specific character classifications |

iswalnum
Tests for alpha-numeric wide characters.

```c
#include <wctype.h>
int iswalnum(wchar_t wc);
```

Table 46.2  iswalnum

| wc | wchar_t | The wide character to test |

Remarks
Provides the same functionality as isalnum for wide character type.

In the "C" locale true is returned for an alphanumeric: [a-z], [A-Z], [0-9]

This function may not be implemented on all platforms.

See Also
“isalnum” on page 55

iswalpha
Tests for alphabetical wide characters.

```c
#include <wctype.h>
int iswalpha(wchar_t wc);
```
### iswalpha

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

#### Remarks

Provides the same functionality as isalpha for wide character type.

In the "C" locale true is returned for an alphabetic: [a-zA-Z]

This function may not be implemented on all platforms.

#### See Also

"isalpha" on page 57

### iswblank

Tests for a blank space or a word separator dependent upon the locale usage.

```c
#include <wctype.h>
int isblank(win_t c);
```

<table>
<thead>
<tr>
<th>c</th>
<th>win_t</th>
<th>character being evaluated</th>
</tr>
</thead>
</table>

#### Remarks

This function determines if a wide character is a blank space or tab or if the wide character is in a locale specific set of wide characters for which iswspace is true and is used to separate words in text.

In the “C” locale, isblank returns true only for the space and tab characters.

#### Return

True is returned if the criteria are met.

This function may not be implemented on all platforms.

#### See Also

"iswspace" on page 621
iswcntrl

Tests for control wide characters.

```c
#include <wctype.h>
int iswcntrl(wchar_t wc);
```

### Table 46.5 iswcntrl

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

### Remarks

Provides the same functionality as iscntrl for wide character type.

- True for the delete character (0x7F) or an ordinary control character from 0x00 to 0x1F.
- This function may not be implemented on all platforms.

### See Also

“iscntrl” on page 58

iswdigit

Tests for digital wide characters.

```c
#include <wctype.h>
int iswdigit(wchar_t wc);
```

### Table 46.6 iswdigit

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

### Remarks

Provides the same functionality as isdigit for wide character type.

- In the “C” locale, true is returned for a numeric character: [0-9].
- This function may not be implemented on all platforms.
See Also

"isdigit" on page 58

iswgraph

Tests for graphical wide characters.

```c
#include <wctype.h>
int iswgraph(wchar_t wc);
```

<table>
<thead>
<tr>
<th>Table 46.7 iswgraph</th>
</tr>
</thead>
<tbody>
<tr>
<td>wc</td>
</tr>
</tbody>
</table>

**Remarks**

Provides the same functionality as isgraph for wide character type.

In the "C" locale `true` is returned for a non-space printing character from the exclamation (0x21) to the tilde (0x7E).

This function may not be implemented on all platforms.

See Also

"isgraph" on page 59

iswlower

Tests for lowercase wide characters.

```c
#include <wctype.h>
int iswlower(wchar_t wc);
```

<table>
<thead>
<tr>
<th>Table 46.8 iswlower</th>
</tr>
</thead>
<tbody>
<tr>
<td>wc</td>
</tr>
</tbody>
</table>

**Remarks**

Provides the same functionality as islower for wide character type.

In the "C" locale `true` is returned for a lowercase letter: [a-z].
iswprint

Tests for printable wide characters.
#include <wctype.h>
int iswprint(wchar_t wc);

Table 46.9 iswprint

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

Remarks

Provides the same functionality as isprint for wide character type.

In the "C" locale true is returned for a printable character from space (0x20) to tilde (0x7E).

This function may not be implemented on all platforms.

See Also

“isprint” on page 60

iswpunct

Tests for punctuation wide characters.
#include <wctype.h>
int iswpunct(wchar_t wc);

Table 46.10 iswpunct

### wctype.h

**Overview of wctype.h**

### Remarks

Provides the same functionality as ispunct for wide character type.

True for a punctuation character. A punctuation character is neither a control nor an alphanumeric character.

This function may not be implemented on all platforms.

