Chapter 1
Introduction

The QuadSPI controller available on selected Kinetis devices supports execute-in-place (XIP) for external SPI flash memory devices. This document describes the usage of MCU bootloader (MCUBOOT) in configuring various features of QuadSPI block, including XIP, generating plaintext and encrypted bootable SB file image, and flashing QuadSPI memory with the SB file image.

QuadSPI features supported by MCU bootloader:

• Various types of SPI NOR flash memory devices available in the market.
• Flash memory booting from QuadSPI directly, using MCU bootloader.
• Single/Dual/Quad and Octal SPI NOR flash memory devices.
• High-performance read/write operation with parallel and DDR modes.
• Protecting intellectual property with AES-128 algorithm.
Chapter 2
Overview

This document mainly focuses on the following topics:

• QuadSPI image boot procedure
• Creating an application image running on QuadSPI memory
• Configuring QuadSPI with MCU bootloader
• Programming QuadSPI memory with SB file
• Advanced usage: QuadSPI encrypted boot image
• Application requirements for re-configuring QuadSPI clock

In addition, the following topics are also covered in the appendix sections:

• QuadSPI configuration block (QCB)
• Re-enter MCU bootloader under direct boot mode
• Explore features supported in QCB
• Working around ROM issues in supported DDR mode devices

2.1 Terminology

The following table summarizes the terms and abbreviations included in this user’s guide.

<table>
<thead>
<tr>
<th>Terminology</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MCUBOOT</td>
<td>MCU bootloader</td>
</tr>
<tr>
<td>BCA</td>
<td>Bootloader Configuration Area, which provides customization of bootloader options, such as enabledPeripherals, peripheralDetectionTimeout, and so on. See the MCU bootloader chapter in the silicon’s reference manual for more details.</td>
</tr>
<tr>
<td>QCB</td>
<td>QuadSPI Configuration Block, a structure containing configurable parameters needed by the MCU bootloader to configure the QuadSPI controller. See the MCU bootloader chapter in the silicon’s reference manual for more details.</td>
</tr>
<tr>
<td>KeyBlob</td>
<td>A data structure which holds the KeyBlob entries. Each keyblob entry defines the encrypted QuadSPI memory region, decryption key, and so on. See the MCU bootloader chapter in the silicon’s reference manual for more details.</td>
</tr>
<tr>
<td>KEK</td>
<td>KeyBlob Encryption Key, an AES-128 key used for encrypting plaintext KeyBlob and decrypting encrypted KeyBlob. See the MCU bootloader chapter in the silicon’s reference manual for more details.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
Table 1. Terminology and abbreviations (continued)

<table>
<thead>
<tr>
<th>Terminology</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SB file</td>
<td>The SB file is the NXP binary file format for bootable images. The file consists of sections and sequence of bootloader commands and data that assists MCU bootloader in programming the image to target memory. The image data in the SB file can be encrypted as well. The file can be downloaded to the target using the MCU bootloader receive-sb-file command. See the MCU bootloader chapter in silicon's reference manual for more details.</td>
</tr>
<tr>
<td>OTFAD</td>
<td>On-the-fly AES Decryption is a powerful IP block in MK81F256 and MK82F256, which supports decryption of the encrypted QuadSPI image on-the-fly using KeyBlob. See the MCU bootloader chapter in the silicon's reference manual for more details.</td>
</tr>
</tbody>
</table>

2.2 Requirements

2.2.1 Hardware requirements

- TWR-K80F150M Tower System module
- FRDM-K82F Freedom Development platform
- TWR-KL82 Tower System module
- FRDM-KL82 Freedom Development platform

2.2.2 Host tools

The following host tools are available with the release package. They assist in generating and provisioning of QuadSPI bootable image for the target device.

- blhost: command line host tool for MCU bootloader.
- elftosb: command line host tool for SB file generation.
- KinetisFlashTool: GUI host tool for MCU bootloader.

2.2.3 Demo application

Led_demo running in internal flash and QuadSPI memory, under `<sdk_package>/boards/<board>/bootloader_examples/demo_apps`

QCBGenerator, under `<sdk_package>/middleware/mcu-boot/apps/QCBGenerator/build`

2.2.4 Required toolchains

2.2.4.1 Firmware project

The following toolchains can be used to build the example led_demo firmware application provided with the release package.

- ARM® Keil® development tool v5.24a with corresponding device pack
- IAR Embedded Workbench for ARM® v8.20.2
2.2.4.2 Host project

The following toolchains can be used to build the example QCBGenerator application provided with the release package.

- Microsoft Visual Studio® Professional 2015 for Windows® OS Desktop
- Codeblocks
- GCC v5.4.0

2.3 QuadSPI image boot procedure

To understand how to boot a QuadSPI image with MCU bootloader, it is necessary to understand the QuadSPI image boot flow. There are two types of QuadSPI image boot flow:

- Boot from a plaintext QuadSPI image. This method can be used on all targets with QuadSPI support.
- Boot from an encrypted QuadSPI image. This method can only be used on K8x processors that include OTFAD support, such as MK81F256 and MK82F256.

2.3.1 Plaintext QuadSPI image boot flow

The figure below shows the boot flow of MCU bootloader in booting the device with a plaintext QuadSPI image.

![Plaintext QuadSPI image boot flow diagram](image)

2.3.2 Encrypted QuadSPI image boot flow

The below figure shows the boot flow of MCU bootloader in booting the device with an encrypted QuadSPI image.
Figure 2. Encrypted QuadSPI image boot flow
Chapter 3
Creating application for QuadSPI memory

This section describes how to modify a normal flash application (led_demo) to run from QuadSPI. The fully functional LED demo example for QuadSPI with source code can be found in <sdk_package>/boards/<board>/bootloader_examples/demo_apps. The chapter also discuss on how to create QCB data structure for a typical QuadSPI flash memory device.

3.1 Starting point: Basics of internal flash memory mapped led-demo example project

Start from the LED demo example project code for the MK82F256 device. The example led-demo project files for each of the supported toolchains are available in <sdk_package>/boards/<board>/bootloader_examples/demo_apps folder of the package. This document focuses on the IAR project examples only. Open the led_demo.eww file from the IAR folder and select the led_demo_PFLASH project as the active project. See the following figure.

Note that the linker file for the led_demo_PFLASH project shows all sections located in the internal flash memory region, including the vector table, flash config area, and text sections.

When the led_demo_PFLASH image is built and flashed to the internal flash memory of the target device and begins its execution, it causes the blue and green LEDs to blink on the target board.

The subsequent sections show the changes needed to convert the led_demo_PFLASH project to run on the QuadSPI memory for the target device.
3.2 Changes to the led-demo project

The following subsections describe the steps to map the led-demo to run from the external QuadSPI flash memory.

3.2.1 Changes to the linker file

The first step is to update the linker file. The \texttt{m\_text\_start}, and \texttt{m\_text\_end} symbol names must be updated. The address of \texttt{m\_text\_start} should be changed to 0x68001000, and \texttt{m\_text\_end} to 0xFFFFFFF or the actual end address of the selected SPI flash device. See the changes in the following figure.
3.2.2 Changes to flash config area

The bit 7-6 in the FOPT (0x40D) must be changed to 0b'10 to select the ROM as the boot source upon reset. The QuadSPI is configured after the ROM starts and when the QCB is present. After this operation, the flash config area is changed, as shown in the following figure.

![Figure 5. Change flash config area for QuadSPI image](image)

See the `startup_MK82F2515_qspi.s` file in the `led_demo-><sdk_package>/middleware/mcu-boot/apps/demo_qspi/led_demo/devices/MK80F25615/startup/<toolchain>` folder for more details.

3.2.3 Configure BCA

After the previous step, the target is able to run the led-demo application once the active peripheral detection timeout occurs. To customize the boot option for the QuadSPI image, the BCA is required. The first step to is to define `BOOTLOADER_CONFIG` in the project. Implement the operation shown in the following figure for IAR EWARM toolchain as an example.
Figure 6. Enable BCA in EWARM

There are two ways to configure the QuadSPI image boot option:

1. Change the peripheralDetectionTimeoutMs. For example, change it to 0x01F4 (500 ms).
2. Change the bootFlags to 0xFE, which means boot directly from application without delay. To re-enter MCU bootloader again, see Appendix B.

**NOTE**

The first way to configure the QuadSPI image boot option is recommended.

In this example, there is a BootloaderConfig constant variable defined in system_MK82F25615.c. It can be changed as shown in the following figure.

When the BCA change is complete, the target supports execution of led demo image if it has been programmed to internal flash or QuadSPI memory.
3.3 Generate QCB

QuadSPI Config Block (QCB) is required for MCU ROM bootloader to properly configure and access the QuadSPI device. This section shows the QCB structure, determines the QCB parameters for the specified SPI flash device, and generates the QCB with a simple project.

