Chapter 1
Overview

The MCUXpresso Software Development Kit (SDK) provides comprehensive software support for Kinetis and LPC Microcontrollers. The MCUXpresso SDK includes a flexible set of peripheral drivers designed to speed up and simplify development of embedded applications. Along with the peripheral drivers, the MCUXpresso SDK provides an extensive and rich set of example applications covering everything from basic peripheral use case examples to full demo applications. The MCUXpresso SDK contains FreeRTOS and various other middleware to support rapid development.

For supported toolchain versions, see MCUXpresso SDK Release Notes for QN9090DK6 (document MCUXSDKQN9090RN).

For more details about MCUXpresso SDK, refer to MCUXpresso-SDK: Software Development Kit for MCUXpresso.

![MCUXpresso SDK layers]

Figure 1. MCUXpresso SDK layers
Chapter 2
MCUXpresso SDK board support package folders

MCUXpresso SDK board support package provides example applications for NXP development and evaluation boards for Arm® Cortex®-M cores including Freedom, Tower System, and LPCXpresso boards. Board support packages are found inside the top level boards folder and each supported board has its own folder (an MCUXpresso SDK package can support multiple boards). Within each `<board_name>` folder, there are various sub-folders to classify the type of examples it contain. These include (but are not limited to):

- **cmsis_driver_examples**: Simple applications intended to show how to use CMSIS drivers.
- **demo_apps**: Full-featured applications that highlight key functionality and use cases of the target MCU. These applications typically use multiple MCU peripherals and may leverage stacks and middleware.
- **driver_examples**: Simple applications that show how to use the MCUXpresso SDK’s peripheral drivers for a single use case. These applications typically only use a single peripheral but there are cases where multiple peripherals are used (for example, SPI conversion using DMA).
- **rtos_examples**: Basic FreeRTOS™ OS examples that show the use of various RTOS objects (semaphores, queues, and so on) and interfaces with the MCUXpresso SDK’s RTOS drivers
- **wireless_examples**: Applications that use the bluetooth stack.

2.1 Example application structure

This section describes how the various types of example applications interact with the other components in the MCUXpresso SDK. To get a comprehensive understanding of all MCUXpresso SDK components and folder structure, see MCUXpresso SDK API Reference Manual.

Each `<board_name>` folder in the boards directory contains a comprehensive set of examples that are relevant to that specific piece of hardware. Although we use the `hello_world` example (part of the `demo_apps` folder), the same general rules apply to any type of example in the `<board_name>` folder.

In the `hello_world` application folder you see the following contents:
All files in the application folder are specific to that example, so it is easy to copy and paste an existing example to start developing a custom application based on a project provided in the MCUXpresso SDK.

2.2 Locating example application source files

When opening an example application in any of the supported IDEs, a variety of source files are referenced. The MCUXpresso SDK devices folder is the central component to all example applications. It means the examples reference the same source files and, if one of these files is modified, it could potentially impact the behavior of other examples.

The main areas of the MCUXpresso SDK tree used in all example applications are:

- `devices/<device_name>`: The device’s CMSIS header file, MCUXpresso SDK feature file and a few other files
- `devices/<device_name>/cmsis_drivers`: All the CMSIS drivers for your specific MCU
- `devices/<device_name>/drivers`: All of the peripheral drivers for your specific MCU
- `devices/<device_name>/<tool_name>`: Toolchain-specific startup code, including vector table definitions
- `devices/<device_name>/utilities`: Items such as the debug console that are used by many of the example applications
- `devices/<device_name>/project template`: Project template used by MCUXpresso IDE to create new projects
- `devices/<device_name>/image tool`: Post build scripts used by IAR and MCUXpresso IDE
- `devices/<device_name>/project`: Project template used in CMSIS PACK new project creation

For examples containing an RTOS, there are references to the appropriate source code. RTOSes are in the `rtos` folder. The core files of each of these are shared, so modifying one could have potential impacts on other projects that depend on that file.
Chapter 3
Set up toolchain

This section contains the steps to install the necessary components required to build and run an MCUXpresso SDK demo application with the Arm GCC toolchain, as supported by the MCUXpresso SDK. There are many ways to use Arm GCC tools, but this example focuses on a Windows operating system environment.

3.1 Install GCC Arm Embedded tool chain

Download and run the installer from developer.arm.com/open-source/gnu-toolchain/gnu-rm. This is the actual toolset (in other words, compiler, linker, and so on). The GCC toolchain should correspond to the latest supported version.