### See Also

“ispunct” on page 60

---

#### iswspace

Tests for whitespace wide characters.

```c
#include <wctype.h>
int iswspace(wchar_t wc);
```

**Table 46.11 iswspace**

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

### Remarks

Provides the same functionality as isspace for wide character type.

In the "C" locale, `true` is returned for a space, tab, return, new line, vertical tab, or form feed.

This function may not be implemented on all platforms.

### See Also

“isspace” on page 61

---

#### iswupper

Tests for uppercase wide characters.

```c
#include <wctype.h>
int iswupper(wchar_t wc);
```
wctype.h
Overview of wctype.h

Table 46.12 iswupper

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

Remarks
Provides the same functionality as isupper for wide character type.
In the "C" locale true is returned for an uppercase letter: [A-Z].
This function may not be implemented on all platforms.

See Also
“isupper” on page 61
“iswlower” on page 619

iswxdigit

Tests for a hexadecimal wide character type.

```c
#include <wctype.h>
int iswxdigit(wchar_t wc);
```

Table 46.13 iswxdigit

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to test</th>
</tr>
</thead>
</table>

Remarks
Provides the same functionality as isxdigit for wide character type.
True for a hexadecimal digit [0-9], [A-F], or [a-f].
This function may not be implemented on all platforms.

See Also
“isxdigit” on page 62
Overview of wctype.h

towctrans

Maps a wide character type to another wide character type.

```c
#include <wchar.h>
wint_t towctrans(wint_t c, wctrans_t value);
```

**Remarks**
Maps the first argument to an upper or lower value as specified by `value`.
- Returns the remapped character.
- This function may not be implemented on all platforms.

**See Also**
- ["wctrans" on page 624](#)

<table>
<thead>
<tr>
<th>c</th>
<th>wint_t</th>
<th>The character to remap</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>wctrans_t</td>
<td>A value returned by towctrans</td>
</tr>
</tbody>
</table>

Towlower

Converts wide characters from upper to lowercase.

```c
#include <wctype.h>
wchar_t towlower(wchar_t wc);
```

**Remarks**
Provides the same functionality as `tolower` for wide character type.
- The lowercase equivalent of a uppercase letter and returns all other characters unchanged

---

towupper

Converts wide characters from lower to uppercase.

#include <wctype.h>
wchar_t towupper(wchar_t wc);

Table 46.16 towupper

<table>
<thead>
<tr>
<th>wc</th>
<th>wchar_t</th>
<th>The wide character to convert</th>
</tr>
</thead>
</table>

Remarks
Provides the same functionality as toupper for wide character type.
The uppercase equivalent of a lowercase letter and returns all other characters unchanged.
This function may not be implemented on all platforms.

See Also
“toupper” on page 63
“towlower” on page 623

wctrans

Constructs a property value for “toupper” and “tolower” for character remapping.

#include <wchar.h>
wctrans_t wctrans(const char *name);
Constructs a value that represents a mapping between wide characters. The value of name can be either `toupper` or `tolower`.

A `wctrans_t` type

This function may not be implemented on all platforms.

“towctrans” on page 623
WinSIOUX.h

The SIOUX and WinSIOUX (Simple Input and Output User eXchange) libraries handle Graphical User Interface issues. Such items as menus, windows, and events are handled so your program doesn’t need to for C, Pascal and C++ programs.

Overview of WinSIOUX

The following section describes the Windows versions of the console emulation interface known as WinSIOUX. The facilities and structure members for the Windows Standard Input Output User eXchange console interface are as follows:

- “Using WinSIOUX” on page 627 explains SIOUX properties.
- “WinSIOUX for Windows” on page 628 explains the SIOUX library for Windows 95 and Windows NT.

NOTE If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

See Also

“MSL Extras Library Headers” on page 4, for information on POSIX naming conventions.

Using WinSIOUX

Sometimes you need to port a program that was originally written for a command line interface such as DOS or UNIX. Or you need to write a new program quickly and don’t have the time to write a complete Graphical User Interface that handles windows, menus, and events.