3.3.1 The QCB structure

The QCB is a data structure containing the most common used parameters for QuadSPI module. See the MCU bootloader chapter in the silicon's reference manual for more details. The QCB is organized as follows.
<table>
<thead>
<tr>
<th>Offset</th>
<th>Size (bytes)</th>
<th>Configuration field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0x00 - 0x03 | 4            | tag                 | Magic number to verify whether QCB is valid. Must be set to ‘kqcf’.  
|            |              |                     | [31:24] - 'f' (0x66)  
|            |              |                     | [23:16] - 'c' (0x63)  
|            |              |                     | [15: 8] - 'q'(0x71)  
|            |              |                     | [7: 0] - 'k'(0x6B)  |
| 0x04 - 0x07 | 4            | version             | Version number of QuadSPI config block.  
|            |              |                     | [31:24] - name: must be 'Q'(0x51)  
|            |              |                     | [23:16] - major: must be 1  
|            |              |                     | [15: 8] - minor: must be 1  
|            |              |                     | [7: 0] - bugfix: must be 0  |
| 0x08 - 0x0b | 4            | lengthInBytes       | Size of QuadSPI config block, in terms of bytes. Must be 512. |
| 0x0c - 0x0f | 4            | dqs_loopback        | Enable DQS loopback support:  
|            |              |                     | 0 DQS loopback is disabled.  
|            |              |                     | 1 DQS loopback is enabled, the DQS loopback mode is determined by subsequent ‘dqs_loopback_internal’ field. |
| 0x10 - 0x13 | 4            | data_hold_time      | Serial flash data hold time. Valid value 0/1/2. See the QuadSPI Chapter for details. |
| 0x14 - 0x1b | 8            | -                   | Reserved. |
| 0x1c - 0x1f | 4            | device_mode_config_en | Configure work mode enable for external flash devices:  
|            |              |                     | 0 Disabled - ROM does not configure work mode of external flash devices.  
|            |              |                     | 1 Enabled - ROM configures work mode of external flash devices based on "device_cmd" and LUT entries indicated by "write_cmd_ipcr". |
| 0x20 - 0x23 | 4            | device_cmd          | Command to configure work mode of external flash devices. Effective only if "device_mode_config_en" is set to 1. This command is device-specific. |

</tbody>
</table>

**NOTE**

1. Though there are several parameters in QCB, only a few parameters need to be configured for most SPI flash devices available on the market. See the example QCB for more details.

2. While using MCU ROM bootloader, make sure the "ips_cmd_second_divider" is not greater than 0x08 under SDR mode, and it is not greater than 2 under DDR mode.

3. It is recommended to configure QSPI to SDR mode and switch to DDR mode in the application where possible to achieve higher program performance with MCU bootloader.

In the QCB, the most important field is the Lookup Table (LUT), which contains command sequence for QuadSPI instructions, such as erase, read, and program. The command sequence in the LUT should appear in the order as shown in the following table:

Table 3. Look-up table entries for MCU bootloader

<td>All of these sequences are free to be used for other purposes. I.e., index 5 can be used for enabling Quad mode of SPI flash devices. For more details, see Section 3.3.2, &quot;Example QCB for MX25U3235F device on TWR-K80F150M Tower System module&quot;.</td>
</tr>
</tbody>
</table>

For most types of SPI, flash devices are available in the market. Only index 0, 1, 3, 4, 7, and 8 are required. However, for other types of high-end SPI flash devices, such as Cypress HyperFlash, additional indexes listed above may be required.

### 3.3.2 Example QCB for MX25U3235F device on TWR-K80F150M Tower System module

This section creates an example QCB data structure for TWR-K80F150M Tower System module. There are two MX25U3235F QuadSPI flash devices connected to QuadSPI0A and QuadSPI0B ports, respectively, on the board. The datasheet for MX25U3235F are available on the MXIC website, and the schematics for the TWR-K80F150M Tower System module is available on the NXP website.

The following are some attributes which are essential to create the QCB for the MX25U3235F flash device. The same (but not limited to the following) information can be found in its data sheet as well:

</tr>
<tr>
<td>Read Status</td>
<td></td>
<td>This command is used to check if the SPI flash device is busy after having issued a program/erase command to it. The command sequence for this operation is: 1. CMD: 0x05, single pad 2. READ: 1 (byte) single pad</td>
</tr>
</tbody>
</table>

The information needed for QCB creation for the TWR-K80F150M Tower System module is summarized in Table 4. The “Programmable Sequence Engine” and “Example Sequences” sections within the QuadSPI chapter of the MK80F256 Reference Manual can be referenced to create customized QCBs. The “Description” column in Table 4 also provides the LUT instructions for each command.

Based on the above summary, the ‘qspi_config_block_generator’ project is provided with the package as an example along with this user’s guide. The example project can be used as a basis to generate customized QCBs.
Generate the QCB with a simple example project

The project can be found in the package at location `<sdk_package>/middleware/mcu-boot/apps/QCBGenerator/build`. Currently, two projects are provided to build from toolchains Microsoft Visual Studio 2013 and codeblocks. Launch Microsoft Visual Studio example project available in the Visual Studio folder. Edit the file `qspi_config_block_generator.c` to configure `qspi_config_block` in the main function.

There are two examples using different ways to enable Quad mode. The first one enables Quad mode using the device mode config feature, while the second one enables Quad mode using the config cmd feature. See the below examples for more details.

1. QCB using the device mode config feature:

```c
const qspi_config_t qspi_config_block =
{
    .tag = kQspiConfigTag, // Fixed value, do not change.
    .version = { .version = kQspiVersionTag }, // Fixed value, do not change.
    .lengthInBytes = 512, // Fixed value, do not change.
    .sflash_A1_size = 0x400000, // 4MB - MX25U3235F connected to QSPI0A
    .sflash_B1_size = 0x400000, // 4MB - MX25U3235F connected to QSPI0B
    // In K80 ROM bootloader, QSPI serial clock frequency is 96MHz
    .sclk_freq = kQspiSerialClockFreq_High, // High frequency, 96MHz / 1 = 96MHz
    .sflash_type = kQspiFlashPad_Quad, // SPI Flash devices work under quad-pad mode
    .sflash_port = kQspiPort_EnableBothPorts, // Both QSPI0A and QSPI0B are enabled.
    .busy_bit_offset = 0,   // Busy offset is 0
    .ddr_mode_enable = 0,   // disable DDR mode
    .dqs_enable = 0,       // Disable DQS feature
    .parallel_mode_enable = 0, // QuadSPI module work under serial mode
    .pagesize = 256,             // Page Size: 256 bytes
    .sectorsize = 0x1000,       // Sector Size: 4KB
    .device_mode_config_en = 1,   // configure quad mode for SPI flash device
    .device_cmd = 0x40,   // Enable quad mode
    .write_cmd_ipcr = 0x05000000U, // IPCR indicating enable seqid (5<<24), see QCB structure
    // Set second divider for QSPI serial clock to 3 if K80 ROM Bootloader cannot program
    // SPI flash at 96 MHz, in this configuration, the program speed is 96MHz/4 = 24MHz
    .ips_command_second_divider = 3,
    .look_up_table =
    {
        // Seq0: Quad Read (maximum supported freq: 104MHz)
        /*
         * CMD: 0xEB - Quad Read, Single pad
         * ADDR: 0x18 - 24bit address, Quad pads
         * DUMMY: 0x06 - 6 clock cycles, Quad pads
         * READ: 0x80 - Read 128 bytes, Quad pads
         * JUMP_ON_CS: 0
         */
        [0] = 0x0A1804EB,
        [1] = 0x1E800E06,
        [2] = 0x2400,
        // Seq1: Write Enable (maximum supported freq: 104MHz)
        /*
         * CMD: 0x06 - Write Enable, Single pad
         */
        [4] = 0x406,
        // Seq2: Erase all (maximum supported freq: 104MHz)
        /*
         * CMD: 0x60 - Erase All chip, Single pad
         */
    }
};
```
const qspi_config_t qspi_config_block = {
    .tag = kQspiConfigTag,  // Fixed value, do not change
    .version = {.version = kQspiVersionTag},  // Fixed value, do not change
    .lengthInBytes = 512,  // Fixed value, do not change
    .sflash_A1_size = 0x400000,  // 4MB
    .sclk_freq = kQspiSerialClockFreq_High,  // High frequency, in K82-256, it means 96MHz/1
    .sflash_type = kQspiFlashPad_Quad,  // SPI Flash devices work under quad-pad mode
    .sflash_port = kQspiPort_EnableBothPorts,  // Both QSPI0A and QSPI0B are enabled.
    .busy_bit_offset = 0,  // Busy offset is 0
    .drr_mode_enable = 0,  // disable DDR mode
    .dqs_enable = 0,  // Disable DQS feature
    .parallel_mode_enable = 0,  // QuadSPI module work under serial mode
    .pagesize = 256,  // Page Size: 256 bytes
    .sectorsize = 0x1000,  // Sector Size: 4KB
};
Creating application for QuadSPI memory

Generate QCB

```c
.config_cmd_en = 1, // Enable config cmd feature
.config_cmdcs = {{0} = 5UL << 24}, // IPCR indicating seq id for Quad Mode Enable
.config_cmdcs_args = {{0} = 0x40}, // Enable quad mode via setting bit 6 in status
register to 1

.ips_command_second_divider = 3, // Set second divider for QSPI serial clock to 3
.lookup_table =
{
    // Seq0 : Quad Read (maximum supported freq: 104MHz)
    /*
    CMD: 0xEB - Quad Read, Single pad
    ADDR: 0x18 - 24bit address, Quad pads

    ADDR: 0x18 - 24 bit address, single pad
    */
    [28] = 0x08180420,

    // Seq8: Dummy
    /*
    */
```
CMD: 0 - Dummy command, used to force SPI flash to exit continuous read mode.

unnecessary here because the continuous read mode is not enabled.