3.2 Add the new system environment variables

Create a new system environment variable and name it as ARMGCC_DIR. The value of this variable should point to the Arm GCC Embedded tool chain installation path. For this example, the path is:

C:\GNU Tools Arm Embedded\7 2018-q2-update

See the installation folder of the GNU Arm GCC Embedded tools for the exact path name of your installation.

![Figure 3. Add ARMGCC_DIR system variable](image)

Add the bin directory path of the GNU Arm GCC Embedded tools in System variables -> Path. For this example, the path is:

C:\GNU Tools Arm Embedded\7 2018-q2-update\bin

![Figure 4. Select Path and click Edit](image)
3.3 Install Python3

Download and run the Python3 installer from https://www.python.org/downloads/.

Remember to select the Add Python 3.7 to PATH checkbox.

**NOTE**

Only the version newer than 3.2 is supported while generating the JN518x binaries.

Download and run the VCFORPython installer from https://download.microsoft.com.

After the installation, please confirm that the installation path is added into System variables Path. If not, please do it manually.
Follow the below steps to install the Crypto library for Python 3.

1. Press Windows+R to open the Run box.
2. Type cmd and then click OK to open a regular Command Prompt.
3. Type and run the command: pip3 install pycryptodome.
Chapter 4
Run a demo application using IAR

This section describes the steps required to build, run, and debug example applications provided in the MCUXpresso SDK. The hello_world demo application targeted for the qn9090dk6 hardware platform is used as an example, although these steps can be applied to any example application in the MCUXpresso SDK.

4.1 Build an example application

Do the following steps to build the hello_world example application.

1. Open the desired demo application workspace. Most example application workspace files can be located using the following path:

   `<install_dir>/boards/<board_name>/<example_type>/<application_name>/iar`

   Using the qn9090dk6 hardware platform as an example, the hello_world workspace is located in:

   `<install_dir>/boards/qn9090dk6/demo_apps/hello_world/iar/hello_world.eww`

   Other example applications may have additional folders in their path.

2. Select the desired build target from the drop-down menu.

   For this example, select hello_world – debug.

   ![Figure 8. Demo build target selection](image)

3. To build the demo application, click Make, highlighted in red in Figure 9.
4. The build completes without errors.

4.2 Run an example application

To download and run the application, perform these steps:

1. Download and install LPCScrypt or the Windows® operating systems driver for LPCXpresso boards from www.nxp.com/lpcutils. This installs required drivers for the board.

2. Connect the development platform to your PC via USB cable between the Link2 USB connector (J2) and the PC USB connector. Ensure JP5 is removed so the Link2 boots from internal flash. If connecting for the first time, allow about 30 seconds for the devices to enumerate.

3. Open the terminal application on the PC, such as PuTTY or TeraTerm, and connect to the debug COM port (to determine the COM port number, see #unique_12). Configure the terminal with these settings:
   a. 115200 or 9600 baud rate, depending on your settings (reference the BOARD_DEBUG_UART_BAUDRATE variable in the board.h file)
   b. No parity
   c. 8 data bits
   d. 1 stop bit
4. In IAR, click **Download and Debug** to download the application to the target.

5. The application is then downloaded to the target and automatically runs to the `main()` function.
6. Run the code by clicking **Go** to start the application.

7. The `hello_world` application is now running and a banner is displayed on the terminal. If this is not true, check your terminal settings and connections.
Chapter 5
Run a demo using MCUXpresso IDE

NOTE
Ensure that the MCUXpresso IDE toolchain is included when generating the MCUXpresso SDK package.

This section describes the steps required to configure MCUXpresso IDE to build, run, and debug example applications. The hello_world demo application targeted for the QN9090DK6 hardware platform is used as an example, though these steps can be applied to any example application in the MCUXpresso SDK.

5.1 Select the workspace location

Every time MCUXpresso IDE launches, it prompts the user to select a workspace location. MCUXpresso IDE is built on top of Eclipse which uses workspace to store information about its current configuration, and in some use cases, source files for the projects are in the workspace. The location of the workspace can be anywhere, but it is recommended that the workspace be located outside of the MCUXpresso SDK tree.

5.2 Build an example application

To build an example application, follow these steps.

1. Drag and drop the SDK zip file into the Installed SDKs view to install an SDK. In the window that appears, click OK and wait until the import has finished.