To help you, CodeWarrior provides you with the WinSIOUX libraries, which handles all the Graphical User Interface items such as menus, windows, and titles so your program doesn’t need to. It creates a window that’s much like a dumb terminal or TTY but with scrolling. You can write to it and read from it with the standard C functions and C++ operators, such as printf(), scanf(), getchar(), putchar() and the C++ inserter and extractor operators << and >>. The SIOUX and WinSIOUX libraries also creates a File menu that lets you save and print the contents of the window. There is also an Edit menu that lets you cut, copy, and paste the contents in the window.
WinSIOUX.h
WinSIOUX for Windows

This function may not be implemented on all platforms.

See Also

“Overview of console.h” on page 41.

NOTE
If you’re porting a UNIX or DOS program, you might also need the functions in other UNIX compatibility headers.

WinSIOUX for Windows

The WinSIOUX window is a re-sizable, scrolling text window, where your program reads and writes text.

With the commands from the Edit menu, you can cut and copy text from the WinSIOUX window and paste text from other applications into the WinSIOUX window. With the commands in the File menu, you can print or save the contents of the WinSIOUX window.

- “Creating a Project with WinSIOUX” on page 628 basic steps to create a WinSIOUX program.
- “Customizing WinSIOUX” on page 629 settings used to create the WinSIOUX console
- “clrscr” on page 630 is used to clear the WinSIOUX console screen and buffer

Creating a Project with WinSIOUX

To use the WinSIOUX library, create a project from a project stationery that creates a WinSIOUX Console style project.

A Win SIOUX project must contain at least these libraries:

- ANSIC_WINSIOUX.LIB
- ANSIC_WINSIOUXD.LIB
- Mwcrt.lib
- MWCRTD.lib

The Win32SDK libraries:

- Winspool.lib
- Comdlg32.lib
- Gdi32.lib
- Kernel32.lib
- User32.lib
WinSIOUX offers the user a limited ability to customize the WinSIOUX window display. The following sections describe how you achieve this customization by modifying the structure SIOUXSettings, of type tSIOUXSettings. WinSIOUX examines some of the data fields of SIOUXSettings to determine how to create the WinSIOUX window and environment.

**NOTE** To customize WinSIOUX, you must modify SIOUXSettings before you call any function that uses standard input or output. If you modify SIOUXSettings afterwards, WinSIOUX does not change its window.

### Table 47.1 The SIOUX Settings Structure

<table>
<thead>

<td>char</td>
<td>autocloseonquit</td>
</tr>
<tr>
<td>char</td>
<td>asktosaveonclose</td>
</tr>
<tr>
<td>char</td>
<td>showstatusline</td>
</tr>
</tbody>
</table>
clrscr

Clears the WinSIOUX window and flushes the buffers.

#include <WinSIOUX.h>

void clrscr(void);

Remarks

This function simply calls the function WinSIOUXclrscr, that clears the screen.

This function is not implemented directly on Windows console.

Windows compatible, only.

This appendix contains a description of the macros and defines that are used as switches or flags in the MSL C library.

**Overview of the MSL Switches, Flags and Defines**

The MSL C library has various flags that may be set to customize the library to users specifications. The flags are explained as follows:

- `__ANSI_OVERLOAD__` on page 633
- `__MSL_C_LOCALE_ONLY` on page 634
- `__MSL_IMP_EXP` on page 634
- `__MSL_INTEGRAL_MATH` on page 634
- `__MSL_MALLOC_0_RETURNS_NON_NULL` on page 635
- `__MSL_NEEDS_EXTRAS` on page 635
- `__MSL_OS_DIRECT_MALLOC` on page 635
- `__MSL_CLASSIC_MALLOC` on page 635
- `__MSL_USE_NEW_FILE_APIS` on page 636
- `__MSL_USE_OLD_FILE_APIS` on page 636
- `__MSL_POSIX` on page 636
- `__MSL_STRERROR_KNOS_ERROR_NAMES` on page 637
- `__SET_ERRNO__` on page 637

---

**__ANSI_OVERLOAD__**

When defined (and when using the C++ compiler) the math functions are overloaded with float and long double versions as specified by 26.5 paragraph 6 of the C++ standard. Disabling this flag removed the overloaded functions.
_MSL_C_LOCALE_ONLY

The flag _MSL_C_LOCALE_ONLY provides for disabling the locale mechanism in the library.