*/

[32] = 0,

};

After modifying the qspi_config_block variable, right-click the QCBGenerator project and choose to build.

If the project successfully builds, run QCBGenerator.exe from the Debug folder. The output file named 'qspi_config_block.bin' is generated under the Debug folder.

Both the QuadSPI project and QCB are ready. The next chapter describes how to flash the QuadSPI image to the target device with MCU bootloader.

**NOTE**

For some SPI Flash devices, the Quad mode configuration bit is non-volatile. It is recommended to set "device_mode_config_en" to 0 after the first configuration completes.
Chapter 4
Configure QuadSPI with MCU bootloader

QuadSPI can be configured using the MCU bootloader by:
1. Configure QuadSPI at runtime.
2. Configure QuadSPI at start-up.

4.1 Configure QuadSPI at runtime

The TWR-K80F150M Tower System module is shipped without any pre-programmed QCB in QuadSPI memory or in internal flash memory. The following figure shows a simple example demonstrating steps to write and configure QCB. See the following figure.

1. Hold the NMI button, press the reset button, then release the reset button and NMI button, in that order.
2. Use the blhost property command to get the Reserved Region property value from MCU bootloader. This provides the RAM region reserved by MCU bootloader.
3. Choose a free RAM region, and using blhost, write QCB to that region.
4. Configure the QuadSPI with the "configure-memory" command.

NOTE
The first command line parameter to configure-memory command is "1" to represent the QuadSPI0, and the second parameter "0x2000_0000" to represent the start address of the QCB.

Figure 8. configure-memory at runtime with blhost
4.2 Configure QuadSPI at start-up

The previous sections show how to configure QCB when there is no QCB pre-programmed on the device. For subsequent boots, it makes sense to save the QCB to non-volatile memory, such as internal flash pointed by the BCA member field, 'qsplConfigBlockPtr', or at the start offset of QuadSPI memory. Next time the device boots from the ROM, the MCU bootloader in ROM detects the presence of the QCB and configure the QuadSPI automatically at start-up. The following steps are the recommended procedure based on the previous section. To program QCB at the start address of QuadSPI memory, see the following figure for the blhost command sequence.

1. Erase the first sector in QuadSPI memory before programming the QCB.
2. Write the QCB to the start of QuadSPI memory.
3. Erase the flash config area.
4. Program the FOPT with the desired value. Make sure FOPT[7:6] (0x40D address in internal flash) is set to 0b10 to default to boot from MCU bootloader in ROM.
5. Reset the target device and use the "read-memory command" to check and ensure if QuadSPI is configured successfully at start-up, as shown in the following figure.

When all of the above operations are completed, the QuadSPI is configured at start-up.

So far, we understand the basic steps of creating QCB and configuring QuadSPI using the MCU bootloader. The next sections describe how to program the QuadSPI image.
Figure 9. Configure QuadSPI at start-up

```bash
$ blhost -u -- flash-erase-region 0x68000000 4096
Inject command 'flash-erase-region'
Successful generic response to command 'flash-erase-region'
Response status = 0 (0x0) Success.

846522@846522-11 /d/tmp
$ blhost -u -- write-memory 0x68000000 qspi_config_block.bin
Preparing to send 512 (0x200) bytes to the target.
Successful generic response to command 'write-memory'
Successful generic response to command 'write-memory'
Response status = 0 (0x0) Success.
Wrote 512 of 512 bytes.

846522@846522-11 /d/tmp
$ blhost -u -- flash-erase-region 0x0 0x800
Inject command 'flash-erase-region'
Successful generic response to command 'flash-erase-region'
Response status = 0 (0x0) Success.

846522@846522-11 /d/tmp
$ blhost -u -- write-memory 0x40c {{FEBFFFFF}}
Inject command 'write-memory'
Successful generic response to command 'write-memory'
Successful generic response to command 'write-memory'
Response status = 0 (0x0) Success.
Wrote 4 of 4 bytes.

846522@846522-11 /d/tmp
$ blhost -u -- reset
Inject command 'reset'
Successful generic response to command 'reset'
Response status = 0 (0x0) Success.

846522@846522-11 /d/tmp
$ blhost -u -- read-memory 0x68000000 512

Chapter 5
Flash QuadSPI image via SB file

Generally, the QuadSPI image contains separate segments. For example, the vector table and the flash config area are in the internal flash and the executable code is located in the QuadSPI memory. Additionally, the corresponding regions must be erased before programming. It is inconvenient to use separate commands to finish this task. Here, we introduce the SB files and the “receive-sb-file” command to simplify the programming procedure.

5.1 Brief introduction of SB file

The MCU bootloader supports loading of the SB files. The SB file is a NXP-defined boot file format designed to ease the boot process. The file is generated using the NXP elftosb tool. The format supports loading of elf or srec files in a controlled manner, using boot commands such as load, jump, fill, erase, and so on. The boot commands are prescribed in the input command file (boot descriptor .bd) to the elftosb tool. The format supports encryption of the boot image using AES-128 input key.

elftosb and SB file formats are described in greater detail in the accompanying documentation in the package.

In this user’s guide, the typical use case is provided to demonstrate the usage of elftosb host tool and how to download the SB file with MCU bootloader.

5.2 Generate SB file for QuadSPI image

This section describes the generation of the SB file. The output led-demo.srec file is used to generate the SB file (for KEIL, a similar approach can be followed).

- Open the led_demo_qspi project using the IAR EWARM toolchain. Using the project options dialog, select the "linker" and make sure the extension of the output file is ".out".

- Select the "Output Converter" and change the output format to "Motorola" for outputting the .srec format image. See the following figure.
Build either the Debug or the Release configuration of the project. When the build is completed, the led_demo_QSPI.srec file should be available in the output/Debug or output/Release folders.

The next step is to generate the SB file using a command-line host tool, elftosb. The boot descriptor file, qspi_image.bd, is passed as the input to the elftosb tool on the command line. The following figure shows the BD file content, the "Sources" section provides the path to the input srec and QCB files and "Section (0)" shows the flow of the boot commands.

After creating the BD file shown in the following figure, copy the "qspi_config_block.bin", elftosb.exe, "led_demo_QSPI.srec", and BD files into the same directory. Then open the window with the command prompt and invoke the elftosb as "elftosb –V –c qspi_image.bd –o image.sb". The elftosb processes the qspi_image.bd file and generates the image.sb file. The elftosb also outputs the commands list, as shown in Figure 12. Notice that the list corresponds to the BD file Section(0) statements.
Figure 11. Create a BD file for the QuadSPI image

```
# The sources block assigns file names to identifiers.
sources {
    # SRC file path
    mySrcFile = "led_demo_QSPI.srec";
    # QCB file path
    qspiConfigBlock = "qspi_config_block.bin";
}

# The section block specifies the sequence of boot commands to be written to
# the SB file.
ssection (0) {
    #1. Erase the vector table and flash config field.
    erase 0..0x800;

    # Step 2 and Step 3 are optional if the QuadSPI is configured at startup
    #2. Load the QCB to RAM
    load qspiConfigBlock > 0x20000000;

    #3. Configure QuadSPI with the QCB above
    enable qspi 0x20000000;

    #4. Erase the QuadSPI memory region before programming.
    erase 0x68000000..0x68004000;

    #5. Load the QCB above
    load qspiConfigBlock > 0x68000000;

    #6,7. Load all the RO data from srec file, including vector table,
    # Flash config area and codes.
    load mySrcFile;

    #8. Reset target
    reset;
}
```

Figure 12. elftosb command line usage example and output text

```
$ elftosb -V -c qspi_image.bd -o image.sb

RESET
```

5.3 Flash QuadSPI image via MCU bootloader

When the SB file image is generated, either the blhost or KinetisFlashTool can be used to program the image to the target. The following figure shows an example of programming the SB file with blhost.
Figure 13. Flash SB file with blhost