   ![Figure 15. Install an SDK](image)

2. On the Quickstart Panel, click Import SDK example(s)....
3. In the window that appears, expand the QN909x folder and select QN9090. Then, select qn9090dk6 and click Next.
4. Expand the `demo_apps` folder and select `hello_world`. Then, click **Next**.
5. Ensure **Redlib: Use floating point version of printf** is selected if the example prints floating point numbers on the terminal for demo applications such as `adc_basic`, `adc_burst`, `adc_dma`, and `adc_interrupt`. Otherwise, it is not necessary to select this option. Then, click **Finish**.
5.3 Run an example application

The application can be downloaded into DK6 QN9090/K32W061 module either:

- via the LPC-LINK2 USB port using an IDE debugger (MCUXpresso or IAR)
- via UART0 using the DK6 Flash Programmer
UART0 can be routed to several ports of the DK6:

- the LPC-LINK2 USB port (JP4 and JP7 in the leftmost position as shown in Figure 20)
- the FTDI USB connector (JP4 and JP7 in the middle position)
- J3 connector pins 8 and 9 using a USB-to-Serial converter (e.g. Prolific model obtainable from nxp.com)

UART0 is user port and UART1 instance is a debug console. The debug console can be accessed via J3 pins 10 and 11 using a USB-to-Serial converter. The easiest way to utilize BLE applications on the DK6 board is to plug a mini-USB cable into LPC-LINK2 USB connector. This acts as a power source and UART interface that can be used to download the binaries. Refer to the DK6-UG-3127-Production-Flash-Programmer.pdf for additional information.

To download and run the application, perform these steps:

1. Connect the development platform to your PC via USB cable between the Link2 USB connector (named Link for some boards or LPC-LINK2 or QN9090/K32W061 boards) and the PC USB connector. If connecting for the first time, allow about 30 seconds for the devices to enumerate.

2. Open the terminal application on the PC, such as PuTTY or TeraTerm, and connect to the debug serial port number (to determine the COM port number, see How to determine COM port). Configure the terminal with these settings:
   a. 115200 or 9600 baud rate, depending on your board (reference BOARD_DEBUG_UART_BAUDRATE variable in the board.h file)
   b. No parity
   c. 8 data bits
   d. 1 stop bit
Figure 21. Terminal (PuTTY) configurations

3. On the **Quickstart Panel**, click **Debug**.
4. The first time you debug a project, the **Debug Emulator Selection** dialog is displayed, showing all supported probes that are attached to your computer. Select the probe through which you want to debug and click **OK**. (For any future debug sessions, the stored probe selection is automatically used, unless the probe cannot be found.)
5. The application is downloaded to the target and automatically runs to `main()`.
Figure 24. Stop at main() when running debugging

6. Start the application by clicking **Resume**.

Figure 25. Resume button

The **hello_world** application is now running and a banner is displayed on the terminal. If this is not the case, check your terminal settings and connections.
Figure 26. Text display of the `hello_world` demo
Appendix A
How to determine COM port

This section describes the steps necessary to determine the debug COM port number of your NXP hardware development platform. All NXP boards ship with a factory programmed, on-board debug interface LPC Link2.

1. To determine the COM port, open the Windows operating system Device Manager. This can be achieved by going to the Windows operating system Start menu and typing **Device Manager** in the search bar, as shown in Figure 27.
2. In the Device Manager, expand the **Ports (COM & LPT)** section to view the available ports.
Appendix B
Updating Debugger firmware

The hardware platform comes with a CMSIS-DAP-compatible debug interface that has the ability to update the debugger firmware. This typically means switching from the default application (CMSIS-DAP) to a SEGGER J-Link. This section contains the steps to switch the CMSIS-DAP firmware to a J-Link interface. However, the steps can also be applied to restoring the original image.

NXP provides the LPCScrypt utility, which is the recommended tool for programming the latest versions of CMSIS-DAP and J-Link firmware onto LPC-Link2 or LPCXpresso boards. The utility can be downloaded from www.nxp.com/lpcutilities.

These steps show how to update the debugger firmware on your board for Windows operating system. For Linux OS, follow the instructions described in LPCScrypt user guide (www.nxp.com/lpcutilities, select LPCScrypt, then select documentation tab).

1. Unplug the board's USB cable.
2. Install the LPCScript utility.
3. For LPCXpresso board: make DFU link (install the jumper labelled DFUlink (JP5)).
4. Connect the probe to the host via USB (use Link USB connector (J2)).
5. Open a command shell and call the appropriate script located in the LPCScrypt installation directory (<LPCScrypt install dir>),
   a. To program CMSIS-DAP debug firmware: <LPCScrypt install dir>/scripts/program_CMSIS
   b. To program J-Link debug firmware: <LPCScrypt install dir>/scripts/program_JLINK
6. Remove DFU link (remove the jumper installed in Step 3).
7. Re-power the board by removing the USB cable and plugging it again.
Information in this document is provided solely to enable system and software implementers to use NXP products.