The MSL C library should be recompiled after changing the value of the flag.

When off, the locale mechanism works as described by the ANSI C standard. When on, there are no locales, and anything which is dependent upon locales will function as if the “C” locale is in place. This saves code size and increases execution speed slightly.

_MSL_IMP_EXP

This macro determines how the standard headers are decorated for importing and exporting symbols from/to a shared version of the standard runtime/C/C++ library.

If this macro is defined to nothing then the headers are configured for linking against static libraries.

In the header file UseDLLPrefix.h the macro is defined to __declspec(dllimport). This will allow you to link against one of the supplied shared libraries. Other related macros

_MSL_IMP_EXP_C
_MSL_IMP_EXP_SIOUX
_MSL_IMP_EXP_RUNTIME

allow you to link with “part” of the shared library and an individual static library.

By default the previous macros are set to whatever _MSLIMP_EXP is set to (see ansi_parms.h). As an example, if you wish to link in the static version of the SIOUX library then you would edit ansi_parms.h and define _MSL_IMP_EXP_SIOUX to nothing and link in the appropriate static SIOUX lib.

_MSL_INTEGRAL_MATH

When defined (and when __ANSI_OVERLOAD__ is defined and when using the C++ compiler), additional overloads to the math functions with integral arguments are created. This flag is meant to prevent compile time errors for statements like:

```c
double c = cos(0);
// ambiguous with __ANSI_OVERLOAD__
```
// and not _MSL_INTEGRAL_MATH

_MSL_MALLOC_0_RETURNS_NON_NULL

This flag determines the implementation of a null allocated malloc statement. If not defined `malloc(0)` returns 0. If defined `malloc(0)` returns non-zero.
The C lib must be recompiled when flipping this switch.

_MSL_NEEDS_EXTRAS

Macintosh and Windows programs have the ability to use extra C functions when they have the MSL Extras Library linked into their project. This flag determines if they can be accessed from a C standard header or not. The flag `_MSL_NEEDS_EXTRAS` default setting is `true` for Windows and `false` for the Macintosh.
Macintosh developers must specify a non standard header to access the non standard extra functions. If Macintosh programmers wishes to access non standard functions via a standard header in legacy code, they need to do is to set `_MSL_NEEDS_EXTRAS` to `true` in `ansi_prefix.mac.h`.
Windows users can access the functions in a standard header to be legacy compatible as well as the actual header where they are declared. If a Windows programmer does not want to access non standard functions via a standard header then they need to turn off `_MSL_NEEDS_EXTRAS` in `ansi_prefix.Win32.h`.

_MSL_OS_DIRECT_MALLOC

If defined `malloc` will call straight through to the OS without forming memory pools. This will likely degrade performance but may be valuable for debugging purposes.
The C lib must be recompiled when flipping this switch.

_MSL_CLASSIC_MALLOC

Enables the version of malloc that was in Pro 4 (for backward compatibility).
The C lib must be recompiled when flipping this switch.
### _MSL_USE_NEW_FILE_APIs_

You can use this flags to turn on and off the new-style use of the new HFS+ file system APIs, present starting with Mac OS 9.0. Using the new file system APIs gets filenames greater than 32 characters and file sizes of greater than 2GB. However, due to the standard interfaces for C, you can only access files in 2GB chunks.

Prototypes for `fread()`, for example, take a `long` as parameter for the amount of data to be read from a file, so to access more than 2GB in a file, you must make successive calls to `fread()`.

The C lib must be recompiled when flipping this switch.

---

### _MSL_USE_OLD_FILE_APIs_

You can use this flags to turn on and off the old-style use of the Mac file system APIs. Using the old file system APIs limits you to filenames of 32 characters or less and file sizes of 2GB or less.

The C lib must be recompiled when flipping this switch.

---

### _MSL_POSIX_

This flag adds the POSIX function `stat` to the global namespace. This is on by default.

Turning this off should allow the user to link against a third party POSIX library with the same names. The POSIX names preceded by a leading underscore are always available in MSL. For example, `_open` and `_stat`.

#### Remarks

This macro is located in the prefix files `ansi_prefix.win32.h` or `ansi_prefix.macos.h`.