```bash
$ blhost -p COM33 -- receive-sb-file image.sb
Ping responded in 1 attempt(s)
Inject command 'receive-sb-file'
Preparing to send 3408 (0x50) bytes to the target.
Successful generic response to command 'receive-sb-file'
Data phase write aborted by status 0x2712 kStatus_AbortDataPhase
Response status = 10002 (0x2712) kStatus_AbortDataPhase
Wrote 3360 of 3408 bytes.
```
Chapter 6
Advanced Usage: Encrypted QuadSPI image

The SB file generated in Section 5.2 is in plaintext form and not encrypted. This section focuses on several aspects of encrypted boot with MCU bootloader.

To use the encrypted boot feature, user must have basic knowledge of the SB key, KeyBlob Block, and KeyBlob Encryption Key (KEK), SB Key, AES-128 CTR, AES-128 CBC-MAC, and so on. See the MCU bootloader chapter in the silicon’s reference manual for a detailed description. The following is a brief introduction to these terms:

• The KeyBlob Block is a data structure that contains up to four groups of KeyBlob entries. Each entry consists of the start address, length, decryption key, and counter of an encrypted QuadSPI memory region.

• The KeyBlob Block itself is encrypted by another AES key, called Key encryption key (KEK). KEK needs to be pre-programmed in flash’s IFR region. In MK82F256, the Flash IFR index for KEK is from index 0x20 to 0x23. With the Key Blob and KEK, sections belonging to encrypted QuadSPI memory region (QuadSPI image data) can be encrypted using elftosb tools. The generated SB file has encrypted image data for the encrypted QuadSPI memory region.

• For devices with flash security enabled, only encrypted SB file images are allowed to be provisioned. MCU bootloader decrypts the encrypted SB image as it receives from the host using a separate SB key. The SB key is an AES-128 key pre-programmed into flash’s IFR region at word offsets 0x30 to 0x33. The elftosb tool allows generation of encrypted SB file image using the SB key.

In general, the QuadSPI image is encrypted using the parameters in the KeyBlob with AES-128 CTR mode, the KeyBlob Block itself encrypted with KEK, and the SB file is encrypted via SB key with AES-128 CBC-MAC. The following figure shows an SB file containing plaintext QuadSPI image data. The vector table and other regions are in plaintext.

Based on the application type, the user can choose to have plaintext or encrypted QuadSPI image or encrypted SB file image solution.

![Figure 14. Plaintext SB file with Plaintext QuadSPI image](image-url)
6.1 Generate an SB file with KEK and SB KEY

Here is an example of generating an SB file with just the KEK and SB KEY. The generated SB file can be provisioned using MCU bootloader to program the keys into IFR region of the device.

The SB KEY is a 16 byte array. For example:

```c
uint8_t sbKey[16] = {0x00, 0x11, 0x22, 0x33, 0x44, 0x55, 0x66, 0x77, 0x88, 0x99, 0xa0, 0xb1, 0xc2, 0xd3, 0xe4, 0xff};
```
The KEK is also a 16 byte array. For example:

```c
uint8_t kek[16] = {0x00, 0x01, 0x02, 0x03, 0x05, 0x06, 0x07, 0x08, 0x09, 0x0a, 0x0b, 0x0c, 0x0d, 0x0e, 0x0f};
```

Pay attention to the correct order of the data to be programmed to Flash IFR, because each IFR field needs to be programmed with 32-bit little-endian data. See the example BD file content provided in the following figure to understand how to specify the SB key and KEK to generate SB file image to program the keys.

To generate SB file, a specified BD file needs to be generated first, assuming the BD file is called "program_keys.bd".

```c
# No source file needed, keep this block empty
sources [];

# The section block specifies the sequence of boot commands to be written to
# the SB file.
section (0) {
    # Use the 'load ifr' statement to program the SB key to IFR memory.
    # The SB key occupies IFR index 0x30-0x33.
    # The SB key is 128-bit specified as 4 little-endian long-word values.
    load ifr 0x33221100 > 0x30;
    load ifr 0x76655444 > 0x31;
    load ifr 0xbbaa9888 > 0x32;
    load ifr 0xfeeddccc > 0x33;

    # Use the 'load ifr' statement to program the OTFAD KEK to IFR memory.
    # The KEK is used to unwrap (decrypt) the keyBlob at boot time in order to
    # correctly set up the OTFAD engine.
    # The KEK is specified as 4 little endian values, with the "least significant"
    # key word going into the lowest IFR index.
    # KEK = {0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07, 0x08, 0x09, 0x0a, 0x0b, 0x0c, 0x0d, 0x0e, 0x0f}
    load ifr 0x0f0e0d0c > 0x20;
    load ifr 0x0b0a0908 > 0x21;
    load ifr 0x07060504 > 0x22;
    load ifr 0x03020100 > 0x23;

    # reset target in order to let these keys take effect.
    reset;
}
```

**Figure 17. Specified BD file for SB key and KEK**

Using elftosb, the desired SB file is generated. The elftosb command line and output is shown in the following figure.

```
$ elftosb -V -c program_keys.bd -o program_keys.sb

Figure 18. Generate program_keys.sb
```

Either blhost or KinetisFlashTool can be used to flash the SB file to the target device.

### 6.2 Generate an SB file with encrypted QuadSPI image

After the previous operation, another SB file (which contains the encrypted QuadSPI image) is still needed. Similar to how the SB file was generated in the previous section, the BD file is needed to describe all the operations in this SB file. Besides
the operations listed in Chapter 4, it also contains the Key Blob Block, encrypted QuadSPI image, and Key Blob encryption wrapper.

### 6.2.1 The KeyBlob Block

This section shows the syntax of the keyBlob entry in the BD file with an example in the following figure. The example shows one QuadSPI memory region identified by the counter value.

```c
keyblob (0) {
  # key blob 0
  {
    start = address1,
    end = address2,
    key=keystring,
    counter=counterstring
  }
  # key blob 1, keep this blank if this key blob isn’t needed.
  {}  
  # key blob 2, keep this blank if this key blob isn’t needed.
  {}  
  # key blob 3, keep this blank if this key blob isn’t needed.
  {}  
}
```

Figure 19. KeyBlob definition

### 6.2.2 Encrypt QuadSPI image

This section shows BD file changes required to encrypt the QuadSPI image using the KeyBlob. The encrypt (0) section in the BD file, shown in the following figure, causes elftosb to encrypt the QuadSPI image data falling in the QuadSPI memory regions pointed by the keyBlob counter.
The keyBlob itself is encrypted with the KEK. The keywrap (0) section in the BD file causes elftosb to wrap the keyBlob using the KEK specified in the load command of keywrap section.

The syntax for the keywrap section of BD file is as follows:

```plaintext
keywrap (0) {
    load {{KEK hex string}} > destination of encrypted key blob block;
}
```

The memory address 0x1000 in the example shown in the following figure is where the wrapped keyBlob is loaded during provisioning of SB file to the target device using MCU bootloader.

```
# The section block specifies the sequence of boot commands to be written to
# the SB file.
section (0) {
    #1. Erase the vector table and flash config field.
    erase 0..0x800;
    #2. Load the QCB to RAM
    load qspiConfigBlock > 0x20000000;
    #3. Configure QuadSPI with the QCB above enable qspi 0x20000000;
    #4. Erase the QuadSPI memory region before programming.
    erase 0x68000000..0x68004000;
    #5. Load the QCB above
    load qspiConfigBlock > 0x68000000;
    encrypt (0) {
        # Load all the RO data from srec file.
        load mySrecFile;
    }  # range of one of the keyBlob entries is left unencrypted.
    #6. The encrypt statement indicates that load commands should encrypt data from the srec file
    # using AES-CTR mode encryption. The encrypt argument (0) specifies the keyBlob parameters
    # to use (see the keyBlob block above). Section from the srec file that do not fall in the
    # range of one of the keyBlob entries are left unencrypted.
    keywrap (0) {
        load {{{000102030405060708090A060C00000E0F}}} > 0x1000;
    }
    #8. Load the encrypted keyBlob block to specified location.
    # The keywrap statement wraps (encrypts) the keyBlob specified in the argument(0) using the
    # specified key encryption key (KEK) and loads the keyBlob to internal flash. The load
    # destination(0x1000) must match the default location (0x10) or the keyBlob pointer in the
    # Bootloader Configuration Area (BCA) contained in the srec image. Make sure the sector at
    # 0x1000 has not been written by the srec file load above, otherwise it will need to be
    # erased again.
    #9. Reset target
    reset;
}
```

![Figure 20. Encrypt QuadSPI image and KeyBlob](image)

### 6.2.3 Encrypting SB file with the SB key

To encrypt the SB file with the elftosb, a file containing the SB key must be created, as shown in the following figure.
Figure 21. Create key.txt containing SB key

The following figure shows the generation of the encrypted SB file using the BD file drafted in the previous sections. The SB key is passed on the command line to the elftosb using the -k option.

Figure 22. Generate encrypted SB file with encrypted QuadSPI image

The output image.sb file can be programmed to the target device using the bloader or KinetisFlashTool, as shown in the earlier examples. Based on the example BD file, the image.sb file has the wrapped keyBlob, the keyBlob encrypted QuadSPI image data, and the entire content of the SB file encrypted with the SB key.
Chapter 7  
Change QuadSPI clock in QuadSPI image 

When using MCU bootloader, if the target is booted from the QuadSPI image, both the QuadSPI serial clock and core clock are from MCGFLL. MCG is under FEE mode, using the IRC48M as the clock source. In some cases, this may not meet the system's accuracy and performance requirement. The MCG mode needs to be switched from FEE to PEE, with an external OSC as clock source. Be aware that this operation has great impact on the QuadSPI serial clock, so avoid running the clock switch function on the QuadSPI image directly. A relatively safer way to avoid this is to either copy this function to SRAM, or place this function in internal flash. 

This chapter provides an example for how to create a clock switch function running on RAM. 

7.1 Create a RAM function via IAR EWARM 

In order to create a RAM function with IAR EWARM, two sections need to be defined. The first is "ramfunc_section_init", which is used to store the data of a RAM function, and a "ramfunc_section", which is the actual execution section of the RAM function. The following code snippets provide an example of how to define and place code to these sections. 