Commenting this out does not require recompilation of the library.
The flag `_MSL_STRERROR_KNOWS_ERROR_NAMES` controls what happens when the `strerror()` call is made.

When the flag is on, `strerror()` will return robust error messages. When the flag is off, `strerror()` will always return with an “unknown” error. This provides for a huge savings in code/data size in the executable.

If this flag is defined it will cause the standard math functions to set the global `errno` to either `EDOM` or `ERANGE` as specified in the 1989 C standard. The modern C standard specifies that setting `errno` for the mathlib is optional. So in the spirit of the new standard on x86 it is now optional.

Turning this off will improve performance by reducing checks for incorrect input values but will not set `errno`. Most of the standard math functions are now in the header `math_x87.h`.

**Remarks**

Since these definitions are in a header file they can be configured when building your application and therefore you do NOT need to rebuild the library. This switch is on by default.

This flag is only for Win32 x86 libraries.
Secure Library Functions

This chapter contains a description of the secure library functions that are an extension to the C99 Standard. These functions promote safer, more secure programming. The functions verify that output buffers are large enough for intended results and return a failure indicator if not. Data is never written past the end of an array and all string results are null terminated.

The secure library functions are only accessed by their respective headers if the __USE_SECURE_LIB__ macro is defined in the source file where the header file is included. If a header file is included more than once in a given scope, this will result in undefined behavior if __USE_SECURE_LIB__ is defined for some inclusions and not others.

Input/Output

If the __USE_SECURE_LIB__ macro is defined in the source file where <stdio.h> is included, then stdio.h defines the following macros.

L_tmpnam_s
This macro expands to an integer constant expression that is the size needed for an array of char large enough to hold a temporary file name string generated by the tmpnam_s function.

TMP_MAX_S
This macro expands to an integer constant expression that is the maximum number of unique file names that can be generated by the tmpnam_s function.

File Operations

tmpnam_s

The tmpnam_s function generates a unique string that represents a valid file name. File names created by the tmpnam_s function are temporary only in the sense that their names should not collide with those generated by conventional naming rules. It is still
necessary to use the `remove` function to remove such files when their use is ended, and
before program termination.

The function is capable of generating `TMP_MAX_S` different strings. Any or all of them
may already be in use by existing files and thus not be suitable return values. The lengths
of these strings shall be less than the value of the `L_tmpnam_s` macro. The `tmpnam_s`
function generates a different string each time it is called.

```c
#define __USE_SECURE_LIB__
#include <stdio.h>

int tmpnam_s(char *s, size_t maxsize);
```

**Remarks**

If no suitable string is generated, or if the length of the string is not less than the value of
`maxsize`, the `tmpnam_s` function writes a null character to `s[0]` (if `maxsize` is greater than
zero) and returns `ERANGE`.

Otherwise, the `tmpnam_s` function writes the string in the array pointed to by `s` and
returns zero.

The value of the `TMP_MAX_S` macro should be at least 25.

---

**Formatted input/output functions**

**fscanf_s**

The `fscanf_s` function is equivalent to `fscanf` except that the `c`, `s`, and `\` conversion
specifiers apply to a pair of arguments, unless assignment is suppressed by an asterisk (`*`).
The first of these arguments is the same as for `fscanf`. That argument is followed by the
second argument in the argument list, which has a type of `size_t` and gives the number
of elements in the array pointed to by the first argument of the pair. If the first argument
points to a scalar object, it is considered to be an array of one element.

If the format is known, an implementation may issue a diagnostic for any argument used
to store the result from a `c`, `s`, or `\` conversion specifier if that argument is not followed by
an argument of type `size_t`. Limited checking may be done if the format is not known at
translation time. For example, a diagnostic may be issued for each argument after a format
of type `pointer` to one of char, signed char, unsigned char, or void, if not followed by an
argument of type `size_t`. The diagnostic could provide a warning that unless the pointer
is being used with a conversion specifier using the `hh` length modifier, a length argument
must follow the pointer argument. Another useful diagnostic could flag any non-pointer
argument that follows a format that was not a `size_t` type.
Secure Library Functions
Input/Output

A matching failure occurs if the number of elements in a receiving object is insufficient to hold the converted input (including any trailing null character).
#define __USE_SECURE_LIB__
#include <stdio.h>
int fscanf_s(FILE * restrict stream, const char * restrict
format, ...);

Remarks
The fscanf_s function returns the value of the macro EOF if an input failure occurs before any conversion. Otherwise, the fscanf_s function returns the number of input items assigned, which can be fewer than provided for, or zero if an early match failure occurs.

Example
#define __USE_SECURE_LIB__
#include <stdio.h>
/* ... */
int n; char s[5];
n = fscanf_s(stdin, "%s", s, sizeof s);
Providing hello as the input line will assign 0 to n since a matching failure will occur. The end of line character attached to hello (hello\0) requires that the total array size can hold six characters. No assignment to s occurs.

scanf_s
The scanf_s function is equivalent to fscanf_s with the stdin argument inserted before the arguments to scanf_s.
#define __USE_SECURE_LIB__
#include <stdio.h>
int scanf_s(const char * restrict format, ...);

Remarks
The scanf_s function returns the value of the EOF macro if an input failure occurs before conversion. Otherwise, the scanf_s function returns the number of input items assigned, which can be fewer than provided for or zero if an early match failure occurs.
Secure Library Functions
Input/Output

sscanf_s

The sscanf_s function is equivalent to fscanf_s, except that input is obtained from a string rather than from a stream. Reaching the end of the string is equivalent to encountering end-of-file for the fscanf_s function. If copying takes place between objects that overlap, the behavior is undefined.

#define __USE_SECURE_LIB__
#include <stdio.h>
int sscanf_s(const char * restrict s, const char * restrict format, ...);

Remarks
The sscanf_s function returns the value of the EOF macro if an input failure occurs before conversion. Otherwise, the number of input items assigned are returned, which can be fewer than provided for, or zero if an early match failure occurs.

vfscanf_s

The vfscanf_s function is equivalent to fscanf_s, although the variable argument list is replaced by arg, which is initialized by the va_start macro (and possibly subsequent va_arg calls). The vfscanf_s function does not invoke the va_end macro.

Since the functions vfscanf_s, vscanf_s, and vsscanf_s invoke the va_arg macro, the value of arg will vary after the return.

#define __USE_SECURE_LIB__
#include <stdarg.h>
#include <stdio.h>
int vfscanf_s(FILE * restrict stream, const char * restrict format, va_list arg);

Remarks
The vfscanf_s function returns the value of the EOF macro if an input failure occurs before conversion. Otherwise, it returns the number of input items assigned, which can be fewer than provided for, or zero if an early match failure occurs.
vscanf_s

The vscanf_s function is equivalent to scanf_s, although the variable argument list is replaced by arg, which is initialized by the va_start macro (and possibly subsequent va_arg calls). The vscanf_s function does not invoke the va_end macro.

Since the functions vfscanf_s, vscanf_s, and vsscanf_s invoke the va_arg macro, the value of arg will vary after the return.

#define __USE_SECURE_LIB__
#include <stdarg.h>
#include <stdio.h>
int vscanf_s(const char * restrict format, va_list arg);

Remarks
The vscanf_s function returns the value of the EOF macro if an input failure occurs before conversion. Otherwise, the vscanf_s function returns the number of input items assigned, which can be fewer than provided for, or zero if an early match failure occurs.

vsscanf_s

The vsscanf_s function is equivalent to sscanf_s, although the variable argument list is replaced by arg, which is initialized by the va_start macro (and possibly subsequent va_arg calls). The vsscanf_s function does not invoke the va_end macro.

Since the functions vfscanf_s, vscanf_s, and vsscanf_s invoke the va_arg macro, the value of arg will vary after the return.

#define __USE_SECURE_LIB__
#include <stdarg.h>
#include <stdio.h>
int vsscanf_s(const char * restrict s, const char * restrict format, va_list arg);

Remarks
The vsscanf_s function returns the value of the EOF macro if an input failure occurs before conversion. Otherwise, it returns the number of input items assigned, which can be fewer than provided for, or zero if an early match failure occurs.