```c
void copy_to_ram(void) 
{
    uint8_t *codeRelocateRomStart;
    uint32_t codeRelocateSize;
    uint8_t *codeRelocateRomStart;

    codeRelocateRomStart = (uint8_t *)__section_begin("ramfunc_section_init");
    codeRelocateSize = (uint32_t)__section_size("ramfunc_section_init");
    codeRelocateRomStart = (uint8_t *)__section_begin("ramfunc_section");

    while (codeRelocateSize)
    {
        *codeRelocateRomStart++ = *codeRelocateRomStart++;
        codeRelocateSize--;
    }
}
```

**Figure 23. Declare ram function section in EWARM project** 

After the previous operation, we still need to define another function. For example, `copy_to_ram()` to copy the RAM func codes from QuadSPI memory to RAM. The following figure provides an example. 

```c
/// @brief switch to PEE mode from FEE mode.
/// @brief In this function, the QuadSPI source clock is changed to MCGFLL,
/// @brief The QuadSPI serial clock divider is set to 1.
/// @brief The SystemCoreClock is updated to 120MHz, the MCG is switched from FEE to PEE mode.
#if defined (__ICCARM__)
#pragma section = "ramfunc_section"
#pragma section = "ramfunc_section_init"
void clock_change(void) $ "ramfunc_section";
```

**Figure 24. Implement copy_to_ram() function in EWARM project** 

Finally, change the linker file in order to let the linker know a RAM function section has been defined. The location to place this section, and the section, need to be copied to RAM manually.
7.2 Create a RAM function via Keil MDK

Keil also supports the creation of a RAM function, using a similar method as described for IAR EWARM. To create a RAM function via KEIL, declare a section. In this example, "ramfunc_section" has been declared. See the following figure.

```c
extern uint32_t Load$EXEC_m_ramfunc$Base; // Base address for loading ram function
extern uint32_t Load$EXEC_m_ramfunc$Length; // Size of ram function
extern uint32_t Image$EXEC_m_ramfunc$Base;
void clock_change(void) __attribute__((section("ramfunc_section"))): // Execute address of ram function
```

Figure 26. Declare RAM function in MDK project

A copy_to_ram function is still necessary to copy the data from ROM to an actual execution address. See the following figure.

```c
void copy_to_ram(void)
{
    uint8_t *codeRelocateRomStart;
    uint32_t codeRelocateSize;
    uint8_t *codeRelocateRamStart;

    codeRelocateRomStart = (uint8_t *)Load$EXEC_m_ramfunc$Base;
    codeRelocateSize = (uint32_t)Load$EXEC_m_ramfunc$Length;
    codeRelocateRamStart = (uint8_t *)Image$EXEC_m_ramfunc$Base;

    while (codeRelocateSize)
    {
        *codeRelocateRamStart++ = *codeRelocateRomStart++;
        codeRelocateSize--;
    }
}
```

Figure 27. Implement copy_to_ram() function in MDK project

To let the linker know a RAM function has been defined, add some information to the linker file. For example:
A complete project for this example can be found in the `<sdk_package>/boards/<board>/bootloader_examples/demo_apps`.

### 7.3 Create a RAM function with MCUXpresso IDE

This section shows the steps required for the MCUXpresso IDE to create the RAM function.

First, declare a section to place the RAM function codes to. In this example, a section called “ramfunc_section” is declared as follows:

```c
extern uint32_t ramfunc_load_address[];
extern uint32_t ramfunc_length;
extern uint32_t ramfunc_execution_address[];
void clock_change(void) __attribute__((section("ramfunc_section"))); // Execute address of ram function
```

Then, implement the `copy_to_ram()` function in the MCUXpresso IDE project. An example is shown in the following figure:
Finally, the linker file must be updated to let the MCUXpresso IDE realize that the RAM function is defined, and must be placed somewhere. The following figure demonstrates the changes for the RAM function in the linker file. A complete project for this example can be found in the `<sdk_package>/boards/<board>/bootloader_examples/demo_apps` folder.

```c
void copy_to_ram(void)
{
    uint8_t* codeRelocateRomStart;
    uint32_t codeRelocateSize;
    uint8_t* codeRelocateRamStart;

    codeRelocateRomStart = (uint8_t*)ramfunc_load_address;
    codeRelocateSize = ramfunc_length;
    codeRelocateRamStart = (uint8_t*)ramfunc_execution_address;

    while(codeRelocateSize)
    {
        *codeRelocateRamStart++ = *codeRelocateRomStart++;
        codeRelocateSize--;
    }
}
```

Figure 30. Implement copy_to_ram() function in MCUXpresso IDE project

Figure 31. Linker file changes for RAM function in MCUXpresso IDE
7.4 Ensure no timing issue after clock change

After performing the changes listed in the previous section, the clock switch function can be implemented. Note that the clock switch function must not violate the timing requirements for the QuadSPI module and the external SPI flash device. For example, if the external SPI flash is working in the SDR mode and you plan to switch the QuadSPI clock source to PLL 120 MHz, it is required to set the QuadSPI_MCR [SCLKCFG] to at least 1 (which means that the QuadSPI serial clock frequency is 120 MHz/2 = 60 MHz), because the maximum supported clock for the SDR mode is 100 MHz. See the clock_change() function in the example for more details.
Chapter 8
Application running on QuadSPI alias area

For reasons such as performance improvements, the application should be addressed to run from QuadSPI alias area (0x0400_0000 to 0x07FF_FFFF on MK82F256) instead of physical addresses. MCU ROM bootloader does not support downloading the application running on the alias area directly. However, a workaround solution is described in this section to allow application to run from the alias region. Here we use the led_demo demonstrated before as an example and show how to download and run such application from the alias memory region.

NOTE
This section is only applicable to MCU ROM Bootloader in K80, K81, and K82.

8.1 Create an application to run on QuadSPI Alias Area

Using the led_demo_QSPI as a starting point, modify the linker file using the IAR project as an example. The following figure shows the changes to the address symbols in the linker file to allocate the sections to the QuadSPI alias memory.

```
53 define symbol m_interru sts_start   = 0x04001000;
54 define symbol m_interru ts_end     = 0x040013BF;
55 define symbol m_bootloader_config_start = 0x040013C0;
56 define symbol m_bootloader_config_end = 0x000013FF;
58 define symbol m_flash_config_start = 0x04001400;
59 define symbol m_flash_config_end = 0x0400140F;
61 define symbol m_text_start = 0x04001000;
63 define symbol m_text_end = 0x07FFFFFF;
```

Figure 32. Linker file changes for QuadSPI Alias image in IAR project

Next, remove the BOOTLOADER_CONFIG macro from the IAR project, because the BCA is placed in the internal flash memory. In this example, the application is placed in the QuadSPI alias memory. See the following figure for details.
Finally, change the "Output Converter" option, and let the IAR generate a binary file. See the following figure.

Figure 33. Remove BOOTLOADER_CONFIG macro from IAR project
Let IAR output binary file

8.2 Create a simple boot application

As previously mentioned, MCU bootloader does not support boot from QuadSPI alias memory directly, and as such the host tool should command MCU bootloader to write the led_demo_QSPI application image to the physical address of QuadSPI memory starting with 0x6800_0000 address range. The workaround to make the QuadSPI application run out of alias memory is to create a simple boot application that, when invoked at boot, causes the PC to jump to the alias address where led_demo_QSPI application is linked. The boot application functionality includes:

• Change the VTOR to the actual base address of the vector table in the led_demo_QSPI application.
• Change the stack pointed to the actual address pointed to in the start of the vector table for the led_demo_QSPI application.
• Jump to the led_demo_QSPI application.

In addition, the BCA and keyBlob also need to be included in the boot application. The example boot application is provided along with the led_demo_QSPI in <sdk_package>/boards/<board>/bootloader_examples/demo_apps. The following steps demonstrate how to generate the project for the boot application:

First, use the led_demo_PFLASH as a starting point, and replace the main() function with the code snippet from the following figure.
typedef void(*application_handler_t)(void);

enum
{
    QuadSPI_Image_Start = 0x04001000ul,
};

int main(void)
{
    static uint32_t s_stackPointer = 0;
    static application_handler_t runApplication;

    // Set the VTOR to the application vector table address
    SCB->VTOR = QuadSPI_Image_Start;

    s_stackPointer = *(uint32_t*)QuadSPI_Image_Start;
    runApplication = *(application_handler_t*)(QuadSPI_Image_Start + 4);

    __set_MSP(s_stackPointer);
    __set_PSP(s_stackPointer);

    runApplication();

    // Never run here
    while(1)
    {
    }
}

Figure 35. Jump to application running on QuadSPI Alias Area

Next, change the startup_MK82F25616.s file. Ensure that FOPT [7:6] (loaded from address 0x40D) is set to 0b10. See the following figure.

<table>
<thead>
<tr>
<th>319</th>
<th>FlashConfig</th>
</tr>
</thead>
<tbody>
<tr>
<td>320</td>
<td>DCD 0xFFFFFFFF</td>
</tr>
<tr>
<td>321</td>
<td>DCD 0xFFFFFFFF</td>
</tr>
<tr>
<td>322</td>
<td>DCD 0xFFFFFFFF</td>
</tr>
<tr>
<td>323</td>
<td>DCD 0xFFFFFFFF</td>
</tr>
</tbody>
</table>

Figure 36. Change FOPT to 0xBD

Enable BCA in the boot project by defining BOOTLOADER_CONFIG macro. See the following figure.
Application running on QuadSPI alias area
Create a simple boot application

![Options for node "boot_to_qspi_alias_memory"](image)

**Figure 37. Change Enable BCA in IAR project**

Change the BCA fields as needed. For example, if 'peripheralDetectionTimeoutMs' needs to be changed to 500 and the 'keyBlobPointer' to 0x1000. The example BCA structure is shown in the following figure.
Finally, change the "Output Converter" option, and let the IAR output SREC file.

8.3 Downloading application running on QuadSPI alias memory with SB file

Assume that the application running on QuadSPI alias memory is called "led_demo_qspi_alias.bin", the boot application is called "boot_to_qspi_alias_memory.srec", and the QCB is called "qspi_config_block.bin". An example BD file to generate the required SB file is shown in the following figure. Note that only one SB file is needed to load both boot application "boot_to_qspi_alias_memory.srec" and led_demo_QquadSPI_alias.bin.
As previously mentioned, MCU bootloader does not recognize the QuadSPI alias memory addresses. Therefore, in the BD file the QuadSPI physical memory addresses should be specified for load and erase commands as shown in the following figure.

Generate the SB file and download it to the target device following instructions provided in Section 5.3.

```c
# The sources block assigns file names to identifiers.
# SREC File path
mySrecFile = "boot_to_qspi_alias_memory.srec";
# QCB file path
qspiConfigBlock = "qspi_config_block.bin";
# Alias QSPI image File path
myBinFile = "led_demo_QSPI_alias.bin";

# The section block specifies the sequence of boot commands to be written to
# the SB file.
section (0) {
    #1. Erase the vector table and flash config field.
    erase 0x0000..0x0800;

    # Step 2 and Step 3 are optional if the QuadSPI is configured at startup
#2. Load the QCB to RAM
    load qspiConfigBlock > 0x20000000;

#3. Configure QuadSPI with the QCB above
    enable qspi 0x20000000;

#4. Erase the QuadSPI memory region before programming.
    erase 0x68000000..0x68004000;

#5. Load the QCB above
    load qspiConfigBlock > 0x68000000;

#6 Load all boot_to_qspi_alias_memory application
    load mySrecFile;

#7 Load alias QSPI image
    load myBinFile > 0x68001000;

#8. Reset target
    #reset;
}
```

Figure 40. Create a SB file contained boot application and QuadSPI demo application

### 8.4 Creating encrypted QuadSPI application running on QuadSPI Alias memory with SB file

Using the steps mentioned in Section 6.1 and Section 6.2 and using the same SB key, KEK, and KeyBlob, an encrypted SB file containing the encrypted QuadSPI alias image can be generated. See the following BD file for more details.

**NOTE**

1. The application is linked to the alias address range (0x0400_0000).
2. The application is loaded to the physical address range (see BD file step #7).
3. In the KeyBlob block, the OTFAD range is programmed to the physical address range.
# The sources block assigns file names to identifiers.
sources {
    # SREC file path
    mySrcFile = "boot_to_quadspilibrarian.srec";
    # Aliases
    qspilibrarian = "led_demo_quadspi_alias.bin";
    # QCB file path
    qspiConfigBlock = "qspi_config_block.bin";
}

# The keyblob entry creates a structure with up to 4 keyblobs.
# Note: the start and end address should be physical QuadSPI address
keyblob (0) {
    start=0x68001000,
    end=0x68001FFF,
    key="0001020304050607089a0b0c0d0e0f",
    counter="0123456789abcdef"
}
}

section(0) {
    # 1. Erase the vector table and flash config field.
    erase 0..0x800;

    # 2. Load the QCB to RAM
    load qspiConfigBlock > 0x20000000;

    # 3. Configure QuadSPI with the QCB above
    enable qspi 0x20000000;

    # 4. Erase the QuadSPI memory region before programming, using physical address
    erase 0x68000000..0x68004000;

    # 5. Load all boot_to_quadspilibrarian application
    load mySrcFile;

    # 6. Load QCB to QuadSPI memory
    load qspiConfigBlock > 0x68000000;

    # 7. Encrypt QuadSPI Alias Application and load it to QuadSPI memory
    encrypt (0)
    {
        load myBinFile > 0x69000000;
    }

    # 8. Encrypt KeyBlob structure with KEK and load it to 0x1000
    keywrap (0)
    {
        load ((0001020304050607089a0b0c0d0e0f)) > 0x1000;
    }

    # 9. Reset target
    reset;
}

Chapter 9
Appendix A - QuadSPI configuration procedure

For MCU bootloader, follow the below steps to perform QuadSPI configuration using the QCB data. The following figure depicts the corresponding flow chart:

- Detect the location of QCB from either start address of QuadSPI memory or internal flash
- Configure QuadSPI pinmux based on the information from QCB
- Enable QuadSPI clock gate, prepare to configure QuadSPI registers
- Configure look-up table
- Configure QuadSPI registers such as AHB buffer size and DDR mode as needed
- Configure work mode of external SPI flash device, for example, Quad Mode or Octal Mode
- Additional configuration for external SPI flash device, if required in the QCB

Figure 42. QuadSPI Configuration Flow in MCU bootloader
Chapter 10
Appendix B - Re-enter MCU bootloader under direct boot mode

When direct boot is enabled in the BCA with bootFlags field set to 0xFE, ROM configures the QCB and jumps to the QuadSPI application image directly, bypassing the detection of active peripherals for firmware update from host. In this case, the QuadSPI application has to implement a workaround to invoke MCU bootloader when the host needs to update the application image. The QuadSPI application has to detect boot pin (NMI pin) assertion by the user and if asserted can follow below procedure to invoke MCU bootloader:

1. Erase the first sector of the internal flash to clear the BCA. Note that the flash configuration field of the BCA may have to be restored back, as shown in the code snippet in Figure 43.

2. Jump to the runBootloader() ROM API using the bootloader API tree pointer.

The following figure shows sample implementation of re-entry into bootloader from application code. The example code with the package contains the implementation of this feature in the led_demo_QuadSPI application.

```c
void app_enter_bootloader(void)
{
    // Get Kinetis Bootloader Tree pointer.
    const bootloader_tree_t * bootloaderTree = (const bootloader_tree_t *)BOOTLOADER_TREE_ROOT;
    // Initialize Flash Driver
    flash_driver_t flashInstance;
    bootloaderTree->flashDriver->flash_init(&flashInstance);
    // Save the flash config field before erase
    uint32_t flashConfigField[4];
    const uint32_t *flashConfigFieldStart = (const uint32_t*)0x400;
    for(uint32_t i=0; i<sizeof(flashConfigField)/sizeof(flashConfigField[0]); i++)
    {
        flashConfigField[i] = *flashConfigFieldStart++;
    }
    // Erase the first sector.
    bootloaderTree->flashDriver->flash_erase(flashInstance, 0, 0x800, kFlashEraseKey);
    // Write the flash config field back.
    bootloaderTree->flashDriver->flash_program(flashInstance, 0x400, flashConfigField, sizeof(flashConfigField));
    // Enter Kinetis Bootloader
    bootloaderTree->runBootloader(0);
}
```

Figure 43. Implementation of re-entering MCU bootloader in application
Chapter 11
Appendix C - Explore more features in QCB

Several more features of QuadSPI are supported by MCU bootloader such as parallel mode, continuous read mode, and so on. The following sections provide examples of generating QCB with these modes enabled.

11.1 Parallel mode

This section provides an example of generating a QCB with the parallel mode support. Pay attention to these key points:

- The sector size and page size should be twice the actual size for the parallel mode.
- The 'parallel_mode_enable' field in QCB must be set to 1.
- The Program command should be replaced by the Page Program command, as the QuadSPI module only supports single-pad parallel programming.

This is the example:

```c
// This is the QCB for the use case that two MX25U3235F are connected to QuadSPI0A and QuadSPI0B ports.
// Work under parallel mode
const qspi_config_t qspi_config_block =
{
    .tag = kQspiConfigTag,
    .version = { .version = kQspiVersionTag },
    .lengthInBytes = 512,
    .sflash_A1_size = 0x400000,     // 4MB
    .sflash_B1_size = 0x400000,     // 4MB
    .sclk_freq = kQspiSerialClockFreq_High,  // High frequency
    .sflash_type = kQspiFlashPad_Quad,      // SPI Flash devices work under quad-pad mode
    .sflash_port = kQspiPort_EnableBothPorts,  // Both QSPI0A and QSPI0B are enabled.
    .busy_bit_offset = 0,  // Busy offset is 0
    .ddr_mode_enable = 0,  // disable DDR mode
    .dqs_enable = 0,      // Disable DQS feature
    .parallel_mode_enable = 1, // QuadSPI module work under parallel mode
    .pagesize = 512,                // Page Size : 256 *2 = 512 bytes
    .sectorsize = 0x2000,           // Sector Size: 4KB * 2 = 8KB
    .device_mode_config_en = 1,       // configure quad mode for spi flash
    .device_cmd = 0x40,             // Enable quad mode
    .write_cmd_ipcr = 0x05000000U,  // IPCR indicating enable seqid (5<<24)
    .ips_command_second_divider = 3,// Set second divider for QSPI serial clock to 3
    .look_up_table =
    {
        // Seq0: Quad Read (maximum supported freq: 104MHz)
        /*
        CMD: 0xEB - Quad Read, Single pad
        ADDR: 0x18 - 24bit address, Quad pads
        DUMMY: 0x06 - 6 clock cycles, Quad pads
        READ: 0x80 - Read 128 bytes, Quad pads
        JUMP_ON_CS: 0
        */
        [0] = 0x0A1804EB,
        [1] = 0x1E800E06,
        [2] = 0x2400,
        // Seq1: Write Enable (maximum supported freq: 104MHz)
    }
};
```
NOTE

The previous example must be placed in the `<sdk_package>/middleware/mcu-boot/apps/QCBGenerator/src` folder.
11.2 Continuous read mode

The MX25U3235F supports the continuous read mode (performance enhance mode) to provide high performance reads. The important item to be configure for this use case is:

- The Dummy LUT entry must be configured according to the condition of the exiting continuous read mode. Otherwise, the device fails to perform an erase or a program operation as it cannot exit this mode correctly.

The following is an example:

```
// This is the QCB for when two MX25U3235F are connected to QuadSPI0A and QuadSPI0B ports.
// Work under parallel mode
const qspi_config_t qspi_config_block = {
    .tag = kQspiConfigTag,
    .version = { .version = kQspiVersionTag },
    .lengthInBytes = 512,
    .sflash_A1_size = 0x400000,  // 4MB
    .sclk_freq = kQspiSerialClockFreq_High,  // High frequency
    .sflash_type = kQspiFlashPad_Quad,  // SPI Flash devices work under quad-pad mode
    .sflash_port = kQspiPort_EnableBothPorts,  // Both QSPI0A and QSPI0B are enabled.
    .busy_bit_offset = 0,  // Busy offset is 0
    .ddr_mode_enable = 0,  // disable DDR mode
    .dqs_enable = 0,      // Disable DQS feature
    .parallel_mode_enable = 1,  // QuadSPI module work under parallel mode
    .pagesize = 512,                // Page Size : 256 *2 = 512 bytes
    .sectorsize = 0x2000,           // Sector Size: 4KB * 2 = 8KB
    .device_mode_config_en = 1,       // configure quad mode for spi flash
    .device_cmd = 0x40,             // Enable quad mode
    .write_cmd_ipcr = 0x05000000U,  // IPCR indicating enable seqid (5<<24)
    .ips_command_second_divider = 3,// Set second divider for QSPI serial clock to 3
    .look_up_table = {
        // Seq0: Quad Read (maximum supported freq: 104MHz)
        /*
        CMD: 0xEB - Quad Read, Single pad
        ADDR: 0x18 - 24bit address, Quad pads
        MODE: 0x05 - Continuous read mode, Quad Pads
        DUMMY: 0x04 - 4 clock cycles, Quad pads
        READ: 0x80 - Read 128 bytes, Quad pads
        JUMP ON CS: 1
        */
        [0] = 0x0A1804EB,
        [1] = 0x0E04012A5,
        [2] = 0x24011E80,
        // Seq1: Write Enable (maximum supported freq: 104MHz)
        /*
        CMD: 0x06 - Write Enable, Single pad
        */
        [4] = 0x406,
        // Seq2: Erase All (maximum supported freq: 104MHz)
        */
```
CMD:    0x60 - Erase All chip, Single pad
        */
        [8] = 0x460,
        // Seq3: Read Status (maximum supported freq: 104MHz)
        */
        CMD:    0x05 - Read Status, single pad
        READ:   0x01 - Read 1 byte
        */
        [12] = 0x1c010405,
        // Seq4: Page Program (maximum supported freq: 104MHz)
        */
        CMD:    0x02 - Page Program, Single pad
        ADDR:   0x18 - 24bit address, Single pad
        WRITE:  0x40 - Write 64 bytes at one pass, Single pad
                (0x40 is ignored, because it will be overwritten by page size)  
        */
        [16] = 0x08180402,
        [17] = 0x2040,
        // Seq5: Write status register to enable quad mode
        */
        CMD:    0x01 - Write Status Register, single pad
        WRITE:  0x01 - Write 1 byte of data, single pad
        */
        [20] = 0x20010401,
        // Seq7: Erase Sector
        */
        CMD:    0x20 - Sector Erase, single pad
        ADDR:   0x18 - 24 bit address, single pad
        */
        [28] = 0x08180420,
        // Seq8: Dummy
        */
        CMD:    0xFF - Dummy command, used to force SPI flash to exit continuous read mode.
                Unnecessary here because the continuous read mode isn't enabled.
        */
        [32] = 0xFF,
    },

NOTE

See the example from the <sdk_package>/middleware/mcu-boot/apps/QCBGenerator/src folder.
Chapter 12
Appendix D - DDR mode issue workaround

The MCU bootloader in the ROM of MK80F256 devices supports programming and booting from QuadSPI devices with double data rate (DDR) mode. However, due to an issue in the ROM code, a workaround is needed to use the DDR feature. This workaround should be implemented in the application image. This appendix provides the details on implementing the workaround. The package contains example application code with the workaround implemented.

ROM provides DDR mode support using the values provided in the QCB data structure. Specifically, these two fields of QCB are used to support DDR mode:

- ddr_mode_enable - must be set to 1.
- data_hold_time - can be either 1 or 2 depending on the type of SPI Flash device.

NOTE
1. This workaround is only applicable to ROM bootloader for K80, K81, K82, KL81, and KL82.
2. All QCB examples are applicable to both ROM bootloader and MCU bootloader 2.5.0.

12.1 Example QCB for QuadSPI device N25Q256A with DDR mode support

The following is an example QCB for the N25Q256A with the DDR mode support:

```c
const qspi_config_t qspi_config_block = {
    .tag = kQspiConfigTag,
    .version = { .version = kQspiVersionTag },
    .lengthInBytes = 512,
    .sflash_A1_size = 0x2000000,     // 32MB
    .sclk_freq = kQspiSerialClockFreq_High, // High frequency, 96MHz/4 = 24MHz
    .sflash_type = kQspiFlashPad_Quad,  // SPI Flash devices work under quad-pad mode
    .sflash_port = kQspiPort_EnablePortA,    // Only QSPI0A is enabled.
    .busy_bit_offset = 0x00010007,  // Busy offset is 7, polarity: 0 means busy
    .ddr_mode_enable = 1,  // Enable DDR mode
    .data_hold_time = 1,   // Data aligned with 2x serial flash half clock
    .ddrsmp = 0,
    .dqs_enable = 0,      // Disable DQS feature
    .dqs_loopback = 0,
    .pagesize = 256,                // Page Size : 256 bytes
    .sectorsize = 0x1000,           // Sector Size: 4KB
    .ips_command_second_divider = 0,
    .device_mode_config_en = 1,     // Configure the device to 4-byte address mode
    .device_cmd = 0,                // Not needed.
    .write_cmd_1pcr = 5UL<<24,      // Seq5 for setting address type to 4 bytes
    .look_up_table = {

```
12.3 Changes to user application for implementing DDR mode path

The following subsections describe the steps required to map the led-demo to run from the external QuadSPI flash memory in the DDR mode. See the led_demo_QSPI_patch project in the <sdk_package>/boards/<board>/bootloader_examples/demo_apps folder for more details.

12.3.1 Workaround solution

A workaround solution is required for the SPI flash devices with the DDR mode. The ROM missed a step in its implementation steps to set the QuadSPI_FLSHCR [TDH], QuadSPI_SOCCR[DLYTAPSELA], and QuadSPI_SOCCR[DLYTAPSELB] register bit fields. Therefore, the workaround patch consists of a very small piece of code to set the missed bit fields before jumping to the application image residing in the external QuadSPI flash memory. The patch function may reside in the internal flash memory.

The workaround patch function is defined with the following prototype in the package:

```c
int rom_patch(uint32_t qcbBaseAddress);
```

The following code shows how the workaround patch function is implemented in the example project provided with the package:

```c
int rom_patch(qspi_config_t *base) {
    volatile uint32_t *qspi_flshcr_reg = (volatile uint32_t*)QuadSPI0_FLSHCR_BASE;
    volatile uint32_t *qspi_soccr_reg = (volatile uint32_t*)QuadSPI0_SOCCR_BASE;

    *qspi_flshcr_reg &= (uint32_t)-QuadSPI0_FLSHCR_TDH_MASK;
    *qspi_flshcr_reg |= (base->data_hold_time)<<QuadSPI0_FLSHCR_TDH_SHIFT;

    *qspi_soccr_reg &= (uint32_t)-QuadSPI0_SOCCR_DLYTAPSELA_MASK;
    *qspi_soccr_reg |= (base->dqs_fa_delay_chain_sel << QuadSPI0_SOCCR_DLYTAPSELA_SHIFT) & QuadSPI0_SOCCR_DLYTAPSELA_MASK;

    *qspi_soccr_reg &= (uint32_t)-QuadSPI0_SOCCR_DLYTAPSELB_MASK;
    *qspi_soccr_reg |= (base->dqs_fb_delay_chain_sel << QuadSPI0_SOCCR_DLYTAPSELB_SHIFT) & QuadSPI0_SOCCR_DLYTAPSELB_MASK;
}
```
return kStatus_Success;
}

The binary position-independent code generated using the IAR compiler for the ROM patch function (available with the package) is shown here:

```c
const uint8_t s_rom_patch[128] =
{
  0x10, 0xB5, 0x01, 0x00, 0x18, 0x4A, 0x10, 0x00,
  0x18, 0x30, 0x18, 0x4B, 0x1B, 0x68, 0x15, 0x4C,
  0x1C, 0x40, 0x14, 0x60, 0x13, 0x68, 0x0C, 0x69,
  0x24, 0x04, 0x1C, 0x43, 0x14, 0x60, 0x02, 0x68,
  0x11, 0x48, 0x13, 0x40, 0x03, 0x60, 0xD0, 0x22,
  0x52, 0x00, 0x89, 0x02, 0x68, 0x0B, 0x68,
  0x1B, 0x04, 0x8C, 0x24, 0x84, 0x03, 0x1C, 0x40,
  0x14, 0x43, 0x04, 0x60, 0x02, 0x68, 0x0B, 0x4B,
  0x13, 0x40, 0x03, 0x60, 0x02, 0x68, 0x49, 0x68,
  0x09, 0x06, 0x8C, 0x23, 0x9B, 0x05, 0x0B, 0x40,
  0x13, 0x43, 0x03, 0x60, 0x00, 0x20, 0x10, 0x8B,
  0x0C, 0x80, 0x0D, 0x40, 0x24, 0x80, 0x04, 0x40,
  0x0C, 0x80, 0x05, 0x40, 0x0F, 0x0F, 0x8C, 0x4F,
  0x0F, 0x8C, 0x0C, 0x0F, 0x0F, 0x0F, 0x8C, 0x4F
};
```

These are the limitations for this workaround solution:
1. The DDR commands are only allowed in a second QCB after invoking this rom_patch workaround.
2. The CRC check feature is not allowed to validate the integrity of the image on the QuadSPI memory.
3. The QCB must be placed at a specific location in the internal flash pointed to by the qspiConfigBlockPointer in the BCA.

### 12.3.2 Changes to linker file

Using the led_demo_QSPI as a starting point and using the IAR project as an example, the first step is to update the linker file. Two separate sections are needed in the memory for this change. See the led_demo_QSPI_patch project in the led_demo projects for more details.

```c
define symbol m_rom_patch_code_start   = 0x00000410;
define symbol m_rom_patch_code_end     = 0x0000050F;
define symbol m_rom_patch_handler_start= 0x00000510;
define symbol m_rom_patch_handler_end  = 0x00000FFF;
define region m_rom_pach_code_region = mem:[from m_rom_patch_code_start to m_rom_patch_code_end];
define region m_rom_patch_handler_region = mem:[from m_rom_patch_handler_start to m_rom_patch_handler_end];
place in m_rom_patch_handler_region { readonly section BootloaderPatchHandler };
place in m_rom_pach_code_region {readonly section rom_patch_code };
```

The “m_rom_patch_handler_region” defined above is used for holding the section that contains the functions to invoke the ROM patch function.

The “m_rom_patch_code_region” defined above is used for placing the section that contains the ROM patch code mentioned in the previous section.
12.3.3 Changes to startup file

The Reset_Handler must be placed in the internal flash (for example, placing it in m_rom_patch_handler_region) and the ROM patch function must be called before the other functions when the QuadSPI application is executed. See the changes in the following figures.

```c
;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;;
;;
;; Default interrupt handlers.
;;
THUMB

PUBWEAK Reset_Handler
SECTION BootloaderPatchHandler:CODE:REORDER:NOROOT(2)
Reset_Handler
  CPSID I           ; Mask interrupts
  LDR R0, =ROM_PatchHandler
  BLX R0
  LDR R0, =SystemInit
  BLX R0
  LDR R0, =init_data_bss
  BLX R0
  CPSIE I           ; Unmask interrupts
  LDR R0, =__iar_program_start
  BX R0
```

Figure 44. Changes to startup file for DDR support

---

NOTE

The ROM_Patchhandler is the function placed in the m_rom_patch_handler_region.

12.3.4 Changes to system_MK82F25615.c file

The ROM patch code must be placed in the internal flash. For example, place it into the rom_patch_code section. See the following figure for these changes.
The ROM_PatchHandler must be placed in the internal flash as well. For example, it can be placed in the BootloaderPatchHandler section. See the following figure for these changes.

```c
#pragma language=extended
#pragma section = "rom_patch_code"
const uint8_t s_rom_patch[128] @ "rom_patch_code" =
{
    0x10, 0xBB, 0x01, 0x00, 0x18, 0x4A, 0x10, 0x00,
    0x18, 0x30, 0x18, 0x4B, 0x1B, 0x68, 0xF0, 0x24,
    0x24, 0x04, 0x1C, 0x40, 0x20, 0xD0, 0x16, 0x4A,
    0x10, 0x00, 0x18, 0x30, 0x13, 0x68, 0x15, 0x4C,
    0x1C, 0x40, 0x14, 0x60, 0x13, 0x68, 0x0C, 0x69,
    0x24, 0x04, 0x1C, 0x43, 0x14, 0x60, 0x02, 0x68,
    0x11, 0x4B, 0x13, 0x40, 0x03, 0x60, 0xDA, 0x22,
    0x52, 0x00, 0x89, 0x18, 0x02, 0x68, 0x0B, 0x68,
    0x1B, 0x04, 0xFC, 0x24, 0xA4, 0x03, 0x1C, 0x40,
    0x14, 0x43, 0x04, 0x60, 0x02, 0x68, 0x0B, 0x4B,
    0x13, 0x40, 0x03, 0x60, 0x02, 0x68, 0x49, 0x68,
    0x09, 0x06, 0xFC, 0x23, 0x9B, 0x05, 0x0B, 0x40,
    0x13, 0x43, 0x03, 0x60, 0x00, 0x20, 0x10, 0xBD,
    0xC0, 0xA0, 0xD0, 0x40, 0x24, 0x80, 0x04, 0x40,
    0xC0, 0xA0, 0x05, 0x40, 0xFF, 0xFF, 0xFC, 0x0F,
    0xFF, 0xFF, 0xC0, 0xFF, 0xFF, 0xFF, 0xC0
};
```

Figure 45. Definitions of ROM patch code in IAR project

/* Pragma to place the ROM_PatchHandler on correct location defined in linker file. */
#pragma language=extended
#pragma section = "BootloaderPatchHandler"
void ROM_PatchHandler (void) @ "BootloaderPatchHandler"
{
    typedef int (*patch_handler_t) (uint32_t);
    uint32_t s_rom_patch_start = (uint32_t)&section_begin("rom_patch_code");

    uint32_t patch_start = s_rom_patch_start + 1;
    patch_handler_t patch_run = (patch_handler_t)patch_start;
    patch_run (BootloaderConfig.qspiConfigBlockPtr);
}

Figure 46. Define ROM patch handler in IAR project
12.4 Workaround block diagram

The following figure shows the flow of MCU bootloader using QuadSPI DDR patch workaround mechanism described earlier in provisioning the application image on the QuadSPI with DDR mode enabled.

Figure 47. Workaround provisioning image on QuadSPI memory in DDR mode

The following figure shows the flow of MCU bootloader using QuadSPI DDR patch workaround mechanism described earlier in booting the application image from the QuadSPI with DDR mode enabled.
Appendix D - DDR mode issue workaround
BD file for downloading QuadSPI image under DDR mode

12.5 BD file for downloading QuadSPI image under DDR mode

The application image with the implemented workaround needs to be provisioned using the receive-sb-file Kinets bootloader command to let the MCU bootloader support program and read with DDR mode. The following figure provides example BD file changes to call the patch function.

The "K80_ROM_QSPI_patch.bin" in the below BD file is a binary file with the ROM patch code, mentioned above. It is needed to be loaded to SRAM out of the reserved RAM region. For example, 0x2000_0200, which then needs to be executed via the call command.

NOTE

1. Because the MK82F256 only supports thumb instructions, the address should be an odd value, namely 0x2000_0201 in this example.

2. The second parameter for call command is the base address for QCB, namely 0x2000_0000 in this example.
Appendix D - DDR mode issue workaround
